NCHS Data on Drug-poisoning Deaths

About NCHS

The National Center for Health Statistics (NCHS) is the nation's principal health statistics agency, providing data to identify and address health issues. NCHS compiles statistical information to help guide public health and health policy decisions.

Collaborating with other public and private health partners, NCHS uses a variety of data collection mechanisms to obtain accurate information from multiple sources. This process provides a broad perspective on the population’s health, influences on health, and health outcomes.

NCHS drug-poisoning data

Poisoning is the leading cause of injury death in the United States. Drugs—both pharmaceutical and illicit—cause the vast majority of poisoning deaths.

NCHS uses the National Vital Statistics System (NVSS) to monitor deaths due to drug poisoning (overdose). NVSS collects mortality information from death certificates in all 50 states and the District of Columbia. NCHS identifies the number of drug-poisoning deaths from the underlying cause of death on death certificates. Multiple causes of death are used to identify deaths involving specific drugs. In 2016, approximately 15% of death certificates for drug-poisoning deaths lacked information on the specific drugs involved.

Recent findings

- From 1999 to 2016, drug-poisoning death rates more than tripled, from 6.1 per 100,000 to 19.8 per 100,000. In 2016, there were 63,632 deaths due to drug poisoning. Provisional estimates for 2017 suggest an increase to 72,287 drug-poisoning deaths.
- In 2016, the age-adjusted rate for drug-poisoning deaths for males (26.2 per 100,000) was almost double that of females (13.4).
- From 1999 to 2016, the age-adjusted rate of drug-poisoning deaths increased from 8.2 per 100,000 to 26.2 per 100,000 for males, and from 3.9 per 100,000 to 13.4 per 100,000 for females.

Who is most at risk?

- From 1999–2016, the drug-poisoning death rates increased for all age groups.
- In 2016, the drug-poisoning death rates were highest for persons aged 35–44 (35.0 per 100,000), 25–34 (34.6), and 45–54 (34.5).
- In 2016, the age-adjusted death rate was 25.3 for non-Hispanic white persons, 17.1 for non-Hispanic black persons, and 9.5 for Hispanic persons.

- Significant increasing trend from 1999 to 2016 with different rates of change over time, \( p < 0.001 \).
- 2016 rate for male was significantly higher than for female, \( p < 0.001 \).

Drug-poisoning death rates by opioid category

- The rate of drug-poisoning deaths involving natural and semisynthetic opioids, which include drugs such as oxycodone and hydrocodone, increased from 1.0 in 1999 to 4.4 in 2016.
- The rate of drug-poisoning deaths involving methadone increased from 0.3 in 1999 to 1.8 in 2006, then declined to 1.0 in 2016.
- The rate of drug-poisoning deaths involving heroin increased from 0.7 in 1999, to 1.0 in 2010, to 4.9 in 2016.
- The rate of drug-poisoning deaths involving synthetic opioids other than methadone, which includes drugs such as fentanyl, fentanyl analogs, and tramadol, doubled from 2015 to 2016. The rate increased from 0.3 per 100,000 in 1999 to 1.0 in 2013, 1.8 in 2014, 3.1 in 2015, and 6.2 in 2016.

Challenges and future opportunities

- Improve reporting of the specific drug(s) involved in drug-poisoning deaths on the death certificate.
- Enhance capacities to search the cause-of-death description on the death certificate for drug mentions.
- Work with medical examiners and coroners to improve timeliness of reporting drug-poisoning deaths.
- Improve automated cause-of-death coding systems for faster reporting.
- Explore opportunities to link electronic death records to electronic health records.
- Develop capacity to support monthly reporting of drug-poisoning deaths.
