The *HIV/AIDS Surveillance Report* is published semiannually by the Division of HIV/AIDS Prevention — Surveillance and Epidemiology, National Center for HIV, STD, and TB Prevention, Centers for Disease Control and Prevention (CDC), Atlanta, GA 30333. The year-end edition contains additional tables and graphs. All data are provisional.

Suggested Citation: Centers for Disease Control and Prevention. *HIV/AIDS Surveillance Report*, 2001;13(No. 1):[inclusive page numbers].

Single copies of the *HIV/AIDS Surveillance Report* are available from the CDC National Prevention Information Network, P.O. Box 6003, Rockville, MD 20849-6003; telephone 1–800–458–5231 or 1–301–562–1098. Individuals or organizations can be added to the mailing list by writing to CDC, MASO/MSB, Mailstop F-07, 4770 Buford Hwy, Chamblee, GA 30341-3717. Internet users may view an electronic copy of the *Report* by visiting CDC's home page (www.cdc.gov) and selecting the topic "Publications, Software, & Products." Confidential information, referrals, and educational material on AIDS are available from the CDC National AIDS Hotline: 1–800–342–2437, 1–800–344–7432 (Spanish access), and 1–800–243–7889 (TTY, deaf access).

The HIV/AIDS Surveillance Report is accessible via Internet: http://www.cdc.gov/hiv/stats/hasrlink.htm

The HIV/AIDS masthead on the cover is used with permission of the American Red Cross.

Commentary

This report includes new tables which present trends in estimated annual AIDS incidence from 1996 through 2000, by U.S. region, race/ethnicity, and exposure category (tables 22-24). The number of estimated AIDS cases diagnosed annually declined substantially from 1996 through 1999, but the rate of decline slowed during 1999 and 2000. The number of AIDS cases diagnosed in 2000 was 1.4% lower than that in 1999. From 1999 to 2000, changes in estimated AIDS incidence varied slightly by region (table 22), and race/ethnicity (table 23), and varied more by exposure category (table 24). The leveling in overall AIDS incidence is occurring as the composition of the epidemic is changing. AIDS incidence declined in most populations but increases were observed in some groups, notably women and persons infected through heterosexual contact. Fluctuations in some categories that have small numbers of AIDS cases reflect uncertainties in the estimation procedure rather than changing trends in AIDS incidence.

From 1999 to 2000, the number of estimated deaths among persons with AIDS declined 11%; this decline, however, was less than that observed from 1996 to 1997 (42%) (table 28) when the widespread introduction of highly active antiretroviral therapy (HAART) had its greatest impact. Declines in the estimated number of deaths among adults and adolescents with AIDS occurred in virtually all categories by region (table 28), race/ethnicity (table 29), and exposure category (table 30). Declines in deaths, which have been attributed in part to the impact of HAART, also reflect declines in AIDS incidence which in turn reflect both underlying trends in new HIV infections as well as delays in disease progression among HIV infected persons who are receiving treatment. Other factors associated with the slowing of declines in deaths from 1999 to 2000 compared with those previously observed may include delayed test seeking among certain populations, limited access to or use of health care services, and limitations of current therapies among persons in care.

From 1999 to 2000, the estimated number of persons living with AIDS increased 7.9% (table 25). CDC estimates that about 339,000 persons were living with AIDS as of December 2000: 41% were black, 38% were white, 20% were Hispanic, 1% were Asian/Pacific Islander, and <1% were American Indian/Alaska Native (table 26). Most (99%) persons living with AIDS were adults; and among adults, most (79%) were

men. These prevalence data are useful for allocating resources and planning services required to meet the continuing social and medical needs of people living with AIDS.

Numbers and proportions of AIDS cases are presented by year of report and also by year of diagnosis in this and previous reports. Characteristics of cases presented by year of report are useful to health department personnel in targeting their surveillance and public health efforts to appropriate facilities and populations to promote complete and timely case reporting. Tables that present cases by year of report represent the most up-to-date information reported to CDC; however, cases by year of report do not represent incident cases or the most recent diagnoses or deaths. That is, because of delays in reporting, not all cases diagnosed in the most recent 12 months will have been reported by the end of the reporting period. In addition, because information on mode of HIV exposure is frequently not available when a case is initially reported, the exposure mode for a larger proportion of the more recently reported cases is classified as "risk not reported or identified." To characterize trends in incidence, deaths, and prevalence, data by year of diagnosis or year of death may be statistically adjusted to account for delays in reporting and the anticipated reclassification of exposure mode for cases initially reported without risk. Both reporting delay adjustment and risk redistribution apply observed reporting patterns to inform the statistical adjustments. A lapse of at least two reporting quarters is required before the data can be adjusted. Therefore, this report includes cases reported to CDC through June 2001 and presents estimated AIDS incidence trends through December 2000 (see Technical Notes). conclusions about trends in the epidemic, readers of this report are encouraged to use tables that present trends by year of diagnosis, year of death, or year-end prevalence (tables 22-30).

