Abstract

Objective

This report compares five methods of waist circumference (WC) measurements: 1) the National Heart, Lung, and Blood Institute (NHLBI-WC); 2) the World Health Organization (WHO-WC); 3) the Multi-Ethnic Study of Atherosclerosis (MESA-WC) using Gulick II Plus tape; 4) the Multi-Ethnic Study of Atherosclerosis (MESA-WC) using Lufkin tape; and 5) assisted self-measurement over clothes (MESA-assisted).

Method

During 2016, measurements were obtained from 2,297 participants aged 20 and over, who participated in the National Health and Nutrition Examination Survey (NHANES). The mean differences and sensitivity and specificity for abdominal obesity (AO) were calculated between the NHLBI-WC (reference) and the other four WC measurements.

Results

The mean difference between NHLBI-WC and WHO-WC was 0.81 cm for men and 3.21 cm for women ($p \leq 0.0125$ for both); between NHLBI-WC and MESA-WC (Gulick) was –0.68 cm for men ($p \leq 0.0125$) and –0.89 cm for women; between NHLBI-WC and MESA-WC (Lufkin) was 0.02 cm for men and 0.08 cm for women; and between NHLBI-WC and MESA-assisted was –0.71 cm for men and 1.34 cm for women ($p \leq 0.0125$ for both). Sensitivity and specificity for AO, with NHLBI-WC as a reference, for men were greater than 90% for all methods; for women, sensitivity and specificity for AO for MESA-WC (Lufkin) were greater than 90%; for women, WHO-WC, MESA-WC (Gulick), and MESA-assisted methods were greater than 85%.

Conclusion

Aside from the differences between NHLBI-WC and WHO-WC measurements among women, other differences between NHLBI and other protocols were less than or equal to 1.5 cm.

Keywords: abdominal obesity • NHANES

Introduction

Waist circumference (WC) is a measurement used to estimate abdominal subcutaneous and visceral fat stores. Higher values of WC (WC greater than 102 cm for men and greater than 88 cm for women) are associated with an increased risk for type 2 diabetes, high blood cholesterol, high blood pressure, and heart disease (1). The underlying metabolic process for this risk factor is insulin resistance syndrome associated with increased visceral fat stores (1). Increased WC is also one of the diagnostic criteria for metabolic syndrome, which is highly correlated with cardiovascular diseases (1–4). A number of factors are associated with the variation in visceral adipose tissue distribution, including body mass index (BMI), age, sex, and race and ethnicity (1).

The National Health and Nutrition Examination Survey (NHANES) collects data on selected chronic diseases, such as cardiovascular disease and diabetes. Since 1988 to the present, NHANES measures WC in the mobile examination center (MEC) using a protocol recommended by the National Heart, Lung, and Blood Institute, referred to as NHLBI-WC (5–7). However, there are a number of different protocols to measure WC in clinical or research settings. Among them are the World Health Organization (WHO) protocol, referred to as WHO-WC (5) and the Multi-Ethnic Study of Atherosclerosis (MESA) protocol, referred to as MESA-WC (8,9).

Since its inception in 1956, NHANES has provided a platform to test and explore methodologies (9). Given that there are several protocols being used by other studies and organizations to measure WC, the National Center for Health Statistics (NCHS) undertook a methodology study...
Waist Circumference Methodology Study Design

The purpose of the study was to compare four protocols to obtain WC measurements: 1) WHO-WC, 2) MESA-WC using Gulick II Plus tape, 3) MESA-WC using Lufkin, and 4) MESA-assisted with NHLBI-WC, which is the standard reference protocol. The main intent was to assess similarities and differences among these protocols. However, it should be emphasized that there is no plan to change how WC is collected in NHANES, namely using the NHLBI protocol. The data collected from the WC measurement study are available to researchers via a restricted-use data file, which can be accessed through the NCHS Research Data Centers (RDC) from: https://www.cdc.gov/rdc/.

