Global Routine Vaccination Coverage, 2015

Rebecca M. Casey, MBBS1-3; Laure Dumolard, PhD3; M. Carolina Danovaro-Holliday, MD3; Marta Gacic-Dobo, MSc3; Mamadou S. Diallo, PhD4; Lee M. Hampton, MD3; Aaron S. Wallace, MPH

In 1974, the World Health Organization (WHO) established the Expanded Program on Immunization* to provide protection against six vaccine-preventable diseases through routine infant immunization (1). Based on 2015 WHO and United Nations Children’s Fund (UNICEF) estimates, global coverage with the third dose of diphtheria-tetanus-pertussis vaccine (DTP3), the first dose of measles-containing vaccine (MCV1) and the third dose of polio vaccine (Pol3) has remained stable (84%–86%) since 2010. From 2014 to 2015, estimated global coverage with the second MCV dose (MCV2) increased from 39% to 43% by the end of the second year of life and from 58% to 61% when older age groups were included. Global coverage was higher in 2015 than 2010 for newer or underused vaccines, including rotavirus vaccine, pneumococcal conjugate vaccine (PCV), rubella vaccine, Haemophilus influenzae type b (Hib) vaccine, and 3 doses of hepatitis B (HepB3) vaccine. Coverage estimates varied widely by WHO Region, country, and district; in addition, for the vaccines evaluated (MCV, DTP3, Pol3, HepB3, Hib3), wide disparities were found in coverage by country income classification. Improvements in equity of access are necessary to reach and sustain higher coverage and increase protection from vaccine-preventable diseases for all persons.

WHO and UNICEF derive national coverage estimates through an annual country-by-country review of all available data, including administrative† and survey-based‡ reviews (2,3). To analyze equity of vaccination coverage, countries were categorized by World Bank income classification (low, lower-middle, upper-middle, high) based on 2015 per capita gross national income (GNI) (4) and eligibility for financial support from Gavi, the Vaccine Alliance (Gavi), for new vaccine introduction at any time since 2005§ (5). Eligibility for Gavi support is typically based on a country’s GNI per capita; the threshold for support started at US$1,000 per capita in 2000 and increased to US$1,580 by 2016.

*The original EPI vaccines were Bacille Calmette-Guérin vaccine (BCG) (to protect against tuberculosis), polio vaccine (Pol), measles-containing vaccine (MCV), and diphtheria-tetanus-pertussis vaccine (DTP).
†Administrative coverage is calculated as the number of vaccine doses administered to persons in a specified target group divided by the estimated target population.
‡During vaccination coverage surveys, a representative sample of households are visited and caregivers of children in a specified target group (aged 12–23 months) are interviewed. Dates of vaccination are transcribed from the child’s home-based record or are recorded based on caregiver recall or from health facility records. Coverage is calculated as the proportion of persons in a target age group who received a vaccine dose.
§Gavi Phase 2 classification (73 eligible countries).

Endorsed by the World Health Assembly in 2012, the Global Vaccine Action Plan 2011–2020 (6) calls on all countries to reach ≥90% national coverage and ≥80% coverage in every district or equivalent administrative unit for all vaccines in the country’s national immunization schedule by 2020. DTP3 coverage by age 12 months is an indicator of immunization program performance (2). During 2015, a total of 116 million children received DTP3; DTP3 coverage ranged from 76% in the WHO African Region to 94% in the Western Pacific Region (Table 1). National DTP3 coverage estimates ranged from 16% to 99% and the national DTP1 (first dose of DTP) to DTP3 dropout rates (the proportion of children who received DTP1 but did not receive DTP3) ranged from 0% to 61%. Overall, 124 (65%) countries achieved ≥90% national DTP3 coverage (Table 2). National DTP3 coverage was 80%–89% in 34 countries, 70%–79% in 12 countries, and <70% in 22 countries. Among the 19.4 million children worldwide who did not receive 3 DTP doses during the first year of life, 11.7 million (60%) lived in 10 countries (Figure). Among all children who did not complete the 3-dose DTP series, 12.8 million (66%) never received the first DTP dose, and 6.6 million (34%) started, but did not complete the series.

DTP3 coverage estimates in low-income countries were lower than in higher-income countries (Table 2). On average, DTP3 coverage was 11% lower in countries eligible for 2016 Gavi support (see supplemental figure at https://stacks.cdc.gov/view/cdc/42377). More than half of the 10 countries with the lowest 2015 DTP3 coverage estimates (Equatorial Guinea [16%]; Ukraine [23%]; South Sudan [31%]; Syrian Arab Republic [41%]; Somalia [42%]; Central African Republic [47%]; Guinea [51%]; Liberia [52%]; Chad [55%]; and Nigeria [56%]) are currently experiencing civil unrest or economic turmoil, which can lead to disruption of vaccination services (7). Complete subnational coverage data, based on country-reported administrative sources, were available for 158 countries in 2015; among these, 54 (34%) reported achieving ≥80% DTP3 coverage in every district, and 21 (13%) reported that ≥10% of districts had DTP3 coverage <50%.