Because appropriate use of antiretroviral therapy delays progression of HIV infection to AIDS, AIDS surveillance data alone are no longer sufficient for monitoring trends in HIV incidence, or for meeting federal, state, or local data needs for planning and allocating resources for HIV prevention and care programs. In regard to a nationwide integrated HIV/AIDS case surveillance system, as of July 2001, 34 states, the Virgin Islands, and Guam had implemented confidential HIV reporting of cases among adults and adolescents or

among children and had reported cases without personal identifiers to CDC (table 3 and Technical Notes). Other states had implemented alternative forms of HIV reporting (e.g., coded identifiers instead of patient names); the remaining states, the District of Columbia and other territories were considering implementation (see Technical Notes for more detailed information).

¹Includes only persons reported with HIV infection who have not developed AIDS.

²Age group based on person's age as of June 30, 2001.

³Persons reported with vital status "alive" as of the last update. Excludes persons whose vital status is unknown.

⁴Includes only persons reported from areas with confidential HIV reporting. Excludes 2,273 adults/adolescents and 49 children reported from areas with confidential HIV infection reporting whose area of residence is unknown or are residents of other areas.

⁵Includes 431 adults/adolescents and 6 children whose area of residence is unknown.

⁶Connecticut has confidential HIV infection reporting for pediatric cases only; Oregon has confidential HIV infection reporting for children less than 6 years old. Texas reported only pediatric HIV infection cases from February 1994 until January 1999.

Table 2. AIDS cases and annual rates per 100,000 population, by area and age group, reported through June 2001, United States

| | | | | | | | | | | | | |

¹Includes 1 person whose sex is unknown.

²Includes persons known to be infected with human immunodeficiency virus type 2 (HIV-2). See MMWR 1995;44:603-06.

³Forty-one adults/adolescents and 2 children developed AIDS after receiving blood screened negative for HIV antibody. Thirteen additional adults developed AIDS after receiving tissue, organs, or artificial insemination from HIV-infected donors. Four of the 13 received tissue, organs, or artificial insemination from a donor who was negative for HIV antibody at the time of donation. See *N Engl J Med* 1992;326:726-32.

⁴Thirty-four adults/adolescents are included in the "other" exposure category who were exposed to HIV-infected blood, body fluids, or concentrated virus in health care, laboratory, or household settings, as supported by seroconversion, epidemiologic, and/or laboratory evidence. See *MMWR* 1993;42:329-31, *MMWR* 1993;42:948-51, and XI International Conference on AIDS; Vancouver, Canada: July 7-12, 1996;1:179 [abstract Mo.D.1728]. One person was infected following intentional inoculation with HIV-infected blood. Additionally, 194 persons acquired HIV infection perinatally and were diagnosed with AIDS after age 13. These 194 persons are tabulated under the adult/adolescent, not pediatric, exposure category. See Technical Notes.

⁵Includes 3 children who were exposed to HIV-infected blood as supported by seroconversion, epidemiologic, and/or laboratory evidence: 1 child was infected following intentional inoculation with HIV-infected blood and 2 children were exposed to HIV-infected blood in a household setting (see *MMWR* 1992;41:228-31 and *N Engl J Med* 1993;329:1835-41). Twelve of the children had sexual contact with an adult with or at high risk for HIV infection (see *Pediatrics* 1998;102:e46).

¹Includes only persons reported with HIV infection who have not developed AIDS.

²See table 3 for areas with confidential HIV infection reporting.

³Includes 9 persons whose sex is unknown.

⁴For HIV infection cases, "risk not reported or identified" refers primarily to persons whose mode of exposure was not reported and who have not been followed up to determine their mode of exposure, and to a smaller number of persons who are not reported with one of the exposures listed above after follow-up. See Technical Notes.

¹Includes only persons reported with HIV infection who have not developed AIDS.

See table 3 for areas with confidential HIV infection reporting of adults and adolescents.

³For HIV infection cases, "risk not reported or identified" refers primarily to persons whose mode of exposure was not reported and who have not been followed up to determine their mode of exposure, and to a smaller number of persons who are not reported with one of the exposures listed above after follow-up. See Technical Notes.

⁴Includes 1,401 men whose race/ethnicity is unknown.

¹Includes only persons reported with HIV infection who have not developed AIDS.

²See table 3 for areas with confidential HIV infection reporting of adults and adolescents.
³For HIV infection cases, "risk not reported or identified" refers primarily to persons whose mode of exposure was not reported and who have not been followed up to determine their mode of exposure, and to a smaller number of persons who are not reported with one of the exposures listed above after follow-up. See Technical Notes.

⁴Includes 388 women whose race/ethnicity is unknown.

¹Includes only persons reported with HIV infection who have not developed AIDS. ²See table 3 for areas with confidential HIV infection reporting.