During NHANES 2016, 2,781 adults aged 20 and over were eligible for the methodology study. Among these adults, 309 never received NHLBI measurements, 25 were pregnant women and therefore excluded, and an additional 150 NHANES participants missed one or more of the other WC measurements. There was a final analytic sample of 2,297 participants: 1,143 were men and 1,154 were women. The overall response rate for survey years 2015–2016 for adults aged 20 and over was 54.8%.

Five WC measurements were performed during the MEC visit with each eligible NHANES participant. Table A describes the five measurements, which are further described under “outcome variables.” MESA-assisted was performed, with coaching from the health technician (HT). The HT alone performed the other four WC measurements over the skin and at the level of the specific anatomical landmarks.

1The MESA-assisted WC measurement was carried out before changing into the MEC examination gown or before leaving the MEC after changing back into street clothes.

NOTES: MESA is Multi-Ethnic Study of Atherosclerosis. WC is waist circumference. WHO is World Health Organization. NHLBI is National Heart, Lung, and Blood Institute. MEC is mobile examination center.

landmarks while the MESA-assisted component was time independent of the other WC measurements obtained by the HT.

Since NHANES 1999, an outside consultant expert in anthropometric measurement has been observing quarterly the HT doing the measurements. The expert established internal tolerance limits for inter-observer differences for each anthropometric measurement. For the NHLBI-WC, the tolerance limit is ±1.0 cm for a waist circumference measuring less than 100 cm and ±1.5 cm for those measuring greater than or equal to 100 cm. The same tolerance limits were used to assess HT performances obtaining WHO-WC and MESA-WC measurements in the methodology study. Of note, because MESA-assisted was done by the examinee, these criteria were not applied, instead the HT was observed quarterly doing the procedure by the reference evaluator guided by the protocol, and the HT was corrected if they were assisting incorrectly. Moreover, the observed HT was retrained by the reference evaluator if necessary and observed again to ensure that they were correctly assisting the examinee doing the measurement.

Table C shows the results of the inter-evaluator reliability measurements. For a sample of 60 adults, the mean differences between the reference evaluator and HTs for all protocols was not statistically significant, and all the correlations were at or greater than 0.99. The lowest technical error of measurement was associated with MESA-Lufkin and the highest was associated with NHLBI-WC (6). This evaluation was done during survey year 2016, quarterly.

1Difference is significant by paired t test (indicates bias).

NOTES: N is number of subjects measured. NHLBI is National Heart, Lung, and Blood Institute. WHO is the World Health Organization. MESA is Multi-Ethnic Study of Atherosclerosis. NS is not significant. TEM is technical error of measurement (TEM = \(\sqrt{\sum D^2/2N}\), where D is the difference between measures and N is the number of subjects measured. The r values are determined by Pearson correlation coefficients. MESA-assisted was not assessed using these criteria.

**Figure 1. Lufkin tape**

understanding of how they compare with NHLBI-WC. Lastly, because MESA-assisted is a modification of MESA-WC, the protocol used the Gulick II Plus tape (9). This resulted in the only change between the original MESA-WC protocol, and MESA-assisted was the individual doing the measurement.

The Lufkin tape measure is a retractable stainless steel tape measure that is 200 cm (78.7 inch) long and 0.6 cm wide. The Gulick II Plus tape measure is a 1.6 cm wide, 305 cm (120 inch) long, no-stretch, polyester reinforced, retractable tape with both centimeter and inch gradations. The most important part of the Gulick II Plus tape measure is its tensioning device, which provides a known amount of tension while measuring and adds precision to the measurement. Each individual tensioning device is calibrated to indicate precisely a 4-ounce tension.

### Outcome Variables

#### Waist Circumference Measurements

NHLBI-WC, the reference measurement, was obtained following a standardized protocol used in NHANES since 1988 (5). The NHANES HT asked the participant to stand upright with body weight evenly distributed on both feet. The HT, standing at the participant’s right side, palpated the hip area to locate the right iliac crest of the pelvis. Then with a cosmetic pencil, the HT drew a horizontal line just above the uppermost lateral border of the right ilium, and crossed this mark at the mid-axillary line. The Lufkin tape measure was extended around the waist at the level of the iliac crest with the help of a mirror and a second person (recorder) to ensure that the tape was horizontal to the floor with no gaps or constrictions. The HT read the measurement to the nearest 0.1 cm at the end of the participant’s normal expiration (Figure 3). Only one measurement was taken.

