

Veterans' Health Activities

Since its inception, the Centers for Disease Control and Prevention (CDC) has been involved in protecting the health of U.S. military personnel and veterans. In fact, CDC was established to address concerns about malaria among our troops during World War II. In more recent years, CDC's National Center for Environmental Health (NCEH) has taken the lead in addressing the health concerns of veterans of the Vietnam War and the Gulf War, and NCEH is working with the Departments of Defense (DoD) and Veterans Affairs (VA) to protect the health of our future military forces. NCEH's ongoing and completed activities in these areas are described below.

Postservice Mortality Among Vietnam Veterans

In 1987, the Centers for Disease Control and Prevention (CDC) compared the postservice mortality (through December 1983) of a group of 9,324 U.S. Army veterans who served in Vietnam with that of 8,989 Vietnam-era veterans who served in Korea, Germany, or the United States. Over the entire follow-up period, the total death rate for Vietnam veterans was 17% higher than for other veterans. The excess mortality, especially through motor vehicle accidents, suicide, homicide, and accidental poisonings, occurred mainly in the first 5 years after discharge from active duty and involved. Thereafter, mortality among Vietnam veterans was similar to that of other Vietnam-era veterans, except for drug-related deaths, which continued to be elevated. The excess in postservice deaths due to external causes among Vietnam veterans is similar to that found among men returning from combat areas after World War II and the Korean War.

In 2004, an update of the 1987 mortality study was published. This follow-up study further assessed the health effects of the Vietnam experience on cause-specific mortality, especially chronic conditions. It compared mortality rates between Vietnam veterans and veterans who did not serve in Vietnam. Vital status and underlying cause of death were retrospectively ascertained from the end of the original study in 1983 through 2000. Data were analyzed using Cox proportional hazards regression to factor in the effects of multiple risk factors on survival. Death from all causes was slightly higher among Vietnam veterans than non-Vietnam veterans over the entire follow-up period. Despite the increasing age of the study group (mean = 53 years) and longer follow-up period (average 30 years), death rates from disease-related conditions, including cancers and circulatory system diseases, did not differ between Vietnam veterans and their peers. Vietnam veterans continued to experience higher mortality than non-Vietnam veterans from unintentional poisonings and drug-related causes.

Agent Orange Validation Study

This study investigated whether military records could be used to identify U.S. Army Vietnam veterans who were likely to have been exposed to the “Agent Orange” herbicide mixture. Blood levels of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), a toxic contaminant in Agent Orange, were measured for 646 ground combat troops who served in heavily sprayed areas of Vietnam and for 97 veterans who did not serve in Vietnam. The blood TCDD levels of the Vietnam veterans were nearly identical to the levels found among the non-Vietnam veterans. In addition, the blood TCDD levels were not related to the estimate of Agent Orange exposure derived from military records or self-reported exposure.

Vietnam Experience Study

The Vietnam Experience Study was a multidimensional assessment of the health of Vietnam veterans. From a random sample of enlisted men who entered the U.S. Army from 1965 to 1971, 7,924 Vietnam and 7364 non-Vietnam veterans participated in a telephone interview. A random subsample of 2,490 Vietnam and 1,972 non-Vietnam veterans also underwent a comprehensive health examination, including medical examination, laboratory tests, and a psychological evaluation. During the telephone interview, Vietnam veterans reported current and past health problems more frequently than did non-Vietnam veterans. The Vietnam veterans also reported more health problems among their children, including more birth defects, and more problems with impaired fertility.

The results of the medical and laboratory examinations showed few current objective differences in physical health between the two groups. The Vietnam veterans did have more hearing loss. Also, among a subsample of 571 participants who had semen samples evaluated, Vietnam veterans had lower sperm concentrations and lower mean proportions of "normal" sperm. Despite differences in sperm characteristics, however, the Vietnam and non-Vietnam veterans had fathered similar numbers of children. An examination of hospital birth records showed that the children of Vietnam veterans were not more likely to have birth defects recorded on hospital birth records than were children of non-Vietnam veterans. The rates of birth defects were similar among children of Vietnam and non-Vietnam veterans. The psychological evaluation found that certain psychological problems were more common among the Vietnam veterans than among non-Vietnam veterans. These problems included depression, anxiety, and combat-related post-traumatic stress disorder.

