

A FACT SHEET FOR PROVIDERS

All Children 6 to 23 Months Old Should Get Flu Shot

A New Recommendation

Beginning this influenza season, CDC recommends that all children 6 months to 23 months old get a flu shot.

Children Less Than 2 More Likely to Be Hospitalized

Recent studies have shown that children less than 2 years old – even healthy children – are more likely than older children to end up in the hospital with serious complications if they get influenza. These complications can include pneumonia, dehydration, worsening of long-term medical problems like heart disease or asthma, encephalopathy, and other bacterial infections, including sinus and ear infections. In some cases, these complications can lead to death.

To protect their health, all children 6 months to 23 months old should be vaccinated against the flu. (The flu shot is not approved for use in children less than 6 months old.)

The Studies

Two studies published in 2000 showed the same results: that otherwise healthy children under 2 years old were more likely to be hospitalized for serious influenza complications than older, healthy children. These studies were published in the *New England Journal of Medicine* and the *Journal of Pediatrics*.

Based on this information, the Advisory Committee on Immunization Practices (ACIP) – a group that advises CDC on vaccinations – first moved to “encourage” vaccination among this age group. This season, that was strengthened to a “recommendation,” which is the strongest endorsement for vaccination.

Influenza-Related Deaths in Children Last Season

During last year’s influenza season, CDC received reports of 152 influenza-related deaths among children (people under 18 years old) from 40 states.

- All of these children had influenza infection diagnosed by laboratory tests.
- Most of the children were less than 5 years old.
- Twenty-seven percent of the children had a condition that placed them at high risk for serious complications from influenza and were recommended for vaccination by ACIP. Thirty-one percent had some other underlying medical condition. Forty percent of the children were previously healthy.
- Of the 135 children who died that could have been vaccinated, only 5 were “adequately” vaccinated against influenza. Seventy-six children had not been vaccinated against influenza at all.