³For HIV infection cases, "risk not reported or identified" refers primarily to persons whose mode of exposure was not reported and who have not been followed up to determine their mode of exposure, and to a smaller number of persons who are not reported with one of the exposures listed above after follow-up. See Technical Notes.

⁴Includes 18 children whose race/ethnicity is unknown.

| Men who have sex with men; injecting drug use; hemophilia/coagulation disorder; heterosexual contact; receipt of transfusion/transplant | 6 | (0) |
| Multiple modes of exposure subtotal | 112,534 | (14) |
| Risk not reported or identified ⁴ | 74,913 | (10) |
| Total | 784,032 | (100) |

¹Includes 41 adult/adolescents who developed AIDS after receiving blood screened negative for HIV antibody.

²Thirteen adults developed AIDS after receiving tissue, organs, or artificial insemination from HIV-infected donors. Four of the 13 received tissue or organs from a donor who was negative for HIV antibody at the time of donation. See *N Engl J Med* 1992;326:726-32.

³"Other" includes 194 persons who acquired HIV infection perinatally, but had AIDS diagnosed after age 13. See Technical Notes.

⁴See Technical Notes.

Table 18. Deaths in persons with AIDS, by race/ethnicity, age at death, and sex, reported through June 2001, United States

¹These numbers do not represent actual AIDS cases among men. Rather, these numbers are point estimates adjusted for delays in the reporting of AIDS cases and for redistribution of cases initially reported with no identified risk, but not adjusted for incomplete reporting of cases. See Technical Notes.

²Statistical estimates for AIDS incidence in 2000 among persons exposed to HIV through hemophilia/coagulation disorder or receipt of blood transfusion, blood components, or tissue are not presented, but are included in the exposure category "other." The relatively small number of AIDS cases in these categories in recent years does not provide information that results in reliable annual estimates of incidence (* = data not available); only cumulative estimates are presented. CDC is evaluating and revising the algorithm for estimating AIDS incidence among persons infected in the early 1980's through these exposure categories.

³For 2000, estimates of "other" include cases exposed through hemophilia/coagulation disorder and receipt of blood transfusion, blood components, or tissue.

⁴Totals include estimates of cases among men whose race/ethnicity is unknown.

| | | | | | | | | |

¹These numbers do not represent actual AIDS cases. Rather, these numbers are point estimates adjusted for delays in the reporting of AIDS cases and for redistribution of cases initially reported with no identified risk, but not adjusted for incomplete reporting of cases. See Technical Notes.

²Statistical estimates for AIDS incidence in 2000 among persons exposed to HIV through hemophilia/coagulation disorder or receipt of blood transfusion, blood components, or tissue are not presented, but are included in the exposure category "other." The relatively small number of AIDS cases in these categories in recent years does not provide information that results in reliable annual estimates of incidence (* = data not available); only cumulative estimates are presented. CDC is evaluating and revising the algorithm for estimating AIDS incidence among persons infected in the early 1980's through these exposure categories.

³For 2000, estimates of "other" include cases exposed through hemophilia/coagulation disorder and receipt of blood transfusion, blood components, or tissue.

Estimated adult/adolescent AIDS incidence, by region of residence and year Table 22. of diagnosis, 1996–2000, United States¹

| Other/risk not reported or identified ³ | 67 | 66 | 53 | 57 | 345 |
| Female subtotal | 13,175 | 11,423 | 10,108 | 9,823 | 10,305 |
| Total ⁴ | 60,747 | 49,407 | 42,508 | 40,671 | 40,106 |

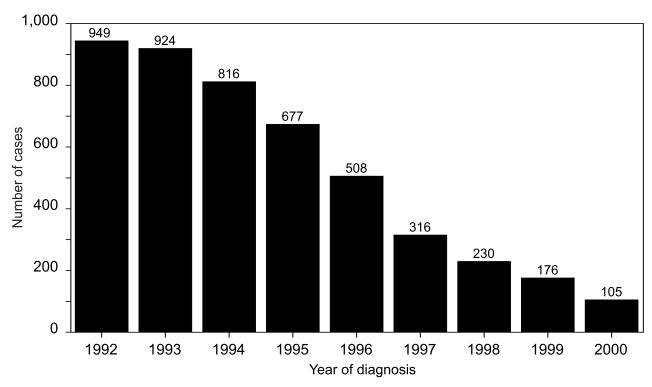

¹These numbers do not represent actual cases among persons with AIDS diagnosed. Rather, these numbers are point estimates adjusted for reporting delays of AIDS cases and for redistribution of cases initially reported with no identified risk, but not for incomplete reporting of cases. See Technical Notes.

²Statistical estimates for AIDS incidence in 2000 among persons exposed to HIV through hemophilia/coagulation disorder or receipt of blood transfusion, blood components, or tissue are not presented, but are included in the exposure category "other." The relatively small number of AIDS cases in these categories in recent years does not provide information that results in reliable annual estimates of incidence (* = data not available); only cumulative estimates are presented. CDC is evaluating and revising the algorithm for estimating AIDS incidence among persons infected in the early 1980's through these exposure categories.