Selected Cancers Study

This was a population-based, case-control study to determine whether Vietnam veterans are at an increased risk of developing particular types of cancer that have been suggested as being possibly related to dioxin exposure. Specific cancers studied included non-Hodgkin's lymphoma, soft tissue sarcoma, Hodgkin's disease, nasopharyngeal cancer, and primary liver cancer. An increased risk of non-Hodgkin's lymphoma was found among Vietnam veterans compared with men who did not serve in Vietnam, but no increased risk was identified for the other five cancers. The risk of having non-Hodgkin's lymphoma increased with length of service in Vietnam and was higher among men in the sea-based Navy than among other veterans. However, little difference in risk was noted according to dates of service, type of unit, military region, or any other characteristics that may have been associated with the use of the “Agent Orange” herbicide formulation.

Gulf War Studies

Health Effects of Exposure to Smoke From Oil Well Fires

Researchers from the Centers for Disease Control and Prevention (CDC) and several other federal agencies conducted surveys of workers in Kuwait City in May 1991, and of firefighters in the oil fields in October 1991. Blood samples were tested for 31 volatile organic compounds (VOCs) and were compared with samples from a group of people living in the United States. The samples from people living in the United States were collected as part of the Third National Health and Nutrition Examination Survey (NHANES III), a national survey of the health of Americans. The median concentration of VOCs among the firefighters was quite elevated. However, among the non-firefighting personnel, VOC concentrations were equal to or lower than the levels found among the people living in the United States.

NCEH also collaborated with the U.S. Department of Defense on a study of 30 members of an Army unit located in Germany. Blood from these military personnel was tested for VOCs at three points in time: before, during, and after their deployment to Kuwait. Tetrachloroethylene, a compound found in degreasing agents used to clean equipment, was the only VOC found to be elevated.

Birth Defects

In 1994, CDC collaborated with the Mississippi Department of Health and the U.S. Department of Veterans Affairs to investigate reports of adverse birth outcomes among members of two Mississippi National Guard Units that served in the Gulf War. This investigation found no increase above expected rates in the total number of birth defects or in the frequency of premature births and low birth-weight babies. The frequency of other health problems, such as respiratory infections, gastroenteritis, and skin diseases among children born to these veterans also did not appear to be elevated.

Publication

Penman A, Tarver RS, Currier MM. No evidence of increase in birth defects and health problems among children born to Persian Gulf War veterans in Mississippi. *Military Medicine* 1996;161:1-6.

In 1995, the Naval Health Research Center asked CDC to assist in a study of Goldenhar syndrome. Goldenhar syndrome is characterized by abnormal prenatal development of facial structures. Two clinicians from CDC reviewed birth records of 75,414 infants conceived after the Gulf War and born in military treatment facilities (34,069 infants born to Gulf War veterans and 41,345 born to nondeployed veterans). They identified five infants with Goldenhar syndrome who were born to Gulf War veterans and two infants born to nondeployed veterans. Because of the small number of cases found by the study,

the statistical power of the study was low. It was not possible to conclude solely from this study whether there is a higher or lower risk for Goldenhar syndrome among infants born to Gulf War veterans.

Air Force Study

Various members of a Pennsylvania Air National Guard unit reported illnesses potentially associated with their previous deployment to the Gulf War. In November 1994, the Pennsylvania State Health Department, the U.S. Department of Veteran Affairs, and the U.S. Department of Defense requested that CDC conduct an independent investigation of those illnesses. The investigation, carried out by CDC's National Center for Infectious Diseases, involved three phases:

- 1) interviews with and examination of ill Gulf War veterans from the Air National Guard unit (the index unit) and review of medical records to verify and characterize illness;
- 2) a survey of 3,723 military personnel from four Air Force units, including veterans who were and were not deployed to the Gulf War, to determine the relative prevalence of symptoms and to develop a working case definition of illness; and
- 3) a clinical evaluation of 158 Gulf War veterans from the index unit to further clinically characterize illness and to identify risk factors (by examination and laboratory tests).

