

NCHS Data Presentation Standards for Rates: Vital Statistics

Jennifer D. Parker
Director, Division of Research and Methodology
National Center for Health Statistics

Meeting of the NCHS Board of Scientific Counselors
January 9, 2020

NCHS data products

- **General health data products** with a large set of health outcomes by many population subgroups, often from multiple data sources
 - Interest in many (often predetermined) subgroups, including small groups, multiply crossed categories and geographic areas
 - Some stand-alone estimates, although standard errors/intervals can be available
 - Minimal or no discussion in text
- **Topic specific data products:** Data Briefs; National Health Statistics Reports; journal articles.
 - Choice of subgroups often determined for specific report
 - Expected precision of estimates can be considered (e.g. coarsening age groups, collapsing race/eth or income groups)
 - Standard errors or confidence intervals can be provided and are discussed in the text.

Statistical Notes

July 2002

Healthy People 2010 Criteria for Data Suppression

Richard J. Klein, M.P.H.; Suzanne E. Proctor, M.S.P.H.; Manon A. Boudreault, M.P.H.;
and Kathleen M. Turczyn, M.P.H.

- Listed criteria for about 20 data sources, including surveys and vital statistics.
 - At the time, most standards based on RSE and sample size.
- Did not make recommendations or compare criteria.

The first NCHS workgroup on data presentation standards

- NCHS workgroup formed in May 2013
- Task
 - Define scope
 - Assess of alternate methods of precision
 - Develop of proposed guidelines
 - Develop of software for implementation across different NCHS data systems
 - Compare former to proposed guidelines across data systems
- Focused on **proportions**, as most common statistic produced by NCHS

NCHS Data Presentation Standards for Proportions released August 2017

- Standard
 - Criteria based on minimum sample size and absolute and relative width of exact confidence interval
 - Estimated proportions with few degrees of freedom or with suppressed complementary proportions are to be evaluated individually
- Implementation generally, although not always, led to more estimates presented compared to prior criteria

The second NCHS workgroup on data presentation standard: Rates

- Rates are widely disseminated by NCHS, e.g.
 - Vital statistics
 - Death rates
 - Birth rates
 - Health care statistics
 - Visit rates
 - Hospitalization rates

The second NCHS workgroup on data presentation standard: Rates (2)

- Workgroup was formed in 2018 and includes representatives from DRM, DAE, DVS, DHCS, OCD and a DRM contractor (mathematical statistician)
- Approach
 - Identify current practice for data suppression of rates
 - Define scope
 - Review and examine statistical principles for rates, particularly properties of intervals calculated for rates

What are rates?

- The working definition of a rate is the estimated number of events for a given time period (typically year) divided by a population count for the number at risk during that year (typically a Census mid-year population count) and often multiplied by a constant
- Crude rates and age-specific rates
- Age-adjusted rates: linear combination of age-specific rates standardized to standard US population

Examples of rates

- Diabetes Death Rate for 2017
 - the number of deaths attributed to diabetes in 2017, divided by the US resident mid-year population for 2017, multiplied by 100,000
- Outpatient visit rate for preventive care, by region, 2017
 - the number of visits for preventive care divided by the US civilian non-institutionalized mid-year population by region for 2017, multiplied by 1000

Types of rates

- Rates with 'random' numerators and 'fixed' denominators from vital statistics, including:
 - national and state death rates, birth rates, rates for some subgroups
- Rates with 'random' numerators and 'fixed' denominators from surveys, including:
 - national and some subnational visit rates

Types of rates (2)

- Rates with 'random' numerators and 'random' denominators, including
 - some subnational and subgroup rates from vital statistics where population denominator estimated from American Community Survey
 - condition specific rates where population denominator is estimated from survey, such as the National Health Interview Survey
- Infant mortality rates (unlinked, period linked, cohort linked)

First step

- Rates with ‘random’ numerators and ‘fixed’ denominators from vital statistics, including:
 - national and state death rates, birth rates, rates for some subgroups
- Strategy
 - Identify and compare current presentation guidelines, methods of interval estimation, relative standard errors

