

## Hearing Ablity of Persome by Soclodemographic and Health Charrectoriotics: United States

Numbers and proportions of persons are estimated according to hearing ability and speech comprehension groups by age, sex, race, years of completed education, family income, usual activity, geographic region, place of residence, limitation of activity due to chronic conditions, annual bed days, number of physician contacts, and respondent-assessed health status. Estimates are based on data collected in household interviews during 1977.

# Hearing Ability of Persons by Sociodemographic and Health Characteristics 

by Peter W. Ries, Division of Health Interview Statistics

## Introduction

Hearing trouble is the most prevalent of all impairments. Once every several years, the National Health Interview Survey includes a special supplement to obtain data on the hearing ability of the civilian noninstitutionalized population of the United States. A hearing supplement was included in the 1977 National Health Interview Survey for persons 3 years of age and over. The data were collected for the National Center for Health Statistics in household interviews conducted by the U.S. Bureau of the Census.

This report describes the relationship between different degrees and types of hearing loss and selected sociodemographic and health-related characteristics. Because the same hearing scales were used in
the 1971 and 1977 National Health Interview Survey, the results of these two surveys are compared in the final section.

About the time of the 1977 National Health Interview Survey, other National Center for Health Statistics surveys also were used to collect data related to hearing ability or ear problems. These include the Health and Nutrition Examination Survey, with data based on audiological examinations; ${ }^{1}$ the National Hospital Discharge Survey, which includes data from hospital records on operations and treatment related to hearing or ear problems; ${ }^{2}$ the National Ambulatory Medical Care Survey, containing data received from office-based physicians on the diagnosis and treatment of hearing or ear problems; ${ }^{3}$ and the National Nursing Home Survey, which includes estimates of the number of persons in nursing homes who have trouble hearing. ${ }^{4}$

## Highlights

- An estimated 14.2 million persons 3 years of age and over had some trouble hearing in one or both ears. Of these, about 7.2 million had hearing trouble in both ears. About 3.2 million of the persons with bilateral hearing trouble had severe hearing problems (that is, they could at best hear and understand shouted speech), and an estimated 367,000 could not hear any speech even if shouted into the better ear.
- Hearing trouble had a very high positive association with age, especially for adults with mild and moderate hearing trouble. About 1 of 10 persons with normal hearing, about 4 of 10 persons with all levels of hearing trouble, and about 6 of 10 persons with severe hearing trouble were 65 years of age or over.
- Males had a higher prevalence rate of hearing trouble than females had. Fifty-seven percent of persons with all levels of hearing trouble and 56 percent of persons with severe hearing trouble were male.
- White persons had a higher prevalence rate of hearing trouble than black persons had. While 12 percent of persons with normal hearing were black, only 7 percent of those with all levels of hearing trouble and 6 percent of persons with severe hearing trouble were black.
- Persons with trouble hearing had less education and smaller annual family incomes than persons
with normal hearing had. This relationship was more pronounced for persons with severe hearing trouble than for persons with lesser degrees of hearing trouble.
- Adults with severe hearing trouble were underrepresented among persons whose usual activity was working or going to school. Adults with lesser degrees of hearing trouble were overrepresented among those usually working and underrepresented among adults attending school.
- The prevalence rates for hearing trouble were highest in the South Region of the country and nationwide in areas outside of standard metropolitan statistical areas.
- Persons with trouble hearing had proportionately more annual bed days because of health problems, more annual doctor visits, and greater limitation of activity due to chronic conditions than persons with normal hearing had. This relationship holds across the entire age span and within specific age groups.
- The prevalence rates of all levels of hearing trouble were similar in 1971 and 1977 (69.0 and 70.2 persons per 1,000 persons 3 years of age and over, respectively). However, the prevalence rate for persons with severe hearing trouble increased from 12.8 per 1,000 to 15.5 during this period. The increase was statistically significant only for the 45 years and over age group.

## Sources and limitations of the data

The information in this report is based on data collected in a continuing nationwide sample survey conducted by household interview. Each week interviewers visit a probability sample of households in the United States to obtain information about healthrelated characteristics of each member of the household. During the 52 weeks in 1977, interviews were conducted in approximately 41,000 households containing about 111,000 persons. The total noninterview rate was 3.3 percent, of which 57 percent (1.9 percent of the total) was due to respondent refusal and the remainder to the failure to find an eligible respondent at home after repeated calls.

Estimates of the hearing-impaired population were derived from questions 32 a , items A and B , and 33a, item 3, on the questionnaire (figure 1). All persons for whom a "yes" response was given to any one of the questions "Does anyone in the family now have deafness in one or both ears?" "Does anyone in the family now have any other trouble hearing with one or both ears?" and "Does anyone in the family use a hearing aid?" were recorded as individuals with hearing problems. The series of questions reproduced in figure 2 was asked for all such persons. The flashcard shown in figure 3 was used in administering questions 2 a and 2 b .

Questions 2a and 2 b constitute the "self-rating hearing scale"; questions 3 a through 3 g are the "Gallaudet scale." For background concerning the development of these scales and references relating to their validity see references 5 and 6 .

Because of the nature of the hearing-scale questions and the obvious difficulty in eliciting valid responses to these questions for children under 3 years of age, the scale was administered only for persons 3 years of age and over. Since proxy responses from eligible family respondents were
accepted, reference 7 also should be consulted. This publication addresses the issue of the reporting of hearing ability by self- and proxy respondents. In 1977 about 75 percent of the responses to the two hearing scales were received either from adult selfrespondents or from adult family members responding for the children residing in the household.

In this report, estimates of the hearing-impaired population exclude persons who did not report a hearing problem but indicated that they had tinnitus. Reference 8 provides a discussion of the approximately 16.2 million persons reported to have a hearing problem, tinnitus, or both.

A description of the design of the survey, the methods used in estimations, and general qualifications of the data obtained from the survey are presented in appendix I. Because the estimates shown in this report are based on a sample of the population rather than on the entire population, they are subject to sampling error. Therefore, particular attention should be paid to the section "Reliability of estimates." When a given estimate of the numerator of a rate or percentage is small, the sampling error may be relatively high. Cells containing estimates with relative standard errors of more than 30 percent (noted by asterisks) have been provided solely for the purpose of allowing readers to combine cells in useful groupings with greater reliability. Charts of relative sampling errors and instructions for their use are given in appendix I.

Certain terms used in this report are defined in appendix II. As many of these terms have specialized meanings for the purpose of this survey, familiarity with these definitions will assist in the interpretation of the data. Appendix III contains the parts of the questionnaire from which the estimates shown in this report were derived.

Figure 1. Questions from which estimates of persons with hearing trouble were derived

Figure 2. Questions asked of respondents who indicated hearing trouble in question 32

# Kinds and types of hearing trouble 

Although persons were rated on the two hearing scales discussed above, the estimates presented in this report are not shown separately for each scale. Rather, the results for each scale are combined to form a composite system of classification according to degree and type of hearing loss. The crossclassifications and the composite categories that serve as the basis for presenting the data are shown in table A.

The numerical column headings of table A indicate a person's score on the Gallaudet scale. As noted in figure 2, interviewers were instructed to ask the questions on the Gallaudet scale only until they received a "yes" response. This procedure implies the assumption of a unidimensional scale, with the inference that in the great preponderance of cases once a "yes" was obtained, all subsequent items would be answered affirmatively. Thus each person is classified according to the number of the item for which an affirmative response was obtained. For instance, persons who scored 3 indicated that they usually could not hear and understand what a person said without seeing his face if that person whispered
(item 1) or talked in a normal voice (item 2) from across a quiet room, but that they could hear and understand the speech if it was shouted from across a quiet room (item 3). As the scale consists of seven items, the score 8 indicates that the respondent answered "no" to all seven items.

The self-rating scale consists of four ratings for each ear (figure 3), making 10 possible combinations of responses when the distinction between right and left ear is ignored. If the rating of 1 equals "hearing is good," 2 "little trouble hearing," 3 "lot of trouble hearing," and 4 "deaf," the 10 possible scores are 1-1, 1-2, 1-3, 1-4, 2-2, 2-3, 2-4, 3-3, 3-4, and 4-4. In table A persons with a score of 1-1 are classified as "hearing good in both ears"; persons with scores of 1 for either ear and 2,3 , or 4 for the other ear are classified as "unilateral hearing loss." All other persons are classified as having bilateral hearing trouble. Those with scores of 4-4 are classified as "deaf, both ears"; those with scores of 3-3 or 3-4 as "at best, a lot of trouble hearing in both ears"; and those with scores of $2-2,2-3$, or $2-4$ as "at least some trouble hearing in both ears."