MCV1 coverage in 2015 ranged from 74% in the African Region to 96% in the Western Pacific Region (Table 1) and from 20% to 99% by country; MCV2 coverage varied from 18% to 93% by region and from 8% to 99% by country. Globally, 119 (61%) countries achieved the ≥90%
The 2015 milestone in the Global Measles and Rubella Strategic Plan of vaccines by strengthening health systems and accelerating delivery of equitable immunization services. The Demographic and Health Surveys and Multiple Indicator Cluster Surveys conducted during 2005–2013 indicate that DTP3 coverage is lower in children from poorer households.

**The 2015 milestone in the Global Measles and Rubella Strategic Plan 2012–2020 was to achieve ≥90% coverage with the first routine dose of MCV (or measles-rubella-containing vaccine as appropriate) nationally and >80% vaccination coverage in every district or equivalent administrative unit. http://measlesrubellainitiative.org/wp-content/uploads/2013/06/Measles-Rubella-Strategic-Plan.pdf.

Discussion

Commitment by country governments and the collaboration of multiple global immunization partners has led to a reduction in the number of incompletely vaccinated children to an all-time low of 19.4 million in 2015. Since 2000, approximately 70 low- and middle-income countries have benefitted from Gavi support to increase equitable use of vaccines by strengthening health systems and accelerating the introduction and use of newer and underused vaccines such as PCV and rotavirus and rubella vaccines. However, despite substantial progress in increasing the number of children vaccinated worldwide, global DTP3, MCV1 and Pol3 coverage has remained at 84%–86% since 2010, with coverage improving in some countries and deteriorating in others; 68 (35%) countries have not yet met the Global Vaccine Action Plan 2011–2020 target of 90% national DTP3 coverage. Coverage varies widely among and within WHO Regions, countries, and communities. Even though vaccines are being introduced into low-income countries more rapidly than ever before (8), equity in coverage has not yet been achieved, and disparities exist, even for vaccines with long-standing recommendations, such as DTP and MCV, with higher coverage in higher-income countries. Furthermore, in lower middle-income countries, vaccination coverage in Gavi-eligible countries still lags behind coverage in non–Gavi-eligible countries despite Gavi support, and nine of the 10 countries with the largest number of incompletely vaccinated children are current or former Gavi-eligible countries, indicating that continued Gavi support for immunization system strengthening is necessary. Ensuring that eligible persons within each district are fully vaccinated according to the national schedule regardless of location, age, sex, ethnicity, educational level, and socioeconomic level is a considerable challenge to the successful delivery of equitable immunization services.

WHO/UNICEF vaccination coverage estimates are supported by or based on vaccination coverage surveys that disaggregate coverage data by demographic and other factors. The Demographic and Health Surveys and Multiple Indicator Cluster Surveys conducted during 2005–2013 indicate that DTP3 coverage is lower in children from poorer households.

and increases with higher economic status in most low- and middle-income countries (9). These surveys also indicate that coverage is generally higher in urban than rural areas and increases with level of mother’s education; no significant differences in coverage are observed by sex.

The findings in this report are subject to at least two limitations. First, inaccuracy in estimation of target population figures might result in over- or under-estimation of administrative coverage. Second, parental recall bias could lead to inaccurate estimates of survey-based coverage (2,3).
Summary
What is already known about this topic?
In 1974, the World Health Organization (WHO) established the Expanded Program on Immunization to ensure that all children have access to routinely recommended vaccines. Since then, global coverage with vaccines to prevent tuberculosis, diphtheria, tetanus, pertussis, poliomyelitis, and measles has increased from <5% to ≥85%, and additional vaccines have been added to the recommended schedule. Coverage with the third dose of diphtheria-tetanus-pertussis vaccine (DTP3) by age 12 months is an indicator of immunization program performance.

What is added by this report?
Global DTP3 coverage has not increased above 85%–86% since 2010. Vaccination coverage varies widely across WHO Regions, countries, and districts, and between population groups and communities, with lower coverage and higher numbers of under-immunized children in lower-income countries and among children from poorer households.

What are the implications for public health practice?
Equitable access to immunization to achieve and sustain high coverage and reduce child mortality can be enhanced through continued financial and technical support for program strengthening and vaccine introductions in lower-income settings; community engagement to increase vaccination acceptance and demand; the collection and use of high quality vaccination data; and government commitment to initiatives to improve immunization services.

Equitable access to immunization is a key goal of the Global Vaccine Action Plan 2011–2020 and is essential to reducing child mortality. Equity-oriented immunization programs that include effective community-centered activities to communicate the value and benefits of vaccination are required to reach marginalized populations and sustain high coverage. Because disease burden is often disproportionately higher in disadvantaged populations, reaching these persons could also have a larger health impact and contribute to economic development (6). National commitment and ownership of initiatives to introduce new vaccines and achieve high vaccination coverage is essential to the success of such programs.

Although global commitment and Gavi support have improved introduction of new vaccines into low-income countries (8), wide disparities in vaccination coverage by country income group exist, even for vaccines recommended since the inception of the Expanded Program on Immunization. The proportion of lower middle-income countries reaching the Global Vaccine Action Plan 2011–2020 targets of 90% coverage could be improved for both Gavi-eligible and non-Gavi-eligible countries, reflecting that resources are still needed to provide adequate system strengthening even after vaccines have been introduced. Strengthening immunization services, especially in countries with the highest numbers of undervaccinated children, should be a priority to help achieve the United Nation’s third Sustainable Development Goal of ending preventable deaths of newborns and children aged <5 years by 2030 (10).