MESA-WC measurements were obtained twice in a randomized order, once using the Lufkin tape measure (MESA-Lufkin) and once using the Gulick II Plus tape measure (MESA-Gulick) following a standardized protocol. The HT located the participant’s umbilicus and, if necessary, lowered the waistband of the pants and underclothing to expose it. The HT moved to the participant’s right side and extended the tape measure (Lufkin or Gulick II Plus) around the waist, positioning the tape in a horizontal plane at the level of the umbilicus parallel to the floor. When needed, the HT used the wall mirror to ensure the horizontal alignment of the tape.
The HT read the measurement to the nearest 0.1 cm at the end of the participant’s normal expiration.

WHO-WC measurements were obtained using their standard WHO protocol (8). The HT stood at the participant’s right side and drew a line at the uppermost lateral border of the right ilium and the lower margin of the last palpable rib. Then, the HT used the two lines to obtain the midpoint, using a white plastic ruler, and indicated this measurement site using a (+) sign. The WC was measured at the level of the (+) sign using the Lufkin tape measure. The measurement was taken only once (Figure 9). The HT read the measurement to the nearest 0.1 cm at the end of the participant’s normal expiration.

Covariates

Demographic Covariates

In addition to sex, results were analyzed by age and race and ethnicity. Age was categorized into the following groups: 20–39, 40–59, and 60 and over. Race and ethnicity, based on self-reported information, was classified as non-Hispanic white, non-Hispanic black, non-Hispanic Asian, and Hispanic. Participants not fitting the above self-classification were classified as “other.” Data for the “other” group, including persons who reported multiple races, were included in the total sample results, but because of small sample size, the information was not reported separately in the data tables.
As per the standard NHANES anthropometry measurements, weights were obtained in kilograms using a digital scale while wearing a standardized two-piece examination outfit. Height in cm was obtained using a stadiometer with a fixed vertical backboard and an adjustable headpiece (6). BMI was calculated as weight in kilograms divided by height in meters squared (kg/m²), and was categorized using criteria established by the National Institutes of Health as underweight (less than 18.5 kg/m²), normal (18.5–24.9 kg/m²), overweight (25.0–29.9 kg/m²), and obese (greater than or equal to 30 kg/m²) (15). Due to the relatively small number of participants in the underweight category, the underweight category was combined with the normal category after a sensitivity analysis showed no significant difference in the results whether underweight was excluded or included in the normal weight category.

### Statistical Analyses

Mean WC was derived for each measurement method, overall and within selected covariates (age group, race and ethnicity, obesity category). Using the NHLBI-WC as the reference, mean of the difference between NHLBI-WC and four methods (WHO-WC, MESA-WC Gulick, MESA-WC Lufkin, MESA-assisted) was calculated for each. All statistical analyses were stratified by sex and performed using survey procedures in SAS 9.4 for Windows (SAS Institute, Inc., Cary, NC) and SUDAAN 11.0 software (Research Triangle Institute, Research Triangle Park, NC).

The WC study was conducted only during a single year (2016) rather than a typical NHANES 2-year data collection period. Therefore, the single-year weight (WTNA) was used for all statistical analyses. The delete-1-Jackknife method was used for variance estimation (16).

A paired t test was used to test if the mean differences between two measurements were statistically significantly different from zero. Because there were four comparisons (each method compared with NHLBI), Bonferroni correction of 0.05/4 = 0.0125 as the cutoff value of statistical significance was used.

For the purpose of assessing agreement of abdominal obesity classification, where abdominal obesity was classified as a measured WC is greater than 102 cm for men and greater than 88 cm for women, sensitivity and specificity of abdominal obesity defined by different WCs were derived (17). NHLBI-WC-determined abdominal obesity was defined as the reference. All sensitivity and specificity data calculations were based on weighted data.