Table A. Number of persons 3 years of age and over for whom hearing trouble was reported, by their Gallaudet Hearing Scale score and self-rating scale status: United States, 1977

Figure 3. Questions on Card $H$, shown to respondent to determine responses to questions $2 a$ and $2 b$

Table A shows the frequencies for each composite score, and enclosures indicate the cells that have been combined to produce the categories of hearing trouble according to which the data on hearing ability will be discussed in this report. Table B shows the total number of persons represented for these combinations of cells, as well as for the total civilian noninstitutionalized population 3 years of age and over, and for the persons in the population who reported no hearing trouble. All of the detailed tables
in this report contain the column headings shown in table B.

There are two readily apparent problems in using the composite categories defined in table A; these both relate to the last column in table B ("Hearing trouble: Borderline or unclear whether unilateral or bilateral'), which is the sum of the last two rows of table A minus the 78,000 persons for whom both scale scores were unknown.

First, 614,000 persons who classified their hearing as "good" in both ears are included among the approximately 14.2 million persons defined as having trouble hearing because they indicated some level of hearing trouble or the use of a hearing aid on the screener questions (figure 1) and so probably had some type of minimal hearing trouble.

Second, because about 449,000 persons did not respond to the self-rating scale, they cannot be classified in terms of the major analytic distinction between unilateral and bilateral hearing trouble. Technically, these persons should appear in a separate category, "unclear whether unilateral or bilateral hearing trouble." However, because the Gallaudet scale scores show that the vast majority of these persons have at most a minor hearing loss (79 percent can hear and understand whispered speech), and because their total number is small, the data for these persons have been combined with those of the persons discussed above who rated their hearing "good" in both ears and are shown in all detailed tables as a single category labeled "Hearing trouble: Borderline or unclear whether unilateral or bilateral."

Table B. Number of persons 3 years of age and over, by hearing ability and levels and types of hearing trouble: United States, 1977

[^0]
## Presentation of the results

The discussion of the results of the survey is limited to comparisons of three hearing ability groups: (1) persons with normal hearing, (2) persons with all degrees and types of hearing loss, and (3) persons with severe hearing trouble. This third category is a subgroup of the second category and is defined as those persons with a bilateral hearing problem who can at best hear and understand shouted speech (Gallaudet Hearing Scale scores of 3-8). Because the age distributions of the three hearing ability groups are so different, all estimates are shown for three age-specific distributions (3-44 years, $45-64$ years, and 65 years and over). Further refinement through age adjustments within each of these three broad age groups may lead to a reduction in the strength of a number of the relationships discussed in this report.

The percent distributions shown in the detailed tables and discussed in the text were calculated on
the basis of known data only. Each detailed table in which percents were tabulated on this basis includes the denominator of the known cases used in the calculation so that the reader not wishing to assume equal distributions for the known and unknown cases may reproduce the approximate frequencies of the reported data and recalculate the percents to include the category "unknown" in the percent distributions.

Finally, in comparative statements in this report, terms such as "similar" and "the same" mean that no statistically significant difference exists between the statistics being compared. Terms relating to difference ("greater," "less," and so forth) indicate that the differences are statistically significant. The $t$-test with a critical value of 1.96 ( 0.05 level of significance) was used to test all comparisons that are discussed. Lack of comment regarding the difference between any two statistics does not mean that the difference was tested and found to be not significant.

## Selected sociodemographic characteristics

## Age and sex

The overwhelming influence of increasing age on hearing ability is shown in figure 4 and table 1. Among persons 3 years of age and over with no trouble hearing, about 71 percent were under 45 years of age, while only about 26 percent of persons with hearing trouble and 14 percent of persons with severe hearing trouble were under 45 years of age. The proportions of persons 65 years of age and over in each of the hearing ability groups equally dramatize the association between age and hearing trouble: About 1 out of 10 persons with normal hearing, about 4 out of 10 persons with all levels of hearing trouble, and about 6 out of 10 persons with severe hearing trouble were 65 years of age and over.

Figure 5 shows the sex composition of the three hearing ability groups. Among persons with normal hearing, fewer than half ( 48 percent) were male, although 57 percent of persons with hearing trouble and 56 percent of persons with severe hearing trouble were male. These differences were accentuated when the sex distributions were examined within each of

Figure 4. Percent distribution of persons 3 years of age and over by age, according to hearing ability

Figure 5. Percent distribution of persons 3 years of age and over by sex, according to age and hearing ability
the age groups shown, especially for persons 45-64 years of age. Within this age group, there were roughly twice as many males as females in the two hearing trouble groups, while among persons with normal hearing there were more females ( 54 percent) than males ( 46 percent).

Because of the large sex differences and the
overwhelming influence of age on hearing ability, data by smaller age groups by sex are shown in table C. The differences in the age-sex distributions among the three hearing ability groups are highlighted by the population "pyramids" shown in figure 6, which for persons with hearing trouble are shaped more like diamonds.

This distinct shape for persons with hearing trouble reflects the relationship of two overriding factors: (1) the increase of hearing trouble with advancing age (starting later for persons with severe hearing trouble than for persons with all levels of hearing trouble) and (2) the increase in the death rate and the rate of institutionalization with advancing age. At a point in the $60-69$ years age range for persons with all levels of hearing trouble, and in the 70-79 years age range for persons with severe hearing trouble, the increasing rate of death and institutionalization becomes greater than the increasing prevalence rate of hearing trouble. At this point more persons are leaving the noninstitutionalized population of persons with hearing trouble, by death and institutionalization, than are entering it due to the increased hearing trouble associated with aging. As the shapes of the population "pyramids" indicate, this point occurs several years later for females than it does for males in each of the hearing ability groups, reflecting females' greater longevity.

## Race

In the 1977 NHIS, interviewers were instructed to classify (by observation) each person in the household as "white," "black," or "other." According to the data shown in table 2, persons classified as "black" and "other" were proportionately underrepresented among persons with hearing trouble in comparison with normal hearing: Whereas 12 percent of persons with normal hearing were classified as black, only about 7 percent of persons with all levels
of hearing trouble and about 6 percent of persons with severe hearing trouble were classified as black.

Figure 7 shows the distribution by race for white and black persons according to hearing ability and age. Black persons were underrepresented in each of the two older age groups. However, for persons 3-44 years of age in the civilian noninstitutionalized population, there was no statistically significant difference between the proportions of black persons among those with normal hearing and among those with severe hearing trouble.

Because the frequencies for persons classified as "other" are small, most comparisons in that category for different levels of hearing ability are not very meaningful. At best, the estimates shown in table 2 suggest that in comparison to white persons, these persons (as is the case for black persons) were underrepresented among persons with trouble hearing.

## Education

The amount of completed education of persons 20 years of age and over is highly associated with their hearing ability (figure 8 , table 3 ). The higher the degree of hearing loss, the fewer the years of completed education. For example, 30 percent of persons 20 years of age and over with normal hearing did not receive a high school diploma, but 66 percent of persons with severe hearing loss did not complete high school. While the relationship between increasing hearing loss and decreasing level of education is accentuated because both education level and hearing trouble are associated with age, it holds to a lesser but nevertheless substantial degree for persons in each of the three age groups.

## Annual family income

The association between persons' annual family incomes and their ability to hear (table 4, figure 9)

Table C. Percent distribution of persons 3 years of age and over by sex and age, according to hearing ability: United States, 1977

[^1]

Figure 6. Percent distribution of persons 3 years of age and over by sex and age, according to hearing ability

Figure 7. Percent distribution of persons 3 years of age and over by race, according to age and hearing ability
was similar to that between years of completed education and hearing ability. While only 21 percent of persons with normal hearing lived in families with annual incomes of under $\$ 7,000$, 47 percent of persons with severe hearing trouble lived in families at this income level. However, the pattern within each of the three age groups is neither as strong nor as consistent as for completed years of education, especially for persons 65 years of age and over. Nevertheless, family income tended to be lower when the level of hearing trouble was higher even when the comparisons are limited to age-specific groups.

## Usual activity

Information on usual activity during the year preceding the interview is sought for each person 6 years of age and over in the ongoing survey. Only women are asked if their usual activity is "keeping house," and only persons 45 years of age and over are asked whether they are retired. However, retired persons are not classified as retired if they consider different activities as their major activities. Thus the number of persons classified as retired (table 5)

Figure 8. Percent distribution ${ }^{1}$ of persons 3 years of age and over by years of completed education, according to age and hearing ability
should not be interpreted as an estimate of the total number of persons in the noninstitutionalized population of the United States who have retired.

Table 5 and figure 10 show the results for this item according to levels of hearing ability and age. For persons 17 years of age and over, about 57 percent of persons with normal hearing, 40 percent of persons with any degree of hearing trouble, and 23 percent of persons with severe hearing trouble were usually working during the year preceding the interview. The other major distributional difference is in the percent of persons in each hearing ability group classified as retired. About 6 percent of persons with normal hearing, 24 percent of those with all levels of hearing loss, and 36 percent of persons with severe hearing trouble had their usual activity reported as being retired.

This pattern of the relationship for all persons 17 years of age and over between levels of hearing ability on the one hand and the activity status of usually working or being retired on the other is similar to that for persons $45-64$ years of age and 65 years of age and over. However, for those 17-44 years of age, a higher percent of persons with hearing trouble were

Figure 9. Percent distribution ${ }^{1}$ of persons 3 years of age and over by annual family income, according to age and hearing ability
usually working than were persons with normal hearing.

