Even if a mother has HIV, her baby doesn’t have to.

Get screened for HIV before your baby is born.
Getting a new life off to a great start

You just found out that you’re having a baby. It’s an exciting time, full of hope and joy. You want to take good care of yourself—and do everything you can to protect the new life growing inside of you. These days, that includes getting screened for HIV as early as possible in your pregnancy.

What is HIV? How does it spread?

HIV is the human immunodeficiency virus, the virus that causes AIDS. HIV weakens the immune system, which is the body’s defense against disease.

HIV spreads through body fluids such as blood, semen, and vaginal fluid. It can be passed by having sex without a condom or by sharing needles with a person with HIV. And most important for you to know now, HIV can also be passed from a mother with the virus to her baby.

Why is HIV screening so important for pregnant women?

Important reasons to know if you have HIV:

• A woman can pass HIV to her baby during pregnancy, during labor, or through breastfeeding.
• If a pregnant woman’s infection is found before she gives birth, doctors can treat her with drugs that fight HIV. These drugs can greatly reduce the risk of her baby being infected with HIV.

How is the HIV test done?

Nearly all pregnant women today get an HIV test as part of their prenatal care. Usually blood is drawn to test for HIV. Blood can be drawn for other prenatal tests at the same time. It takes a few weeks to get the results unless a rapid test is given.
Today, women with HIV who get treatment are living longer and staying healthier.

What can a pregnant woman with HIV do to protect her health and her baby?

If a pregnant woman has HIV, she can take action to protect her health and her baby. Drugs are now available that can improve the woman’s health, prolong her life, and help prevent her baby from getting HIV.

A woman with HIV may have a surgical (cesarean or “C” section) delivery to help protect her baby from the disease. A doctor or nurse can talk with her about this option.

It’s important to remember that HIV can pass through breast milk. So if a woman has HIV, she should not breastfeed.

It’s never too late for a pregnant woman to get screened for HIV.

The earlier in pregnancy that treatment begins, the lower the baby’s chances of getting HIV.

Out of 100 pregnant women with HIV, the risk of passing HIV to their babies is about:

- 1 baby out of 100 when women begin treatment during pregnancy.
- 22 babies out of 100 when women do NOT get treatment.

However, there are still health benefits to starting HIV treatment during labor or shortly after the baby is born if treatment has not been started earlier.
Glossary

**AIDS:** Acquired immunodeficiency syndrome. AIDS is the late stage of HIV infection, when a person’s immune system is severely damaged and has difficulty fighting diseases and certain cancers.

**HIV:** Human immunodeficiency syndrome. This virus weakens the immune system. HIV infection can lead to AIDS.

**Immune system:** This is the body’s defense system against infection and disease. It is made up of a number of organs and cells.
