EXECUTIVE SUMMARY

In December 2007 and January 2008, the Centers for Disease Control and Prevention (CDC) measured formaldehyde levels in a stratified random sample of 519 FEMA-supplied occupied travel trailers, park models, and mobile homes (i.e., “trailers”). At the time of the study, sampled trailers were in use as temporary shelter for Louisiana and Mississippi residents displaced by hurricanes Katrina and Rita. The study aimed to determine formaldehyde levels in occupied trailers, determine trailer characteristics that could affect formaldehyde levels, and provide information to assist FEMA in deciding whether to relocate residents from FEMA-supplied trailers in the Gulf Coast area. This study assessed only current formaldehyde levels in the occupied trailers; it was not a health effects study.

To evaluate levels of formaldehyde, investigators conducted a 1-hour continuous indoor air sample and sample measurements of indoor temperature and relative humidity. To determine factors that could affect formaldehyde levels, investigators administered a short questionnaire to adult residents about occupant demographics and trailer characteristics. To observe the exterior and interior of the trailer, investigators conducted a walk-through survey.

In many of the trailers tested, formaldehyde levels were higher than typical U.S. indoor levels. The geometric mean level of formaldehyde in sampled trailers was 77 ppb (range: 3–590 ppb). Formaldehyde levels varied by trailer type, but all types tested had some levels ≥ 100 ppb, the level at which health effects have been described in sensitive persons.

In this study, travel trailers had significantly higher average formaldehyde levels than did park models and mobile homes. A higher proportion of travel trailers than park models and mobile homes also had formaldehyde levels ≥ 100 ppb and ≥ 300 ppb. In multivariate analysis, factors such as temperature; relative humidity; trailer type and brand; opened windows, doors, and scuttles; and presence of mold (≥ 1 ft²) were significantly associated with formaldehyde levels.

Because formaldehyde levels tend to be higher in newly constructed trailers and during warmer weather, levels measured in this study are likely to underrepresent long-term exposures; many of these trailers are approximately 2 years old, and the study was conducted during the winter. In addition, the study did not evaluate any specific patterns of use with respect to specific types of trailers.

On the basis of the data reported here and in previous scientific reports and publications about adverse health effects associated with exposure to elevated formaldehyde levels,
CDC recommended that FEMA relocate Gulf Coast residents displaced by hurricanes Katrina and Rita and still living in trailers. Relocation priority should be given to occupants suffering symptoms potentially attributable to formaldehyde exposure and to vulnerable populations, such as children, elderly persons, and persons with chronic respiratory illnesses.
BACKGROUND

On August 28 and 29, 2005, Hurricane Katrina—a Category 4 storm—made landfall on the U.S. Gulf Coast between New Orleans, Louisiana (LA), and Mobile, Alabama. On September 24, 2008, Hurricane Rita—a Category 3 storm—made landfall along the Texas-Louisiana border. Many families evacuated from the U.S. Gulf Coast region returned later to find their homes severely damaged.

Starting in October 2005, the Federal Emergency Management Agency (FEMA) provided temporary housing along the Gulf Coast by supplying approximately 100,000 trailers (see box). In LA, more than 60% of trailers provided to residents were on private property. In Mississippi (MS), more than 78% of trailers were on private property. The remaining trailers in both states were in FEMA-designated trailer parks.

CDC Testing of Occupied Trailers

From December 21, 2007, to January 23, 2008, the Centers for Disease Control and Prevention (CDC) assessed levels of formaldehyde in indoor air of a random sample of occupied FEMA-supplied trailers. Formaldehyde testing was one of several actions CDC initiated in response to a July 13, 2007, request from FEMA to investigate concerns about formaldehyde in occupied FEMA trailers in LA and MS. This report details only the testing of occupied trailers for formaldehyde levels; it was not a health effects study.
Definitions for Trailers Used by FEMA for Gulf Coast Residents Displaced by Hurricanes Katrina and Rita

- **Mobile homes** are manufactured homes wider than 8 feet or longer than 40 feet (for an area >320 ft²). They are built on permanent chassis; contain plumbing, heating, air-conditioning, and electrical systems; and are designed for use as permanent dwellings. Mobile homes are defined and regulated by the U.S. Department of Housing and Urban Development (HUD).

- **Park models** are manufactured homes of 320–400 ft² administratively exempted from HUD formaldehyde standards. Park models may be regulated by transportation authorities and by manufacturer acceptance of a voluntary American National Standards Institute standard applying to their construction.

- **Travel trailers** are wheel-mounted trailers designed to provide temporary living quarters during periods of recreation, camping, or travel. Travel trailers generally have size limits, such as 8 feet wide and 40 feet long, for an area <320 ft². Travel trailers generally are considered vehicles rather than structures and are regulated by state transportation authorities rather than by housing authorities. Travel trailers have been used principally for short-term housing needs. They are placed on private sites while a homeowner’s permanent residence is repaired or in group configurations primarily to support displaced renters.

- **Manufactured homes** include mobile homes and park models and are used to meet both short- and long-term disaster housing needs. Manufactured homes typically are placed on commercial pads or in group sites developed expressly for this purpose.

- **“Trailers”** in this report refers collectively to travel trailers, park models, and mobile homes.
Formaldehyde Levels in Residential Indoor Air

Formaldehyde in homes is a longstanding issue. Formaldehyde frequently is used in plywood, fiberboard, resins, glues, carpets, and several other construction components. In the past, formaldehyde also was used in insulation of many homes. In March 1982, the U.S. Consumer Product Safety Commission (CPSC) called for a ban on urea foam formaldehyde insulation (UFFI) (US CPSC, 1982). Although several commercial groups challenged this ban, citing greater formaldehyde exposure from carpets and other building materials, UFFI use had dropped precipitously by the mid 1980s. However, homes built before or around the UFFI ban still had this insulation.

The 1982 ban on UFFI contributed to the decreased levels of formaldehyde in more recent studies. Changes in the type of pressed wood products containing formaldehyde resins or glues also contributed to the decrease. In the past, pressed wood products often contained urea-formaldehyde resins. Today these resins are not as widely used. Instead, many pressed wood products are constructed with phenol-formaldehyde products (commonly known as exterior-grade products). Phenol-formaldehyde products emit much less formaldehyde (US EPA, 2007).

Temperature, relative humidity (RH), ventilation, and age of house also contribute to differences in measured formaldehyde levels. In longitudinal studies, formaldehyde emission rates were nearly constant over the first 8 months after construction, and then began to decline, suggesting that formaldehyde off-gassing continues for extended periods but decreases with the age of the home (Park and Ikeda, 2006). Studies also show that older homes have lower formaldehyde levels than do newer homes (Hodgson et al., 2000; Gordon et al., 1999).

A 1985 U.S. study investigated formaldehyde levels in different types of housing (Stock and Mendez, 1985). Formaldehyde levels in 38 conventional U.S. homes averaged 40 parts per billion (ppb), with highs of 140 ppb. Nineteen apartments and 11 condominiums had average formaldehyde levels of 80 ppb and 90 ppb, respectively, with highs of 290 ppb. A more recent study of new homes found geometric mean (GM) formaldehyde levels of 34 ppb in manufactured homes and 36 ppb in site-built homes (Hodgson et al., 2000). This study suggested that formaldehyde levels in conventional homes have decreased greatly since the 1980s, possibly because of decreased use of plywood paneling and reduced emissions from the composite wood products used.