³For 2000, estimates of "other" include cases exposed through hemophilia/coagulation disorder and receipt of blood transfusion, blood components, or tissue. See table 5, footnote 4 for a discussion of the "other" category, and Technical Notes.

⁴Because column totals were calculated independently of the values for the subpopulations, the values in each column may not sum to the column total.

Figure 6. Estimated pediatric AIDS incidence, by year of diagnosis, 1992 through 2000, United States¹

¹These numbers do not represent actual cases among children with AIDS diagnosed. Rather, these numbers are point estimates based on cases diagnosed using the 1987 definition, adjusted for reporting delays. The 1993 AIDS surveillance case definition change affected only the adult/adolescent cases, not pediatric cases.

Table 25. Estimated number of persons living with AIDS, by region of residence and year, 1993 through 2000, United States¹

| | | Year | | | | | | | | |
|--|---------|---------|---------|---------|---------|---------|---------|---------|--|--|
| Region of residence ² | 1993 | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | | |
| Northeast | 51,789 | 59,218 | 65,700 | 72,694 | 80,504 | 86,869 | 93,439 | 101,209 | | |
| Midwest | 18,464 | 20,370 | 21,868 | 23,803 | 26,283 | 28,320 | 30,540 | 32,816 | | |
| South | 58,738 | 68,002 | 75,530 | 85,673 | 97,445 | 108,510 | 118,756 | 128,740 | | |
| West | 39,376 | 42,756 | 45,516 | 49,080 | 53,896 | 58,038 | 62,031 | 66,340 | | |
| U.S. dependencies, possessions, and associated nations | 5,617 | 6,213 | 6,638 | 7,171 | 7,958 | 8,666 | 9,289 | 9,873 | | |
| Total ³ | 173,984 | 196,559 | 215,252 | 238,420 | 266,086 | 290,403 | 314,054 | 338,978 | | |

¹These numbers do not represent the actual number of persons living with AIDS. Rather, these numbers are point estimates of the number of persons living with AIDS derived by subtracting the estimated cumulative number of deaths in persons with AIDS from the estimated cumulative number of persons with AIDS diagnosed. Estimated AIDS incidence and estimated deaths are adjusted for reporting delays, but not for incomplete reporting. The year 2000 is the most recent year for which reliable estimates are available. See Technical Notes.

²See Technical Notes for a list of states or U.S. dependencies, possessions, and associated nations which make up each region of residence.

³Because column totals were calculated independently of the values for the subpopulations, the values in each column may not sum to the column total.

Table 26. Estimated number of persons living with AIDS, by race/ethnicity and year, 1993 through 2000, United States¹

| | | T ear | | | | | | | | |
|-------------------------------|---------|---------|---------|---------|---------|---------|---------|---------|--|--|

| Total ⁴ | 45,598 | 50,418 | 51,117 | 38,025 | 21,999 | 18,397 | 17,172 | 15,245 | | |

¹These numbers do not represent the actual number of deaths among persons with AIDS. Rather, these numbers are point estimates adjusted for delays in the reporting of deaths and for redistribution of cases initially reported with no identified risk, but not for incomplete reporting of deaths. The year 2000 is the most recent year for which reliable estimates are available. See Technical Notes.

year 2000 is the most recent year for which reliable estimates are available. See Technical Notes.

2 Statistical estimates for deaths in 2000 among persons with AIDS exposed to HIV through hemophilia/coagulation disorder or receipt of blood transfusion, blood components, or tissue are not presented, but are included in the exposure category "other." The relatively small number of AIDS cases in these categories in recent years does not provide information that results in reliable annual estimates of deaths (* = data not available); only cumulative estimates are presented. CDC is evaluating and revising the algorithm for estimating deaths among persons with AIDS infected in the early 1980's through these exposure categories.

³For 2000, estimates of "other" include cases exposed through hemophilia/coagulation disorder and receipt of blood transfusion, blood components, or tissue.

⁴Because column totals were calculated independently of the values for the subpopulations, the values in each column may not sum to the column total.

Technical Notes

Surveillance of AIDS

All 50 states, the District of Columbia, U.S. dependencies and possessions, and independent nations in free association with the United States¹ report AIDS cases to CDC using a uniform surveillance case definition and case report form. The original definition was modified in 1985 (MMWR 1985;34:373-75) and 1987 (MMWR 1987;36[suppl. no. 1S]:1S-15S). The case definition for adults and adolescents was modified again in 1993 (MMWR 1992;41[no. RR-17]:1-19; see also MMWR 1995;44:64-67). The revisions incorporated a broader range of AIDS-indicator diseases and conditions and used HIV diagnostic tests to improve the sensitivity and specificity of the definition. The laboratory and diagnostic criteria for the 1987 pediatric case definition (MMWR 1987;36:225-30, 235) were updated in 1994 (MMWR 1994;43[no. RR-12]:1-19). Effective January 1, 2000, the surveillance case definition for HIV infection was revised to reflect advances in laboratory HIV virologic tests. The definition incorporates the reporting criteria for HIV infection and AIDS into a single case definition for adults and children (MMWR 1999;48[no.RR-13]:29-31).