Another major distributional difference in the $17-44$-year age range is the high proportion of persons in each of the hearing trouble groups who did not give "going to school" as their major activity and who were classified as doing "something else." While about 14 percent of the persons in this age group with normal hearing were attending school, only about 8 percent of persons with all levels of hearing trouble and 8 percent of persons with severe hearing trouble reported attending school as their usual activity (figure 10). Also, while only about 4 percent of persons with normal hearing indicated that they were doing something else, 6 percent of persons with all levels of hearing trouble and 15 percent of persons with severe hearing trouble were classified in this category.

## Geographic region

Table 6 and figure 11 show the distribution of persons with different levels of hearing ability by geographic region. In comparison to persons with

Figure 10. Percent distribution ${ }^{2}$ of persons 17 years of age and over by usual activity during the 12 months preceding interview, according to age and hearing ability
normal hearing, persons with hearing trouble, especially those with severe hearing trouble, tended to be underrepresented in the Northeast and overrepresented in the South. This relationship for all persons 3 years of age and over reflects the regional distribution for persons 65 years of age and over. None of the differences shown in figure 11 with respect to the Northeast and South for persons under 65 years of age are statistically significant.

## Place of residence

A similar proportion of persons in each of the hearing ability groups lived in central cities of standard metropolitan statistical areas (SMSA's) (figure 12, table 7). This relation holds for persons of all ages and for each of the three age groups. The main distributional differences among the residence groups are the relatively large number of persons with hearing trouble living outside SMSA's and the rela-

Figure 11. Percent distribution of persons 3 years of age and over by geographic region, according to age and hearing ability
tively small number living in the noncentral-city portion of SMSA's. While not all of the differences among the age groups are statistically significant, the tendency for persons with trouble hearing to be overrepresented in the less urbanized sections of the country and to be underrepresented in suburban areas holds for each of the age groups shown in figure 12.

Figure 12. Percent distribution of persons 3 years of age and over by place of residence, according to age and hearing ability

The following sections show selected healthrelated characteristics of persons according to level of hearing ability. The focus of the presentations is on the association between hearing ability and healthrelated characteristics, rather than on the specific effects of hearing trouble on health-related behavior. Only limitation of activity due to chronic conditions is considered separately in relation to the reported direct effect of hearing trouble on a particular health characteristic. The special attention to this health characteristic reflects the fact that limitation of activity due to chronic conditions is the NHIS concept most closely resembling the more widely used term "disabled." An estimate of the "disabled" population of the United States is one of the most frequent data requests made of the NHHS.

## Limitation of activity

The concept of limitation of activity as used in this report refers to any long-term reduction in activity resulting from chronic disease or impairment. Persons classified as "limited in major activity" are (1) those who were unable to carry on the usual activity for their age-sex group, whether it was working, keeping house, or going to school, and (2) persons able but limited in their ability to carry out these tasks. A second group consists of persons not limited in their major activity but who were "limited in other activities." The third classification is "not limited in activity."

Table 8 shows estimates for limitation of activity in terms of the above three categories. However, the following discussion of the relationship between hearing ability and limitation of activity due to chronic conditions is restricted mainly to distinguishing persons with any degree of limitation of activity from those who are not at all limited.

Figure 13 shows the strong association between hearing ability and limitation of activity. Whereas only 12 percent of persons with normal hearing were limited in activity, 42 percent of persons with trouble

Figure 13. Percent distribution of persons 3 years of age and over by whether limited in actual activity due to chronic conditions, according to age and hearing ability
hearing and 61 percent of persons with severe hearing trouble were limited in activity. The relationship between hearing ability and activity holds for each of the three age groups shown in figure 13. While the proportion of persons who were limited in their usual activity increased with age for all of the hearing ability groups, the disparity according to hearing level was greatest for persons 3-44 years of age. In this age
group about half of all persons with severe hearing trouble were limited, while only 6 percent of persons with normal hearing were limited.

Not only were persons with hearing trouble much more likely to be limited in activity, but they also were more likely to be limited in major activity (table 8). Thus; for instance, while persons with hearing trouble were 2.7 times as likely as persons with normal hearing to be limited in other activities, they were 3.8 times as likely to be limited in major activity. The difference in activity limitations was even greater between persons with normal hearing and persons with severe hearing trouble (the corresponding ratios are 3.3 and 5.7).

In interpreting the results shown in table 8 and discussed above, it is important to recognize the distinction between (1) a high association of hearing ability with limitation of activity status and (2) trouble hearing as a cause of limitation of activity. Respondents who reported a limitation of activity were asked to list all conditions that caused this limitation. When more than one condition was listed, respondents were asked to designate the single condition they considered the main cause of the limitation. Table 9 and table D show the estimates for the conditions reported as the cause of the limitation among persons reported to be limited in activity according to the three hearing ability groups discussed above.

About 88 percent of persons with hearing trouble and about 80 percent of persons with severe hearing problems did not list their hearing trouble as even a secondary cause of their limitation. And of persons who did list their hearing trouble as a cause of their limitations, only about 7 percent of all persons with hearing trouble and 12 percent of those with severe hearing trouble gave their hearing trouble as the main cause of their limitation. This relationship, however, was strongly affected by age: Relatively few persons 65 years of age and over claimed their hearing trouble as a cause of their limitation, but about one-third of persons 3-44 years of age with hearing trouble and more than half of those with severe hearing trouble reported their hearing trouble as a cause of their limitation. Equally important is that many of these younger persons reported hearing trouble as the main cause of their limitation whereas most of the older persons listed hearing trouble as a secondary cause of their limitation.

## Annual bed days

Limitation of activity relates to long-term chronic conditions and impairments. Respondents also are asked in the NHIS to estimate the number of days they have spent in bed because of any type of illness or injury during the 12 months preceding the interview. This measure of disability thus includes the

Table D. Number and percent distribution of persons limited in activity due to chronic conditions by whether hearing trouble is a cause of the limitation, according to age and hearing ability: United States, 1977

| Age and whether hearing trouble is a cause of limitation | All hearing levels | Trouble hearing | At best, can hear shouted speech | All hearing levels | Trouble hearing | At best, can hear shouted speech |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 3 years of age and over | Number of persons in thousands |  |  | Percent distribution |  |  |
| All persons limited in activity | 28,411 | 5,965 | 1,925 | 100.0 | 100.0 | 100.0 |
| Hearing trouble is main cause | 413 | 413 | 239 | 1.5 | 6.9 | 12.4 |
| Hearing trouble is secondary cause | 281 | 281 | 147 | 1.0 | 4.7 | 7.6 |
| Hearing trouble is not a cause | 27,717 | 5,270 | 1,540 | 97.6 | 88.3 | 80.0 |
| 3-44 years of age |  |  |  |  |  |  |
| All persons limited in activity | 8,831 | 833 | 222 | 100.0 | 100.0 | 100.0 |
| Hearing trouble is main cause | 223 | 223 | 109 | 2.5 | 26.8 | 49.1 |
| Hearing trouble is secondary cause | 45 | 45 | *12 | 0.5 | 5.4 | *5.4 |
| Hearing trouble is not a cause | 8,563 | 566 | 100 | 97.0 | 67.9 | 45.0 |
| 45-64 years of age |  |  |  |  |  |  |
| All persons limited in activity | 10,003 | 1,871 | 432 | 100.0 | 100.0 | 100.0 |
| Hearing trouble is main cause | 104 | 104 | 60 | 1.0 | 5.6 | 13.9 |
| Hearing trouble is secondary cause | 73 | 73 | *30 | 0.7 | 3.9 | *6.9 |
| Hearing trouble is not a cause | 9,826 | 1,694 | 343 | 98.2 | 90.5 | 79.4 |
| 65 years of age and over |  |  |  |  |  |  |
| All persons limited in activity | 9,577 | 3,260 | 1,271 | 100.0 | 100.0 | 100.0 |
| Hearing trouble is main cause | 86 | 86 | 70 | 0.9 | 2.6 | 5.5 |
| Hearing trouble is secondary cause | 164 | 164 | 104 | 1.7 | 5.0 | 8.2 |
| Hearing trouble is not a cause | 9,328 | 3,011 | 1,097 | 97.4 | 92.4 | 86.3 |

impact of all types of acute conditions as well as of chronic conditions and impairments.

Table 10 and figure 14 show that while only a slightly greater proportion of persons with normal hearing ( 55 percent) than of persons with trouble hearing ( 51 percent for both hearing trouble groups) spent no days in bed because of illness or injury during the year preceding their interview, a far greater proportion of persons with hearing trouble reported 8 or more days in bed because of illness or injury ( 21 percent for all levels of hearing trouble and 28 percent for severe hearing trouble compared with 11 percent for no hearing trouble). This pattern holds for each of the three age groups shown in figure 14.