The U.S. Environmental Protection Agency’s National Human Exposure Assessment Survey found a median formaldehyde level of 17 ppb, with a high of 332 ppb, in 189 Arizona homes (Gordon et al., 1999). In a recent study of 184 single-family homes in three cities, Weisel et al. (2005) found mean formaldehyde levels of 3 ppb in outdoor ambient air; 17 ppb in home indoor air; and 16–25 ppb in trailers.

These studies indicate a trend. Even though all homes have some formaldehyde, levels generally seem to have decreased since the early 1980s. Lower ventilation rates in manufactured homes and greater ratios of surface area to volume may factor in this trend (US CPSC, 1997).
Health Effects
Symptoms from acute exposure to formaldehyde commonly manifest as irritation of the throat, nose, eyes, skin, and upper respiratory tract. This upper respiratory tract irritation can exacerbate symptoms of asthma and other respiratory illnesses (Main et al., 1983; Bracken et al., 1985; Kilburn et al., 1985; Imbus et al., 1985; Anderson et al., 1979; Garret et al., 1999; Hendrick and Lane, 1977; Institute of Medicine, 2000; Jaakkola et al., 2004; Kryzanowski et al., 1990; McCoy, 2008; NHLBI et al., 2007; Nordman et al., 1985; Rumchev et al., 2002; Staab et al., 2008; Thompson and Grafstrom, 2008).

Acute and chronic health effects of exposure to formaldehyde vary by individual. At 800 ppb, nearly everyone develops some acute irritative symptoms; however, formaldehyde-sensitive persons have reported symptoms at levels around 100 ppb (Main et al., 1983; Bender et al., 1983; Hanrahan et al., 1984). Additional studies have found health effects at 100 ppb in sensitive persons chronically exposed to formaldehyde (Ritchie et al., 1987; ATSDR 2010). Typically olfactory recognition occurs around 500 ppb, leaving the average exposure from a home below this level. Sensitive and sensitized persons can experience symptoms without detecting odor and thus receive little or no warning of exposure (Kulle et al. 1987; Weisel et al. 2005; Fischer et al., 1995; Garrett et al., 1999; Kiec–Swierczynska, 1996; Lee et al., 1984; Maibach, 1983; Marks et al., 1998; Wantke and Wantke, 1996).

In addition to acute health effects from formaldehyde, chronic effects in occupational settings have been studied. A study of 186 male plywood workers associated formaldehyde exposure with several respiratory symptoms, including cough and chronic bronchitis, and suggested that formaldehyde exposure induces symptoms of chronic obstructive lung disease (Malaka and Kodama, 1990). Funeral home workers reported chronic bronchitis more frequently than did controls who were not occupationally exposed to formaldehyde (Holness, 1989).

However, studies attempting to correlate worker-reported symptoms, such as cough or shortness of breath, with formal objective pulmonary function testing have shown conflicting results. Two studies demonstrated a small and reversible decrease in forced expiratory volume and forced vital capacity (Alexandersson et al., 1989; Alexandersson et al., 1982). Additional studies employing formal pulmonary function testing demonstrated no significant difference in pulmonary function testing parameters (Horvath, 1988; Holness et al., 1989).

The carcinogenicity of formaldehyde has been extensively studied during the last 30 years. In June 2004, the International Agency for Research on Cancer (IARC) reclassified formaldehyde from “probably carcinogenic to humans” to “carcinogenic to humans.” IARC has concluded that formaldehyde exposure causes nasopharyngeal cancer (http://monographs.iarc.fr/ENG/Meetings/88-formaldehyde.pdf). However, the National Institutes of Health National Toxicology Program has not adopted IARC’s classification change and continues to classify formaldehyde as “reasonably anticipated to be a carcinogen in humans” (http://ntp.niehs.nih.gov/ntp/roc/eleventh/profiles/s089form.pdf).

1 CDC added this reference on December 15, 2010 in response to an Information Request for Correction (http://aspe.hhs.gov/infoquality/request&response/35b8.pdf)
How to quantitatively relate measured air levels of formaldehyde to cancer risk is uncertain. Because many other factors play a role in the development of cancer and because formaldehyde is ubiquitous in the environment, no definitive level can be established that places humans in a “high-risk” category. The safest way to reduce risk for cancer is to limit exposure. Clinically useful biologic markers, such as blood or urine tests, also are lacking, further complicating the ability to link exposure with outcome. Because formaldehyde plays integral physiologic roles and has a short half-life in the body, determining what is necessary for normal physiologic function and what is excessive and potentially harmful is difficult (Sullivan and Kreiger, 2001; Baselt, 1994). In general, the lower the level and shorter the duration of exposure, the lower the risk for cancer and other health effects.

**Regulations and Standards of Formaldehyde Levels**

No federal regulation or standard exists for formaldehyde levels in residential settings. Occupational levels are not appropriate to apply to residential settings for a variety of reasons. For example, residential populations include children and elderly persons and thus are more diverse than occupational populations and possibly more susceptible to illness from exposure because of preexisting health conditions. Exposure times and circumstances in homes can vary substantially from those in occupational settings. Many occupational settings have ongoing monitoring programs and may have safety requirements to reduce formaldehyde exposure (US Department of Labor, 2007). Even for workers, regulations and standards established for formaldehyde by government agencies and other organizations—such as the Occupational Safety and Health Administration, CDC’s National Institute for Occupational Safety and Health, and the American Conference of Governmental Industrial Hygienists—differ markedly for both long- and short-term exposures (Federal Register, 1992; NIOSH, 1992; ACGIH, 1993).

Various nonoccupational standards also vary. The U.S. Department of Housing and Urban Development (HUD) regulates formaldehyde emissions from wood products used in the construction of manufactured housing. HUD’s maximum allowed levels for formaldehyde emissions from wood products are 200 ppb for plywood and 300 ppb for particle board (http://ecfr.gpoaccess.gov). The World Health Organization guideline for formaldehyde in nonoccupational settings is 100 ppb for 30 minutes. This guideline was developed to protect against sensory irritation in the general population, but it also represents an exposure level at which risk for upper respiratory tract cancer in humans is negligible (WHO, 1989). The State of California Office of Environmental Health Hazard Assessment (OEHHA) guideline for formaldehyde is less than typical ambient levels, it recommended an office level of 23 ppb (http://www.oehha.ca.gov/air/chronic_rels/AllChrels.html).

**OBJECTIVES**

The objectives of this study were to

1. Determine formaldehyde levels in occupied trailers.
2. Determine factors or characteristics of occupied trailers—not specific to any particular type of trailer—that could affect formaldehyde levels.
3. Provide information to assist FEMA in making decisions about relocating residents from FEMA-supplied trailers still used in the Gulf Coast area.
METHODS

To evaluate the formaldehyde levels and to determine potential factors and characteristics of occupied trailers that can impact formaldehyde levels, study investigators collected the following data for each participating trailer:

- A concurrent sample measurement of indoor temperature and RH.
- A short questionnaire administered to adult residents to obtain demographic information about trailer residents and typical daily activities.
- A short walk-through survey to assess the indoor environment and the home exterior.

Study Personnel

Staff who collected the data were contractors from Bureau Veritas (Kennesaw, GA). Their training at the beginning of the study included review of recruitment, data collection, trailer visits, data records, and the protocol. CDC staff monitored contract staff throughout the study and were always available for consultation.

Trailer Selection

Using disproportionate stratified random sampling, CDC investigators selected 519 trailers for participation from a FEMA-provided list of 46,970 trailers in LA and MS that were identified as occupied as of November 2007. SAS 9.1 was used to randomly generate a list of sample trailers.

