Use of Unamplified RNA/cDNA-Hybrid Nanopore Sequencing for Rapid Detection and Characterization of RNA Viruses

Andy Kilianski, Pierce A. Roth, Alvin T. Liem, Jessica M. Hill, Kristen L. Willis, Rebecca D. Rossmaier, Andrew V. Marinich, Michele N. Maughan, Mark A. Karavis, Jens H. Kuhn, Anna N. Honko, C. Nicole Rosenzweig

Nanopore sequencing, a novel genomics technology, has potential applications for routine biosurveillance, clinical diagnosis, and outbreak investigation of virus infections. Using rapid sequencing of unamplified RNA/cDNA hybrids, we identified Venezuelan equine encephalitis virus and Ebola virus in 3 hours from sample receipt to data acquisition, demonstrating a fieldable technique for RNA virus characterization.

Portable and reliable molecular epidemiology techniques and field approaches for assessing virus genomes are desired to inform clinical diagnostics and public health operations. Need for such methods has been highlighted by the recent Middle East respiratory syndrome and Ebola virus disease (EVD) epidemics, during which it became necessary to characterize novel viruses and to evaluate genetic drift, transmission chains, and zoonotic introductions.

To determine if nanopore sequencing can be used as an accelerated viral genome sequencing tool, we utilized a rapid cDNA/RNA-hybrid library preparation procedure to sequence cell cultures of Venezuelan equine encephalitis virus vaccine (VEEV) strain TC-83 or Ebola virus (EBOV) isolate Makona-C05 stock IRF0137. To evaluate nanopore sequencing for rapid, field-deployable pathogen characterization, we collected raw read data and statistics for VEEV and EBOV sequence runs on the MinION sequencing device (Oxford Nanopore Technologies, Oxford, UK). To determine the level of identification and accuracy of genome characterization over sequencing runtime, these

DOI: http://dx.doi.org/10.3201/eid2208.160270

reads were then mapped to VEEV and EBOV genomes and to reference databases (RefSeq [http://www.ncbi.nlm.nih. gov/RefSeq/]). From the results of these analyses, we determined that the current and future versions of nanopore sequencing technology can be used to rapidly identify and characterize pathogens.

The Study

This approach for pathogen identification and characterization differs from the previously used methods on the MinION platform. Biased techniques, such as amplicon sequencing, have proven to be effective in complex sample backgrounds in which titers of the target pathogen might be low, but such approaches limit characterization to known pathogens and require additional viral genome amplification (1-4). Unbiased techniques that require viral genome amplification (5) or that have been optimized for bacterial genomes (6,7) require longer sample and library preparation times, but can detect low pathogen titers or create highly accurate genomic data. We sequenced unamplified poly(A)-tailed viral RNA using rapid cDNA library preparation coupled with real-time data analysis to determine its potential application for pathogen genomic characterization.

VEEV has a single-stranded, linear, poly(A)-tailed RNA genome. Thus, poly-dT primers can be used for cDNA production without further genomic RNA manipulation. The workflow to isolate the RNA and prepare it for sequencing (online Technical Appendix, http://wwwnc.cdc. gov/ article/22/8/16-0270-Techapp1.pdf) took \approx 3 hours from the initiation of sample processing to data acquisition on MinION (Figure, panel A). The sequencing of VEEV genomic RNA/cDNA hybrids attained in hours by using MinION revealed reads that mapped to the VEEV TC-83 genome within minutes by using the LAST (Computational Biology Research Consortium, Tokyo, Japan) multiple sequence alignment program (online Technical Appendix; Figure, panel B [2,4,6]). The coverage increased from 15-60 min from the 3' end of the VEEV genome with reads aligning directionally from the 3' to 5' end of the VEEV genome (Figure, panel B). These alignment characteristics are indicative of the poly-dT priming strategy for poly(A)tailed RNA.

