Characteristics of Residential Care Communities by Percentage of Resident Population Diagnosed With Dementia: United States, 2016
by Manisha Sengupta, Ph.D., and Christine Caffrey, Ph.D.

Abstract

Introduction—Increasingly, residential care communities (RCCs) are becoming a source of care for older adults with Alzheimer’s disease and other dementias. Nationally in 2016, 41.9% of RCC residents were diagnosed with dementia. This report examines selected characteristics of RCCs and characteristics of their residents by the prevalence of Alzheimer’s disease and other dementias.

Methods—Data in this report are from the RCC survey component of the 2016 wave of the biennial National Study of Long-Term Care Providers (NSLTCP), conducted by the National Center for Health Statistics. RCCs were grouped into three categories indicating prevalence of Alzheimer’s disease and other dementias in their communities: RCCs with less than 25% of their residents diagnosed with dementia, RCCs with 25%–75% of their residents diagnosed with dementia, and RCCs with more than 75% of their residents diagnosed with dementia. RCC characteristics included bed size, metropolitan statistical area location, provision of mental health services, and staff hours per resident day. Resident characteristics included selected conditions and need for assistance with activities of daily living.

Results—Approximately one-quarter of RCCs (25.3%) had more than 75% of their residents diagnosed with Alzheimer’s disease and other dementias. More RCCs with over 75% of their residents diagnosed with dementia were in metropolitan statistical areas (90.5%) compared with RCCs with 25%–75% (81.4%) and less than 25% of their residents diagnosed with dementia (76.4%). Aide and activities staff hours per resident day were higher in RCCs with more than 75% of their residents diagnosed with dementia compared with the other dementia prevalence categories. The prevalence of depression and the need for assistance with activities of daily living were higher in RCCs with more than 75% of the residents diagnosed with dementia compared with the other dementia prevalence categories.

Keywords: assisted living • long-term services and supports • Alzheimer’s disease • National Study of Long-Term Care Providers

Introduction

Assisted living and similar residential care communities (RCCs) provide care to older adults and younger adults with disabilities who cannot live independently in their homes (1). On any given day in 2016, an estimated 811,500 residents lived in 28,900 RCCs. Increasingly, RCCs are becoming an important source of care for older adults with Alzheimer’s disease and other dementias (2). Nationally in 2016, 41.9% of RCC residents were diagnosed with dementia (3).

RCCs are varied in the organizational characteristics and the services they provide (1). More than one-half (60.9%) of all RCCs have 4–25 beds and a majority are in metropolitan statistical area settings (82.5%) (1,4). RCCs provide a host of services, including dietary, pharmacy, therapeutic, mental health, and social work services.

Along with serving residents with Alzheimer’s disease and other dementias, RCCs are increasingly serving residents with multiple and complex needs (1). In 2016, 30.9% of RCC residents had depression, 34.3% had heart disease, and 18.1% had diabetes (1). While all residents in RCCs may need services and supports, residents...
with dementia could have a greater need for mental health services and supports, as shown in community-based studies (5,6). This report examines the selected characteristics of RCCs and characteristics of their residents by prevalence of Alzheimer’s disease and other dementias.

Methods

Data source

Data in this report are from the RCC survey component of the 2016 wave of the biennial National Study of Long-Term Care Providers (NSLTCP), conducted by the National Center for Health Statistics (NCHS). To be eligible for the study, a RCC must (a) have been regulated by the state to provide room and board with at least two meals a day, around-the-clock onsite supervision, and help with personal care such as bathing and dressing or health-related services such as medication management; (b) have had four or more licensed, certified, or registered beds; (c) have had at least one resident currently living in the community at the time of the survey; and (d) have been serving a predominantly adult population. The survey used a combination of probability sampling and taking a census.

Respondents to the survey were RCC administrators, directors, or otherwise knowledgeable staff. The survey was administered by mail, web, and computer-assisted telephone interviewing follow-up for nonrespondents. The questionnaire was completed for 4,578 eligible RCCs, for a weighted response rate of 50.7%. For additional information about NSLTCP and RCC survey methodology and variable construction, see the 2016 NSLTCP Survey Documentation (7,8). The 2016 NSLTCP data are accessible for restricted use only. Information on how to access the data is available from: https://www.cdc.gov/nchs/nsltcp/nsltcp_rdc.htm.

Data analysis

Estimates of selected characteristics by the percentage of prevalence of dementia in the resident population in RCCs for 2016 are presented. Analyses took into account the complex survey design of the 2016 NSLTCP. Weights were used to adjust for unknown eligibility status of nonresponding RCCs and for nonresponse bias. Results are nationally representative. See the 2016 NSLTCP documentation for details about the weighting methods (7,8).