The three trailer types most commonly used—travel trailer, park model, and mobile home—were divided into a total of 11 strata. Travel trailers comprised seven strata: the top six manufacturers (Gulfstream, Forest River, Fleetwood, Fleetwood CA, Pilgrim, and Keystone [which together represented 61% of occupied travel trailers]) and “all other” travel-trailer brands. Because Gulfstream was the most frequently used travel trailer, that brand was oversampled. Park models comprised two strata: the most common model manufactured by Silver Creek (21% of park models) and “all other” park model manufacturers. Mobile homes also comprised two strata: the most common model manufactured by Cavalier (17% of mobile homes used) and “all other” manufacturers. Each brand in the “all other” groups made up <3% of the trailers.

The number of trailers selected was based on power calculations that allow researchers to draw statistically valid conclusions about the population of occupied trailers studied (i.e., FEMA-supplied trailers used) and for common trailer types and brands within that population of FEMA-supplied trailers. With a level of significance of 5% (95% confidence) and power of 80%, the goal was to sample a minimum of 38 trailers to detect an average difference of 30 ppb for each stratum. Sample sizes were calculated as tests for each stratum mean against the mean for the entire sample.

Within each stratum, each trailer was assigned a random number (e.g., SAS: Randval=randuni[number]). Each list then was sorted in numeric order according to the random number assignment. In recruiting eligible households, investigators followed a specific protocol (Appendix A) and used these ordered active call lists to recruit participants for the study, beginning with number 1 and ending with number 120 for the Gulfstream stratum and with
number 38 for each of the other 10 strata. When the occupant of a selected trailer could not be contacted, declined participation, or was ineligible, investigators called the next trailer on the list, adding trailers as necessary from a reserve list, until they had successfully enrolled 120 trailers in the Gulfstream stratum and 38 trailers in each of the other 11 strata.

Up to three telephone numbers were provided for each trailer. Over a 1-week period, investigators attempted a total of 15 times separate attempts to contact a selected trailer. The 15 attempts included various times of the day and days of the week. If unsuccessful after 15 attempts, the trailer was moved to the “unable to contact” list and a new trailer from the reserve list was added to the active call list.

Contract staff followed a phone script (Appendix B) when speaking with the self-identified adult resident and recorded each attempt in a phone log (Appendix B). If the adult resident of an eligible household agreed to participate, a time was scheduled to conduct the sampling. If the adult resident declined to participate, the trailer was moved to the “refused to participate” list and a new trailer from the reserve list was added to the active call list.

Some enrolled households were expected to not complete the study for a variety of reasons. Each time it was determined that an enrolled trailer was to be removed from the list of participants, a new trailer from the reserve list was substituted and recruitment procedures as described above were followed.

Eligibility Criteria
Adult residents who agreed to participate were enrolled in the study. Eligibility criteria for participation in the study specified that:

- The consenting adult resident was ≥ 18 years of age.
- The adult resident resided in a FEMA-issued trailer in MS or LA at the time of phone recruitment.
- The adult resident reported that he or she spent at least 6 hours each day in a FEMA-issued trailer.
- The adult resident agreed to participate.

Consent/Assent Process
Adult residents provided informed assent (Appendix C) which was first obtained from the contacted adult resident during the scripted recruitment phone call. A second informed consent form was provided to the participant and signed in person sample collection (Appendix D). All participants received appropriate notification of confidentiality. CDC’s Institutional Review Board reviewed and approved this study (CDC Protocol #5320, approved by CDC IRB-G on December 20, 2007).
Variables
The primary outcome variable was the 1-hour average level of formaldehyde measured in the air of occupied trailers. To determine potential factors of occupied trailers that can affect the measured formaldehyde levels, other variables were collected during an exposure assessment and walk-through.

Exposure Assessment Questionnaire
Investigators administered a short questionnaire (Appendix E) to the adult resident during the 1-hour sample collection process. The questionnaire inquired about the demographics of the trailer occupants and the average number of hours spent inside and outside the trailer. It also inquired about factors that can influence the indoor environment of the trailer, such as occupant smoking and frequency of air conditioning, heating, and window use. Daily and recent activities in the trailer, such as cooking, also were recorded.

Environmental Walk-Through Survey
During the walk-through survey (Appendix E), investigators surveyed the interior and exterior of the trailer, observing such factors as holes and leaks, mold, type of cooking fuel, and working smoke detectors.

Formaldehyde Sample Collection
Investigators and FEMA field workers were present for each scheduled sampling appointment. Investigators collected a 1-hour sample of air in each participating trailer using the NIOSH Manual of Analytical Methods Method 2016 using Supelco S10 LpDNPH cartridges (St. Louis, MO) (http://www.cdc.gov/niosh/nmam/pdfs/2016.pdf). Staff also measured indoor temperature and RH. In an attempt to standardize living conditions between trailers, residents were asked to configure doors and windows as they would have them while they slept. No cooking or smoking was allowed in the travel trailers or mobile homes during the 1-hour sample collection period because these activities could affect formaldehyde levels.

Samples were collected using standard industrial hygiene pumps. Samples were drawn at a flow rate of 500±50 mL per minute for 1 hour at a height of 4 feet, which is comparable to a person’s breathing zone while sitting. An investigator observed sample collection at all times. Investigators followed all quality assurance and quality control standards as outlined in the standard operating procedures for field collection (Appendix F).

Samples were analyzed for formaldehyde levels at the Bureau Veritas laboratory in Novi, Michigan. The Bureau Veritas laboratory is a contract laboratory for NIOSH and follows NIOSH data quality objectives in its sampling and analysis.

Temperature and Relative Humidity Sample Collection
A concurrent 1-hour reading of temperature and RH was collected in the center of the trailer primary living room using a HOBO® temperature and RH logging instrument manufactured by Onset Computer Corporation (Bourne, MA). The instrument collected data at 5-minute intervals. Data were collected for a minimum of 70 minutes, beginning at least 5 minutes before and lasting at least 5 minutes after collection of the formaldehyde sample at each trailer.
Sample Collection Data Sheet
Investigators completed a data sheet (Appendix G) for formaldehyde, temperature, and RH. Information included sample start and finish time, location of sample collection, and flow calibration results before and after sample collection was recorded. The data sheet accompanied the questionnaire and the walk-through survey (Appendix E).

Data Collection, Entry, Editing, and Management
Investigators collected all questionnaire, survey, and field data; labeled all samples and documentation with a unique alphanumeric identifier; and logged all paperwork and samples as they completed each trailer. Strict quality assurance and quality control procedures were observed.

Investigators entered all field data into an electronic database. All participant information remained confidential and was used only for the study. Access to data was restricted to those involved in conducting the study. In addition, all reports—published and internal—were based only on aggregate data. Investigators returned or destroyed all data sources after delivering the final approved database to CDC.

Statistical Analysis
All statistical analyses were conducted using SAS 9.1. The SURVEYMEANS, SURVEYREG, and SURVEYFREQ procedures were used to account for the stratified sampling design. Unweighted frequencies of questionnaire items were calculated using the FREQ procedure.

Data were examined and potential misclassifications of trailers resolved. The manufacturer, manufacturer’s vehicle identification number, and trailer type were examined to confirm the categorization of each trailer. In cases where a trailer was recategorized, two independent evaluators agreed on the new classification.