To determine if the reads generated from VEEV TC-83 would align to the correct viral genome within a set

Figure. Use of unamplified RNA/cDNA-hybrid nanopore sequencing for genomic characterization of Venezuelan equine encephalitis virus (VEEV) TC-83. A) Sample preparation workflow for nanopore sequencing. First, viral RNA from BHK21 cell cultures of VEEV TC-83 was isolated, then single strand complimentary DNA (cDNA) was synthesized. The resulting RNA/cDNA hybrids were then prepared for nanopore sequencing and sequenced with data analysis occurring in real time. B) Genome organization and sequencing coverage over time of VEEV TC-83. VEEV is an alphavirus; its genome consists of a single strand of positive-sense RNA that can be translated into a polyprotein. Translation is critically dependent on the genomic 3' poly(A)-tail. This tail can be used for reverse transcription priming by using poly-(dT) primers that anneal to it. Read data were aligned to VEEV TC-83 (accession number L01443) by using the multiple sequence alignment program LAST (Computational Biology Research Consortium, Tokyo, Japan [online Technical Appendix, wwwnc.cdc.gov/ article/22/8/16-0270-Techapp1.pdf). The coverage map shows the depth of genome coverage over 15, 30, 45, and 60 minutes of sequencing runtime, with the greatest depth observed at the 3' end of the VEEV genome. Nsp, nonstructural protein; C, capsid; E, envelope.

of reference sequences, we used the viral genome reference sequences (http://www.ncbi.nlm.nih.gov/genomes/ GenomesGroup.cgi?taxid=10239&opt=Virus), plus the VEEV TC-83 genome database (GenBank accession no. L01443). We then used LAST to align nanopore reads against this set of references (online Technical Appendix). These alignments were used to generate a top hit table and the associated read alignment statistics against each hit. VEEV TC-83 was the top hit based on LAST alignment versus virus RefSeq genome sequences; wildtype VEEV placed second (Table). VEEV TC-83 was also identified as the top hit when the 15- and 60-min sequencing datasets were compared with alphavirus genome sequences (online Technical Appendix) (Table), demonstrating accuracy and depth achieved in a short time. We also analyzed the VEEV TC-83 dataset using the cloud-based metagenomic detection platforms Pathosphere (8) and One Codex (www.onecodex.com), and found that the sample contained VEEV (online Technical Appendix).

Molecular epidemiology, including use of viral genomics, played a major role during the 2013–2016 EVD response, informing contact tracing, diagnostic operability, and public health measures (9-11). To determine if EBOV is amenable to the same rapid sequencing methodology that was used for VEEV, unamplified negative-stranded RNA isolated from EBOV in Trizol (Thermofisher Scientific, http://www.thermofisher.com/us/en/home/brands/product-brand/trizol.html) was poly(A)-tailed, a single complementary strand of cDNA synthesized, and RNA/cDNA hybrids sequenced. The EBOV samples sequenced on MinION rapidly provided usable, accurate data, despite less raw data than the VEEV TC-83 dataset (137kbp for EBOV versus 2.4Mbp for VEEV at 60 min). Using 15-and 60-min time points and an identical alignment strategy to VEEV TC-83 above, we detected EBOV as the top hit within the sequencing dataset when compared to all virus RefSeq sequences (Table).

Despite success against the RefSeq database, the lack of depth within the dataset did not enable differentiation between the EBOV isolate sequenced here and the >1,500 EBOV draft genomes sequenced during the 2013–2016 outbreak (10,12,13), which indicates a limitation in this sequencing approach for negative-stranded RNA viruses. The poly(A)-tailing method was chosen because the reverse transcription primer adapters designed by Oxford Nanopore were developed to interact directly with the motor protein necessary for guiding DNA through the nanopores. This method greatly reduced preparation time and eliminated need for adaptor ligation reagents. This approach can

be revisited for sequencing negative-strand RNA viruses (2,5). Despite this limitation, the RefSeq alignments and nearest neighbor calls were possible with limited data, demonstrating the potential power of long-read rapid sequencing on nanopore platforms.

Conclusions

The current Middle East respiratory syndrome, EVD, and Zika virus disease outbreaks illustrate the necessity for rapid characterization of pathogens for environmental detection, clinical evaluation, and epidemiologic investigation. To determine whether nanopore sequencing can fill this role in a fieldable platform, we tested an RNA/cDNAhybrid sequencing approach on VEEV TC-83 (a positivestranded RNA virus) and EBOV (a negative-stranded RNA virus) prepared from cell-culture supernatants. This method definitively identified VEEV TC-83 and differentiated it from wild-type VEEV in \approx 3 hours, including only 15 min of data acquisition on MinION. VEEV TC-83 was also differentiated from other alphavirus genomes, facilitating strain-level identification of TC-83. EBOV was also identified rapidly by this approach, differentiating the virus in the sample analyzed here from available virus reference genomes. However, variant/isolate level characterization was not possible due to limited data generated from the RNA/ cDNA-hybrid approach.

