On May 24, 2016, the New York City Department of Health and Mental Hygiene notified CDC of two cases of *Exophiala dermatitidis* bloodstream infections among patients with malignancies who had received care from a single physician at an outpatient oncology facility (clinic A). Review of January 1–May 31, 2016 microbiology records identified *E. dermatitidis* bloodstream infections in two additional patients who also had received care at clinic A. All four patients had implanted vascular access ports and had received intravenous (IV) medications, including a compounded IV flush solution containing saline, heparin, vancomycin, and ceftazidime, compounded and administered at clinic A.

*E. dermatitidis* (previously known as *Wangiella dermatitidis*) is a neurotropic, dark pigment–forming fungus that is found in the environment (1). Health care–associated infections have been reported and include catheter-associated fungemia (1) and an outbreak of *E. dermatitidis* meningitis associated with contaminated injectable steroids prepared by a compounding pharmacy (2).

A case was defined as any non-*Candida* species yeast or mold identified on culture of blood or central venous catheter (CVC) (implanted port or peripherally inserted central catheter) from a patient who received care at clinic A during January 1–May 31, 2016. Case finding included microbiology record review, medical record review, and requests for screening blood and CVC cultures for all patients who had received an IV medication at clinic A during this period. Twenty-four of the 29 patients had a CVC, and five received IV medications through a peripheral line; all 17 patients with a positive culture had a CVC (attack rate of 71% compared with 0% among those with a peripheral line). After the screening blood culture was obtained, all patients with a CVC had their venous access removed and began 4–6 weeks of antifungal therapy. The five patients who received IV medications through a peripheral line had negative screening blood cultures, and antifungal treatment was not recommended.

Assessment of clinic A revealed failures to meet CDC infection control standards for outpatient oncology settings (3) as well as standards for sterile medication compounding and handling of hazardous drugs as outlined by U.S. Pharmacopeia chapters 797 and 800 (4,5) and the Food and Drug Administration (6). Investigators learned that IV flush bags containing saline, heparin, vancomycin, and ceftazidime had been compounded under substandard conditions, stored in a refrigerator, and accessed daily for multiple patients over approximately 4–8 weeks until the solution was depleted.

Upon issuance of an order by the commissioner of the New York City Department of Health and Mental Hygiene on May 31, 2016, the provider ceased treating patients at clinic A until it became compliant with medication preparation and infection prevention standards. This outbreak highlights the gaps in both awareness and enforcement of national and state pharmacy and infection control standards in outpatient settings that perform parenteral medication compounding and infusion services (3–6).