A natural log transformation was applied to the formaldehyde levels to normalize the distribution. Tests for normality were conducted on the transformed levels, and the levels were plotted to examine the form of the distribution. Univariate linear regression models were constructed to evaluate the significance of selected questionnaire items in predicting the natural log of formaldehyde levels. Variables with cell counts of five or fewer were not included in the regression models.

Temperature and RH were evaluated separately as both continuous and categorical variables. Recorded signs of mold in the living area of the trailer were used to create a dichotomous variable indicating whether the trailer had <1 ft² of mold versus ≥1 ft² of mold.

Because the SAS SURVEYREG procedure does not include an option for automated model selection, CDC staff manually performed a backward elimination procedure. All independent variables with cell counts greater than five initially were entered into the linear regression model. At each step, the variable contributing the least to the model, as assessed by the F statistic, was removed. The final model included variables that were significant at a P of ≤0.05.
RESULTS

Participation Rates
During recruitment, investigators contacted residents at 1137 (76%) of the 1489 trailers on the FEMA-supplied list (Figure 1). Of the 717 eligible trailers, occupants in 519 (72%) participated. Reasons for ineligibility of the remaining 420 trailers included trailer not occupied (367 [87%]); trailer type no longer needed for its stratum (27 [6%]); trailer occupant unable to schedule an appointment time because of work, travel, hospitalization, or other reasons (15 [4%]); hostility by occupants (3 [1%]); and unknown reasons (8 [2%]).

Most trailers sampled were in LA and were located on private land (Table 1). Most were issued in 2005 and therefore were at least 2 years old at the time of testing. Seventy-seven percent of total occupants were adults. Recategorization of trailers resulted in reclassification of 35 trailers (7%) to new strata. The majority of these reclassified trailers came from the nonspecific “other” strata.

Overall Range and Variability of Formaldehyde Levels
The geometric mean (GM) formaldehyde level for all trailers sampled was 77 ppb (95% confidence interval [CI]: 70–85; range: 3–590 ppb). Throughout this report, when mean formaldehyde levels are discussed they will refer to GM formaldehyde levels. The GM formaldehyde level was 81 ppb for travel trailers (95% CI: 72–92), 44 ppb for park models (95% CI: 38–53) and 57 ppb for mobile homes (95% CI: 49–65) (Figure 2). GM formaldehyde levels varied significantly among travel trailers, park models, and mobile homes ($P < 0.001$) and ranged widely in all types of trailers. In all three trailer types, some trailers had formaldehyde levels $\geq$ 100 ppb. Mobile homes and travel trailers each had levels $\geq$ 300 ppb (Table 2). GM formaldehyde levels differed significantly among strata, but each stratum included some trailers with levels $\geq$ 100 ppb (Table 3).

Occupant Activities
The investigation included occupant activities in the trailers (Table 4). Air conditioning was used <4 hours per day in 71%; heat was used <4 hours a day in 56%; and space heaters were used in 44%. For 34% of trailers, residents reported someone had smoked in the trailer within 2 weeks before the sampling. Eighty-one percent of respondents cooked in their trailers. Pets were present in 25% of trailers, with dogs (20%) most commonly reported. More than 80% of respondents spent >8 hours in their trailer each day.

Occupant activities directly preceding the sampling period were recorded to determine whether they significantly affected sampling results. Within 3 hours before testing, 44% of homes had windows, doors, and scuttles open, and smoking had occurred in 19%. Other activities in the week before testing included use of air fresheners (61%); candles (24%); and glue, paint, or furniture finish (3%). These finding did not correlate with any specific type of trailer.

Trailer Characteristics
Specific characteristics of each sampled trailer were recorded. Respondents reported roof leaks in 17% of trailers, pipe leaks in 15%, and mold in 21%.
Walk-Through Survey
On the day of sampling, investigators walked through each trailer to record specific characteristics and information (Table 5). Propane gas was the most commonly used fuel for cooking (71% of trailers). Six percent of trailers had at least 1 ft² of mold. Twenty-nine percent of trailers did not have a functioning smoke detector.

Multivariate Analysis
Backward elimination modeling yielded a final regression model containing the following statistically significant variables: stratum ($P < 0.0001$); average temperature in degrees F ($P < 0.0001$); RH expressed as a percentage ($P < 0.0001$); a dichotomous variable indicating whether doors, windows, or scuttles were open in the 3 hours before testing ($P = 0.02$); and a dichotomous variable indicating the amount of mold observed in the trailer ($\geq 1$ ft²) ($P = 0.05$).

The dependent variable was the natural log of the formaldehyde levels. Temperature accounted for the most variation in the natural log of formaldehyde levels explained by the model (Figures 3 and 4) show the unadjusted relationship between the natural log of formaldehyde and temperature and humidity, respectively. Temperature ranged from 41°F to 91°F, and RH was 23%–88%.

Temperature and RH were evaluated separately as both continuous and categorical variables. Results were similar, so investigators included the continuous variables in the final model. Interactions between independent variables were not significant.

The presence of $\geq 1$ ft² of mold was associated with a significant increase in GM formaldehyde levels (adjusted mean 86 ppb versus 63 ppb) (Table 6). Windows, doors, or scuttles open in the 3 hours before testing was associated with a significant decrease in GM formaldehyde levels (adjusted mean 65 ppb versus 83 ppb) (Table 7). Although each of three strata (Forest River, other park models, and other mobile homes) contained fewer than 38 trailers, contrasts comparing the GM formaldehyde level in each of them to the overall GM of the others still showed significant differences ($P = 0.01, 0.01, and 0.04$, respectively).

GM formaldehyde levels in travel trailers manufactured by Fleetwood and Fleetwood CA were significantly lower than levels in the other travel trailers combined, after adjustment for covariates ($P < 0.001$ for both). They did not differ significantly from each other. GM formaldehyde levels for Pilgrim, Keystone, and Gulfstream were significantly higher than for the other travel trailers combined, after adjustment for covariates ($P < 0.001$ for all three). They did not differ significantly from each other. After adjustment for covariates, levels in Silver Creek park models were significantly lower than those in other park models ($P = 0.004$), and levels in Cavalier mobile homes were significantly higher than those in other mobile homes ($P = 0.006$). Table 8 presents the adjusted GM formaldehyde level by stratum from the multivariate model.

The parameter estimates (Table 9) can be used to calculate predicted formaldehyde levels. However, extrapolating beyond observed levels is not recommended. As an example, a Keystone travel trailer with an average temperature of 65°F; an average RH of 45%; no open doors, windows, or scuttles in the 3 hours before testing; and mold ($\geq 1$ ft²) would have a predicted formaldehyde level of 88.5 ppb:
DISCUSSION

Formaldehyde levels in the trailers in this study were higher than average levels in U.S. mobile homes and traditional homes reported in recent studies (Weisel et al., 2005; Gordon et al., 1999). As the formaldehyde level rises, risk for health consequences presumably also rises. At higher levels, people can have acute symptoms, such as coughing and irritated eyes, nose, throat, and upper respiratory system. Even at levels too low to cause such symptoms, risk for cancer can increase. No specific level of formaldehyde separates "safe" from "dangerous," especially in regard to cancer.