## Annual physician contacts

Respondents were asked how many times each family member had seen or talked to a doctor during the 12 months before the interview. The data shown in table 11 and figure 15 relate to physician contacts for any reason, including illnesses and injuries not

Figure 14. Percent distribution ${ }^{1}$ of persons 3 years of age and over by estimated days in bed during the 12 months preceding the interview, according to age and hearing ability
related to hearing, and contacts not involving any health problems (such as, for instance, for an annual physical examination).

A larger proportion of persons with normal hearing ( 26 percent) had not seen or talked to a physician during the 12 months preceding the interview than had persons with all levels of hearing trouble ( 17 percent) and persons with severe hearing trouble (16 percent). Proportionately about twice as many persons with hearing trouble ( 30 percent for all levels and 36 percent for severe hearing trouble) as persons with normal hearing ( 16 percent) had seen or talked to a physician six or more times during the preceding year. The pattern of the relationships for each of the three age groups is similar to that for all persons 3 years of age and over (figure 15).

## Respondent-assessed health status

Respondents were asked to evaluate each family member's health status in response to the following question: "Compared to other persons -- -'s age,

Figure 15. Percent distribution ${ }^{1}$ of persons 3 years of age and over by estimated physician contacts during the 12 months preceding interview, according to age and hearing ability
would you say that his health is excellent, good, fair, or poor?" At least three things should be noted about the data derived from responses to this question. First, the question asks about a person's health and not about any impairment the person might have. As such, it is entirely reasonable for a person with profound deafness to be considered in "excellent" health and for a person with normal hearing to be in "poor" health.

Second, although the concept being measured is often called "self-assessed health status," proxy responses are accepted from family members meeting the NHIS eligible-respondent rules for adult family members not participating in the interview and ineligible adult respondents (such as a mentally retarded family member). Further, responses for children and youth under 17 years of age are always sought from eligible adult family members. Research related to self- and proxy responses for adults in the general population has shown that although there may be some significant difference between "excellent" and "good," and between "fair" and "poor," there appear to be no significant differences in the distributions between self- and proxy responses when the categories "excellent" and "good" are combined and compared with the combined categories "fair" and "poor." ${ }^{\text {F }}$ For this reason, although the data shown in table 12 are presented for each of the four categories, the discussion in this text is limited to comparisons for the combined category "fair" or "poor."

Third, among the health-related concepts measured in the NHIS, respondent-assessed health status is the single item that best correlates with other items related to health status and items related to the utilization of health services. As such, it may be viewed as a summary concept for the results related to health presented in the previous sections.

Figure 16 and table 12 show that proportionately about 3 times as many persons with hearing trouble (31 percent) and about 4 times as many persons with severe hearing trouble ( 43 percent) as persons with normal hearing (11 percent) judged their health to be fair or poor in comparison to other persons their age. With some minor variations, the same pattern is reflected in each of the three age groups shown.

As in the normal hearing population, a higher proportion of females with hearing loss ( 34 percent) assessed their health as fair or poor than did males (29 percent). However, among persons with severe hearing trouble the proportions assessing their health as fair or poor were similar for males ( 44 percent) and for females ( 43 percent).

## Hearing aid use

A reported 1.9 million persons used hearing aids at the time of interview during 1977. About 12

Figure 16. Percent distribution ${ }^{1}$ of persons 3 years of age and over by respondent-assessed health status, according to age and hearing ability
percent of persons with all levels of hearing trouble and 34 percent of persons with severe hearing trouble reported the use of a hearing aid (table 13, figure 17). The percent of persons with all levels of hearing trouble using hearing aids was highly associated with age; the proportion increased from 4 percent for persons 3-44 years of age to 20 percent for persons 65 years of age and over. Age was less highly associated with hearing aid use among persons with severe hearing trouble. Among the latter group; the proportion increased from 24 percent for persons $3-44$ years of age to 37 percent for persons 65 years of age and over.

About 54 percent of the persons using hearing aids were male. For persons with all levels of hearing trouble, approximately the same proportion of males and females used hearing aids. However, for persons with severe hearing trouble a greater proportion of females ( 37 percent) than males ( 31 percent) used hearing aids.

Figure 17. Percent distribution ${ }^{1}$ of persons 3 years of age and over by hearing aid use, according to age and hearing ability

## Prevalence rates of hearing trouble in 1971 and 1977

Table E shows the distribution of the total civilian noninstitutionalized population 3 years of age and over by hearing ability for $1971^{5}$ and 1977. In both years a similar proportion of the population had some trouble hearing ( 6.9 percent for 1971 and 7.0 percent for 1977). However, differences between the two periods did occur within the groups of persons with trouble hearing. From 1971 to 1977, the percent of persons with bilateral hearing problems increased from 3.3 percent to 3.6 percent. Within the group of persons with bilateral hearing trouble, the proportional increase from 1971 to 1977 was due entirely to the increase in the proportion of persons with severe hearing trouble-persons who could at best hear and understand shouted speech.

The last column of table E shows this same relationship in terms of the percent increase from 1971 to 1977 in the number of persons for each of the hearing status groups. While the civilian noninstitutionalized population increased by 5.9 percent during this period, the number of persons with severe hearing trouble increased by 28.9 percent. During the same period, the percent of persons who could hear and understand speech spoken in a normal voice or
whispered showed no statistically significant increase.
Table F shows that for persons with all levels and types of hearing trouble, the prevalence rates remained about the same for persons 3-16 years of age, the rate for persons 45-64 years of age showed a slight increase, and the rate decreased for persons $17-44$ years of age and 65 years of age and over.

For persons with all types of bilateral hearing trouble, the increase in the prevalence rate for persons of all ages from 33.5 to 35.5 persons per 1,000 population is not statistically significant. However, for persons in the age group 45-64 years, there was a statistically significant increase in the prevalence rate during the 6-year period (from 44.2 to 50.2 persons per 1,000 population).

For persons with severe hearing trouble, the prevalence rate increased from 12.8 to 15.5 persons per 1,000 population. Only for persons 45 years of age ${ }^{-}$ and over was the increase statistically significant.

In relation to sex, the prevalence rates for females in 1971 and 1977 are similar for each of the levels of hearing trouble and for all of the age groups, indicating that the differences discussed above derive mainly from changes in the prevalence rates of

Table E. Number and percent distribution of persons 3 years of age and over by hearing ability, according to year and percent increase from 1971 to 1977: United States, 1971 and 1977

| Hearing ability | 1971 | 1977 | 1971 | 1977 | $\begin{aligned} & \text { Increase } \\ & 1971-77 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Number of persons in thousands |  | Percent distribution |  | Percent |
| All persons 3 years of age and over | 191,602 | 202,936 | 100.0 | 100.0 | 5.9 |
| No trouble hearing | 178,374 | 188,696 | 93.1 | 93.0 | 5.8 |
| Trouble hearing ${ }^{1}$. . . . . | 13,228 | 14,240 | 6.9 | 7.0 | 7.7 |
| Bilateral hearing trouble ${ }^{2}$ | 6,414 | 7,208 | 3.3 | 3.6 | 12.4 |
| At best, can hear shouted speech | 2,447 | 3,153 | 1.3 | 1.6 | 28.9 |
| Can hear speech spoken in normal voice | 3,878 | 3,984 | 2.0 | 2.0 | 2.7 |
| All other types of hearing trouble | 6,814 | 6,953 | 3.6 | 3.4 | 2.1 |

[^2]hearing trouble for males. For all levels and types of hearing trouble, the prevalence rates for males decreased for the 17-24 years and 65 years and over age groups and increased for the 45-64 years age group. For all types of bilateral hearing trouble, the rates increased for the 45-64 years age group (but not for the 65 years and over age group) and decreased for the 17-24 years age group. For both of these types of hearing trouble, the changes for the age groups tended to cancel each other, leaving the overall prevalence rates for the 2 years relatively unchanged.

There was an overall increase in the prevalence of severe hearing trouble among males 3 years of age and over between 1971 and 1977, from 14.7 to 17.9 per 1,000 males. The rate increased by 44 percent for males $45-64$ years of age and by 56 percent for males 25-44 years of age. However, because the latter age
group is relatively small in number, the large estimated percent increase is not statisticaliy significant, while the estimated 44 percent increase for males 45-64 years is statistically significant and constitutes a substantial increase.

In summary, although the overall prevalence rates for all levels of hearing trouble were similar in 1971 and 1977, there was an increase in the prevalence rate of severe hearing trouble. The prevalence rates for females for each of the levels of hearing trouble and for all ages were similar, while those for males did show changes. The major change for males was the increase in the prevalence rate for those with severe hearing trouble aged $45-64$, producing a rate of 26.2 males per 1,000 in the male population-a rate 44 percent higher than in 1971.

