# Enhanced Perinatal Surveillance— 15 Areas, 2005–2008

This issue of the *HIV Surveillance Supplemental Report* is published by the Division of HIV/AIDS Prevention, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention, Office of Infectious Diseases, Centers for Disease Control and Prevention (CDC), U.S. Department of Health and Human Services, Atlanta, Georgia.

Data are presented for cases of HIV infection among pregnant women reported to CDC through December 2009. All data are provisional.

The *HIV Surveillance Supplemental Report* is not copyrighted and may be used and reproduced without permission. Citation of the source is, however, appreciated.

#### Acknowledgments

Publication of this report was made possible with the contributions of the 15 Enhanced Perinatal Surveillance programs that provided surveillance data to CDC.

This report was prepared by the following staff and contractors of the Division of HIV/AIDS Prevention, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention, CDC: Suzanne K. Whitmore, Sabitha Dasari, Tebitha Kajese, R. Luke Shouse, H. Irene Hall, and Michael Friend (desktop publishing).

## Commentary

In February 1994, the Pediatric AIDS Clinical Trial Group Protocol 076 demonstrated that zidovudine (ZDV) could reduce the risk of mother-to-child HIV transmission from 25% to 8% [1]. As a result, a United States Public Health Service (USPHS) task force issued recommendations in August 1994 for the use of ZDV to reduce perinatal HIV transmission [2]. These guidelines were updated in July 2008 and include treatment options for HIV-infected pregnant women and for infants born to HIV-infected women. The guidelines also include recommendations for the medical monitoring of pregnant women and of infants who receive ZDV [3]. In July 1995, the USPHS published recommendations for HIV counseling and voluntary testing for all pregnant women, which include advice to health care professionals on educating women about the importance of knowing their HIV status and the steps to preventing mother-to-child transmission [4]. Revised recommendations for HIV testing for adults, adolescents, and pregnant women in health care settings were published in 2006. The 2006 HIV testing recommendations seek to provide more opportunities for pregnant women to be tested for HIV. The recommendations were revised to include the following: HIV screening as part of the routine panel screening for all pregnant women unless they decline; repeat HIV testing during the third trimester in areas with high HIV or AIDS incidence and in facilities with one or more HIV cases per 1,000 diagnosed in pregnant women in a year; and rapid HIV testing during delivery for all pregnant women without documented HIV test results [5].

After the HIV counseling and testing recommendations were published in 1995, CDC began conducting enhanced perinatal surveillance activities in 7 states to monitor the effect of the guidelines. Prevention indicators were assessed for the years before, during, and after the implementation of the guidelines (1993, 1995–1996). These indicators included receipt of prenatal care, HIV testing before or during pregnancy, and administration of ZDV to the mother antepartum and intrapartum and to the infant after birth. Data showed that an increased number of pregnant women and infants received ZDV after the recommendations were published. The proportion of infants infected

with HIV decreased from 16% of those who did not receive ZDV to 8% of those who received ZDV [6].

In 1999, the Institute of Medicine issued a report entitled *Reducing the Odds: Preventing Perinatal Transmission of HIV in the United States.* In this report, the committee described factors that lead to perinatal HIV transmission. They include the lack of prenatal care, HIV testing, and antiretroviral therapy (ART) for HIV-infected women and HIV-exposed infants [7]. Also in 1999, Congress appropriated \$10 million per year for activities aimed at reducing perinatal HIV infection. These activities included enhanced perinatal HIV surveillance, initially funded in 24 state and local health departments; perinatal HIV prevention programs, initially funded in 16 state health departments; and partnerships with 6 national organizations.

CDC implemented activities to further reduce perinatal HIV transmission in areas with high HIV prevalence. The Enhanced Perinatal Surveillance (EPS) project was created as an extension of routine HIV surveillance activities. The overall goals of EPS are to (a) assist in timely evaluation of perinatal prevention efforts; (b) monitor the implementation of the USPHS recommendations for counseling and voluntary testing of pregnant women, the use of antiretrovirals to prevent perinatal HIV transmission, and the effect of implementation of the USPHS recommendations on the trends of HIV disease among children; and (c) establish a surveillance system to collect data that will allow states to respond to selected requirements of the Ryan White CARE Act.

This report includes data from the 15 areas conducting EPS for live births from 2005 through 2008 (Figure 1). As of December 31, 2009, a total of 8,054 singleton births had been reported to EPS. The report is organized in 3 sections: (a) demographic, behavioral, and clinical information on HIV-infected pregnant women who gave birth; (b) demographic, behavioral, and clinical information on those women, by race/ethnicity; and (c) clinical information on infants born to HIV-infected women. EPS methods are described in the Technical Notes.