Cases with missing data were excluded on a variable-by-variable basis. The weighted percentage of cases with missing data for variables ranged from 0.4% for ownership to 0.7% for depression, diabetes, and heart disease. Data analyses were performed using the following statistical packages: SAS, version 9.3 (SAS Institute, Cary, N.C.) (9); SAS-callable SUDAAN, version 11.0.0 (RTI International, Research Triangle, N.C.) (10); and Stata/SE, version 14 (StataCorp, College Station, T.X.) (11).

Statements of differences among subgroups were based on two-tailed t-tests with significance at the \( p < 0.05 \) level. A weighted least-squares regression method was used to test the significance of linear trends. Statistically significant differences and trends are indicated in the figures and discussed in the Results section.

Notes.

Statements of differences among subgroups by the percentage of prevalence of dementia in the resident population in RCCs for 2016 are presented. Analyses took into account the complex survey design of the 2016 NSLTCP. Weights were used to adjust for unknown eligibility status of nonresponding RCCs and for nonresponse bias. Results are nationally representative. See the 2016 NSLTCP documentation for details about the weighting methods (7,8).

Cases with missing data were excluded on a variable-by-variable basis. The weighted percentage of cases with missing data for variables ranged from 0.4% for ownership to 0.7% for depression, diabetes, and heart disease. Data analyses were performed using the following statistical packages: SAS, version 9.3 (SAS Institute, Cary, N.C.) (9); SAS-callable SUDAAN, version 11.0.0 (RTI International, Research Triangle, N.C.) (10); and Stata/SE, version 14 (StataCorp, College Station, T.X.) (11). Statements of differences among subgroups were based on two-tailed t-tests with significance at the \( p < 0.05 \) level. A weighted least-squares regression method was used to test the significance of linear trends. Statistically significant differences and trends are indicated in the figures and discussed in the Results section.

Results

Organizational characteristics size

- Across all RCCs, 28.9% had less than 25% of their residents diagnosed with dementia, 45.8% had 25%–75% of residents diagnosed with dementia, and 25.3% had more than 75% of residents diagnosed with dementia (data not shown).
- For all three dementia prevalence categories, bed size of 4–25 beds was most common and was highest among RCCs with more than 75% of residents diagnosed with dementia (77.5%) (Figure 1).
- Bed size of 26–50 (15.6%) was higher among RCCs with less than 25% of their residents diagnosed with dementia compared with more than 75% (11.0%). A bed size of 26–50 was also higher among RCCs with 25%–75% of residents diagnosed with dementia than 75% of residents diagnosed with dementia (data not shown).
- Bed size of more than 50 was higher among RCCs with less than 25% (23.2%) and 25%–75% (28.0%) of residents with RCCs with more than 75% (11.6%) of residents diagnosed with dementia.

Metropolitan statistical area

- The percentage of RCCs in metropolitan statistical areas increased significantly from 76.4% in RCCs with less than 25% of residents diagnosed with dementia, to 81.4% in RCCs with 25%–75%, and 90.5% of RCCs with more than 75% of their residents diagnosed with dementia (Figure 2).
- The percentage of RCCs in nonmetropolitan statistical areas decreased with increasing resident population diagnosed with dementia, from 23.6% (less than 25%), to 18.6% (25%–75%), to 9.5% (more than 75%).
Mental health services

- Mental health services were provided by at least one-half of all RCCs in each of the three dementia prevalence categories (Figure 3).
- Mental health service provision was lower among RCCs with less than 25% (44.5%) and 25%–75% (42.6%) of residents diagnosed with dementia, compared with more than 75% of residents diagnosed with dementia (49.4%). However, the difference between less than 25% and more than 75% of residents diagnosed with dementia was not significant.

Aide and activities staff hours per resident per day

- For both staff types examined, the average staff hours per resident day was higher in RCCs with more than 75% of their residents diagnosed with dementia compared with RCCs in the other dementia prevalence categories (Figure 4).
- Average aide staff hours per day increased from 2.19 (2 hours, 11 minutes) and 2.16 (2 hours, 10 minutes) among RCCs with less than 25% and 25%–75% residents diagnosed with dementia, to 2.73 (2 hours, 44 minutes) among RCCs with more than 75% of residents diagnosed with dementia.
- Activities staff hours also were higher among RCCs with more than 75% of residents diagnosed with dementia (0.42, or 25 minutes) compared with RCCs with less than 25% (0.29, or 17 minutes) and 25%–75% (0.27, or 16 minutes) of residents diagnosed with dementia.