Table F. Number of persons with hearing trouble 3 years of age and over, by hearing ability, year, sex, and age: United States, 1971 and 1977

| Sex and age | All levels of hearing trouble ${ }^{1}$ |  | Bilateral hearing trouble |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

1. Number and percent distribution of persons 3 years of age and over by age and sex, according to hearing ability: United

States, 1977
2. Number and percent distribution of persons 3 years of age and over by race, age, and sex, according to hearing ability: United States, 1977
3. Number and percent distribution of persons 20 years of age and over by education level, age, and sex, according to hearing ability: United States, 1977
4. Number and percent distribution of persons 3 years of age and over by known family income, age, and sex, according to hearing ability: United States, 1977
5. Number and percent distribution of persons 17 years of age and over by known usual activity, age, and sex, according to hearing ability: United States, 1977
6. Number and percent distribution of persons 3 years of age and over by geographic region, age, and sex, according to hearing ability: United States, 1977
7. Number and percent distribution of persons 3 years of age and over by place of residence, age, and sex, according to hearing ability: United States, 1977
8. Number and percent distribution of persons 3 years of age and over by limitation of activity status, age, and sex, according to hearing ability: United States, 1977
9. Number and percent distribution of persons 3 years of age and over who are limited in activity due to chronic conditions by whether hearing loss is a cause of the limitation, age, and sex, according to hearing ability: United States, 1977
10. Number and percent distribution of persons 3 years of age and over by known annual days in bed, age, and sex, according to hearing ability: United States, 1977
11. Number and percent distribution of persons 3 years of age and over by known annual physician contacts, age, and sex, according to hearing ability: United States, 1977
12. Number and percent distribution of persons 3 years of age and over by respondent-assessed health status, age, and sex, according to hearing ability: United States, 197742
13. Number and percent distribution of persons 3 years of age and over by known hearing aid use, age and sex, according to hearing ability: United States, 1977

Table 1. Number and percent distribution of persons 3 years of age and over by age and sex, according to hearing ability: United States, 1977
[Data are based on household interviews of the civilian noninstitutionalized population. The survey design, general qualifications, and information on the reliability of the estimates are given in appendix I. Definitions of terms are given in appendix II]

II. Relative standard errors of percents of population characteristics ..... 51

# Appendix I. Technical notes on methods 

## Background of this report

This report is one of a series of statistical reports prepared by the National Center for Health Statistics (NCHS). It is based on information collected in a continuing nationwide sample of households in the National Health Interview Survey (NHIS).

The National Health Interview Survey utilizes a questionnaire that obtains information on personal and demographic characteristics, illnesses, injuries, impairments, chronic conditions, and other health topics. As data relating to each of these various broad topics are tabulated and analyzed, separate reports are issued that cover one or more of the specific topics.

The population covered by the sample for the National Health Interview Survey is the civilian noninstitutionalized population of the United States living at the time of the interview. The sample does not include members of the Armed Forces or U.S. nationals living in foreign countries. It should also be noted that the estimates shown do not represent a complete measure of any given topic during the specified calendar period, since data are not collected in the interview for persons who died during the reference period. For many types of statistics collected in the survey, the reference period covers the 2 weeks prior to the interview week. For such a short period, the contribution by decedents to a total inventory of conditions or services should be very small. However, the contribution by decedents during a long reference period (e.g., 1 year) might be sizable, especially for older persons.

## Statistical design of the National Health Interview Survey

General plan.-The sampling plan of the survey follows a multistage probability design that permits a continuous sampling of the civilian noninstitutionalized population of the United States. The sample is designed in such a way that the sample of households
interviewed each week is representative of the target population and that weekly samples are additive over time. This feature of the design permits both continuous measurement of characteristics of samples and more detailed analysis of less common characteristics and smaller categories of health-related items. The continuous collection has administrative and operational advantages as well as technical assets, since it permits fieldwork to be handled with an experienced, stable staff.

The overall sample was designed so that tabulations could be provided for each of the four major geographic regions and for selected places of residence in the United States.

The first stage of the sample design consists of drawing a sample of 376 primary sampling units (PSU's) from approximately 1,900 geographically defined PSU's. A PSU consists of a county, a small group of contiguous counties, or a standard metropolitan statistical area. The PSU's collectively cover the 50 States and the District of Columbia.

With no loss in general understanding, the remaining stages can be combined and treated in this discussion as an ultimate stage. Within PSU's, then, ultimate stage units called segments are defined in such a manner that each segment contains an expected four households. Three general types of segments are used:

Area segments, which are defined geographically.
List segments, using 1970 census registers as the frame.
Permit segments, using updated lists of building permits issued in sample PSU's since 1970.
Census address listings were used for all areas of the country where addresses were well defined and could be used to locate housing units. In general the list frame included the larger urban areas of the United States, from which about two-thirds of the NHIS sample was selected.

The usual NHIS sample consists of approximately

12,000 segments containing about 50,000 assigned households, of which 9,000 were vacant, demolished, or occupied by persons not in the scope of the survey. The 41,000 eligible occupied households yield a probability sample of about 111,000 persons.

Descriptive material on data collection, field procedures, and questionnaire development in NHIS, 10,11 as well as a detailed description of the sample design and estimation procedure, ${ }^{12,13}$ have been published.

Collection of data.-Field operations for the survey are performed by the U.S. Bureau of the Census under specifications established by the $\mathrm{Na}-$ tional Center for Health Statistics. In accordance with these specifications the Bureau of the Census participates in survey planning, selects the sample, and conducts the field interviewing as an agent of NCHS. The data are coded, edited, and tabulated by NCHS.

Estimating procedures.-Since the design of NHIS is a complex multistage probability sample, it is necessary to use complex procedures in the derivation of estimates. Four basic operations are involved.

1. Inflation by the reciprocal of the probability of selection.-The probability of selection is the product of the probabilities of selection from each step of selection in the design (PSU, segment, and household).
2. Nonresponse adjustment.-The estimates are inflated by a multiplication factor that has as its numerator the number of sample households in a given segment and as its denominator the number of households interviewed in that segment.
3. First-stage ratio adjustment.-Sampling theory indicates that the use of auxiliary information that is highly correlated with the variables being estimated improves the reliability of the estimates. To reduce the variability between PSU's within a region, the estimates are ratio-adjusted to the 1970 populations within 12 race-residence classes.
4. Poststratification by age-sex-race.-The estimates are ratio-adjusted within each of 60 age-sex-race cells to an independent estimate of the population of each cell for the survey period. These independent estimates are prepared by the Bureau of the Census. Both the first-stage and poststratified ratio adjustments take the form of the multiplication factors applied to the weight of each elementary unit (person, household, condition, and hospitalization).
The effect of the ratio-estimating process is to make the sample more closely representative of the civilian noninstitutionalized population by age, sex, race, and residence, which thereby reduces sampling variance.

As noted, each week's sample represents the population living during that week and characteristics
of the population. Consolidation of samples over a time period, e.g., a calendar quarter, produces estimates of average characteristics of the U.S. population for that period, in this case the calendar quarter. Similarly, population data for a year are averages of the four quarterly figures.

For prevalence statistics, such as number of persons with speech impairments or number of persons classified by time interval since last physician visit, figures are first calculated for each calendar quarter by averaging estimates for all weeks of interviewing in the quarter. Prevalence data for a year are then obtained by averaging the four quarterly figures.

For other types of statistics-namely those measuring the number of occurrences during a specified time period-such as incidence of acute conditions, number of disability days, and number of visits to a doctor or dentist, a similar computational procedure is used, but the statistics are interpreted differently. For these items, the questionnaire asks for the respondent's experience over the 2 calendar weeks prior to the week of interview. In such instances the estimated quarterly total for the statistic is 6.5 times the average 2 -week estimate produced by the 13 successive samples taken during the period. The annual total is the sum of the four quarters. Thus the experience of persons interviewed during a yearexperience that actually occurred for each person in a 2 -calendar-week interval prior to the week of inter-view-is treated as though it measured the total of such experience during the year. Such interpretation leads to no significant bias.

Explanation of hospital recall.-The survey questionnaire uses a 12 -month recall period for hospitalizations. That is, the respondent is asked to report hospitalizations that occurred during the 12 months prior to the week of interview. Information is also obtained as to the date of entry into the hospital and duration of stay. Analysis of this information and also the results of special studies have shown that there is an increase in underreporting of hospitalizations with increase in time interval between the discharge and the interview. Exclusive of the hospital experience of decedents, the net underreporting with a 12 -month recall is in the neighborhood of 10 percent, but underreporting of discharges within 6 months of the week of interview is estimated to be less than 5 percent. For this reason hospital discharge data in this report are based on hospital discharges reported to have occurred within 6 months of the week of interview. Since the interviews were evenly distributed according to weekly probability samples throughout any interviewing year, no seasonal bias was introduced by doubling the 6 -month recall data to produce an annual estimate for that year of interviewing. Doubling the 6 -month data in effect imputes to the entire year preceding the interview the
rate of hospital discharges actually observed during the 6 months prior to interview. However, estimates of the number of persons with hospital episodes (as opposed to estimates of the number of hospital discharges) are based on 12-month recall data, since a person's 12 -month experiences cannot be obtained by doubling his most recent 6 -month experience.

