2014-2015 Influenza Season  
Week 16 ending April 25, 2015

All data are preliminary and may change as more reports are received.

Synopsis: During week 16 (April 19-25, 2015), influenza activity continued to decrease in the United States.

- **Viral Surveillance:** Of 8,294 specimens tested and reported by U.S. World Health Organization (WHO) and National Respiratory and Enteric Virus Surveillance System (NREVSS) collaborating laboratories during week 16, 542 (6.5%) were positive for influenza.
- **Pneumonia and Influenza Mortality:** The proportion of deaths attributed to pneumonia and influenza (P&I) was below the epidemic threshold.
- **Influenza-associated Pediatric Deaths:** Five influenza-associated pediatric deaths were reported.
- **Influenza-associated Hospitalizations:** A cumulative rate for the season of 64.3 laboratory-confirmed influenza-associated hospitalizations per 100,000 population was reported.
- **Outpatient Illness Surveillance:** The proportion of outpatient visits for influenza-like illness (ILI) was 1.4%, which is below the national baseline of 2.0%. Two regions reported ILI at or above region-specific baseline levels. Puerto Rico experienced low ILI activity; New York City and 49 states experienced minimal ILI activity; and the District of Columbia and one state had insufficient data.
- **Geographic Spread of Influenza:** The geographic spread of influenza in three states was reported as widespread; Guam and nine states reported regional activity; Puerto Rico and 14 states reported local activity; the District of Columbia, the U.S. Virgin Islands, and 21 states reported sporadic activity; and three states reported no influenza activity.

**Influenza Positive Tests Reported to CDC by U.S. WHO/NREVSS Collaborating Laboratories, National Summary, 2014-15**

Since the start of the season, influenza A (H3N2) viruses have predominated nationally; however since early March, the proportion of influenza B viruses has been increasing. During week 16, 89% of all influenza positive specimens reported were influenza B viruses, and influenza B viruses accounted for at least half of all influenza viruses reported in all 10 regions.
Influenza Virus Characterization*: CDC has characterized 1,865 influenza viruses [49 A(H1N1)pdm09, 1,220 A(H3N2), and 596 influenza B viruses] collected by U.S. laboratories since October 1, 2014.

Influenza A Virus [1,269]

- **A(H1N1)pdm09 [49]**: All 49 H1N1 viruses tested were characterized as A/California/7/2009-like, the influenza A (H1N1) component of the 2014-2015 Northern Hemisphere influenza vaccine.

- **A(H3N2) [1,220]**: 243 (19.9%) of the 1,220 H3N2 viruses tested have been characterized as A/Texas/50/2012-like, the influenza A (H3N2) component of the 2014-2015 Northern Hemisphere influenza vaccine. 977 (80.1%) of the 1,220 viruses tested showed either reduced titers with antiserum produced against A/Texas/50/2012 or belonged to a genetic group that typically shows reduced titers to A/Texas/50/2012. Among viruses that showed reduced titers with antiserum raised against A/Texas/50/2012, most were antigenically similar to A/Switzerland/9715293/2013, the H3N2 virus selected for the 2015 Southern Hemisphere influenza vaccine. A/Switzerland/9715293/2013 is related to, but antigenically and genetically distinguishable from, the A/Texas/50/2012 vaccine virus. A/Switzerland-like H3N2 viruses were first detected in the United States in small numbers in March of 2014 and began to increase through the spring and summer.

Influenza B Virus [596]

407 (68.3%) of the influenza B viruses tested belong to B/Yamagata/16/88 lineage and the remaining 189 (31.7%) influenza B viruses tested belong to B/Victoria/02/87 lineage.

- **Yamagata Lineage [407]**: 396 (97.3%) of the 407 B/Yamagata-lineage viruses were characterized as B/Massachusetts/2/2012-like, which is included as an influenza B component of the 2014-2015 Northern Hemisphere trivalent and quadrivalent influenza vaccines. Eleven (2.7%) of the B/Yamagata-lineage viruses tested showed reduced titers to B/Massachusetts/2/2012.

- **Victoria Lineage [189]**: 184 (97.4%) of the 189 B/Victoria-lineage viruses were characterized as B/Brisbane/60/2008-like, the virus that is included as an influenza B component of the 2014-2015 Northern Hemisphere quadrivalent influenza vaccine. Five (2.6%) of the B/Victoria-lineage viruses tested showed reduced titers to B/Brisbane/60/2008.