In this study, certain human activities were associated with higher formaldehyde levels. Open windows, doors, or scuttles decreased formaldehyde levels, indicating ventilation of trailers is an important recommendation to occupants. Keeping windows, doors, or scuttles open and the using air conditioning were associated with decreased levels of formaldehyde in trailers in a previous study (ATSDR, 2007). Yet many trailer air conditioners recirculate air and do not provide outside ventilation. Thus, less use of air conditioning may indicate increased ventilation because doors, windows, and scuttles are more likely to be open. Results of this study show a low use of air conditioning during the study period. Most trailers had working air conditioning, but most people did not use it more than 4 hours each day, most likely because the study was conducted during the winter; other factors could include cost and noise.

Smoking by occupants, though not significantly associated with increased formaldehyde levels in the multivariate analysis, was common and remains an important issue because cigarettes are a source of formaldehyde. Cigarette smoke also contains a wide range of other toxic and irritating compounds associated with increased health risk that can worsen air quality in the trailers.

The presence of mold (≥ 1 ft²) (6% of trailers) was associated with higher formaldehyde levels. Mold also can contribute to decreased indoor air quality and cause respiratory symptoms.

Cooking, particularly without outdoor-venting range hoods, can affect formaldehyde levels. The unvented combustion from gas-fired stoves can be a source of formaldehyde and other air pollutants and can increase the temperature and RH inside the trailer.

Increased indoor temperature and RH were associated with increased formaldehyde levels. These associations indicate exposure risks could increase during the summer, perhaps dramatically, with warmer and more humid weather. Formaldehyde levels during the winter may not represent summer levels.

Stratification was conducted to assess the possibility of an elevated formaldehyde level in one brand or a group of brands. Some brands showed higher GM formaldehyde levels than others, although this study showed all brands with some trailers ≥ 100 ppb, levels at which health effects have been described in sensitive persons. Formaldehyde levels varied by trailer type, but all
types tested had some levels $\geq 100$ ppb (Ritchie et al., 1987; Main et al., 1983; Bender et al., 1983).

LIMITATIONS

Study results are not representative of trailers purchased and used in other places and other situations because the sample for this study was selected only from occupied FEMA-supplied trailers in LA and MS. Formaldehyde levels in other trailers used elsewhere could differ by age, characteristics of manufacture, circumstances of use, or characteristics of environment.

Formaldehyde levels are expected to be lower in cooler temperatures and lower RH because of the processes of formaldehyde off-gassing. Therefore, levels measured in this study are likely to underestimate past levels—when trailers were hotter and more humid—and future levels—during summer months. Many of these trailers were $\geq 2$ years old, and previous studies have shown highest formaldehyde levels in newer trailers and homes (Hodgson et al., 2000; Gordon et al., 1999), so residents were probably exposed to higher levels of formaldehyde when their trailers were newer.

Formaldehyde was measured at a central location in the trailer, and different locations in the trailer could have different formaldehyde levels. However, as a gas, formaldehyde is likely to diffuse evenly throughout the trailer. The results of this study do not apply to trailers used in other places and situations because this representative sample was selected only from FEMA-supplied trailers in LA and MS. This study does not assess the health status of people currently living in FEMA trailers, but further studies are planned to investigate potential health effects from living in trailers.

CONCLUSIONS

1. In many trailers tested, formaldehyde levels were higher than typical U.S. indoor levels.
2. The average level of formaldehyde in all trailers was 77 ppb, and many trailers had higher levels (range: 3 ppb–590 ppb). These are higher than U.S. background levels, and occupant health could be affected at the levels recorded in many trailers.
3. These measured levels probably underrepresent occupant exposures in the early months of occupation and even the average exposure over time the trailers were occupied because formaldehyde levels tend to be higher in newly constructed trailers and during warm weather.
4. Higher indoor temperatures and RH were associated with higher formaldehyde levels in this study, independent of trailer type or brand.
5. Formaldehyde levels varied by trailer type, but all types tested had some levels $\geq 100$ ppb, at which acute health effects can occur in sensitive persons.
6. Travel trailers had significantly higher average formaldehyde levels than park models or mobile homes. Travel trailers also had higher proportions of trailers with formaldehyde levels $\geq 100$ and $\geq 300$ ppb than park models or mobile homes.
7. Because some types and brands had lower average formaldehyde levels, trailers might be able to be manufactured or used in ways that reduce levels. Additional studies are under way to address this possibility.
8. Factors such as temperature; RH; closed windows, doors, and scuttles; and presence of
mold (≥ 1 ft²) were associated with increased formaldehyde levels in the trailers. These were not assessed with respect to any specific type of trailer.

9. Only 71% of trailers sampled had a working smoke detector. Education is needed about the need for smoke detectors in the trailers and testing to ensure they function correctly.

RECOMMENDATIONS

Recommendations for Public Health, Emergency Response, and Housing Officials

1. These conclusions support decisions made need to relocate residents of the U.S. Gulf Coast region displaced by hurricanes Katrina and Rita who still live in trailers move quickly before temperatures in the region increased. On the basis of observations and previous scientific literature, priority should be given as follows:
   a. Persons currently experiencing symptoms possibly attributable to formaldehyde exposure,
   b. Especially vulnerable persons (e.g., children, the elderly, and those with chronic diseases), and
   c. Persons living in trailer types that tend to have higher formaldehyde levels.

2. Follow-up will require collaboration among multiple agencies—including FEMA, HUD, CDC, and state and local officials—to achieve safe, healthy housing for people displaced by hurricanes Katrina and Rita who continue to live in FEMA-supplied trailers.

3. Follow-up will require multiagency collaboration involving HUD, CDC, and others to assess the potential for formaldehyde levels in trailers used in other places and contexts, including trailers used for recreation, permanent housing, schools, and offices.

4. Federal, state, and local officials should consider how best to provide necessary assistance to the Louisiana and Mississippi state health departments to ensure adequate follow-up, including medical needs, for residents with health and medical concerns resulting from formaldehyde exposure while residing in FEMA-provided travel trailers, park models, and mobile homes.

5. Federal, state, and local officials should consider supporting establishment of a registry of people who resided in FEMA-supplied trailers in the U.S. Gulf Coast region.

Recommendations for Residents Awaiting Relocation

1. Spend as much time as possible outdoors in fresh air.

2. Open windows, doors, and scuttles as often as possible to let in fresh air.

3. Try to maintain the temperature inside trailers at the lowest comfortable level.

4. Do not smoke, especially not inside.

5. If you have health concerns, see a doctor or another medical professional.

6. All of these recommendations apply particularly to families with children, elderly persons, and those with chronic diseases, such as asthma.

Further CDC Action

1. CDC notified participants about their study results by personal visits from members of the U.S. Public Health Service Commissioned Corps and FEMA representatives and by hand-delivered letters.

2. At a series of 14 public availability sessions in LA and MS, CDC staff were available to talk with concerned and interested persons, provide information, and answer questions.
3. CDC is assessing formaldehyde levels across different models and types of unoccupied trailers to identify factors that decrease or increase those levels. This assessment also involves identifying cost-effective ways to reduce formaldehyde levels in trailers.

4. CDC is developing a protocol for a long-term health study, with a respiratory focus, of children who resided in FEMA trailers and mobile homes in LA and MS.

5. CDC provided educational materials and information to trailer residents about their risk for exposure to formaldehyde and ways to improve indoor air quality and health.

6. CDC reconvened a panel of experts on this issue to identify and provide input on health issues potentially associated with long-term residence in trailers.