A case was defined as a person having one or more chronic symptoms from at least two of three symptom categories (fatigue, mood-cognition, and musculoskeletal). A case was further classified as severe if each case-defining symptom was rated as severe; otherwise, the case was classified as mild-to-moderate. Cases were more likely to demonstrate poorer functioning, depression, and post-traumatic stress disorder. However, no consistent abnormalities were found by physical examination, routine laboratory tests, or tests for several infectious agents endemic to the Middle East. The prevalence of mild-to-moderate and severe cases was 39% and 6%, respectively, among Gulf War veterans versus 14% and 0.7% among nondeployed veterans. Fifty-nine (37%) clinically evaluated Gulf War veterans did not qualify as cases, 86 (54%) were mild-to-moderate cases, and 13 (8%) were severe cases. The investigators identified a chronic multisystem condition that was significantly associated with deployment to the Gulf War, but was not associated with specific Gulf War exposures, and that also affected nondeployed personnel.

Health Assessment of Gulf War Veterans From Iowa

In April 1994, Senator Tom Harkin of Iowa requested that CDC conduct a health assessment of Gulf War veterans his state. The study was initiated in December 1994 and was conducted through a cooperative agreement between the Iowa Department of Public Health and CDC's National Center for Environmental Health. The Iowa Department of Public Health contracted with investigators at the University of Iowa who took the lead in designing and conducting the study. From September 1995 through May 1996, a telephone survey was administered to 1,896 Gulf War veterans and to 1,799 military personnel who were not deployed to the Persian Gulf.

This was one of the first population-based epidemiologic studies to document that Gulf War veterans are reporting more medical and psychiatric conditions than their military peers. The study identified several conditions that need to be studied in more detail, including cognitive dysfunction, depression, chronic fatigue, post-traumatic stress disorder, and respiratory illness (asthma and bronchitis). The conditions identified in this study appear to have measurably affected the functional activity and daily lives of these Gulf War veterans. However, these conditions may not be unique to Gulf War veterans and may be similar to the experience of veterans in other wars. Among Gulf War veterans, minimal differences were observed between the National Guard or Reserve troops and the regular military personnel.

Iowa Asthma Follow-Up Study

The original Iowa study was extended to collect physical examination data on a subset of the telephone survey participants to validate the self-report of asthma. Data were collected on 32 Gulf War veterans who reported asthma during the telephone survey, 42 Gulf War veterans who reported no illnesses during the telephone survey, and 20 non-Gulf War veterans who reported asthma during the telephone survey. The two groups of subjects with reported asthma were similar in symptoms, baseline pulmonary function tests, and bronchial hyperreactivity. The Gulf War veterans who reported asthma had significantly more current symptoms compared with the Gulf War veterans who reported no illness during the telephone survey. They also had comparatively lower baseline spirometry (a measure of how well the lungs exhale) and increased bronchial hyperreactivity. No differences in smoking history were found between the two groups with asthma. However, Gulf War veterans who reported asthma were more likely to be current and past smokers than the Gulf War veterans who did not report illness.

Cognitive Function and Symptom Patterns in Gulf War Veterans

In November 1997, CDC funded a study by the Boston University School of Public Health to examine potential reasons for the memory and thinking problems reported by Gulf War veterans. In one component of this study, functional magnetic resonance imaging (fMRI) was used to examine possible differences in brain activation patterns within specific areas of the brain. Gulf War veterans and their nondeployed peers with differing levels of symptoms were compared. In another component of this study, Danish armed forces personnel were tested to determine whether they are experiencing the same types of memory and thinking problems reported by U.S. troops who participated in the Gulf War. The Danish troops were also asked about any symptoms that they may be experiencing. Both Danish troops who participated in the Gulf War and troops who were not deployed to the Gulf War were tested. The results will be compared with results from a group of U.S. Gulf War veterans that the Boston University School of Public Health and the Boston VA Medical Center have been following since they returned from the Gulf War. Findings have been published regarding the neuropsychological functioning of the Danish Gulf War troops. No significant differences in neuropsychological test performances were found between the Gulf War-deployed and non-Gulf War-deployed groups. Danish troops deployed to the Gulf War reported significantly more mood complaints (i.e., fatigue and confusion) than their nondeployed counterparts. Publications are still pending for the fMRI component of this study.