*CDC routinely uses hemagglutination inhibition (HI) assays to antigenically characterize influenza viruses year-round to compare how similar currently circulating influenza viruses are to those included in the influenza vaccine, and to monitor for changes in circulating influenza viruses. However, a portion of recent influenza A (H3N2) viruses do not grow to sufficient hemagglutination titers for antigenic characterization by HI. For many of these viruses, CDC is also performing genetic characterization to infer antigenic properties.

2015-2016 Influenza Season – U.S. Influenza Vaccine Composition: The World Health Organization (WHO) has recommended vaccine viruses for the 2015-2016 influenza season Northern Hemisphere vaccine composition, and the Food and Drug Administration’s Vaccines and Related Biological Products Advisory Committee (VRBPAC) has made the vaccine composition recommendation to be used in the United States. Both agencies recommend that trivalent vaccines
contain an A/California/7/2009 (H1N1)pdm09-like virus, an A/Switzerland/9715293/2013 (H3N2)-
like virus, and a B/Phuket/3073/2013-like (B/Yamagata lineage) virus. It is recommended that
quadrivalent vaccines, which have two influenza B viruses, contain the viruses recommended for
the trivalent vaccines, as well as a B/Brisbane/60/2008-like (B/Victoria lineage) virus. This
represents a change in the influenza A (H3) and influenza B (Yamagata lineage) components
compared with the composition of the 2014-2015 influenza vaccine. These vaccine
recommendations were based on several factors, including global influenza virologic and
epidemiologic surveillance, genetic characterization, antigenic characterization, antiviral resistance,
and the candidate vaccine viruses that are available for production.

Antiviral Resistance: Testing of influenza A(H1N1)pdm09, A(H3N2), and influenza B virus isolates
for resistance to neuraminidase inhibitors (oseltamivir, zanamivir, and peramivir) is performed at
CDC using a functional assay. Additional A(H1N1)pdm09 and A(H3N2) clinical samples are tested
for mutations of the virus known to confer oseltamivir resistance. The data summarized below
combine the results of both testing methods. These samples are routinely obtained for surveillance
purposes rather than for diagnostic testing of patients suspected to be infected with antiviral-
resistant virus.

High levels of resistance to the adamantanes (amantadine and rimantadine) persist among
A(H1N1)pdm09 and A(H3N2) viruses (the adamantanes are not effective against influenza B
viruses). Therefore, data from adamantane resistance testing are not presented below.

Neuraminidase Inhibitor Resistance Testing Results
 on Samples Collected Since October 1, 2014

In the United States, the vast majority of recently circulating influenza viruses have been
susceptible to the neuraminidase inhibitor antiviral medications, oseltamivir, zanamivir, and
peramivir; rare sporadic instances of oseltamivir-resistant A(H1N1)pdm09 and A(H3N2) viruses
have been detected worldwide. Antiviral treatment is recommended as early as possible for patients
with confirmed or suspected influenza who have severe, complicated, or progressive illness; who
require hospitalization; or who are at high risk for serious influenza-related complications. Additional
information on recommendations for treatment and chemoprophylaxis of influenza virus infection
**Pneumonia and Influenza (P&I) Mortality Surveillance:** During week 16, 6.7% of all deaths reported through the 122 Cities Mortality Reporting System were due to P&I. This percentage was below the epidemic threshold of 6.9% for week 16.

For the 2014-2015 influenza season, CDC/Influenza Division and the National Center for Health Statistics (NCHS) are collaborating on a pilot project to use NCHS mortality surveillance data for the rapid assessment of pneumonia and influenza (P&I) mortality. To view the data, please click [here](#).
Influenza-Associated Pediatric Mortality: Five influenza-associated pediatric deaths were reported to CDC during week 16. Two deaths were associated with an influenza A (H3) virus and occurred during weeks 3 and 8 (the weeks ending January 24 and February 28, 2015, respectively). Three deaths were associated with an influenza B virus and occurred during weeks 10, 12, and 15 (the weeks ending March 14, March 28, and April 18, 2015, respectively).