For persons with laboratory-confirmed HIV infection, the 1987 revision incorporated HIV encephalopathy, wasting syndrome, and other indicator diseases that are diagnosed presumptively (i.e., without confirmatory laboratory evidence of opportunistic disease). In addition to the 23 clinical conditions in the 1987 definition, the 1993 case definition for adults and adolescents includes HIV infection among persons with CD4+ T-lymphocyte counts of less than 200 cells/µL or a CD4+ percentage of less than 14, and persons with a diagnosis of pulmonary tuberculosis, recurrent pneumonia, or invasive cervical cancer. For adults, adolescents, and children ≥18 months of age, the 2000 revised HIV surveillance case definition incorporates positive results or reports of a detectable quantity of HIV nucleic acid or plasma HIV RNA.

The pediatric case definition incorporates the revised 1994 pediatric classification system for evidence of HIV infection. Cases among children with

¹Included among the dependencies, possessions, and independent nations are Puerto Rico, the U.S. Virgin Islands, Guam, American Samoa, the Republic of Palau, the Republic of the Marshall Islands, the Commonwealth of the Northern Mariana Islands, and the Federated States of Micronesia. The latter 5 comprise the category "Pacific Islands, U.S." listed in tables 1 and 2.

their first positive results on Western blot or HIV detection tests before October 1994 were categorized based on the 1987 classification system. Cases among those tested during or after October 1994 are categorized under the revised 1994 pediatric classification system. For children of any age with an AIDS-defining condition that requires evidence of HIV infection, a single positive HIV virologic test (i.e., HIV nucleic acid [DNA or RNA], HIV viral culture, HIV p24 antigen) is sufficient for a reportable AIDS diagnosis if the diagnosis is documented by a physician.

Although completeness of reporting of diagnosed AIDS cases to state and local health departments varies by geographic region and patient population, studies conducted by state and local health departments indicate that reporting of AIDS cases in most areas of the United States is more than 85% complete (J Acquir Immune Def Syndr 1992;5:257-64, Am J Public Health 1992;82:1495-99, AIDS 1999; 13:1109-14, and Ann Epidemiol 2001;11:443-449.). In addition, multiple routes of exposure, opportunistic diseases diagnosed after the initial AIDS case report was submitted to CDC, and vital status may not be determined or reported for all cases. However, among persons reported with AIDS, reporting of deaths is estimated to be more than 90% complete (JAMA 1996:276:126-31). CDC estimates approximately 3% of AIDS cases are duplicates based on matching within the national coded surveillance database.

Since January 1, 1994, CDC has not accepted AIDS case reports that meet only the laboratory-based immunologic criteria of the 1993 expanded surveillance case definition (*MMWR* 1991;41[no. RR-17]:1-19) if they were missing information on sex or race/ethnicity. A small number of cases previously reported to CDC that were missing those variables have been returned to the health departments for follow-up and have been deleted from the totals. Included in this report are persons known to be infected with human immunodeficiency virus type 2 (HIV-2). See *MMWR* 1995;44:603-06.

Surveillance of HIV infection

This report includes HIV case reports from 34 areas that had laws or regulations requiring confidential reporting by name of adults/adolescents, and children with confirmed HIV infection, in addition to reporting of

persons with AIDS, through June 30, 2001. Connecticut required reporting by name of HIV infection only for children <13 years of age; and Oregon required reporting only for children <6 years of age. After removal of personally identifying information, these reports were submitted to CDC, and are included in this report (see table 3 for listing). New York initiated HIV case reporting during 2000 and data will be included in future issues of this report. States have initiated HIV reporting at various times after the development of serum HIV-antibody tests. Before 1991, surveillance of HIV infection was not standardized and reporting of HIV infections was based primarily on passive surveillance. Many cases reported before 1991 do not have complete information. Since then, CDC has assisted states in conducting active surveillance of HIV infections using standardized report forms and software. However, collection of demographic and risk information still varies among states.

HIV infection data should be interpreted with caution. HIV surveillance reports may not be representative of all persons infected with HIV since not all infected persons have been tested. Many HIV-reporting states offer anonymous HIV testing and home collection HIV test kits are widely available in the United States. Anonymous test results are not reported to state and local health departments' confidential name-based HIV registries. Therefore, confidential HIV infection reports may not represent all persons who tested positive for HIV infection. Furthermore, many factors may influence testing patterns, including the extent that testing is targeted or routinely offered to specific groups and the availability of and access to medical care and testing services. These data provide a minimum estimate of the number of persons known to be HIV infected in states with confidential HIV reporting.