The method applied here is greatly accelerated compared to traditional next-generation sequencing library preparation, and was used with reagents and equipment suitable for austere conditions (e.g., little need for cold chain, steps not requiring PCR). This study confirmed the possibility of accurate RNA virus genome characterization from RNA/cDNA hybrids by using limited sample manipulation, albeit from relatively pure samples. If samples derived directly from clinical matrices (e.g., blood, saliva) were used, this method would probably not support the necessary depth to characterize virus genomes unless the pathogen titer within these samples was high. As the depth of sequence data obtained from nanopore sequencing approaches continues to improve (14) and other pore types (such as RNA-specific sequencing pores) are integrated into commercial products, these unamplified techniques can transition from the laboratory to the field for more complex analysis.

Utilization of nanopore sequencing in Western Africa (2,3) has demonstrated potential for its use, and newly developed methods like this RNA/cDNA–hybrid approach can be integrated into fieldable protocols. For the emerging Zika virus, insufficiently high virus titers in clinical samples usually necessitates virus culture before genomic sequencing (15). Genomic Zika virus isolate characterization efforts would greatly benefit from the approaches outlined here, especially regarding materials needed for genomic library preparation and the time reduction for strain-level identification (15). By preparing and sequencing RNA/cDNA hybrids, the sampleto-answer time for RNA sequencing is greatly reduced, providing pathogen identification and characterization rapidly to inform future decision making.

SPOTLIGHT

Zika virus is spread to people through mosquito bites. Outbreaks of Zika have occurred in areas of Africa, Southeast Asia, the Pacific Islands, and the Americas. Because the Aedes species mosquitoes that spread Zika virus are found throughout the world, it is likely that outbreaks will spread to new countries. In December 2015, Puerto Rico reported its first confirmed Zika virus case. In May 2015, the Pan American Health Organization issued an alert regarding the first confirmed Zika virus infection in Brazil.

Use of Unamplified RNA/cDNA-Hybrid Nanopore Sequencing for Rapid Detection and Characterization of RNA Viruses

Technical Appendix

Viral Growth and RNA Isolation

To determine the ability of nanopore sequencing to provide rapid genomic data on RNA virus pathogens, a workflow was adopted and developed from cDNA sequencing protocols created by Oxford Nanopore Technologies (Oxford, UK) (MAP SEQ-002) (Figure 1, panel A). In brief, , Venezuelan equine encephalitis virus (VEEV) vaccine strain TC-83 and Ebola virus (EBOV) variant Makona isolate C05 stock IRF0137 (EBOV/Mak-C05) were grown and RNA isolated from clarified cell-culture supernatants. VEEV TC-83 was prepared from stocks derived from United States Army Venezuelan equine encephalitis virus TC-83 stocks. One MOI of VEEV TC-83 was adsorbed on Vero E6 monolayers for 2 hours. After 48 h of incubation in Minimum Essential Medium- α + 10% fetal bovine serum (GIBCO, Gaithersburg, MD; ThermoFisher Scientific, Pittsburgh, PA), cell culture supernatants were collected and clarified by centrifugation at 650 × *g* for 10 min at 4°C. RNA was isolated from cell-culture supernatant using the QIAamp MinElute virus spin kit (QIAGEN) for isolated VEEV particles.

The C05 isolate of the Makona variant of Ebola virus (full designation: Ebola virus/H.sapiens-tc/GIN/2014/Makona-C05, abbreviation: EBOV/Mak-C05) was isolated in 2014 in Vero E6 cells and kindly provided by Dr. Gary P. Kobinger (Public Health Agency of Canada, Winnipeg, Canada, BioSample: SAMN03611815, internal reference IRF0135). Vero E6 cells were used to propagate EBOV by two additional tissue culture passages in Vero E6 cells using Minimum Essential Medium-α, GlutaMAX, no nucleosides (GIBCO, ThermoFisher Scientific) supplemented with 2% US-origin, certified, heat-inactivated fetal bovine serum (HI-FBS, GIBCO, ThermoFisher Scientific). Following harvest, HI-FBS was QS'd to 10% final concentration before cryopreservation. GenBank accession no. KX000400 BioSample:

SAMN04490241, internal reference IRF0137. RNA was isolated from virus preps in 1:4 supernatant:Trizol after RNA extraction with cleanup using RNeasy MinElute cleanup kit (QIAGEN).