A total of 133 influenza-associated pediatric deaths have been reported during the 2014-2015 season from New York City [3] and 39 states (Arizona [3], Arkansas [4], California [5], Colorado [6], Florida [3], Georgia [1], Illinois [3], Indiana [1], Iowa [3], Kansas [2], Kentucky [3], Louisiana [2], Maryland [1], Massachusetts [1], Michigan [2], Minnesota [10], Mississippi [1], Missouri [1], Nebraska [1], Nevada [8], New Jersey [1], New Mexico [1], New York [3], North Carolina [2], Ohio [6], Oklahoma [6], Oregon [1], Pennsylvania [3], Rhode Island [2], South Carolina [3], South Dakota [1], Tennessee [9], Texas [15], Utah [2], Virginia [5], Washington [1], Wisconsin [6], West Virginia [1], and Wyoming [1]).
Influenza-Associated Hospitalizations: The Influenza Hospitalization Surveillance Network (FluSurv-NET) conducts population-based surveillance for laboratory-confirmed influenza-related hospitalizations in children younger than 18 years of age (since the 2003-2004 influenza season) and adults (since the 2005-2006 influenza season).

The FluSurv-NET covers more than 70 counties in the 10 Emerging Infections Program (EIP) states (CA, CO, CT, GA, MD, MN, NM, NY, OR, and TN) and additional Influenza Hospitalization Surveillance Project (IHSP) states. The IHSP began during the 2009-2010 season to enhance surveillance during the 2009 H1N1 pandemic. IHSP sites included IA, ID, MI, OK and SD during the 2009-2010 season; ID, MI, OH, OK, RI, and UT during the 2010-2011 season; MI, OH, RI, and UT during the 2011-2012 season; IA, MI, OH, RI, and UT during the 2012-2013 season; and MI, OH, and UT during the 2013-2014 and 2014-2015 seasons.

Data gathered are used to estimate age-specific hospitalization rates on a weekly basis, and describe characteristics of persons hospitalized with severe influenza illness. The rates provided are likely to be an underestimate as influenza-related hospitalizations can be missed, either because testing is not performed, or because cases may be attributed to other causes of pneumonia or other common influenza-related complications.

Between October 1, 2014 and April 25, 2015, 17,584 laboratory-confirmed influenza-associated hospitalizations were reported. The overall hospitalization rate was 64.3 per 100,000 population. The highest rate of hospitalization was among adults aged ≥65 years (316.8 per 100,000 population), followed by children aged 0-4 years (56.4 per 100,000 population). Among all hospitalizations, 15,192 (86.4%) were associated with influenza A, 2,241 (12.7%) with influenza B, 92 (0.5%) with influenza A and B co-infection, and 59 (0.3%) had no virus type information. Among those with influenza A subtype information, 5,351 (99.7%) were A(H3N2) and 14 (0.3%) were A(H1N1)pdm09.

Clinical findings are preliminary and based on 7,510 (42.7%) cases with complete medical chart abstraction. The majority (93.7%) of hospitalized adults had at least one reported underlying medical condition; the most commonly reported were cardiovascular disease, metabolic disorders, and obesity. There were 856 hospitalized children with complete medical chart abstraction, 362 (42.3%) had no identified underlying medical conditions. The most commonly reported underlying medical conditions among pediatric patients were asthma, neurologic disorders, and obesity. Among the 537 hospitalized women of childbearing age (15-44 years), 177 (33.0%) were pregnant.

Data from the Influenza Hospitalization Surveillance Network (FluSurv-NET), a population-based surveillance for influenza related hospitalizations in children and adults in 13 U.S. states. Cumulative incidence rates are calculated using the National Center for Health Statistics’ (NCHS) population estimates for the counties included in the surveillance catchment area.
FluSurv-NET data are preliminary and displayed as they become available. Therefore, figures are based on varying denominators as some variables represent information that may require more time to be collected. Data are refreshed and updated weekly. Asthma includes a medical diagnosis of asthma or reactive airway disease; Cardiovascular diseases include conditions such as coronary heart disease, cardiac valve disorders, congestive heart failure, and pulmonary hypertension; does not include isolated hypertension; Chronic lung diseases include conditions such as chronic obstructive pulmonary disease, bronchiolitis obliterans, chronic aspiration pneumonia, and interstitial lung disease; Immune suppression includes conditions such as immunoglobulin deficiency, leukemia, lymphoma, HIV/AIDS, and individuals taking immunosuppressive medications; Metabolic disorders include conditions such as diabetes mellitus; Neurologic diseases include conditions such as seizure disorders, cerebral palsy, and cognitive dysfunction; Neuromuscular diseases include conditions such as multiple sclerosis and muscular dystrophy; Obesity was assigned if indicated in patient's medical chart or if body mass index (BMI) >30 kg/m²; Pregnancy percentage calculated using number of female cases aged between 15 and 44 years of age as the denominator; Renal diseases include conditions such as acute or chronic renal failure, nephrotic syndrome, glomerulonephritis, and impaired creatinine clearance; No known condition indicates that the case did not have any known high risk medical condition indicated in medical chart at the time of hospitalization.
**Outpatient Illness Surveillance:** Nationwide during week 16, 1.4% of patient visits reported through the U.S. Outpatient Influenza-like Illness Surveillance Network (ILINet) were due to influenza-like illness (ILI). This percentage is below the national baseline of 2.0%. *(ILI is defined as fever (temperature of 100°F [37.8°C] or greater) and cough and/or sore throat.)*