As of December 2001, eight areas (HI, IL, KY, MD, MA, PR, RI, and VT) had implemented a code-based system to conduct case surveillance for HIV infection. Some other areas (DE, ME, MT, OR, and WA) had implemented a name-to-code system to conduct HIV infection surveillance: initially, names are collected and, after any necessary public health follow-up, names are converted to codes. Data on cases of HIV infection from these areas are not included in the HIV data tables pending evaluations demonstrating acceptable performance under CDC guidelines and the development of methods to report such data to CDC.

For this report, cases among adults, adolescents, and children ≥18 months of age, were classified using the 2000 revised HIV surveillance case definition

which incorporates positive results or reports of a detectable quantity of HIV nucleic acid or plasma HIV RNA (MMWR 1999;48[no. RR-13]:29-31). For children <18 months of age, the pediatric HIV reporting criteria reflect diagnostic advances that permit the diagnosis of HIV infection during the first months of life. With HIV nucleic acid detection tests, HIV infection can be detected in nearly all infants aged one month and older. The timing of the HIV serologic and HIV nucleic acid detection tests and the number of HIV nucleic acid detection tests in the definitive and presumptive criteria for HIV infection are based on the recommended practices for diagnosing infection in children aged <18 months and on evaluations of the performance of these tests for children in this age group. Children aged <18 months born to an HIV-infected mother will be categorized as having perinatal exposure to HIV infection if the child does not meet the criteria for HIV infection or the criteria for "not infected with HIV" (MMWR 1999;48[no. RR-13]:29-31) (MMWR 1998;47 [no. RR-4]). Children born before 1994 were considered HIV-infected if they met the HIV case definition stated in the 1987 pediatric classiinfection fication system for HIV (MMWR 1987;36:225-30,235).

Because states initiated reporting on different dates, the length of time reporting has been in place will influence the number of HIV infection cases reported. For example, data presented for a given annual period may include cases reported only during a portion of the year. Prior to statewide HIV reporting, some states collected reports of HIV infection in selected populations. Therefore, these states have reports prior to initiation of statewide confidential reporting. A state with confidential HIV infection reporting also may report persons who tested positive in that state but who were residents of other states. Therefore, when HIV data are presented by state of residence, cases reported prior to the date a state initiated reporting may have been reported from other states with confidential HIV infection reporting.

Over time, persons with HIV infection may develop AIDS and be reported to surveillance. HIV infection cases later reported with AIDS are deleted from the HIV infection tables and added to the AIDS tables. Persons with HIV infection may be tested at any point in the clinical spectrum of disease; therefore, the time between diagnosis of HIV infection and AIDS will vary. In addition, because surveillance practices differ, reporting and updating of clinical and vital status of cases vary among states. Completeness of reporting for HIV is estimated to be more than 85% complete

(*MMWR* 1998;47:309-14). CDC estimates approximately 2% of HIV cases are duplicates based on matching within the national coded surveillance database.

Tabulation and presentation of data

Data in this report are provisional. Each issue of this report includes information received by CDC through the last day of the reporting period. In the first part of the report (through table 18), HIV and AIDS data are tabulated by date of report to CDC. In the second part of the report (from table 19 through table 30), data are statistically adjusted to correct for temporal delays in the reporting of cases and deaths, and unreported risk/exposure is statistically redistributed in order to improve the presentation of trends in the epidemic and the distribution of risk characteristics among affected populations. Data for U.S. dependencies and possessions and for associated independent nations are included in the totals.

Age group tabulations for table 1 are based on the person's calculated age as of June 30, 2001. All other age group tabulations are based on the person's age at first documented positive HIV-antibody test for HIV infection cases, and age at diagnosis of AIDS for AIDS cases. Adult/adolescent cases include persons 13 years of age and older; pediatric cases include children under 13 years of age.

Tabulations of persons living with HIV infection and AIDS (table 1) include persons whose vital status was reported "alive" as of last update; persons whose vital status is missing or unknown are not included. Tabulations of deaths in persons with AIDS include persons whose vital status was reported "dead" as of last update; persons whose vital status is missing or unknown are not included. Caution should be used in interpreting these data because states vary in the frequency with which they review the vital status of persons reported with HIV infection and AIDS. In addition, some cases may be lost to follow-up.

Table 4 lists AIDS case counts for each metropolitan area with a census 2000 population of 499,999 or more. AIDS case counts for metropolitan areas with 50,000 to 499,999 population are reported as a combined subtotal. On December 31, 1992, the Office of Management and Budget announced new Metropolitan Statistical Area (MSA) definitions, which reflect changes in the U.S. population as determined by the 1990 census. These definitions were updated most recently on June 30, 1998. The cities and counties which compose each metropolitan area listed in table 4 are provided in the publication "Metropolitan Areas

as of June 30, 1998" (available by calling the National Technical Information Service, 1-703-487-4650, and ordering accession no. PB98-502198 or by visiting www.census.gov/population/www/estimates/metrodef.html). Standards for defining central and outlying counties of metropolitan areas were published in the Federal Register (*FR* 1990;55:12154-60).