Resident characteristics

Medical conditions

- The prevalence of heart disease was lower in RCCs with less than 25% of residents diagnosed with dementia (28.6%) compared with RCCs with 25%–75% (37.5%) and more than 75% (36.6%) of residents diagnosed with dementia (Figure 5).
- The percentage of residents with a diagnosis of depression significantly increased from 25.3% in RCCs with less than 25% of their residents diagnosed with dementia, to 32.3% among RCCs with 25%–75% of residents diagnosed with dementia, to 38.7% in RCCs with more than 75% of their residents diagnosed with dementia.
- The percentage of residents with diabetes was lower among RCCs with more than 75% of residents diagnosed with dementia (15.5%) compared with less than 25% (18.1%) and 25%–75% (18.9%) of residents diagnosed with dementia.
Activities of daily living

- The percentage of residents needing assistance with each activity of daily living significantly increased as percentage of residents diagnosed with dementia increased (Figure 6).
- The percentage of residents needing assistance with bathing accounted for the most need for assistance regardless of the percentage of residents diagnosed with dementia and increased from 47.6% (less than 25%) to 68.5% (25%–75%) to 85.8% (more than 75%).
- The percentage needing assistance with toileting increased from 23.9% to 42.9% to 66.5%.
- The percentage needing assistance with transferring increased from 17.5% to 31.3% to 47.2%.
- The percentage needing assistance with eating increased from 10.5% to 19.7% to 39.9%.

Discussion

This report examines selected characteristics of RCCs and characteristics of their residents by the prevalence of Alzheimer’s disease and other dementias. About one-quarter of all RCCs had more than 75% of their residents diagnosed with dementia. Among RCCs with over 75% of the residents diagnosed with dementia, a greater percentage were small with 4–25 beds and were located in metropolitan statistical areas, and about one-half of these RCCs provided mental health services. On average, staff in these RCCs provided 33 more minutes of aide time and 10 more minutes of activities staff time compared with RCCs with fewer residents diagnosed with dementia. A greater percentage of residents in RCCs with more than 75% of residents diagnosed with dementia were diagnosed with depression and needed assistance with activities of daily living. Diagnosis of diabetes and the provision of mental health services were lower in these RCCs.

The strengths of this analysis include the focus on relationships between the prevalence of dementia and select organizational, service provision, staffing, and resident case mix characteristics in a nationally representative study of RCCs. Despite these strengths, there were some limitations. The study did not assess provision of specialized services for dementia care. The RCC component of the 2016 NSLTCP has aggregated resident characteristics making it impossible to examine comorbidities (one or more conditions) at the resident level.
This report demonstrates that select organizational and staffing characteristics vary by the prevalence of residents diagnosed with dementia in RCCs. RCCs with more than 75% of their residents diagnosed with dementia have more residents diagnosed with depression and in need of assistance with activities of daily living. These findings may inform providers, policy makers, researchers, and consumer advocates about differences in RCCs according to the prevalence of dementia in the resident population.

References

Technical Notes

Definitions of variables

Assistance with selected activities of daily living—Refers to residents needing any help or supervision from another person, or use of assistive devices, with up to five limitations in activities of daily living (bathing, dressing, transferring in and out of a bed or chair, toileting, and eating) that reflect a resident’s capacity for self-care.

Community bed size—Residential care communities (RCCs) were grouped based on the number of licensed, registered, or certified RCC beds (both occupied and unoccupied): 4–25 beds, 26–50 beds, and more than 50 beds.

FTE—Full-time equivalent is a measure of the workload of an employee working on a full-time basis.

Heart disease—Includes congestive heart failure, coronary or ischemic heart disease, heart attack, or stroke.

Hours per resident per day—Refers to the number of hours providing care for one resident per day for a given staff type. To calculate, the number of FTEs for a given staff was converted into hours by multiplying by 35 hours for the staff type, and dividing the total number of hours for the staff type by the number of current residents in the RCC, and by 7 days.

Mental health services provision—Refers to whether RCCs provided mental health services. These services target residents’ mental, emotional, psychological, or psychiatric well-being, and may include diagnosing, describing, evaluating, and treating mental conditions. Mental health services could be provided by paid RCC employees, by outside service providers through arrangement, by referral, or all three.

Metropolitan statistical area—Geographic entities delineated by the Office of Management and Budget (OMB) for use by federal statistical agencies in collecting, tabulating, and publishing federal statistics. A metropolitan area contains a core urban area of 50,000 or more population, and a nonmetropolitan area contains an urban core of at least 10,000 (but less than 50,000) population.

Residential care communities (RCCs)—Includes assisted living communities and other RCCs (e.g., personal care homes, adult care homes, board care homes, or adult foster care) that meet the study eligibility criteria described in the Methods section.