## General qualifications

Nonresponse.-Data were adjusted for nonresponse by a procedure that imputes to persons in a household who were not interviewed the characteristics of persons in households in the same segment who were interviewed. Interviews were completed in 97.1 percent of the sample households.

The interview process. -The statistics presented in this report are based on replies obtained in interviews with persons in the sample households. Each person 19 years of age and over present at the time of interview was interviewed individually. For children and for adults not present in the home at the time of the interview, the information was obtained from a related household member such as a spouse or the mother of a child.

There are limitations to the accuracy of diagnostic and other information collected in household interviews. For diagnostic information, the household respondent can usually pass on to the interviewer only the information the physician has given to the family. For conditions not medically attended, diagnostic information is often no more than a description of symptoms. However, other facts, such as the number of disability days caused by the condition, can be obtained more accurately from household members than from any other source, since only the persons concerned are in a position to report this information.

Rounding of numbers.-The original tabulations on which the data in this report are based show all estimates to the nearest whole unit. All consolidations were made from the original tabulations using the estimates to the nearest unit. In the final published tables, the figures are rounded to the nearest thousand, although these are not necessarily accurate to that detail. Devised statistics such as rates and percent distributions are computed after the estimates on which these are based have been rounded to the nearest thousand.

Population figures. - Some of the published tables include population figures for specified categories. Except for certain overall totals by age, sex, and race, which are adjusted to independent estimates, these figures are based on the sample of households in NHIS. These are given primarily to provide denominators for rate computation, and for this purpose are more appropriate for use with the accompanying measures of health characteristics than other popula-
tion data that may be available. With the exception of the overall totals by age, sex, and race mentioned above, the population figures differ from figures (which are derived from different sources) published in reports of the Bureau of the Census. Official population estimates are presented in Bureau of the Census reports in Series P-20, P-25, and P-60.

## Reliability of estimates

Since the statistics presented in this report are based on a sample, they will differ somewhat from the figures that would have been obtained if a complete census had been taken using the same schedules, instructions, and interviewing personnel and procedures.

As in any survey, the results are also subject to reporting and processing errors and errors due to nonresponse. To the extent possible, these types of errors were kept to a minimum by methods built into survey procedures. ${ }^{14}$ Although it is very difficult to measure the extent of bias in the National Health Interview Survey, a number of studies have been conducted to study this problem. The results have been published in several reports. ${ }^{15-18}$ The standard errors shown in this report were computed using the balanced half-sample replication procedure.

The standard error is primarily a measure of sampling variability, that is, the variations that might occur by chance because only a sample of the population is surveyed. As calculated for this report, the standard error also reflects part of the variation that arises in the measurement process. It does not include estimates of any biases that might be in the data. The chances are about 68 out of 100 that an estimate from the sample would differ from a complete census by less than the standard error. The chances are about 95 out of 100 that the difference would be less than twice the standard error and about 99 out of 100 that it would be less than $21 / 2$ times as large.

Standard error charts. - The relative standard error of an estimate is obtained by dividing the standard error of the estimate by the estimate itself and is expressed as a percent of the estimate. For this report, asterisks are shown for any cell with more than a 30 -percent relative standard error. Included in this appendix are charts from which the relative standard errors can be determined for estimates shown in the report. To derive relative errors that would be applicable to a wide variety of health statistics and that could be prepared at a moderate cost, a number of approximations were required. As a result, the charts provide an estimate of the approximate relative standard error rather than the precise error for any specific aggregate or percent.

Three classes of statistics for the health survey are identified for purposes of estimating variances.

1. Narrow range.-This class consists of (1) statistics that estimate a population attribute, e.g., the number of persons in a particular income group, and (2) statistics for which the measure for a single individual during the reference period used in data collection is usually either 0 to 1 and, on occasion, may take on the value 2 or very rarely 3.
2. Medium range. - This class consists of other statistics for which the measure for a single individual during the reference period used in data collection will rarely lie outside the range 0 to 5 .
3. Wide range.-This class consists of statistics for which the measure for a single individual during the reference period used in data collection can range from 0 to a number in excess of 5 , e.g., the number of days of bed disability.
In addition to classifying variables according to whether they are narrow-, medium-, or wide-range, statistics in the survey are further classified as to whether they are based on a reference period of 2 weeks, 6 months, or 12 months.

General rules for determining relative standard errors.-The following rules will enable the reader to determine approximate relative standard errors from the charts for estimates presented in this report. These charts represent standard errors of NHIS data. They should be used in preference to the charts that have appeared in all previous Series 10 publications.
Rule 1. Estimates of aggregates: Approximate relative standard errors for estimates of aggregates such as the number of persons with a given characteristic are obtained from figure I. The number of persons in the total U.S. population or in an age-sex-color class of the total population is adjusted to official Buregu of the Census figures and is not subject to sampling error.
Rule 2. Estimates of percentages in a percent distribution: Relative standard errors for percents in a percent distribution of a total are obtained from figure II. For values which do not fall on the curves presented in the chart, visual interpolation will provide a satisfactory approximation.
Rule 3. Estimates of rates where the numerator is a subclass of the denominator: This rule applies for prevalence rates or where a unit of the numerator occurs, with few exceptions, only once for any one unit in the denominator. For example, in computing the rate of visual impairments per 1,000 population, the numerator consisting of persons with the impairment is a subclass of the denominator, which includes all persons in the population. Such rates if converted to rates per 100 may
be treated as though they were percents and the relative standard errors obtained from the percent chart for population estimates. Rates per 1,000 , or on any other base, must first be converted to rates per 100; then the percent chart will provide the relative standard error per 100 .
Rule 4. Estimates of rates where the numerator is not a subclass of the denominator: This rule applies where a unit of the numerator often occurs more than once for any one unit in the denominator. For example, in the computation of the number of persons injured per 100 currently employed persons per year, it is possible that a person in the denominator could have sustained more than one of the injuries included in the numerator. Approximate relative standard errors for rates of this kind may be computed as follows:
(a) Where the denominator is the total U.S. population or includes all persons in one or more of the age-sex-color groups of the total population, the relative error of the rate is equivalent to the relative error of the numerator, which can be obtained directly from the appropriate chart.
(b) In other cases the relative standard error of the numerator and of the denominator can be obtained from the appropriate curve. Square each of these relative errors, add the resulting values, and extract the square root of the sum. This procedure will result in an upper bound on the standard error and will overstate the error to the extent that the correlation between numerator and denominator is greater than zero.
Rule 5. Estimates of difference between two statistics (mean, rate, total, etc.): The standard error of a difference is approximately the square root of the sum of the squares of each standard error considered separately. A formula for the standard error of a difference,

$$
d=X_{1}-X_{2}
$$

is

$$
\sigma_{\mathrm{d}}=\sqrt{\left(X_{1} V_{x_{1}}\right)^{2}+\left(X_{2} V_{x_{2}}\right)^{2}}
$$

where $X_{1}$ is the estimate for class $1, X_{2}$ is the estimate for class 2 , and $V_{x_{1}}$ and $V_{x_{2}}$ are the relative errors of $X_{1}$ and $X_{2}$ respectively. This formula will represent the actual

${ }^{1}$ This curve represents estimates of relative standard errors based on 4 quarters of data collection for narrow range estimates of population characteristics or narrow ratimes using a 12-month period.

Example of use of chart: An estimate of $10,000,000$ persons with annual family income of $\$ 15,000$ or more, or $10,000,000$ persons who were hospitalized one or more times in the past year (on scale at bottom of chart) has a relative standard error of 1.7 percent (read from scale at left side of chart), or a standard error of 170,000 ( 1.7 percent of $10,000,000$ ).

Figure 1. Relative standard errors for population characteristics ${ }^{\mathbf{1}}$
standard error quite accurately for the difference between separate and uncorrelated characteristics although it is only a rough approximation in most other cases. The relative
standard error of each estimate involved in such a difference can be determined by one of the four rules above, whichever is appropriate.

${ }^{1}$ These curves represent estimates of relative standard errors of percents of population characteristics based on 4 quarters of data collection for narrow range estimates.
Example of use of chart: An estimate of 20 percent (on scale at bottom of chart) based on an estimate of $10,000,000$ has a relative standard error of 3.6 percent (read from the scale at the left side of chart), the point at which the curve for a base of $10,000,000$ intersects the vertical line for 20 percent. The standard error in percentage points is equal to 20 percent $\times 3.6$ percent, or 0.72 percentage points.

[Base of percent shown on curves in millions]

## Appendix II. Definitions of certain terms used in this report

## Terms relating to conditions

Condition.-A morbidity condition, or simply a condition, is any entry on the questionnaire that describes a departure from a state of physical or mental well-being. It results from a positive response to one of a series of "medical-disability impact" or "illness recall" questions. In the coding and tabulating process, conditions are selected or classified according to a number of criteria (such as whether they were medically attended, whether they resulted in disability, or whether they were acute or chronic) or according to the type of disease, injury, impairment, or symptom reported. For the purposes of each published report or set of tables, only those conditions recorded on the questionnaire that satisfy certain stated criteria are included.