The metropolitan area definitions are the MSAs for all areas except the 6 New England states. For these states, the New England County Metropolitan Areas (NECMA) are used. Metropolitan areas are named for a central city in the MSA or NECMA, may include several cities or counties, and may cross state boundaries. For example, AIDS cases and annual rates presented for the District of Columbia in table 2 include only persons residing within the geographic boundaries of the District. AIDS cases and annual rates for Washington, D.C., in table 4, include persons residing within the several counties in the metropolitan area, including counties in Maryland, Virginia, and West Virginia. State or metropolitan area data tabulations are based on the person's residence at first positive HIV-antibody test result for HIV infection cases, and residence at diagnosis for the first AIDS indicator condition(s) for AIDS cases.

Regions of residence included in this report are defined as follows. Northeast: Connecticut, Maine, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, and Vermont; Midwest: Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin; South: Alabama, Arkansas, Dela-District of Columbia, Florida, Georgia, Kentucky, Louisiana, Maryland, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, and West Virginia; West: Alaska, Arizona, California, Colorado, Hawaii, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming; Territories: Guam, Puerto Rico, the U.S. Pacific Islands listed in the footnote on the first page of these notes, and the U.S. Virgin Islands.

Estimated AIDS incidence (tables 19, 20, and 21), estimated AIDS incidence trends (tables 22, 23, and 24 and figure 6), estimated number of persons living with AIDS (tables 25, 26, and 27), and estimated number of deaths (tables 28, 29, and 30) are not actual counts of cases reported to the surveillance system. The estimates are based on reported cases which have been adjusted for delays in reporting of cases and deaths and a number of assumptions. The date of death for decedents with a missing date of death was imputed as the date that death was reported to CDC minus the estimated median months required to report

deaths. For these estimates, the median reporting delay for deaths was 3 months. If AIDS diagnosis occurred after the date imputed, then the date of AIDS diagnosis was used as the date of death. While these tables were constructed using the best methods currently available, there is inherent uncertainty in these estimates (*Lecture Notes in Biomathematics* 1989; 83:58-88). Small numbers must be interpreted with caution because the inherent uncertainty in estimates is greater for small numbers.

Exposure categories

For surveillance purposes, HIV infection cases and AIDS cases are counted only once in a hierarchy of exposure categories. Persons with more than one reported mode of exposure to HIV are classified in the exposure category listed first in the hierarchy, except for men with both a history of sexual contact with other men and injecting drug use. They make up a separate exposure category.

"Men who have sex with men" cases include men who report sexual contact with other men (i.e., homosexual contact) and men who report sexual contact with both men and women (i.e., bisexual contact). "Heterosexual contact" cases are in persons who report specific heterosexual contact with a person with, or at increased risk for, HIV infection (e.g., an injecting drug user).

Adults/adolescents born, or who had sex with someone born, in a country where heterosexual transmission was believed to be the predominant mode of HIV transmission (formerly classified as Pattern-II countries by the World Health Organization) are no longer classified as having heterosexually-acquired AIDS unless they meet the above stated criteria. Similar to other cases among persons who were reported without behavioral or transfusion risks for HIV, these cases are now classified (in the absence of other risk information which would classify them in another exposure category) as "no risk reported or identified" (MMWR 1994;43:155-60). Cases among children whose mother was born, or whose mother had sex with someone born, in a Pattern II country are now classified (in the absence of other risk information which would classify them into another exposure category) as "Mother with/at risk for HIV infection: has HIV infection, risk not specified."

Cases among persons with no reported history of exposure to HIV through any of the routes listed in the hierarchy of exposure categories are classified as "no risk reported or identified." NIR cases include those which are currently being followed up by local health

department officials; cases among persons whose exposure history is incomplete because they died, declined to be interviewed, or were lost to follow up; and cases among persons who were interviewed or for whom other follow-up information was available and no exposure mode was identified. Cases among persons who have an exposure mode identified at the time of follow-up are reclassified into the appropriate exposure category. Historically, investigations and follow -up for modes of exposure by state health departments were conducted routinely for persons reported with AIDS and as resources allowed for persons reported with HIV infection. Therefore, the percentage of cases among HIV infected persons with risk not reported or identified is substantially higher than for those reported with AIDS.

As of September 2000, the procedures for the investigation of cases reported without risk changed from ascertaining risk for all reported cases to estimating risk distributions from statistical models and population-based samples. States continue to investigate any report of an unusual exposure to HIV and report these cases to CDC. CDC will continue to tabulate the number of documented unusual exposures to HIV as reported by the states.

