Neonatal abstinence syndrome (NAS) is a postnatal drug withdrawal syndrome that occurs primarily among opioid-exposed infants shortly after birth, often manifested by central nervous system irritability, autonomic overactivity, and gastrointestinal tract dysfunction (1). During 2000–2012, the incidence of NAS in the United States significantly increased (2,3). Several recent publications have provided national estimates of NAS (2,3); however, data describing incidence at the state level are limited. CDC examined state trends in NAS incidence using all-payer, hospital inpatient delivery discharges compiled in the State Inpatient Databases of the Healthcare Cost and Utilization Project (HCUP) during 1999–2013. Among 28 states with publicly available data in HCUP during 1999–2013, the overall NAS incidence increased 300%, from 1.5 per 1,000 hospital births in 1999, to 6.0 per 1,000 hospital births in 2013. During the study period, significant increases in NAS incidence occurred in 25 of 27 states with at least 3 years of data, with annual incidence rate changes ranging from 0.05 (Hawaii) to 3.6 (Vermont) per 1,000 births. In 2013, NAS incidence ranged from 0.7 cases per 1,000 hospital births (Hawaii) to 33.4 cases per 1,000 hospital births (West Virginia). The findings underscore the importance of state-based public health programs to prevent unnecessary opioid use and to treat substance use disorders during pregnancy, as well as decrease the incidence of NAS.

NAS is a postnatal withdrawal syndrome that comprises a constellation of symptoms in newborns, including central nervous system irritability (e.g., tremors, increased muscle tone, high-pitched crying, and seizures), gastrointestinal dysfunction (e.g., feeding difficulties), and temperature instability (1). Although other substances have been implicated, NAS is most often attributed to in utero opioid exposure. This exposure can result from maternal prescription opioid use, which has increased nationally in recent years (2,4), nonmedical opioid use, or medication-assisted treatment, which is long-term treatment with a longer acting but less euphoric opioid under medical supervision for opioid use disorder. Data on long-term developmental outcomes related to opioid exposure during pregnancy and NAS are limited.

The State Inpatient Databases include de-identified administrative data from all hospital inpatient discharges in a given state, regardless of payer. Data from State Inpatient Databases are compiled by state partners and then translated into a uniform format as part of HCUP, which is sponsored by the Agency for Healthcare Research and Quality. This analysis includes data from 28 states* whose data for 1999–2013 were publicly available on HCUP’s online central distributor (https://www.hcup-us.ahrq.gov/tech_assist/centdist.jsp). Consistent with previous methodology (2,3), in-hospital births were identified using International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) codes V30.X–V39.X ending in 00 or 01 (indicating single or multiple live born infants), among all hospital discharge records during 1999–2013. Discharge records that did not have a principal or secondary diagnosis code indicating a hospital birth, or that indicated a transfer from another acute care hospital or health care facility, were excluded. Cases of NAS were identified with ICD-9-CM code 779.5 (drug withdrawal syndrome in a newborn). Cases of possible iatrogenic withdrawal, resulting from complications related to prolonged neonatal intensive care stay and not exposure during the antenatal period (ICD-9-CM codes: 765.01–765.05, 770.7, 772.1X, 779.7, 777.5X, 777.6), were excluded from the numerator.

Total incidence rates of NAS (cases per 1,000 births) were calculated for 1999 and 2013, using data available from 14 and 21 states, respectively. In addition, incidence rates of NAS were calculated for each state and year with available data during 1999–2013. Linear trends were assessed using logistic regression with NAS incidence as the outcome variable and infant birth year as the independent variable for the 27 states with at least 3 years of data. Annual incidence rate changes, which reflect average annual change in the incidence rate of NAS over time, were calculated from the beta coefficient of the infant’s birth year with a state-specific intercept for states with significant linear trends. P-values <0.05 were considered to be statistically significant.