Conditions except impairments are classified by type according to the Eighth Revision International Classification of Diseases, Adapted for Use in the United States, ${ }^{16}$ with certain modifications adopted to make the code more suitable for a household interview survey.

Acute condition.-An acute condition is defined as a condition that has lasted less than 3 months and that has involved either medical attention or restricted activity. Because of the procedures used to estimate incidence, the acute conditions included in this report are the conditions that had their onset during the 2 weeks prior to the interview week and that involved either medical attention or restricted activity during the 2 -week period. However, excluded are some conditions that are always classified as chronic even though the onset occurred within 3 months prior to the week of the interview. The codes refer to the Ninth Revision International Classification of Diseases, as modified by the NHIS Medical Coding Manual.

Acute condition groups. - In this report all tables with data classified by type of condition employ a five-category regrouping plus several selected subgroups.

Chronic condition.-A condition is considered chronic if (1) the condition is described by the respondent as having been first noticed more than 3 months before the week of the interview, or (2) it is one of the conditions that are always classified as chronic by NHIS regardless of the date of onset.

## Terms relating to disability

Chronic activity limitation.-Persons are classified into four categories according to the extent to which their activities are limited at present as a result of chronic conditions. Since the usual activities of preschool children, school-age children, housewives, and workers and other persons differ, a different set of criteria is used for each group. There is a general similarity among them, however, as will be seen in the following descriptions of the four categories:

1. Persons unable to carry on major activity for their group (major activity refers to ability to work, keep house, or engage in school or preschool activities)
Preschool children:
Inability to take part in ordinary play with other children.
School-age children: Inability to go to school.
Housewives:
Inability to do any housework.
Workers and all other persons:
Inability to work at a job or business.
2. Persons limited in amount or kind of major activity performed (major activity refers to ability to work, keep house, or engage in school or preschool activities)
Preschool children:
Limited in amount or kind of play with other children, e.g., need special rest periods, cannot play strenuous games, or cannot play for long periods at a time.

School-age children:
Limited to certain types of schools or in school attendance, e.g., need special schools or special teaching or cannot go to school full time or for long periods at a time.
Housewives:
Limited in amount or kind of housework, e.g., cannot lift children, wash or iron, or do housework for long periods at a time.
Workers and all other persons:
Limited in amount or kind of work, e.g., need special working aids or special rest periods at work, cannot work full time or for long periods at a time, or cannot do strenuous work.
3. Persons not limited in major activity but otherwise limited (major activity refers to ability to work, keep house, or engage in school activities)

Preschool children:
Not classified in this category.
School-age children:
Not limited in going to school but limited in participation in athletics or other extracurricular activities.
Housewives:
Not limited in housework but limited in other activities such as church, clubs, hobbies, civic projects, or shopping.
Workers and all other persons:
Not limited in regular work activities but limited in other activities such as church, clubs, hobbies, civic projects, sports, or games.
4. Persons not limited in activities (includes persons whose activities are not limited in any of the ways described above)

## Demographic terms

Age.-The age recorded for each person is the age at last birthday. Age is recorded in single years and grouped in a variety of distributions depending on the purpose of the table.

Race. - The population is divided into three racial groups, "white," "black," and "all other." "All other" includes American Indian, Chinese, Japanese, and any other race. Mexican persons are included with "white" unless definitely known to be Indian or of another race.

Income of family or of unrelated individuals. Each member of a family is classified according to the total income of the family of which he or she is a member. Within the household all persons related to each other by blood, marriage, or adoption constitute a family. Unrelated individuals are classified according to their own income.

The income recorded is the total of all income received by members of the family (or by an unrelated individual) in the 12 -month period preceding the week of the interview. Income from all sources is included, e.g., wages, salaries, rents from property, pensions, and help from relatives.

Education. - The categories of education status show the years of school completed. Only years completed in regular schools, where persons are given a formal education, are included. A "regular" school is one that advances a person toward an elementary or high school diploma or a college, university, or professional school degree. Thus education in vocational, trade, or business schools outside the regular school system is not counted in determining the highest grade of school completed.

Unrelated individuals are classified according to their own education.

Usual activity.-All persons in the population are classified according to their usual activity during the 12 -month period prior to the week of the interview. The "usual" activity, in case more than one is reported, is the one at which the person spent the most time during the 12 -month period. Children under 6 years of age are classified as "preschool." All persons aged 6-16 years are classified as "school age."

The categories of usual activity used in this report for persons aged 17 years and over are usually working, usually going to school, usually keeping house, retired, and other activity. For several reasons these categories are not comparable with somewhat similarly named categories in official Federal labor force statistics. First, the responses concerning usual activity are accepted without detailed questioning, since the objective of the question is not to estimate the numbers of persons in labor force categories but to identify crudely certain population groups that may have differing health problems. Second, the figures represent the usual activity status over the period of an entire year, whereas official labor force statistics relate to a much shorter period, usually 1 week. Third, the minimum age for usually working persons is 17 in the Health Interview Survey, and the official labor force categories include all persons aged 14 or older. Finally, in the definitions of the following specific categories, certain marginal groups are classified differently to simplify procedures.
Usually working includes persons 17 years of age or older who are paid employees; self-employed in their own business, profession, or in farming; or unpaid employees in a family business or farm. Work around the house or volunteer or unpaid work such as for a church is not counted as working.
Usually going to school includes persons 17 years of age or older whose major activity is going to school.
Usually keeping house includes female persons 17 years of age or older whose major activity is described
as "keeping house" and who cannot be classified as "working."
Retired includes persons 45 years old and over who consider themselves retired. In case of doubt, a person 45 years of age or older is counted as retired if he or she has either voluntarily or involuntarily stopped working, is not looking for work, and is not described as "keeping house." A retired person may or may not be able to work.
Other activity includes all persons 17 years of age or older not classified as "working," "retired," or "going to school," and females 17 years of age or older not classified as "keeping house."

Geographic region.-For the purpose of classifying the population by geographic area, the States are grouped into four regions that correspond to those used by the U.S. Bureau of the Census as follows:

## Region

States included

Northeast.
Maine, Vermont, New Hampshire, Massachusetts, Connecticut, Rhode Island, New York, New Jersey, and Pennsylvania.

North Central. . . Ohio, Illinois, Indiana, Michigan, Wisconsin, Minnesota, lowa, and Missouri.
South $\qquad$ Delaware, Maryland, District of Columbia, West Virginia, Virginia, Kentucky, Tennessee, North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, and Arkansas.
West. Washington, Oregon, California, Nevada, New Mexico, Arizona, Texas, Oklahoma, Kansas, Nebraska, North Dakota, South Dakota, Idaho, Utah, Colorado, Montana, Wyoming, Alaska, and Hawaii.

Place of residence. -The place of residence of a member of the civilian noninstitutionalized popula-
tion is classified as inside a standard metropolitan statistical area (SMSA) or outside an SMSA and either farm or nonfarm.

Standard metropolitan statistical areas. - The definitions and titles of SMSA's are established by the U.S. Office of Management and Budget with the advice of the Federal Committee on Standard Metropolitan Statistical Areas. Generally speaking an SMSA consists of a county or group of counties containing at least one city (or twin cities) having a population of 50,000 or more plus adjacent counties that are metropolitan in character and are economically and socially integrated with the central city. In New England, towns and cities rather than counties are the units used in defining SMSA's. There is no limit to the number of adjacent counties included in the SMSA as long as they are integrated with the central city, nor is an SMSA limited to a single State; boundaries may cross State lines. The metropolitan population in this report is based on SMSA's as defined in the 1970 census and does not include any subsequent additions or changes.

Central city of an SMSA.-The largest city in an SMSA is always a central city. One or two additional cities may be secondary central cities in the SMSA on the basis of one of the following criteria:
A. The additional city or cities must have a population of one-third or more of that of the largest city and a minimum population of 25,000.
B. The additional city or cities must have at least 250,000 inhabitants.
Not central city of an SMSA. - This includes all of the SMSA that is not part of the central city itself.

Not in $\cdot S M S A$.-This includes all other places in the country.