The purpose of this report is to describe the population of HIV-infected women who gave birth during

2005–2008. These data provide information for further focusing perinatal prevention efforts in the United States and the dependent areas. The data are presented by child's birth year so that readers can understand the characteristics of this population in a particular year.

#### **HIGHLIGHTS**

- The majority of HIV-infected pregnant women reported to EPS were of race/ethnicity other than white: 65% were black/African American, 23% were Hispanic/Latino, 1% were Asian, <1% were American Indian/Alaska Native, and <1% were Native Hawaiian/other Pacific Islander; whites represented only 9% (Table 1).
- Forty-six percent (46%) of the HIV-infected pregnant women were exposed to HIV through heterosexual contact, 8% were exposed through injection drug use, 8% through other exposure category, and exposure was unknown for 37% (Table 1).
- Most (90%) of the HIV-infected pregnant women received some prenatal care. Seven percent of HIVinfected women did not receive prenatal care (Table 2).
- HIV status was known before the pregnancy for 68% of HIV-infected pregnant women; 3% of women were diagnosed with HIV during labor and delivery (Table 3).
- Eighty-four percent of HIV-infected pregnant women received ARTs during the prenatal period and 85% received ARTs during labor and delivery. Of the infants born to HIV-infected women, 96% received ARTs during the neonatal period (Table 4).
- More than one third (40%) of the HIV-infected pregnant women had an elective cesarean section; 40% had a vaginal birth (Table 5).
- Twenty-eight percent of the HIV-infected pregnant women had used illicit drugs during pregnancy (Table 6).
- By race/ethnicity, the following percentages of HIV-infected pregnant women received prenatal care: 92% of Hispanic/Latino women, 90% of black/African American women, 90% of Asian women, and 89% of white women (Table 9).
- By race/ethnicity, the percentages of HIV-infected pregnant women who were tested before pregnancy

- were: 71% of white women, 68% of black/African American women, 68% of Hispanic/Latino women, and 68% of Asian women (Table 10).
- ARTs during the prenatal period were received by 87% of white women, 87% of Hispanic/Latino women, 86% of Asian women, and 84% of black/ African American women (Table 11).
- ARTs during the intrapartum period were received by 92% of Asian women, 86% of white women, 86% of Hispanic/Latino women, and 85% of black/ African American women (Table 11).
- The following percentages of infants, categorized by mother's race/ethnicity, received ARTs during the neonatal period: 97% of infants born to white women, 96% of those born to black/African American women, 96% of those born to Hispanic/Latino women, and 96% of those born to Asian women (Table 11).
- The percentages of HIV-infected women, by race/ethnicity, who had an elective cesarean section, were: 45% of Hispanic/Latino women, 43% of white women, 39% of black/African American women, and 39% of Asian women (Table 12).
- The following percentages of HIV-infected women, by race/ethnicity, had a vaginal delivery: 41% of black/African American women, 40% of white women, 38% of Hispanic/Latino women, and 38% of Asian women (Table 12).
- The percentage of HIV-infected women who reported illicit drug use during pregnancy varied by race/ethnicity: 50% of white women, 27% of black/ African American women, 24% of Hispanic/Latino women, and 11% of Asian women (Table 13)
- Of 8,054 infants born to HIV-infected women, 179 (2%) were perinatally infected with HIV, 5,683 (71%) were not infected, and 2,192 (27%) remain in the indeterminate category (Table 16).
- By race/ethnicity, the following percentages of HIV-infected pregnant women delivered preterm: 38% of black/African American women, 37% of Hispanic/Latino women, 36% of white women, and 33% of Asian women (Table 19).
- The following percentages of HIV-infected women, by race/ethnicity, had children identified to have a birth defect within their first year of life: 7% of Hispanic/Latino women, 6% of black/African

American women, 5% of white women, and 3% of Asian women (Table 19).

### **Technical Notes**

This surveillance supplemental report describes the data collected from the 15 areas in the United States and the Commonwealth of Puerto Rico that were funded to conduct the Enhanced Perinatal Surveillance (EPS) project. During the time period covered by this report, these project sites included 9 state health departments, Puerto Rico, and 5 city health departments. This project constitutes a population-based and facility-based surveillance system for HIV-infected mothers and their perinatally exposed children. Data were collected by using both the HIV case report form and a supplemental EPS data abstraction form. After the removal of personally identifying information, the data collected for EPS were submitted to CDC (see Figure 1 for participating areas).