Intervals

- Crude and age-specific rates
 - Approximate intervals calculated using normal approximation (Wald method: mean $\pm 1.96 \times SE$) for rates and counts with 100 or more events
 - Exact intervals calculated using Poisson distribution for rates with fewer than 100 events – operationalized using “Gamma method”

- Age-adjusted death rates are more complicated
 - Linear combination of Poisson random variables is not Poisson
 - Approximate intervals calculated using normal approximation for rates and counts with 100 or more events
 - Approximate intervals calculated using Poisson distribution for rates with fewer than 100 events – operationalized using “Gamma method” with “DVS” modification

Current presentation guidelines for crude and age-specific vital rates

- If $x < 20$ (i.e., $x \leq 19$), rate is deemed unreliable and is suppressed
 - Corresponds to relative standard error of $\sim 23\%$
 - Relative width of gamma interval $\sim 96\%$

Proposed change to presentation standard for age-specific and crude rates

FROM: If $x < 20$ (i.e., $x \leq 19$), rate is deemed unreliable and is suppressed

TO: If $x < 10^*$ (i.e., $x \leq 9$), rate is deemed unreliable and is suppressed

*Note that $x < 10$ is the confidentiality cutoff for subnational data

Proposed change to presentation standard for age-specific and crude death rate (2)

— Rationale

- $x < 10$ offers a single cutoff for suppression to ensure both confidentiality of subnational data and reliability
- Whereas $x < 20$ is equivalent to $RSE \geq 23\%$, $x < 10$ is equivalent to $RSE \geq 33\%$
- Relative width (RW) of gamma CI corresponding to $x < 10$ is $RW_{\text{gamma}} > 140\%$ (up from $RW_{\text{gamma}} \geq 96\%$ for $x < 20$)
 - This goes in the same direction as the RW criterion for proportions ($RW_{\text{exact}} > 130\%$)

Current presentation guidelines age-adjusted death rates (AADR)

- If $\sum x_i < 20$ (i.e., $\sum x_i \leq 19$), age-adjusted death rate is deemed unreliable and is suppressed

Proposed change to presentation standard for age-adjusted death rate

FROM: If $\sum x_i < 20$ (i.e., $\sum x_i \leq 19$), AADR is deemed unreliable and is suppressed

TO: If $\sum x_i < 10$ (i.e., $\sum x_i \leq 9$), AADR is deemed unreliable and is suppressed

The AADR should continue to be suppressed when the crude rate $\sum x_i / \sum p_i$ needs to be suppressed for reliability or confidentiality reasons

Proposed change to presentation standard for age-adjusted death rate (2)