APPENDIX A:
PROTOCOL FOR TRAILER SELECTION AND RECRUITMENT

CONTACTING PARTICIPANTS: Materials needed
1. You will receive a stratified list of names and up to 3 phone numbers of residents in trailers from a CDC representative. This list represents the people whom you will contact for participation in the study.
2. For each trailer, you will need one clean phone log form (Appendix B) to log all attempted and successful calls.
3. You will need a copy of the telephone script (Appendix B) to ensure that each conversation is consistent.
4. You will need a clean copy of the “Obtaining Assent” form (Appendix C) for each trailer contacted.

CONTACTING PARTICIPANTS: Conducting the phone calls
1. You will need to make the calls from the provided spreadsheet.
2. Begin with the first name on the list and call them using the first number provided.
3. If you are unable to get an answer, try the next phone number provided.
4. After each attempt, record the information in the phone log (Appendix B).
5. **Fifteen attempts** using each provided number must be made before ending the recruitment of the person from the contact list. **Over half** of these attempts should be made after 5 pm in the event that the contacts are not at home to receive the call during the day.

If you are unable to reach a contact:
6. If you are unable to contact a trailer after making fifteen attempts for each provided phone number, the majority of which attempted after 5 pm, file the recorded phone log into a folder labeled “Unable to Contact”.

If you are able to contact a person in the trailer:
7. When someone answers the phone, use the phone script (Appendix B) to guide the conversation.
8. If the adult resident is not available, you will need to continue efforts to make contact with him/her.
9. If the adult resident is NOT interested in participating, note refusal in the phone log. File the phone log into a folder labeled “Refused”.
10. If the adult resident is interested in participating, ensure that they are eligible using the criteria outlined in the phone script.
11. If the adult resident agrees to participate, obtain verbal assent (Appendix C) and set up an appointment date and time with the adult resident.
12. Record “Agreed” in the phone log and file the phone log AND assent form in a folder labeled “Agreed”.
RECRUITMENT COMPLETION
1. Recruitment is complete when all 11 strata have been completed. This will consist of at least 500 trailers total.

PARTICIPANT FOLLOW-UP: Appointment reminder
1. Prior to their appointment, call the adult resident to confirm the sampling date and time
2. If the respondent can no longer make the appointment, reschedule the appointment.
**APPENDIX B: PHONE LOG FOR PARTICIPANT RECRUITMENT**

Final CDC Findings—Formaldehyde Levels in FEMA-Supplied Trailers  37
APPENDIX B, con’t:
TELEPHONE SCRIPT FOR PARTICIPANT RECRUITMENT

IF CHILD ANSWERS THE PHONE:

Hi, may I speak with your mother or father please?

IF NO ADULT IS HOME:

Okay. Could you please tell me what would be a good time to call back?

[NOTE IN PHONE LOG]

Thank you, I’ll try calling back later.

IF AN ADULT ANSWERS THE PHONE:

Hello, this is __________ calling for the Centers for Disease Control and Prevention.
Is this the ___ (NAME) ____ residence? I am working with FEMA and the
Louisiana and Mississippi Departments of Public Health to find out if there is
formaldehyde (a potentially harmful chemical) in the trailers in which people are living.
We have picked some trailers at random, like flipping a coin. May I ask if you are an
adult resident living in a FEMA-owned trailer?

IF NO,

Okay, we will be working with all adult residents who are 18 years or
older. What is a good time to call back to speak with him or her? And is
this the best number to reach him/her?

[NOTE NAME AND TIME IN PHONE LOG]

Thank you, I’ll try calling back later.

IF YES,

We are asking the people who live in the trailers to let us test the indoor
air for formaldehyde. We have picked your trailer as one that we would
like to test.
What we learn will help the federal government make decisions about if
some people need to be moved out of their trailers to protect their health.
For your inconvenience, a $50 gift card will be given to you at the
completion of the study. Participation is voluntary. Do you think you
may be interested in participating?

IF NO

Thank you. I appreciate you taking time out to talk.

IF YES
Great. I would like to first ask you a few questions about yourself and your trailer. GO TO CRITERIA (below)

CRITERIA

1. Are you, as an adult resident, 18 years in age or older?
   - If YES, continue to question 2
   - If NO, go to “End of interview for exclusions”

2. Do you still live in a FEMA-issued trailer more than 6 hours per day?
   - If YES, continue to next section
   - If NO, go to “End of interview for exclusions”

IF YES is answered for questions 1-2:

If you agree to have us test your trailer, several things will take place:

1. We will set up a time to visit your trailer soon. The visit will not take more than an hour and a half. Cooking and smoking will not be allowed during the testing process.
2. We will ask you some questions about how you cook in your home and if people smoke in your home.
3. We will look around your home and fill out a short form about what type of heating you have, what type of stove you cook on, what type of air conditioner you have, and other similar questions.
4. We will test your trailer for formaldehyde and will also measure the temperature and humidity. We will deliver the test results of your trailer to you about a month after we test it.
5. For your time and inconvenience, you will also receive a $50 gift card

Are you interested in participating in this study?

IF YES

GO TO “WHEN SOMEONE AGREES TO PARTICIPATE”

IF NO

Okay, thank you so much for your time.
[HANG UP AND RECORD IN PHONE LOG AS REFUSAL]

END OF INTERVIEW FOR EXCLUSIONS
Thank you very much for your interest and for your willingness to be in the study. Unfortunately, it is important that people in our study be the adult resident and are 18 years or older. Also, because we are interested in the formaldehyde levels that people are currently exposed to, we are working with those who are still living in their FEMA-issued trailer. Thank you again for your time. [RECORD AS EXCLUSION IN PHONE LOG]
WHEN SOMEONE AGREES TO PARTICIPATE
Go to Appendix C: OBTAINING ASSENT [RECORD AS AGREED IN PHONE LOG]
APPENDIX C: OBTAINING ASSENT

Thank you for helping us with this important project. Everything you tell us and all your test results will be kept private to the extent allowed by the law. To protect your privacy, we will not put your name on the project forms, but we will write down your trailer’s address or a unique identification number assigned by the CDC.

You can change your mind and decide that you do not want us to test your trailer. If you do change your mind, it will not affect any of your benefits from the Federal Government.

APPENDIX D:
INFORMED CONSENT FOR PARTICIPATION

Evaluation of Formaldehyde in Occupied FEMA Owned Temporary Housing Units

For all potential participants, the informed consent document will be available for the participant to read or, if requested by the participant, will be read out loud. Participants will be required to provide a signature to document informed consent. The informed consent document will request permission for collection and testing of a laboratory sample.

(Flesch-Kincaid Reading Level for English text below = 5.2)

1. Introduction and purpose

We are working for the Centers for Disease Control and Prevention (CDC). CDC is working with the Federal Emergency Management Agency (FEMA) to find out whether there is formaldehyde (a potentially harmful chemical) in the trailers people are living in. We have picked some trailers at random, like flipping a coin. We are asking the people who live in those trailers to let us test their inside air for formaldehyde. We have picked your trailer as one that we would like to test. What we learn will help CDC and FEMA make decisions on housing placement priorities and if some people need to be moved into different trailers to protect their health. The testing process will include air testing which will take no more than one hour and a half. At the same time there will be a brief inspection of the trailer for up to 30 minutes, and some questions to be answered by you for up to 15 minutes. Section 301 of the Public Health Act permits us to collect such information. No cooking or smoking will be allowed during the testing process.

We are doing this testing in a scientifically valid way. That means that we choose the trailers to test instead of letting people ask to have their trailer tested. You and FEMA will learn the formaldehyde level in your trailer, and FEMA will learn the formaldehyde levels across many other trailers. This will help FEMA make decisions to protect people’s health.