Defining Gulf War Illness

In November 1997, CDC funded a study to characterize and compare different approaches for defining the medically unexplained illnesses of Gulf War veterans. This study by the University of Medicine and Dentistry of New Jersey-Robert Wood Johnson Medical School compared the symptoms of two groups of Gulf War veterans at two points in time. The study subjects included Gulf War veterans from the Department of Veterans Affairs' Gulf War Registry who had participated in a previous study conducted by the New Jersey researchers, and veterans who had participated in the CDC Air Force study. Data-driven case definitions for illness previously derived from these two groups of Gulf War veterans were compared with standard or existing case definitions for unexplained multi-symptom illnesses (such as chronic fatigue syndrome, fibromyalgia, and multiple chemical sensitivity) to determine which definition best characterized Gulf War veterans' unexplained illnesses. The study also tried to determine how well the derived and existing case definitions could be generalized in a new random sample of

deployed and nondeployed Gulf War era veterans and active duty soldiers. The investigators are preparing manuscripts for publication which are expected by the end of 2005.

Assessing the Potential Health Impact of the Gulf War on Saudi Arabia National Guard Members

This study, initiated in 1999, involved a collaborative effort of health researchers from the United States (U.S. Department of Defense and CDC) and Saudi Arabia. The team examined hospitalization data for 15,612 Saudi Arabia National Guard (SANG) troops. The goal of this study was to compare hospitalization rates and health outcomes among a group of SANG soldiers who were stationed in a combat area in January 1991 (Al Khafji) with soldiers who were stationed in a non-combat area (Riyadh). The investigators identified 148 SANG soldiers who had at least one hospitalization between 1991 and 1999. The adjusted rate of hospitalization was higher in the combat-exposed group (risk ratio = 1.80, 95% confidence interval = 1.25–2.59). No unusual patterns of diagnoses were found. Because the overall number of hospitalizations was low, the absolute difference in risk was found to be very small.

Epidemiologic Study of the Occurrence of Amyotrophic Lateral Sclerosis (ALS) Among Gulf War Veterans

In June 1999, the Department of Veterans Affairs and U.S. Department of Defense requested that CDC assist in a study of amyotrophic lateral sclerosis (ALS) among Gulf War veterans. ALS is a fatal neurodegenerative disease that destroys the brain and spinal cord nerve cells that control muscle movement. As the brain and spinal cord nerve cells die, muscles weaken and shrink, and rapid severe paralysis occurs. Neither a cause nor a cure for ALS is known at this time. This investigation of ALS was initiated to determine if there is a higher than expected incidence of ALS among veterans of the 1991 Gulf War and to examine possible risk factors for the disease. CDC's Environmental Health Laboratory conducted laboratory analyses of blood and urine specimens to look for signs of exposure to heavy metals. Initial results found military personnel who were deployed

to the Gulf region during the 1991 Gulf War experienced a greater post-war risk of ALS than those who were not deployed to the Gulf. Among approximately 2.5 million eligible military personnel, 107 confirmed cases of ALS were identified (an overall occurrence of 0.43 per 100,000 persons per year). Overall, the attributable risk associated with deployment was 18% (95% CL = 4.9% to 29.4%). Findings regarding exposure to heavy metals are pending.

Deployment to the Gulf War and the Subsequent Development of Cancer

In 2002, George Washington University School of Public Health and Health Services began a study to determine if cancer patterns among veterans of the 1991 Gulf War veterans differ from the patterns found among Gulf War era veterans not deployed to the Persian Gulf. CDC and the Association of Schools of Public Health funded the study. Initial work by the study investigators using data from the District of Columbia and the New Jersey Cancer Registries found a statistically significant excess of testicular cancer in Gulf War deployed veterans compared to non-Gulf War veterans. The current study is focusing on extending the analysis to include cancer data from additional states. These states include Texas, California, Florida, New York, Maryland, and Illinois. This study is expected to continue through July 2005.

Gulf War Research Planning Conference

In early 1999, CDC helped sponsor *The Health Impact of Chemical Exposures During the Gulf War: A Research Planning Conference*. The U.S. Department of Health and Human Services' Office of Public Health and Science, the National Institutes of Health, and the Agency for Toxic Substances and Disease Registry cosponsored the conference with CDC. The intent was to obtain broad public input into the development of a multi-year research plan for investigating the relationship between chemical exposures during the Gulf War and illnesses affecting Gulf War veterans. Concurrent workgroups developed research recommendations in the following areas:

- pathophysiology/etiology of illnesses among Gulf War veterans,
- the most appropriate methods for assessing and diagnosing the health effects of chemical exposures,
- the most appropriate treatment approaches, and
- ways to prevent similar illnesses in future military deployments.