— Rationale

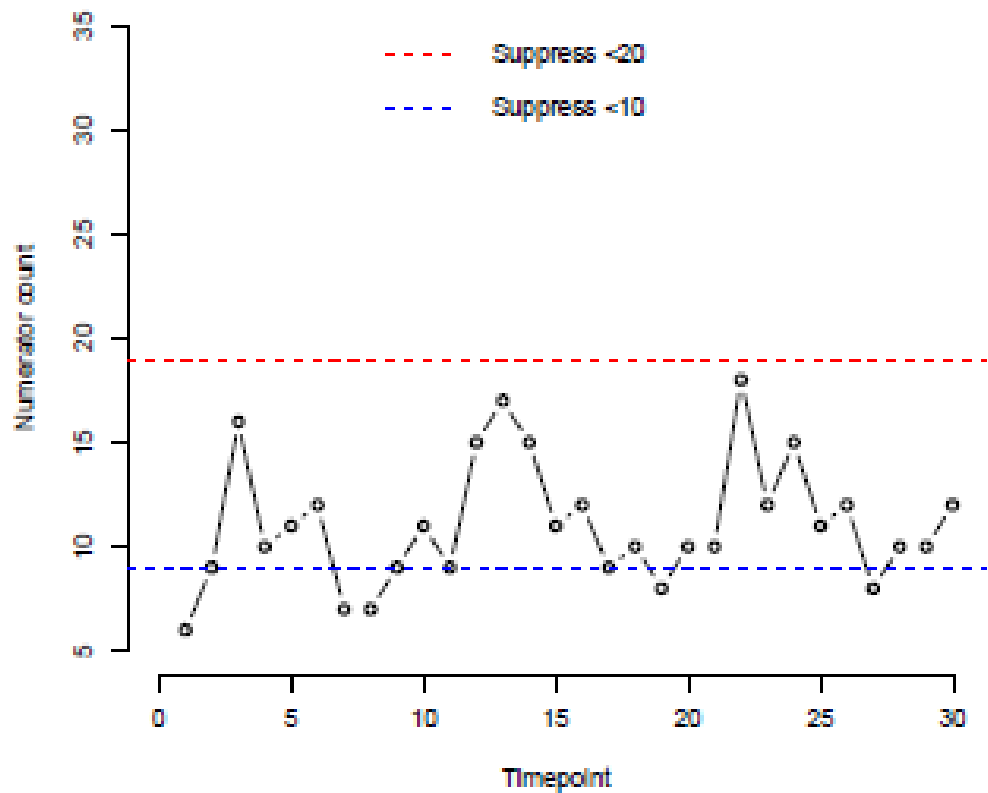

- The AADR can be computed and presented even if the age-specific death rates are all suppressed (as is done in CDC WONDER and NCHS publications)
- These cutoffs are consistent with those for the crude rate, and correspond to $\sum x_i < 10$ and $x_{adj} < 10$
- In simulations, $RW_{DVS \text{ gamma}} > 140\%$ corresponds to $RSE_{AADR} \geq 33\%$

* x_{adj} is defined as $[100/RSE(y)]^2$; $y = \sum w_i(x_i/p_i) = AADR$

Probabilities that crude rate would be suppressed:
existing vs. proposed suppression rule

Simulated numerator counts
Poisson, mean = 12

Simulated numerator counts
Poisson, mean = 12

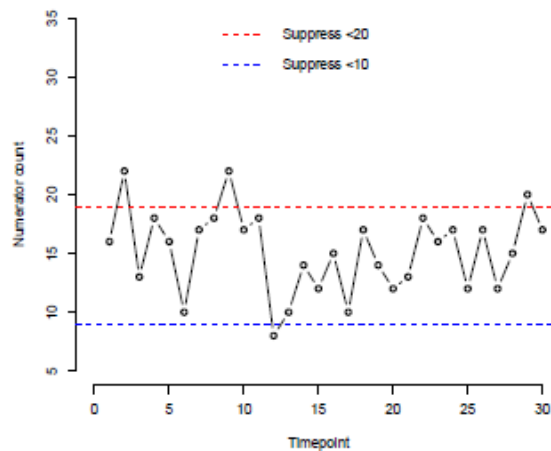

Corresponding RSEs
(expected RSE ~ 29%)

Simulated numerator counts
Poisson, mean = 12

Simulated numerator counts
Poisson, mean = 15

Simulated numerator counts
Poisson, mean = 18

Corresponding RSEs
(expected RSE ~ 29%)

Corresponding RSEs
(expected RSE ~ 26%)

Corresponding RSEs
(expected RSE ~ 23.5%)

Summary

- Recommendation to lower presentation threshold from 20 events to 10 events for crude, age-specific and age-adjusted rates for vital rates with random numerator and fixed denominator
 - Corresponds to RSE increase from 23% to 33%
 - Relative confidence interval width \sim 140%

Current and future activities

- Health care surveys with 'random' numerator and fixed denominator
 - Differences from vitals
 - Survey design (e.g. degrees of freedom, sample weights, etc)
 - Multiple visits per person
- Future
 - 'Random' denominators

Data Presentation Standards Workgroup