RNA/cDNA-Hybrid Sequencing Preparations

A total of 250 ng of VEEV or EBOV RNA were either directly added to a single-strand cDNA reaction (VEEV) primed using poly-dT primers provided by Oxford Nanopore Technologies (ONT; DEV-MAP003) or poly(A)-tailed (*Escherichia coli* poly(A) polymerase, (New England BioLabs) before addition (EBOV). cDNA synthesis was performed using SuperScript II reverse transcription 18064–014 (Life Technologies, Carlsbad, CA) per standard manufacturers protocols at 50°C for 50 min, followed by 70°C for 15 min. After cDNA synthesis, cDNA/RNA hybrids were prepared for nanopore sequencing (DEV-MAP003) by purifying RNA/cDNA hybrids using 0.7× Agencourt AmPure XP beads (Beckman Coulter, Fullerton, CA) followed by 2× 80% ethanol washes. Purified RNA/cDNA hybrids were then incubated with binding buffer for 45 min (ONT; DEV-MAP003), motor protein for 5 min (ONT; DEV-MAP003), then loading buffer for 5 min (ONT; DEV-MAP003) per the manufacturers protocol (ONT; DEV-MAP003). Prepared libraries were then diluted per manufacturers protocol with water and fuel mix (ONT; DEV-MAP003) to a final volume of 300 μl, with 150 μL sequencing solution loaded with p1000 tips onto individual MinION flow cells (7.3) for sequencing.

Data Collection and Analysis

Data were collected in real time using Oxford Nanopore software (VEEV: MinKNOW: 0.50.1.15, Metrichor: 1.13.1; EBOV: MinKNOW: 0.48.2.14, Metrichor: 1.10.1) and analyzed for genome alignment using LAST-648 (*1*) (lastal) with the options (-s 2 -T 0 -Q 0 -a 1). Duplications in the alignments were removed using last-map-probs (*1*). These methods are identical to ones used for previous work with amplicon and native nucleic acid sequencing (2–6). Nanopore reads were aligned against the Viral Genomes database (*7*) of viral reference genome sequences (data for complete genomes: Viruses (taxid 10239); 6,635 total entires, with the 2 stock genomes added from this study) and top hits and alignment statistics were generated.

VEEV reads were also aligned against a database of alphavirus genome sequences (1,440 total entries; detailed below). The read files, associated data and scripts are available at GenBank EU accession numbers SAMEA3865262 (VEEV) and SAMEA3865263 (EBOV) for nanopore data and NCBI BioProject PRJNA311755 and GenBank accession no. KX000400 for the EBOV reference. Sample use of Pathosphere (8) for analysis is publically available at www.pathosphere.org under the manuscript header. One Codex analysis (9) is also publically available at https://app.onecodex.com/analysis/public/57c08743784b41d3. All reference files used for the analysis above are available as 'viralRefSeq.fa' and 'all_alphavirus_complete.fasta' attached here. Scripts are available below in addition to being hosted at www.pathosphere.org.

Scripts

#!/bin/bash # last time alignment pipeline # # This is the main script that aligns reads using LAST according to timestamps # produced by the ExtractTimesFromReads program. It converts the fast5 files to a # fastq, extracts only the reads that were produced before specified time argument, # prepares the reference database for last, aligns and then outputs the top 10 reference hits from # the database. # # Dependencies that must be installed: LAST, JAVA, perl, bash, HDF5 libraries. # # This program was developed exclusively with government funds by # OptiMetrics, Inc. in support of U.S. Army Edgewood Chemical Biological # Center. # # Copyright (C) 2016 OptiMetrics, Inc. # This program is free software: you can redistribute it and/or modify # it under the terms of the GNU General Public License as published by # the Free Software Foundation, version 3 of the License. # # This program is distributed in the hope that it will be useful, # but WITHOUT ANY WARRANTY: without even the implied warranty of