A final report summarizing conference recommendations was released in March 2000 and is accessible at URL: <http://www.cdc.gov/nceh/publications/gulfwar/report.pdf>. The background document prepared for the conference that reviews Gulf War-related research conducted before 1999 is accessible at URL: <http://www.cdc.gov/nceh/publications/gulfwar/bdgw65.pdf>.

Web-Based Central Library (*MedSearch*)

CDC, the U.S. Department of Defense's Deployment Health Support Directorate, and the Department of Veterans Affairs collaborated to create a centralized Internet site, known as *Medsearch*. Veterans and members of the armed forces can visit the site to find information on Gulf War-related medical research developed by or for government agencies. The idea for the online medical library came from a recommendation at a CDC conference in 1999. The conference participants called for a central location where both veterans and researchers could access the latest research on illnesses among Gulf War veterans. The Internet site developers worked with veterans and researchers to ensure that *Medsearch* is easy to use. Many of the documents available on *Medsearch* are written in nontechnical language. *Medsearch* can be accessed at <http://www.gulflink.osd.mil/medsearch>.

Note added September 15, 2010
Information previously located on Medsearch about illnesses related to the 1990-91 Gulf War has been incorporated into a new web site: [DeployMed ResearchLINK](#)

Force Health Protection

Health Risk Communication Research

In March 2001, the Centers for Disease Control and Prevention (CDC) announced funding for a grant program to develop, implement, and evaluate strategies for improving health risk communication related to military deployments among military personnel, veterans, their family members, and their health care providers.

Two health risk communication research projects were funded on September 1, 2001. One grant was awarded to Rutgers University for the project "Improving Health Risk Communications to Prevent Unexplained Illnesses Related to Military Deployments." This project focuses on assessing knowledge, attitudes, and beliefs about chemical, biological, and radiological agents. The intent is to develop and evaluate risk communication materials regarding these agents. The project involves a series of in-depth semistructured interviews and self-administered quantitative surveys. Participants include veterans of the 1991 Gulf War and a random selection of U.S. residents. Using their findings, the study investigators will work with the U.S. Department of Defense (DoD) to develop emergency and crisis communications about new and emerging diseases or bioterrorism and communications about health and disease. The in-depth interviews with veterans have been completed. Investigators are conducting a national survey that focuses on the general public's perceptions, opinions, and knowledge of health and disease. The study continues through August 2005.

Publications

Brewer, N. T., Hallman, W. K., Kipen, H. M., & Fiedler, N. Why do people report better health by phone than by mail? *Medical Care* 2004;42(9):875–83.

Boyd, K C., Hallman, W. K., Wartenberg D., Fiedler, N, Brewer, N. T., & Kipen, H. Reported exposures, stressors, and life events among Gulf War registry veterans. *Journal of Occupational and Environmental Medicine* 2003;45(12):1247–56.

The second grant was awarded to the Henry H. Jackson Foundation for the project "Health-e VOICE: Optimized Implementation of a Stepped Clinical Risk Communications Guideline." This project focuses on the development and evaluation of an interactive, web-based distance learning tool for improving DoD health care providers' capacity to communicate with veterans about deployment-related health concerns. Focus groups were used to determine health care providers' knowledge and attitudes about caring for military personnel and veterans, especially those with deployment-related health concerns and medically unexplained symptoms. The information collected from the focus groups was used to script six electronic patient-care vignettes that interactively teach health care providers appropriate clinical risk communication techniques. The

effectiveness of this interactive teaching tool will be tested in a randomized controlled trial, which should be completed by October 2005.

Behavioral Risk Factor Surveillance Survey (BRFSS)

In 2002, CDC's National Center for Environmental Health was successful in its proposal to add veteran-related questions to the core questionnaire of the 2003 Behavioral Risk Factor Surveillance Survey (BRFSS). These questions will ask about experience in the military and use of Department of Veterans Affairs (VA) health care facilities. The BRFSS is a CDC-supported telephone survey that is administered by all 50 states to collect information on behavioral factors known to be associated with chronic diseases. Information on the BRFSS can be found at URL: <http://www.cdc.gov/brfss/>. The addition of questions on military experience and VA health care will be useful in assessing the overall general health status of veterans. They will also be useful in collecting data on specific behavioral risk factors, such as physical activity levels, smoking, and alcohol use. The information will assist both state and federal health officials in developing strategies for preventing and controlling health problems for the estimated 25.6 million veterans and 1.8 million active duty, Reserve, and National Guard personnel in the United States.