Sensitivity refers to the true positives (i.e., the percentage of participants classified as having abdominal obesity using NHLBI-WC who were also classified as obese using other WC protocols). Specificity refers to the true negatives (i.e., the percentage of participants classified as not having abdominal obesity using NHLBI-WC who were also classified as not having abdominal obesity using other WC protocols).

Finally, post-hoc power analysis was conducted by sex, using variance estimates from the data of the current WC methodology study described in this paper, to test the null hypothesis that the mean difference between the two
measurements (NHLBI compared with another protocol) was equal to zero.

## Results

Tables D and E compare the means of and differences between NHLBI-WC and WHO-WC. Overall, the mean difference between WHO-WC and NHLBI-WC was 0.81 cm for men and 3.21 cm for women, with NHLBI-WC values being, on average, significantly ($p \leq 0.0125$) larger than those of WHO-WC, when stratified by age, race and Hispanic ethnicity, and obesity categories. The differences among men aged 60 and over and with obesity were not statistically significant. For men, the mean differences ranged from 0.20 cm (aged 60 and over) to 1.45 cm (normal weight and underweight). For women, the values ranged from 2.58 cm (non-Hispanic black) to 3.55 cm (normal weight and underweight).

*Significantly different from NHLBI value ($p \leq 0.0125$).

NOTES: $N$ is number of subjects measured. NHLBI is National Heart, Lung, and Blood Institute. WHO is World Health Organization. SE is standard error.

Tables F and G compare the means of and differences between NHLBI-WC and MESA-WC Gulick. Overall, the mean difference between NHLBI-WC and MESA-WC Gulick was $-0.68$ cm for men and $-0.89$ cm for women. Among men, MESA-WC Gulick values were, on average, significantly ($p \leq 0.0125$) larger than those of NHLBI in all categories, except normal weight and underweight and age group 20–39. The differences were not significant for women, except in women who were categorized as being obese. For men, the differences ranged from $-0.81$ cm (ages 40–59) to $-0.46$ cm (normal weight and underweight). For women, the differences ranged from $-1.55$ cm (obese) to $-0.20$ cm (normal weight and underweight).

Tables H and J compare the average measurement differences between NHLBI-WC and MESA-WC Lufkin. Overall, the differences...
difference between the two measurements was 0.02 cm for men and 0.08 cm for women. None of the differences was statistically significant. In men, the differences ranged from 0.01 cm (non-Hispanic white) to 0.27 cm (normal weight and underweight). For women, the differences ranged from –0.56 cm (obese) to 0.72 cm (normal weight and underweight).

Tables K and M compare the measurement differences between the NHLBI-WC and MESA-assisted over clothes measurements. Overall, the difference was –0.71 cm for men and 1.34 cm for women. In men, the difference was statistically significant for those who were aged 20–39 and 40–59, non-Hispanic white, non-Hispanic black, non-Hispanic Asian, normal weight and underweight and overweight. In women, the difference was statistically significant for those who were aged 60 and over, Hispanic, and those with obesity. For men, the values of the difference in the two measurements ranged from –1.74 cm (normal weight and underweight) to –0.03 cm (aged 60 and over). For women,
the differences ranged from −0.21 cm (non-Hispanic Asian) to 2.51 cm (Hispanic).

Table N shows the sensitivity and specificity of abdominal obesity by sex, using NHLBI-WC as the reference. Men had higher sensitivity and specificity values for all measurements compared with those of women, except specificity values for WHO-WC. In men, MESA-WC Gulick had the highest sensitivity (99.0%) and WHO-WC had the lowest sensitivity (94.2%); WHO-WC had the highest specificity (96.2%) and MESA-assisted had the lowest specificity (92.8%). In women, MESA-WC Gulick had the highest sensitivity (93.9%) and WHO-WC had the lowest sensitivity (86.7%); WHO-WC had the highest specificity (99.6%) and MESA-WC Gulick had the lowest specificity (86.2%).
had WC close to 88 cm and were not classified as having the obese group (1.51 cm higher). As a result, women who WC measuring higher than NHLBI-WC, specifically among tape among women (85.88%) was possibly due to MESA-WC. The low specificity of MESA-WC using Gulick II Plus likely be classified as not having obesity based on WHO-abdominal obesity based on the NHLBI measurement would also means that a woman who did not meet the criteria for abdominal obesity using WHOBWC, which led to low sensitivity (86.85%) and high specificity (99.63%); that is, those who were classified as having abdominal obesity using WHO-WC protocol (5–8).