**Percentage of Visits for Influenza-like Illness (ILI) Reported by the U.S. Outpatient Influenza-like Illness Surveillance Network (ILINet), Weekly National Summary, 2014-2015 and Selected Previous Seasons**

![Graph showing percentage of visits for ILI](image)

There was no week 53 in the previous influenza seasons displayed above; therefore the week 53 data point for those seasons is an average of weeks 52 and 1.

On a regional level, the percentage of outpatient visits for ILI ranged from 0.9% to 2.1% during week 16. Two regions (Regions 1 and 8) reported a proportion of outpatient visits for ILI at or above their region-specific baseline levels.
2014-15 Influenza Season – Week 16, ending April 25, 2015

NOTE: Scales differ between regions

*Use of the regional baselines for state data is not appropriate.
**ILINet Activity Indicator Map**: Data collected in ILINet are used to produce a measure of ILI activity* by state. Activity levels are based on the percent of outpatient visits in a state due to ILI and are compared to the average percent of ILI visits that occur during weeks with little or no influenza virus circulation. Activity levels range from minimal, which would correspond to ILI activity from outpatient clinics being below or only slightly above the average, to high, which would correspond to ILI activity from outpatient clinics being much higher than average.

During week 16, the following ILI activity levels were calculated:

- Puerto Rico experienced low ILI activity.
- Data were insufficient to calculate an ILI activity level from the District of Columbia and one state (Colorado).

---

*This map uses the proportion of outpatient visits to health care providers for ILI to measure the ILI activity level within a state. It does not, however, measure the extent of geographic spread of flu within a state. Therefore, outbreaks occurring in a single city could cause the state to display high activity levels.

Data collected in ILINet may disproportionally represent certain populations within a state, and therefore, may not accurately depict the full picture of influenza activity for the whole state.

Data displayed in this map are based on data collected in ILINet, whereas the State and Territorial flu activity map is based on reports from state and territorial epidemiologists. The data presented in this map is preliminary and may change as more data are received. Differences in the data presented here by CDC and independently by some state health departments likely represent differing levels of data completeness with data presented by the state likely being the more complete.
**Geographic Spread of Influenza as Assessed by State and Territorial Epidemiologists:** The influenza activity reported by state and territorial epidemiologists indicates geographic spread of influenza viruses, but does not measure the severity of influenza activity.

During week 16, the following influenza activity was reported:

- Three states (Connecticut, Massachusetts, and New York) reported widespread influenza activity.
- Guam and nine states (Hawaii, Maine, Michigan, New Hampshire, North Dakota, Ohio, Oregon, Utah, and Vermont) reported regional influenza activity.
- Puerto Rico and 14 states (Arizona, Florida, Illinois, Indiana, Iowa, Maryland, Montana, Nebraska, New Jersey, New Mexico, Oklahoma, Rhode Island, South Carolina, and Wisconsin) reported local activity.
- Three states (Arkansas, Mississippi, and North Carolina) reported no influenza activity.

*Weekly Influenza Activity Estimates Reported by State & Territorial Epidemiologists*  
Week ending April 25, 2015 - Week 16

*This map indicates geographic spread & does not measure the severity of influenza activity*
Additional National and International Influenza Surveillance Information

FluView Interactive: FluView includes enhanced web-based interactive applications that can provide dynamic visuals of the influenza data collected and analyzed by CDC. These FluView Interactive applications allow people to create customized, visual interpretations of influenza data, as well as make comparisons across flu seasons, regions, age groups and a variety of other demographics. To access these tools, visit http://www.cdc.gov/flu/weekly/fluviewinteractive.htm.