Mother-infant pairs were identified through several means: pediatric HIV surveillance, reports of HIV-infected pregnant women to surveillance, birth registry matching to birth certificate records, and hospital discharge summaries. Where laws and regulations allowed, areas conducted a linkage of the enhanced HIV/AIDS Reporting System (eHARS) and the birth registry for the birth years 2005–2008 to obtain a list of all possible mother-infant pairs. A small proportion of women who had not been tested or who did not disclose their HIV status during pregnancy were identified through their child's HIV-infection status. The report does not include HIV-exposed children who were not tested but presumed to be negative.

Methods used by the areas to collect these data required linkage of mother-infant pairs and review of the records of both mother and infant. These records include prenatal care records, maternal HIV clinic records, labor and delivery records, pediatric birth records, pediatric HIV medical records, other pediatric medical records, birth certificates, death certificates, and health department records. The area-specific methods for collecting these data, however, differed to comply with local HIV reporting laws and regulations. Using the EPS abstraction forms, the areas collected information on the mother: prenatal care, HIV testing history, receipt of antiretroviral therapy during pregnancy, substance use, and clinical information. The areas also collected birth history and pediatric history for the infant and then conducted follow-up of each

infant every 6 months until the infant's HIV status was determined.

EPS data collection was either population-based or facility-based. Population-based areas were defined as those that included all HIV-exposed infants born to HIV-infected mothers within a geographic area (e.g., state or city). Medical records for all HIV-exposed infants and HIV-infected mothers were abstracted from all facilities within the defined geographic area. Facility-based areas collected data in selected facilities within the geographic area. The selected facilities were those serving large numbers of HIV-infected women (e.g., delivery hospitals or high-risk prenatal clinics) and HIV-exposed children (e.g., specialty pediatric clinics, pediatric HIV clinics). The medical records for HIV-exposed infants and HIV-infected mothers were abstracted from the facilities selected in these geographic areas.

Project areas collected data on HIV-exposed infants (and their mothers) born during 2005 through 2008. All infants born in the state, dependent area, city, or facility specified as the project site have been included. These include each infant of a multiple birth (e.g., twins, triplets).

#### **TABULATION AND PRESENTATION OF DATA**

Data in this report are provisional. This report includes EPS reports received by CDC through December 2009. All data tables are stratified by year of infant's birth.

The race/ethnicity categories are the categories used following the implementation of Office of Management and Budget (OMB) Statistical Policy Directive 15 [1]. These revised standards, which were implemented January 1, 2003, superseded the 1977 standards and reflect a change in federal policy on the collection of data on race and ethnicity.

Table 1 shows the numbers and percentages of HIV-infected women who gave birth to a live infant and who were reported to EPS. Tables 9, 10,11,12, 13, 17, 18, 19, 20, and 21 show data by infant's birth year and the mother's race/ethnicity. The cumulative totals reflect all racial/ethnic categories for the 4 birth cohort years. Because of small numbers for American Indian/ Alaska Natives and Native Hawaiian/other

Pacific Islanders, Tables 9, 10,11,12, 13, 17, 18, 19, 20, and 21 do not show data for these groups.

For the purposes of this report, women with HIV infection are counted only once in a hierarchy of exposure categories. If a woman is reported as having more than one mode of exposure, she is classified in the exposure category listed first in the hierarchy. Women whose exposure category is classified as heterosexual contact are those who reported heterosexual contact with a person with, or at increased risk for, HIV infection (e.g., an injection drug user) [2].

Missing data are categorized in this report as unknown. Missing information is a result of data collection methods. Charts and medical records are often missing key information and are sometimes not available. Patients are also lost to follow-up which makes it difficult to ascertain missing or unknown information. EPS data are collected prospectively and therefore completeness of data may improve over time.

The EPS protocol includes follow-up of all HIVexposed infants until HIV status can be determined. According to the revised HIV surveillance case definition for adults and children published in December 2008 [3], a child younger than 18 months and born to an HIV-infected woman can be classified as not infected only if virologic or antibody testing was performed during specified periods. If the tests were not performed or were not performed during the specified time periods, the child's status is classified as indeterminate [3]. In this report, the status of approximately one third (27%) of the total number of infants is indeterminate. It is presumed that many of these infants are not infected with HIV, but their status is indeterminate because the criteria for classification as not infected have not been met. Therefore, caution must be used in interpreting the perinatal HIV transmission rates. Follow-up of these indeterminate cases is ongoing.
