Total and High-density Lipoprotein Cholesterol in Adults: United States, 2015–2018

Margaret D. Carroll, M.S.P.H., and Cheryl D. Fryar, M.S.P.H.

Key findings

Data from the National Health and Nutrition Examination Survey

- During 2015–2018, 11.4% of adults had high total cholesterol, and prevalence was similar by race and Hispanic origin.
- The prevalence of high total cholesterol was highest among adults aged 40–59.
- Over one-quarter of men (26.6%) and 8.5% of women had low high-density lipoprotein cholesterol (HDL-C).
- In men, the prevalence of low HDL-C was lowest in non-Hispanic black adults. In women, prevalence was highest in Hispanic adults.

High total cholesterol (≥ 240 mg/dL) and low high-density lipoprotein cholesterol (HDL-C, < 40 mg/dL) are independent and modifiable risk factors for coronary heart disease (1–3). Declining trends were seen in the prevalence of high total cholesterol from 1999–2000 to 2015–2016 and in low HDL-C from 2007–2008 to 2015–2016 (4). This report presents 2015–2018 estimates of the prevalence of high total cholesterol and low HDL-C among U.S. adults aged 20 and over and trends through 2017–2018.

What was the prevalence of high total cholesterol among adults during 2015–2018?

During 2015–2018, the prevalence of high total cholesterol in U.S. adults was 11.4%. No significant difference was seen in the prevalence of high total cholesterol between men (10.5%) and women (12.1%) (Figure 1). The prevalence was highest among adults aged 40–59 (15.7%) compared with 60 and over.

NOTES: High total cholesterol is 240 mg/dL or more. All estimates except those by age were age-adjusted by the direct method to the projected 2000 U.S. Census population using the age groups 20–39, 40–59, and 60 and over. Crude estimates are 11.5% for total, 10.3% for men, and 12.6% for women. Access data table for Figure 1 at: https://www.cdc.gov/nchs/data/databriefs/db363-tables-508.pdf#1.

those aged 20–39 (7.5%) and 60 and over (11.4%). Adults aged 60 and over also had a higher prevalence of high total cholesterol than adults aged 20–39. No significant differences were seen between race and Hispanic-origin groups in the prevalence of high total cholesterol among adults.

**What was the prevalence of low HDL-C among adults during 2015–2018?**

The prevalence of low HDL-C among adults aged 20 and over was 17.2% in 2015–2018 and was higher among those aged 20–39 (17.6%) and 40–59 (18.5%) than among those aged 60 and over (14.6%) (Figure 2).

Among men, the prevalence of low HDL-C was higher among those aged 40–59 (29.6%) than those aged 60 and over (24.6%). While the difference in prevalence between men aged 20–39 (25.0%) and 40–59 was similar to the difference between men aged 60 and over and 40–59, it was not statistically significant.

In women, the prevalence of low HDL-C declined with age, from 10.3% among those aged 20–39 to 7.8% among those aged 40–59 and 6.4% among those aged 60 and over.

The prevalence of low HDL-C was over three times higher among men (26.6%) than among women (8.5%). The prevalence was higher among men than among women in each age group.

1Significantly different from adults aged 60 and over.
2Significantly different from women of the same age group.
3Significant decreasing linear trend.

NOTES: Low high-density lipoprotein cholesterol is less than 40 mg/dL. Estimates for the “20 and over” category were age adjusted by the direct method to the projected 2000 U.S. Census population using the age groups 20–39, 40–59, and 60 and over. Crude estimates are 17.1% for total, 26.6% for men, and 8.2% for women. Access data table for Figure 2 at: [https://www.cdc.gov/nchs/data/databriefs/db363-tables-808.pdf?2](https://www.cdc.gov/nchs/data/databriefs/db363-tables-808.pdf?2).

What were the differences in the prevalence of low HDL-C among adults by race and Hispanic origin during 2015–2018?

The prevalence of low HDL-C was lowest in non-Hispanic black (11.9%) adults compared with non-Hispanic white (16.6%), non-Hispanic Asian (15.8%), and Hispanic (21.9%) adults. The prevalence of low HDL-C was also lower in non-Hispanic white and non-Hispanic Asian adults than in Hispanic adults (Figure 3).