Most results fell within NHANES internal established tolerance limits using the NHLBI-WC method (tolerance criteria of ±1.5 cm) as a cut point. The difference between other protocols and the reference NHLBI-WC was less than 1.5 cm for all comparisons except MESA-assisted (normal weight men, women aged 60 and over, Hispanic women, and women with obesity), MESA-Gulick (women with obesity), and NHLBI-WC and WHO-WC, where all of the differences for women were well over 1.5. Similar differences between the WHO-WC protocol and the NHLBI-WC protocol among women were reported elsewhere and have been attributed to differences in male and female anatomy (18,19).

All methods had a sensitivity of 90% to 99%, except WHO-WC for women, meaning that more than 90% of subjects classified by NHLBI-WC as having abdominal obesity were also classified as having abdominal obesity using WC from other protocols. Similarly, all methods had a specificity of 90% to 99%, except MESA-WC using Gulick II Plus tape for women, meaning that more than 90% subjects not classified as abdominal obesity by NHLBI-WC were also not classified as abdominal obesity using WC from other protocols.

Among men, the WC measurements using the other four alternative protocols were close to those of the NHLBI-WC measurements; as a result, sensitivity and specificity were above 90% for all these methods. However, among women, mean WHO-WC was 3.19 cm lower than that of the NHLBI-WC, which led to low sensitivity (86.85%) and high specificity (99.63%); that is, those who were classified as having abdominal obesity using NHLBI-WC had a lower chance to be classified as having abdominal obesity using WHO-WC since the latter was measured 3 cm lower on average. This also means that a woman who did not meet the criteria for abdominal obesity based on the NHLBI measurement would likely be classified as not having obesity based on WHO-WC. The low specificity of MESA-WC using Gulick II Plus tape among women (85.88%) was possibly due to MESA-WC measuring higher than NHLBI-WC, specifically among the obese group (1.51 cm higher). As a result, women who had WC close to 88 cm and were not classified as having abdominal obesity using NHLBI-WC were still likely to be classified as having abdominal obesity with MESA-WC using Gulick II Plus tape.

Some recent studies compared WC measurement protocols. Statistics Canada used both the WHO-WC and the NHLBI-WC methods during a recent 2-year survey cycle for a subsample of adult men (n = 824) and women (n = 908) aged 20–79. The Canadian study showed that men had a smaller difference in WC (0.8 cm) than women (2.2 cm). Similar to the results in this report, obesity was associated with increased differences in WC, more so in women than in men (1.7 cm and 0.3 cm, respectively) (19). Mason and Katzmarzyk compared WHO-WC and NHLBI-WC methods using a convenient sample of men (n = 223) and women (319). Their results showed that, similar to the current study and Canadian study, men had a smaller difference in WC (0.3 cm) than women (2.1 cm) (18).

The strength of this analysis is the use of NHANES’ 1-year nationally representative sample of participants aged 20 and over. Power for testing the differences between the two measurements was high (power greater than 0.99 for men; power greater than 0.9 for women except the MESA-Gulick method, where power = 0.89) based on the power analysis using variance estimates from the current WC study, assuming a mean difference of 1.5 cm between two measurements (NHLBI compared with another protocol). Besides following standardized WC measuring protocols, the reliability of these WC measurements (except MESA-assisted) was evaluated by a reference evaluator, who had obtained interobserver reliability with HT.

The findings in this study are subject to several limitations. First, the MESA-assisted measures were obtained in the NHANES MEC and may not be generalizable to conducting them in the participants’ homes. Second, while the NHLBI-WC measurements were taken at the MEC by the HTs and were evaluated by a reference interevaluator, no such reliability measure was available for the MESA-assisted WC measurements, other than observation of the HT.