## Appendix III. Relevant questions from the 1977 questionnaire

| Ages $17+$ | 19a. What was -- doing MOST OF THE PAST 12 MONTHS - (For males): working or doing something else? <br> If "something else," ask: <br> (For females): keeping house, working, or doing <br> b. What was -- doing? something else? <br> If 45+ years and was not "working," "keeping house," or "going to school," ask: <br> c. Is -- retired? <br> d. If "retired," ask: Did he retire because of his health? | $\begin{gathered} 19 . \\ 8 \\ 20 . \end{gathered}$ | Working (24a) Keeping house (24b) <br> 3 Retired, health (23) Retired, other (23) <br> 5 Going to school (26) |
| :---: | :---: | :---: | :---: |
| $\begin{aligned} & \text { Ages } \\ & 6-16 \end{aligned}$ | 20a. What was -- doing MOST OF THE PAST 12 MONTHS - going to school or doing something else? <br> If "something else," ask: <br> b. What was =- doing? |  | $6 \square 17+$ something eise (23) <br> $7 \square$ 6-16 something else (25) |
| Ages under 6 |  |  | O- years (21) $0 \square$ Under 1 (22) |
| 21a. Is -- able to take part at all in ordinory play with other children? |  | 21 c . | $Y$ Y ${ }^{\text {r }}$ N (28) |
| b. Is he limited in the kind of play he can do because of his health? |  | b. | 2 Y (28) N |
| c. Is he limited in the amount of play because of his health? |  | c. | 2 Y (28) N (27) |
| 22a. Is -- limited in any way because of his health? |  | 22a. |  |
| b. In what way is he limited? Record limitation, not condition. |  | b. | (28) |
| 23a. Does -- heolth now keep him from working? |  | 23a. | 1 Y (28) N |
| b. Is he limited in the kind of work he could do because of his health? |  | b. | 2 Y (28) |
| c. Is he limited in the amount of work he could do because of his health? |  | c. | 2 Y (28) |
| d. Is he limited in the kind or omount of other activities because of his health? |  | d. | 3 Y (28) N (27) |
| 24a. Daes -- NOW have a job? |  | 24a. | Y(24c) |
| b. In terms of health, is --NOW able to (work - keep house) at all? |  | b. | $Y \quad 1 \mathrm{~N}$ (28) |
| c. Is he limited in the kind of (work - housework) he con do because of his heal th? |  | c. | $2 \mathrm{Y}(28)$ |
| d. Is he limited in the amount of (work - housework) he can do because of his health? |  | d. | 2 Y (28) |
| e. Is he limited in the kind or amount of other activities because of his health? |  | e. | 3 Y (28) N (27) |
| 25. In terms of health would -- be able to go to school? |  | 25. | $Y$ Y $1 \times(28)$ |
| 26a. Does (would) - - have to go to a certain type of school because of his health? |  | 26a. | 2 Y (28) N |
| b. Is he (would he be) limited in school attendance beccuse of his health? |  | b. | 2 Y (28) N |
| c. Is he limited in the kind or amount of other activities because of his health? |  | c. | 3 Y (28) N |
| 27a. Is -- limited in ANY WAY becouse of a disability or health? |  | 27 a . | Y ${ }^{5}$ N (NP) |
| b. In what way is he limited? Record limitation, not condition. |  | b. |  |
| 28a. About how long has he $\left\{\begin{array}{l}\text { been limited in -- } \\ \text { been unable to -- } \\ \text { had to go to a certain type of school ? }\end{array}\right\}$ <br> b. What (other) condition causes this limitation? <br> If "old age" only, ask: Is this limitation caused by any specific condition? <br> c. Is this limitation coused by any other condition? <br> Mark box or ask: <br> d. Which of these conditions would you say is the MAIN cause of his limitation? |  | 28. | 000 Less than I month $\qquad$ Mos. <br> 2 $\qquad$ Yrs. |
|  |  | c. | $\begin{aligned} & Y(\text { Reask } \\ & \text { 28b and } \mathrm{c}) \end{aligned} \mathrm{N}$ |
|  |  | d. | Only 1 condition <br> Enter main condition |

## Vital and Health Statistics series descriptions

SERIES 1. Programs and Collection Procedures.-Reports describing the general programs of the National Center for Health Statistics and its offices and divisions and the data collection methods used. They also include definitions and other material necessary for understanding the data.
SERIES 2. Data Evaluation and Methods Research.-Studies of new statistical methodology including experimental tests of new survey methods, studies of vital statistics collection methods, new analytical techniques, objective evaluations of reliability of collected data, and contributions to statistical theory.
SERIES 3. Analytical and Epidemiological Studies.-Reports presenting analytical or interpretive studies based on vital and health statistics, carrying the analysis further than the expository types of reports in the other series.
SERIES 4. Documents and Committee Reports.-Final reports of major committees concerned with vital and health statistics and documents such as recommended model vital registration laws and revised birth and death certificates.
SERIES 10. Data from the National Health Interview Survey.-Statistics on illness, accidental injuries, disability, use of hospital, medical, dental, and other services, and other health-related topics, all based on data collected in the continuing national household interview survey.
SERIES 11. Data From the National Health Examination Survey and the National Health and Nutrition Examination Survey.Data from direct examination, testing, and measurement of national samples of the civilian noninstitutionalized population provide the basis for (1) estimates of the modically defined prevalence of specific diseases in the United States and the distributions of the population with respect to physical, physiological, and psychological characteristics and (2) analysis of relationships among the various measurements without reference to an explicit finite universe of persons.
SERIES 12. Data From the Institutionalized Population Surveys.-Discontinued in 1975. Reports from these surveys are included in Series 13.
SERIES 13. Data on Health Resources Utilization.-Statistics on the utilization of health manpower and facilities providing
long-term care, ambulatory care, hospital care, and family planning services.
SERIES 14. Data on Health Resources: Manpower and Facilities.Statistics on the numbers, geographic distribution, and characteristics of health resources including physicians, dentists, nurses, other health occupations, hospitals, nursing homes, and outpatient facilities.

SERIES 15. Data From Special Surveys.-Statistics on health and health-related topics collected in special surveys that are not a part of the continuing data systems of the National Center for Health Statistics.

SERIES 20. Data on Mortality.-Various statistics on mortality other than as included in regular annual or monthly reports. Special analyses by cause of death, age, and other demographic variables; geographic and time series analyses; and statistics on characteristics of deaths not available from the vital records based on sample surveys of those records.
SERIES 21. Data on Natality, Marriage, and Divorce.-Various statistics on natality, marriage, and divorce other than as included in regular annual or monthly reports. Special analyses by demographic variables; geographic and time series analyses; studies of fertility; and statistics on characteristics of births not available from the vital records based on sample surveys of those records.

SERIES 22. Data From the National Mortality and Natality Surveys.Discontinued in 1975. Reports from these sample surveys based on vital records are included in Series 20 and 21, respectively.
SERIES 23. Data From the National Survey of Family Growth.Statistics on fertility, family formation and dissolution, family planning, and related maternal and infant health topics derived from a periodic survey of a nationwide probability sample of ever-married women 15-44 years of age.

## HITSY

From the Office of Health Research, Statistics, and Technology

[^0]:    1 Includes 78,221 persons who did not respond to either hearing scale.
    ${ }^{2}$ Includes 71,144 persons who did not respond to the Gallaudet scale.

[^1]:    1 Includes unknown level of hearing trouble.

[^2]:    11977 total includes 78,221 persons who did not respond to either scale.
    21971 total includes 89,000 persons and 1977 total includes $\mathbf{7 1 , 1 4 4}$ persons who did not respond to the Gallaudet Hearing Scale.

[^3]:    ${ }^{1}$ Includes unknown level of hearing trouble.

[^4]:    I Includes 78,221 persons who did not respond to either hearing scale. Excludes persons reporting tinnitus only.
    2 Includes $\mathbf{7 1 , 1 4 4}$ persons who did not respond to the Gallaudet scale.

[^5]:    1 Includes 78,221 persons who did not respond to either hearing scale. Excludes persons reporting tinnitus only.
    2 Includes 71,144 persons who did not respond to the Gallaudet scale.

[^6]:    I Includes 78,221 persons who did not respond to either hearing scale. Excludes persons reporting tinnitus only.
    2Includes $\mathbf{7 1 , 1 4 4}$ persons who did not respond to the Gallaudet scale.

[^7]:    1 Includes 78,221 persons who did not respond to either hearing scale. Excludes persons reporting tinnitus only.
    2 Incluces 71,144 persons who did not respond to the Gallaudet scale.

[^8]:    1 Includes 78,221 persons who did not respond to either hearing scale. Excludes persons reporting tinnitus only.
    2 Includes 71,144 persons who did not respond to the Gallaudet scale.

[^9]:    ${ }^{1}$ Includes 78,221 persons who did not respond to either hearing scale. Excludes persons reporting tinnitus only.
    2includes 71,144 persons who did not respond to the Gallaudet scale.

[^10]:    Includes $\mathbf{7 8 , 2 2 1}$ persons who did not respond to either hearing scale. Excludes persons reporting tinnitus only.
    2Includes 71,144 persons who did not respond to the Gallaudet scale.

[^11]:    ${ }^{1}$ Includes 78,221 persons who did not respond to either hearing scale. Excludes persons reporting tinnitus only.
    2Includes 71,144 persons who did not respond to the Gallaudet scale.

[^12]:    ${ }^{1}$ Includes 78,221 persons who did not respond to either hearing scale. Excludes persons reporting tinnitus only.
    2 Includes 71,144 persons who did not respond to the Gallaudet scale.