Among men, similar to differences seen among all adults, the prevalence of low HDL-C was lowest in non-Hispanic black men (17.0%) compared with non-Hispanic white (26.3%), non-Hispanic Asian (26.3%), and Hispanic (31.9%) men, and was lower in both non-Hispanic white and non-Hispanic Asian men than in Hispanic men.

Among women, the prevalence of low HDL-C was lower in non-Hispanic white (7.4%), non-Hispanic black (7.9%), and non-Hispanic Asian (6.7%) women than in Hispanic women (12.3%).

The prevalence of low HDL-C was consistently lower among women than among men across all race and Hispanic-origin groups.

What were the trends in high total cholesterol and low HDL-C among adults?

The prevalence of high total cholesterol declined from 18.3% in 1999–2000 to 10.5% in 2017–2018. The prevalence of low HDL-C declined from 22.2% during 2007–2008 to 16.0% during 2017–2018 (Figure 4).

Summary

During 2015–2018, 11.4% of adults had high total cholesterol, and 17.2% had low HDL-C. No significant difference was seen in the prevalence of high total cholesterol between men and women, but the prevalence of low HDL-C was over three times higher in men than women. No significant differences in prevalence of high total cholesterol were observed between race and Hispanic-origin groups. The prevalence of low HDL-C was lowest in non-Hispanic black adults overall and among men, but not among women. Declining trends were seen in the prevalence of high total cholesterol between 1999–2000 and 2017–2018 and low HDL-C between 2007–2008 and 2017–2018.

In this report, low HDL-C for both men and women is defined as an HDL-C level of less than 40 mg/dL. In contrast, a sex-specific definition of less than 40 mg/dl for men and less than 50 mg/dL for women is used to define metabolic syndrome, a group of risk factors that raise the risk of heart disease (5).

In its task of monitoring the health of the U.S. population, Healthy People 2020 established a goal of lowering the percentage of adults with high total cholesterol to no more than 13.5% (6). During 2015–2018, the overall prevalence in both men and women met this goal, however, the prevalence of high total cholesterol among adults aged 40–59 was above this goal.

Definitions

High total cholesterol: Serum total cholesterol greater than or equal to 240 mg/dL.

Low high-density lipoprotein cholesterol (HDL-C): Serum HDL-C less than 40 mg/dL.
Data source and methods

Data from the National Health and Nutrition Examination Survey (NHANES) from 1999–2000 through 2017–2018 were used for these analyses. Data from NHANES 2015–2018 were used to test differences between subgroups. Ten 2-year cycles (1999–2018) were used in testing for trends in the prevalence of high total cholesterol, and six 2-year cycles (2007–2018) were used for prevalence of low HDL-C. The methods used to measure HDL-C concentration prior to 2007 differed and may not be directly comparable with 2007–2008 and subsequent cycles (7).

NHANES is a cross-sectional survey designed to monitor the health and nutritional status of the civilian noninstitutionalized U.S. population using highly stratified, multistage probability designs (8). The survey consists of an interview conducted in participants’ homes and standardized physical examinations conducted in mobile examination centers.

In 2015–2018, non-Hispanic black, non-Hispanic Asian, and Hispanic persons, among other groups, were oversampled to obtain reliable estimates for these population subgroups. Specific race and Hispanic-origin estimates reflect persons reporting only one race. Those reporting more than one race are included in the total only and are not shown separately.

Examination sample weights, accounting for the differential selection probabilities and adjusting for nonresponse and noncoverage, were used to estimate prevalence. Standard errors of these prevalences were estimated by Taylor series linearization (9), a design-based method. Estimates were age adjusted to the projected 2000 U.S. standard population (10) using the age groups 20–39, 40–59, and 60 and over, to compare prevalence estimates between subgroups or over time that differ with respect to their age distributions.

Differences between groups were tested using a t statistic at the $p < 0.05$ significance level. Linear trends were tested using orthogonal contrast matrices. All differences reported are statistically significant unless otherwise indicated. Adjustments were not made for multiple comparisons. Statistical analyses were conducted using the SAS System for Windows version 9.4 (SAS Institute, Inc., Cary, N.C.) and SUDAAN version 11.1 (RTI International, Research Triangle Park, N.C.).