This study compared four alternative protocols for measuring waist circumference to the reference NHLBI protocol. Generally, differences were minimal between the protocols with a few exceptions. These results, based on a large representative sample of the U.S. noninstitutionalized population aged 20 and over, may inform future studies that aim to use other WC measurement protocols.

**Active Series**

**Series 1. Programs and Collection Procedures**
Reports describe the programs and data systems of the National Center for Health Statistics, and the data collection and survey methods used. Series 1 reports also include definitions, survey design, estimation, and other material necessary for understanding and analyzing the data.

**Series 2. Data Evaluation and Methods Research**
Reports present new statistical methodology including experimental tests of new survey methods, studies of vital and health statistics collection methods, new analytical techniques, objective evaluations of reliability of collected data, and contributions to statistical theory. Reports also include comparison of U.S. methodology with those of other countries.

**Series 3. Analytical and Epidemiological Studies**
Reports present data analyses, epidemiological studies, and descriptive statistics based on national surveys and data systems. As of 2015, Series 3 includes reports that would have previously been published in Series 5, 10–15, and 20–23.

**Discontinued Series**

**Series 4. Documents and Committee Reports**
Reports contain findings of major committees concerned with vital and health statistics and documents. The last Series 4 report was published in 2002; these are now included in Series 2 or another appropriate series.

**Series 5. International Vital and Health Statistics Reports**
Reports present analytical and descriptive comparisons of U.S. vital and health statistics with those of other countries. The last Series 5 report was published in 2003; these are now included in Series 3 or another appropriate series.

**Series 6. Cognition and Survey Measurement**
Reports use methods of cognitive science to design, evaluate, and test survey instruments. The last Series 6 report was published in 1999; these are now included in Series 2.

**Series 10. Data From the National Health Interview Survey**
Reports present statistics on illness; accidental injuries; disability; use of hospital, medical, dental, and other services; and other health-related topics. As of 2015, these are included in Series 3.

**Series 11. Data From the National Health Examination Survey, the National Health and Nutrition Examination Surveys, and the Hispanic Health and Nutrition Examination Survey**
Reports present 1) estimates of the medically defined prevalence of specific diseases in the United States and the distribution of the population with respect to physical, physiological, and psychological characteristics and 2) analysis of relationships among the various measurements. As of 2015, these are included in Series 3.

**Series 12. Data From the Institutionalized Population Surveys**
The last Series 12 report was published in 1974; these reports were included in Series 13, and as of 2015 are in Series 3.

**Series 13. Data From the National Health Care Survey**
Reports present statistics on health resources and use of health care resources based on data collected from health care providers and provider records. As of 2015, these reports are included in Series 3.

**Series 14. Data on Health Resources: Manpower and Facilities**
The last Series 14 report was published in 1989; these reports were included in Series 13, and are now included in Series 3.

**Series 15. Data From Special Surveys**
Reports contain statistics on health and health-related topics from surveys that are not a part of the continuing data systems of the National Center for Health Statistics. The last Series 15 report was published in 2002; these reports are now included in Series 3.

**Series 16. Compilations of Advance Data From Vital and Health Statistics**
The last Series 16 report was published in 1996. All reports are available online; compilations are no longer needed.

**Series 20. Data on Mortality**
Reports include analyses by cause of death and demographic variables, and geographic and trend analyses. The last Series 20 report was published in 2007; these reports are now included in Series 3.

**Series 21. Data on Natality, Marriage, and Divorce**
Reports include analyses by health and demographic variables, and geographic and trend analyses. The last Series 21 report was published in 2006; these reports are now included in Series 3.

**Series 22. Data From the National Mortality and Natality Surveys**
The last Series 22 report was published in 1973. Reports from sample surveys of vital records were included in Series 20 or 21, and are now included in Series 3.

**Series 23. Data From the National Survey of Family Growth**
Reports contain statistics on factors that affect birth rates, factors affecting the formation and dissolution of families, and behavior related to the risk of HIV and other sexually transmitted diseases. The last Series 23 report was published in 2011; these reports are now included in Series 3.

**Series 24. Compilations of Data on Natality, Mortality, Marriage, and Divorce**
The last Series 24 report was published in 1996. All reports are available online; compilations are no longer needed.