2. Freedom of choice

You can choose to be part of this project or not. We will explain what we want to do to you so you can decide. Please ask us questions if you do not understand something. If you choose to be part of this project, you will need to sign this form. Then we will give you a copy of this form.

3. Benefits/Risks

If you agree to be in this evaluation, you can learn more about your home environment. If the formaldehyde level in your trailer is high, you may be given priority for housing relocation.
4. Confidentiality
   Everything you tell us and all your test results will be kept private to the extent allowed by the law. To protect your privacy, we will not put your name on the project forms, but we will write down your trailer’s address or a unique identification number assigned by the CDC. We will tell FEMA about the levels of formaldehyde in each trailer. Personally identifying data will be destroyed by the CDC, but left at the Louisiana and Mississippi Departments of Public Health at the completion of the study.

5. Cost/Payment
   It will not cost you anything to have your trailer tested as part of this project. You will be compensated for your time and inconvenience with a $50 gift card at the completion of the study.

6. Right to refuse or withdraw
   Before we start, we want to make sure you understand that it is up to you whether or not to join this project. You have the right to ask us to stop the testing at any time for any reason.

7. Persons to contact
   If you have any questions please feel free to ask us now.

   If you have questions later, please contact:
   Matt Murphy at 770-488-3417 or
   Gary Noonan at 770-488-3449

   If you feel that you have been harmed by this evaluation or if you have any concerns about your rights, please contact the CDC Deputy Associate Director for Science in Atlanta, Georgia, USA at 800-584-8814.

8. Your consent
   I agree to allow the air in my trailer to be tested. The information in this informed consent form has been explained to me. I have been given a chance to ask questions. I feel that all of my questions have been answered. I know that it is my choice to allow the air testing or not. I know that if I agree to the testing I can have it stopped at any time.

   I give permission for an air sample to be collected and tested for formaldehyde, and for the temperature and humidity to be measured in my home.

   □ YES  □ NO

   I have read or had this form read to me. By signing below, I consent to the air testing and to providing answers to the survey questions.

INTerviewer script:

The purpose of this part of the interview is to collect some information about you and your FEMA trailer environment. If there is a question that you do not want to answer, please let me know and we can skip it. All of your responses will be kept private and will not affect any of the home or health care services that you currently receive.

This interview will begin with a few questions about your age and where you work. We will then look at the inside and outside of your trailer. We will walk around and through your trailer with you to make some observations.
EXPOSURE ASSESSMENT QUESTIONNAIRE AND WALK THROUGH SURVEY

Date   ___________________ (mm/dd/yyyy)
Interviewer initials ___________________

Trailer VIN ________________________ Trailer barcode _________________
Trailer type: □ Travel trailer □ Mobile home □ Park □ Other
Street address: _______________________________________________________
County: ________________________ State (circle one): LA / MS
Zip code: _______________________

Is this home located on private land or in a federal/commercially owned park?

Public reporting burden of this collection of information is estimated to average 10 minutes per response,
including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data
needed, and completing and reviewing the collection of information. An agency may not conduct or sponsor, and a
person is not required to respond to a collection of information unless it displays a currently valid OMB control
number. Send comments regarding this burden estimate or any other aspect of this collection of information, including
suggestions for reducing this burden to CDC/ATSDR Reports Clearance Officer, 1600 Clifton Road NE, MS D-74, Atlanta, Georgia 30333; ATTN: PRA (0920-0008)
### Pests

1. Have pesticides been sprayed inside your home the past **month**?
   - Yes
   - No
   - Don’t know

### Indoor environment

2. Does your trailer have air conditioning?
   - Yes
   - No (go to question # 4)

3. During the **past 2 weeks**, how many hours—on average—did you keep your air conditioning running every day?
   - Less than 1 hour
   - 1–4 hours
   - 5–8 hours
   - More than 8 hours
   - Don’t know

4. During the **past 2 weeks**, how many hours—on average—did you keep your heater running every day?
   - Less than 1 hour
   - 1–4 hours
   - 5–8 hours
   - More than 8 hours
   - Don’t know
   - No working heater in trailer

5. Do you regularly use space heaters?
   - Yes
   - No
   - Don’t know

6. Were the windows, scuttles, and/or door open in the past 3 hours?
   - Yes
   - No (go to question # 8)
   - Don’t know

7. Approximately how long did you keep your windows and/or door open before this visit?
   - Less than 1 hour
   - 1–4 hours
   - 5–8 hours
   - More than 8 hours
   - Don’t know

8. Did anyone smoke in here in the past 3 hours?
   - Yes
   - No
   - Don’t know

9. During the past **two weeks**, how many people have smoked in here?
   - # People: _____________

10. How many packs of cigarettes are smoked in this house each day?
    - None
    - < ½ pack
    - ½ - 1 pack
    - >1 – 2 packs
    - > 2 packs
    - Don’t know

11. Does anyone cook in here?
    - Yes
    - No (go to question #13)

| **Daily activities** |   |   |
| 13. | What is the average amount of time that you spend inside your trailer each day? |  
|   |   | Less than one hour  
|   |   | 1-4 hours  
|   |   | 5-8 hours  
|   |   | More than 8 hours  
|   |   | Don’t know  
| 14. | Do you or your household members sleep in this trailer? |  
|   |   | Yes  
|   |   | No  
|   |   | Don’t know  
| 15. | Were any of the following used here in the past week? |  
|   |   | Candles  
|   |   | Air fresheners  
|   |   | Glue, paint, furniture finish  
|   |   | Mothballs  
|   |   | Closet fresh (mildewcide)  
|   |   | Nail polish  
| 16. | Do you have any pets that you keep in here and how many? |  
|   |   | Dog #:_____  
|   |   | Cat #:_____  
|   |   | Bird #:_____  
|   |   | Other:____________ #:___  
| 17. | Have you noticed the roof leaking in the past 3 months? |  
|   |   | Yes  
|   |   | No  
|   |   | Don’t know  
| 18. | Have you noticed pipes leaking in the past 3 months? |  
|   |   | Yes  
|   |   | No  
|   |   | Don’t know  
| 19. | Have you noticed mold in your home during the past 3 months? |  
|   |   | Yes  
|   |   | No  
|   |   | Don’t know

<tr>
<th>Questions pertaining to the trailer</th>
<th>(Check all that apply)</th>
</tr>
</thead>
</table>
| 1. Do you see any problems with the | ☐ Yes  
|    roof (for example sagging or   | ☐ No  
|    holes)?                        | ☐ Unable to see entire roof |
| 2. Are there signs that water spills| ☐ Yes  
|    onto siding?                   | ☐ No |
| 3. Are there any signs of mold in  | ☐ Yes  
|    the living area of the trailer?| ☐ No  
|                                 | If YES, estimate size of mold growth?  
|                                 | ☐ < 1 sq. foot  
|                                 | ☐ 1-4 sq. feet  
|                                 | ☐ > 4 sq. feet |
| 4. Is there carpeting in the trailer? | ☐ Yes  
|                                         | ☐ No |
| 5. What type of air conditioning does | ☐ Central AC/forced air  
|    the trailer have?               | ☐ AC/chiller on roof of Trailer  
|                                         | ☐ No working AC system  
|                                         | ☐ Other: ___________________ |
| 6. What type of heating does the trailer have? | ☐ Central heating/forced air  
|                                         | ☐ Space heaters  
|                                         | ☐ No working heating system  
|                                         | ☐ Other: ___________________ |
| 7. What type fuels are used for cooking? | ☐ Electricity  
|                                         | ☐ Propane Gas  
|                                         | ☐ Natural Gas  
|                                         | ☐ Charcoal or wood  
|                                         | ☐ Other: ___________________ |
| 8. Is there a functioning smoke detector? | ☐ Yes  
|                                         | ☐ No |

APPENDIX F:
ENVIRONMENTAL SAMPLING PROTOCOL

Formaldehyde Samples

Analysis Method:
Formaldehyde samples will be collected using the NIOSH Manual of Analytical Methods (NMAM) Method 2016 with Supelco S10 LpDNPH cartridges. The limit of detection (LOD) shall be 0.07 microgram per sample and the limit of quantification (LOQ) shall be 0.23 microgram. Lower LOD and LOQ are acceptable. A minimum quantifiable concentration of 0.0063 parts per million is required with a 30 liter sample volume collected over one hour. The definition from the NMAM should be used for LOD and LOQ (http://www.cdc.gov/niosh/nmam/pdfs/glossary.pdf).