Because recently reported AIDS cases are more likely to be reported as NIR, recent AIDS incidence in some exposure categories will be underestimated unless an adjustment is made. For estimated AIDS incidence tables and estimated AIDS trends figures, the adjustment of NIR adult/adolescent cases is based on sex-, race-, and region-specific exposure category redistributions of cases diagnosed from 1990 through 1998 that were initially assigned to the NIR category but have subsequently been reclassified. Similar adjustment of NIR pediatric cases are based on exposure category redistribution of all cases diagnosed between 1990 through 1998 and subsequently reclassified. See *J Acquir Immune Def Syndr*, 1992;5:547-55 and *J Acquir Immune Def Syndr*, 1997;14:465-74.

Trends in AIDS incidence

Because of the temporary distortion caused by the 1993 expansion of the case definition, trends in AIDS incidence had previously been estimated by statistically adjusting cases reported based on the criteria added to the case definition in 1993. This adjustment estimated when persons reported on the basis of immunologic criteria (CD4+ T-lymphocytes counts less than 200 cells/µL or percentage less than 14) would develop an AIDS-related opportunistic illness (AIDS-OI), and thereby approximated trends in AIDS-OI inci-

dence as if the case definition had not changed (J Acquir Immune Defic Syndr 1997;16:116-21). However, by the end of 1996, the temporary distortion caused by reporting prevalent as well as incident cases that met criteria added in 1993 had almost entirely waned. In addition, after the end of 1996, the incidence of AIDS-OIs could no longer be reliably estimated because data are not currently available to model the increasing effects of therapy on rate of disease progression. Therefore, from 1996 forward, trends in AIDS incidence are adjusted for reporting delay, but not for the 1993 expansion of the case definition. These trends represent the incidence of AIDS (1993) criteria) in the population and increasingly represent persons with HIV newly diagnosed at the time of AIDS diagnosis, those identified with HIV who did not seek or receive treatment, and those for whom treatment has failed. Thus, despite the effects of treatment on AIDS incidence, AIDS incidence remains an important measure of the impact and need for resources for the severely ill.

Reporting delays

Reporting delays (time between diagnosis of HIV infection or AIDS and report to CDC) may vary among exposure, geographic, racial/ethnic, age, sex, and vital status categories, and have been as long as several years for some AIDS cases. About 40% of all AIDS cases were reported to CDC within 3 months of diagnosis and about 80% were reported within 1 year. Among persons with AIDS, estimates of death reporting delay show that approximately 90% of deaths are reported within 1 year. For HIV infection cases diagnosed since implementation of uniform reporting through the HIV/AIDS reporting system on January 1, 1994, about 68% of all HIV infection cases were reported to CDC within 3 months of diagnosis and about 92% were reported within 1 year.

Reporting delay adjustments to estimated AIDS data are calculated by a maximum likelihood statistical procedure, taking into account differences in reporting delays among exposure, geographic, racial/ethnic, age, sex, and vital status categories, and assuming that reporting delays within these groups have not changed over time (*Statist Med* 1998;17:143-54 and *Lecture Notes in Biomathematics* 1989;83:58-88).

Rates

Rates were calculated for the 12-month period per 100,000 population for AIDS cases. Population denominators for computing AIDS rates for the 50 states and the District of Columbia were based on official postcensus estimates and census 2000 counts from the U.S. Bureau of Census. Denominators for U.S. dependencies and possessions and associated independent nations were based on official postcensus estimates from the U.S. Bureau of the Census International Database. Each 12-month rate is calculated by dividing the number of cases reported during the 12-month period by the 1999 or 2000 population, multiplied by 100,000. The denominators used for computing the table of race-specific rates (year-end edition only) are based on 2000 census estimates published by the U.S. Bureau of Census: "National Population Estimates for the 1990's. Monthly Postcensal Resident Population, by single year of age, sex, race and Hispanic origin"; (http://eire.census.gov-/popest/archives/national/nat_90s_detail/nat_90s_1.php). The age/sex/race proportions from the July 2000 estimates were applied to the census 2000 national population total to estimate the age, sex, and racespecific subpopulations. Race-specific rates are calculated by dividing the number of cases reported for a particular racial/ethnic group during the preceding 12month period by the projected population for that race/ ethnicity, multiplied by 100,000.

Table 14. HIV infection cases¹ in adolescents and adults under age 25, by sex and exposure category, reported through December 2000, from the 34 areas with confidential HIV infection reporting² — *Errata* (replaces Table 14 in *HASR*, Volume 12, Number 2)

¹Includes only persons reported with HIV infection who have not developed AIDS.

²See table 3 for areas with confidential HIV infection reporting of adults and adolescents.

³For HIV infection cases, "risk not reported or identified" refers primarily to persons whose mode of exposure was not reported and who have not been followed up to determine their mode of exposure, and to a smaller number of persons who are not reported with one of the exposures listed above after follow-up. See Technical Notes.

⁴Includes 2 persons whose sex is unknown.
