MILD AND UNILATERAL HEARING LOSS: OUTCOMES (REVIEW)

REFERENCE (Review)	OBJECTIVE	ARTICLES INCLUDED	RESULTS	AUTHOR'S CONCLUSIONS
Bess FH: The minimally hearing- impaired child. Ear Hear. 1985; 6: 43–7.	Reviewed research on 3 specific groups of children with minimal hearing loss to examine whether hearing loss causes more educational and/or communicative difficulty than previously supposed.	Articles including those who had: Middle ear disease with effusion and associated hearing loss. UHL.* Mild bilateral sensorineural hearing loss.	Middle Ear Disease with Effusion: Abundance of literature supports assumption that children prone to otitis media are at risk for delays in speech-language, cognition, and education. However, research is severely criticized for limitations in design. Hence cause-effect relationship cannot be assumed. Despite limitations, there are many consistencies in these studies. Unilateral Sensorineural: Review of literature shows UHL children experience greater difficulty with communication and/or educational progress than previously supposed. In general, they exhibit problems in directionality, understanding under many listening conditions, and educational and behavioral complications. Bilateral Sensorineural: Children assumed not to experience difficulties in communication or education. Several studies since the 1930's are summarized to demonstrate that such children can experience difficulties in school achievement, standardized achievement tests, grade retention, and speech recognition, especially when there is a lot of background	Review offers evidence to support the premise that children with mild forms of hearing loss can experience greater problems than previously thought. This should be recognized and professionals should reconsider the current definition of hearing handicap. Practice to use average dB* loss to define hearing handicap is not appropriate, especially when the population described in this report is considered.

MILD AND UNILATERAL HEARING LOSS: OUTCOMES (REVIEW)

REFERENCE (Review)	OBJECTIVE	ARTICLES INCLUDED	RESULTS	AUTHOR'S CONCLUSIONS
Tharpe AM, Bess FH: Identification and management of children with minimal hearing loss. Int J Pediatr Otorhinolaryng. 1991; 21: 41– 51.	Review of the literature on children with minimal hearing loss, their audiologic and academic performance, and possible management strategies in order to challenge the view that children with minimal hearing loss exhibit few, if any, handicaps and require no special assistance in academic settings.	Unilateral sensorineural, Flat bilateral sensorineural: 15– 25 dB* between 0.5 and 4 kHz*. Conductive hearing loss secondary to middle ear effusion: 10–50 dB. High frequency bilateral sensorineural: <15dB between 0.5–2kHz dropping in the higher frequencies to varying degrees.	Children UHL* have greater difficulty with communicative skills and educational progress than previously supposed. Children with mild bilateral sensorineural hearing loss have greater academic and communicative difficulties than children with no hearing loss. Several studies demonstrate that children with prolonged periods of middle ear effusion score significantly lower on tests of speech and language. Management recommendation for children with minimal hearing loss: More aggressive management. Identification and monitoring of children with mild loss before academic difficulties arise. Appropriate amplification. Possibly have sound field amplification in all classrooms (effect needs to be studied). Preferential seating in classroom. Placement in classrooms with low noise levels. Periodic in-service training for teachers.	Authors hypothesized that changes in medical care may cause decreasing numbers of severe and profound losses, and greater numbers of mild losses. Further research needed to address more specifically the psychoeducational, linguistic, and audiologic status of children with minimal hearing loss.

^{*} dB = decibel; kHz = kilohertz; UHL = unilateral hearing loss

MILD AND UNILATERAL HEARING LOSS: OUTCOMES (REVIEW)

REFERENCE (Review)	OBJECTIVE	ARTICLES INCLUDED	RESULTS	AUTHOR'S CONCLUSIONS
Wake M, Poulakis, Z: Slight and mild hearing loss in primary school children. J Paediatr Child Health. 2004; 40: 11–13.	To explore what is known about prevalence and impact of slight and mild hearing loss in primary school children Review recent articles related to prevalence of hearing loss and its impact on language, academic achievement, behavior, and quality of life. Discuss implications.	PTA* <40dB*. School age children.	Estimates of slight/mild hearing loss vary greatly (0.1% to 14.9%). Children with slight/mild hearing loss have adverse language outcomes, receptive vocabulary, verbal ability and reasoning. Children with slight/mild hearing loss have poorer early educational performance and a substantially higher graderetention rate. Children with mild/moderate hearing loss are much more bothered by background noise.	More large-scale research is needed to better address prevalence of mild hearing loss and its impact on language, learning and quality of life. Mild hearing loss does make a difference to children across many domains, especially during the primary school years.

^{*} PTA = pure tone average; dB = decibel