Sample Collection:
Samples will be collected at a flow rate of 500 ± 50 milliliters per minute for one hour. Each sample will be collected in the center of the trailer primary living room on a four foot tall stand that mimics the breathing zone height of an adult when sitting. Residents will be asked to configure doors and windows as they would have them while they slept. Sampling will be under observation by one of the sampling team members at all times. Every tenth sample collected by a team will be a duplicate sample. Sampling will occur during a specific window of time per day for all trailers which is between 10:00 AM – 8:00 PM. No cooking or smoking in the trailer will be allowed during the one-hour sample collection period.

Quality Assurance and Control:
Six to ten, or additional as required by the lab, media blanks will be taken from each lot of sample tubes. The media blanks should be taken from the start of a lot (2 to 3), from the middle of a lot (2 to 4) and from the end of a lot (2 to 3). All media blanks should be logged on the chain of custody sheet and sent for analysis on the day that they were collected with the field blanks and samples.

Two to ten, or additional as required by the lab, field blanks will be collected on each day in which samples are collected. This can be divided by travel groups, (groups consisting of teams that are operating in close proximity or who are traveling together). All field blanks should be logged on the chain of custody sheet and sent for analysis on the day that they were collected with the media blanks and samples.
Sample Handling:

Sample tubes will be stored in a freezer or in a cooler on ice at all times (upon receipt, while not being used for sampling, and during shipment to the laboratory).

At the end of each sampling day samples will be shipped to the analytical laboratory either overnight or if collected after the last overnight drop off time the next morning in coolers with chain of custody documents enclosed or attached. Samples collected on Saturday and Sunday will be stored on ice or in a freezer and shipped by overnight means with the appropriate chain of custody documents to the analytical laboratory on the following Monday morning.

Temperature and Relative Humidity

Temperature and relative humidity will be logged using a HOBO® brand temperature and relative humidity logging instrument manufactured by Onset Computer Corporation (or equivalent) and will be set to collect data at five minute intervals. Data will be collected during the site visits for a minimum of 5 minutes before and 5 minutes after the collection of the formaldehyde sample at each trailer. Data logs will be divided into individual logs for each sample. A suggested method for this is to flag the start and stop times by an event marker at the start and finish of data collection. Data will be downloaded to a laptop at end of each day. Files will be labeled with site #, date, and visit number in a standard form. Data event flags will be confirmed on the sample collection data sheet. Files will be e-mailed each day to the database manager.

Data Sheets

Data sheets will be filled out prior to and during site visit. Information about trailer received prior to site visit will be confirmed at time of site visit. Data sheets will be faxed or sent overnight each day to the database manager.
SAMPLING STANDARD OPERATING PROCEDURE

Preparation prior to site visit:

*Formaldehyde*

Operational Checks:

1. Pump and calibrator batteries checked for charge and functionality.
2. Pump flow rates calibrated to 500 ± 50 milliliters per minute.
3. Sample tubes lot # and expiration date checked.
   (Expired tubes will be discarded)
4. If necessary, collect media blanks and label.
5. Stock coolers with “Blue Ice”
6. Sample tubes placed in cooler in number to be equal to trip blanks and samples to be collected + 2.

*Temperature and Relative Humidity*

Turn on HOBO® instrument and check for proper operation.

Operational checks:

1. Confirmation of time synchronization
   a) Time must agree ± 1 minute with Formaldehyde Chronometer.
   b) Time should be adjusted if necessary.
2. Confirm readings of HOBO® meet manufacturer’s specifications.
   a) Temperature readings must be ± 0.63°C of average temperature reading of all HOBO® instruments in group.
   b) Humidity readings must be ± 2.5% of average humidity reading of all HOBO® instruments in group.
   c) Any HOBO® falling outside the manufacturer’s specifications will be flagged as out of calibration and removed from service until a calibration is performed.
3. Confirm that HOBO® is set to log Temperature and Humidity measurements at five minute intervals.
   a) Adjust to 5 minute data logging interval if necessary.
   b) Confirm event marker is operating correctly. (If not remove from service)

*Data Sheet*

10. Confirm information is correct for scheduled site visits.
11. Confirm sheets for all scheduled site visits are present.
Site Visit:

Formaldehyde

1. Calibrate pumps to a flow rate of 500 ± 50 milliliters per minute.
2. Record pump identification and pre-sample flow rate data on data sheet.
3. Label Sample tube.
4. Sample tube and trip blank data recorded on data sheet.
5. Sample tube set on tripod at central unobstructed location in the THU at breathing level.
6. Pump started and time recorded on data sheet.
7. Sample collected for 60 ± 2 minutes.
8. Pump stopped sample immediately capped and stop time recorded on data sheet.
9. Sample returned to cooler.
10. Pump post sample flow rate checked and recorded on data sheet.
11. Sample identification on tube confirmed with data on sample sheet.
12. Trip blanks will be recorded, processed, labeled and returned to cooler.

Temperature and Relative Humidity

1. Confirm that data logger is operating.
   a. LED blinks.
2. Activate event marker at least 5 minutes prior to start of formaldehyde sample.
   a. Press button for one second.
3. Record start time for HOBO® sample on data sheet.
4. Continue sampling until at least 5 minutes after completion of Formaldehyde sample, activate event marker to indicate end time of data collection.
   a. Press button for one second
5. Record stop time on data sheet.

Data Sheet

1. Confirm with the occupants that information previously provided is correct
2. Completely fill out data sheet.
3. Have second team member confirm that data sheet is complete.
Post Site Visit:

Formaldehyde

Monday - Friday samples

1. Confirm that the proper numbers of field and media blanks are enclosed.
2. Chain of custody documents completed for each sample.
3. Cooler “Blue Ice” refreshed.
4. Cooler sealed and shipping label affixed for overnight shipment to lab.

Saturday and Sunday samples

1. Confirm that the proper numbers of field and media blanks are enclosed.
2. Chain of custody documents completed for each sample.
3. Samples stored in freezer.

Monday morning

1. Cooler “Blue Ice” refreshed.
2. Cooler sealed and shipping label affixed for overnight shipment to lab.

Temperature and Relative Humidity

1. Data downloaded to a laptop hard drive.
   a. Data files will be named with Site #, date and visit number in the form – LA 001.10-12-2007.01. (Or similar)
2. Data file event marks will be checked against data sheet start and stop times.
3. Data e-mailed to data base manager.

Data sheet

Fax or overnight data sheet to data base manager.
