TENNESSEE ACUTE CARE HOSPITALS

Healthcare-associated infections (HAIs) are infections patients can get while receiving medical treatment in a healthcare facility. Working toward the elimination of HAIs is a CDC priority. The standardized infection ratio (SIR) is a summary statistic that can be used to track HAI prevention progress over time; lower SIRs are better. The infection data are reported to CDC’s National Healthcare Safety Network (NHSN). HAI data for nearly all U.S. hospitals are published on the Hospital Compare website. This report is based on 2014 data, published in 2016.

CLABSIs

CENTRAL LINE-ASSOCIATED BLOODSTREAM INFECTIONS

When a tube is placed in a large vein and not put in correctly or kept clean, it can become a way for germs to enter the body and cause deadly infections in the blood.

- Tennessee hospitals reported no significant change in CLABSIs between 2013 and 2014.
- Among the 64 hospitals in Tennessee with enough data to calculate an SIR, 7% had an SIR significantly higher (worse) than 0.50, the value of the national SIR.

CAUTIs

CATHETER-ASSOCIATED URINARY TRACT INFECTIONS

When a urinary catheter is not put in correctly, not kept clean, or left in a patient for too long, germs can travel through the catheter and infect the bladder and kidneys.

- Tennessee hospitals reported a significant decrease in CAUTIs between 2013 and 2014.
- Among the 84 hospitals in Tennessee with enough data to calculate an SIR, 7% had an SIR significantly higher (worse) than 1.00, the value of the national SIR.

MRSA Bacteremia

LABORATORY IDENTIFIED HOSPITAL-ONSET BLOODSTREAM INFECTIONS

Methicillin-resistant Staphylococcus aureus (MRSA) is bacteria usually spread by contaminated hands. In a healthcare setting, such as a hospital, MRSA can cause serious bloodstream infections.

- Tennessee hospitals reported no significant change in MRSA bacteremia between 2013 and 2014.
- Among the 54 hospitals in Tennessee with enough data to calculate an SIR, 9% had an SIR significantly higher (worse) than 0.87, the value of the national SIR.

SSI: Abdominal Hysterectomy

When germs get into an area where surgery is or was performed, patients can get a surgical site infection. Sometimes these infections involve only the skin. Other SSIs can involve tissues under the skin, organs, or implanted material.

- Tennessee hospitals reported no significant change in SSIs related to abdominal hysterectomy surgery between 2013 and 2014.
- Among the 17 hospitals in Tennessee with enough data to calculate an SIR, 6% had an SIR significantly higher (worse) than 0.83, the value of the national SIR.

SSI: Colon Surgery

- Tennessee hospitals reported no significant change in SSIs related to colon surgery between 2013 and 2014.
- Among the 51 hospitals in Tennessee with enough data to calculate an SIR, 6% had an SIR significantly higher (worse) than 0.98, the value of the national SIR.

C. difficile Infections

LABORATORY IDENTIFIED HOSPITAL-ONSET C. DIFFICILE INFECTIONS

When a person takes antibiotics, good bacteria that protect against infection are destroyed for several months. During this time, patients can get sick from Clostridium difficile (C. difficile), bacteria that cause potentially deadly diarrhea, which can be spread in healthcare settings.

- Tennessee hospitals reported no significant change in C. difficile infections between 2013 and 2014.
- Among the 108 hospitals in Tennessee with enough data to calculate an SIR, 8% had an SIR significantly higher (worse) than 0.92, the value of the national SIR.

* Statistically significant
**LEGEND**

- 2014 state SIR is significantly lower (better) than comparison group in column header
- Change in 2014 state SIR compared to group in column header is not statistically significant
- 2014 state SIR is significantly higher (worse) than comparison group in column header
- 2014 state SIR cannot be calculated

†The number of hospitals that reported to NHSN and are included in the SIR calculation. This number may vary across HAI types; for example, some hospitals do not use central lines or urinary catheters, or do not perform colon or abdominal hysterectomy surgeries.

‡Nat’l baseline time period varies by HAI type. See first column of this table for specifics.

**WHAT IS THE STANDARDIZED INFECTION RATIO?**

The standardized infection ratio (SIR) is a summary statistic that can be used to track HAI prevention progress over time; lower SIRs are better. The SIR for a facility or state is adjusted to account for factors that might cause infection rates to be higher or lower, such as hospital size, teaching status, the type of patients a hospital serves, and surgery and patient characteristics.

**WHAT IS TENNESSEE DOING TO PREVENT HEALTHCARE-ASSOCIATED INFECTIONS?**

Tennessee has a state mandate to publicly report at least one HAI to NHSN. Tennessee is one of 10 state health departments participating in CDC’s Emerging Infections Program, which allows for extra surveillance and research of HAIs.

Prevention efforts to reduce specific HAIs:
- Multidrug-resistant infections (MRSA, C. difficile, CRE)
- Ventilator-associated events
- Long-term care facilities
- Antibiotic stewardship
- Healthcare personnel influenza vaccination
- Targeted Assessment for Prevention (TAP) strategy

For prevention effort details, see glossary.