During 1999–2013, among 29,944,574 hospital births that occurred in the 28 states included in this report, 74,576 NAS cases occurred, reflecting an overall incidence rate of 2.5 cases per 1,000 hospital births. In 1999 (the first year), 2,419 NAS cases were identified among 1,610,733 births in 14 reporting states (1.5 per 1,000 births). In 2013, 8,270 NAS cases were identified among 1,385,371 births in 21 states (6.0 per 1,000 births). Data for at least 5 consecutive years were available for 27 states (Table). In 1999, NAS incidence ranged from

*Arizona, Arkansas, California, Colorado, Florida, Hawaii, Iowa, Kentucky, Maine, Maryland, Massachusetts, Michigan, Mississippi, Nebraska, Nevada, New Jersey, New Mexico, New York, North Carolina, Oregon, Rhode Island, South Carolina, South Dakota, Utah, Vermont, Washington, West Virginia, and Wisconsin.
0.3 per 1,000 births in Iowa to 7.6 per 1,000 births in Maryland. In 2013, NAS incidence ranged from 0.7 per 1,000 births in Hawaii to 33.4 per 1,000 births in West Virginia. During 2012–2013, three of 25 states (Maine, Vermont, and West Virginia), reported NAS incidence rates >30 per 1,000 hospital births (Figure). From 1999 to 2013, the incidence of NAS significantly increased in 25 of the 27 states with at least 3 years of data included in this report (Table). NAS incidence rates did not change significantly in California and South Dakota during 1999–2013. The annual incidence rate change over 1999–2013 was lowest in Hawaii (0.05 per 1,000 births) and highest in Vermont (3.6 per 1,000 births).

**Discussion**

The overall incidence of NAS in the states included in this report has increased almost 300% during 1999–2013, from 1.5 to 6.0 cases per 1,000 hospital births. This increase in NAS incidence is consistent with that reported by other studies, which have described a national increase in incidence of 383% (from 1.2 cases per 1,000 hospital births in 2000 to 5.8 cases per 1,000 hospital births in 2012) (2,3). Substantial variation in NAS incidence and trends by state exist, with incidences in 2013 ranging from 0.7 (Hawaii) to 33.4 per 1,000 births (West Virginia). Differences in NAS incidence might be caused by variations across states in opioid prescribing rates (5), prevalence of illicit opioid use, or use of the ICD-9 code that identifies NAS.

State governments partially finance and fully administer Medicaid programs, direct block-grant funds relevant to treatment of substance use disorders and maternal and child health programs, and license health care professionals. Previous research indicates that Medicaid programs were financially responsible for approximately 80% of the estimated $1.5 billion in NAS-related annual hospital charges in 2012 (3). Taken together, these factors make state-specific NAS estimates important to the formulation of public health plans to improve the health of mothers and infants affected by opioid use.
The findings in this report are subject to at least four limitations. First, the State Inpatient Databases include de-identified administrative data, and counts of NAS cases are based on information collected at the delivery hospitalization. In this analysis, only cases at the originating hospitals were counted. Cases identified as transfers from another hospital were not counted, to minimize possible duplication of counts and thus, overreporting of infants with NAS who might need a higher level of care. However, these rates are likely underestimates, as hospital administrative data identify fewer cases of NAS than does clinical reporting (6). Second, these estimates are not generalizable to births that occur outside of the hospital; however, out-of-hospital deliveries represented only 1.5% of births in 2014 (7). Third, although statistically significant annual changes in incidence rates were observed, these changes might not represent large increases in actual numbers of affected infants, depending on the birth population in each state. Finally, data are not generalizable to the entire United States, but only to the 28 states included in this report.

Primary prevention measures are important in curbing the incidence of NAS. In 2016, CDC released the *Guideline for Prescribing Opioids for Chronic Pain*, which recommends that clinicians 1) consider nonopioid pharmacologic therapy for chronic pain management, 2) discuss family planning and how long-term opioid use might affect future pregnancies before initiating opioid therapy in reproductive-aged women, and 3) prescribe the lowest effective dose when opioids are started (8). Individual states have implemented strategies to address the opioid epidemic and NAS. Prescription drug monitoring programs are operational or will be implemented in 49 states and the District of Columbia (www.cdc.gov/drugoverdose/pdmp) to track prescribing and dispensing of controlled prescription drugs; these programs have been shown to reduce inappropriate prescribing and overdose deaths (9). In addition, Florida, Georgia, Kentucky, and Tennessee have made NAS a reportable condition to state health departments to improve public health surveillance. Implementation of this type of passive surveillance of NAS can help states successfully target prevention and treatment measures, including access to medication-assisted treatment, the standard of care recommended by the American College of Obstetricians and Gynecologists for pregnant women with opioid use disorders (10). As part of the Protecting Our Infants Act of 2015,† CDC continues to provide technical assistance to states and American Indian tribes to improve NAS surveillance and to support implementation of effective public health measures.
