# Chronic Conditions and Impairments of Nursing Home Residents: United States - 1969 

Statistics on six major chronic conditions (heart conditions, cerebrovascular diseases, arteriosclerosis, diabetes, senility, and arthritis or rheumatism) and two major types of impairments (vision and hearing), how they affect nursing home residents and how this compares to the general noninstitutional population. Based on data collected from June through August 1969.

## COOPERATION OF THE BUREAU OF THE CENSUS

Under the legislation establishing the National Health Survey, the Public Health Service is authorized to use, insofar as possible, the services or facilities of other Federal, State, or private agencies.

In accordance with specifications established by the National Center for Health Statistics, the Bureau of the Census, under a contractual arrangement, participated in planning the survey and collecting the data.

# CHRONIC CONDITIONS AND IMPAIRMENTS OF NURSING HOME RESIDENTS 

Alvin Sirrocco, Division of Health Resources Statistics

## INTRODUCTION

A chronic condition, by definition, is one that is prolonged, lingering, and recurrent. Consequently, chronic conditions often cause people to miss work, restrict their everyday activities and, with the elderly in particular, cause confinement to a wheelchair or a bed. Therefore, in discussing the health of any individual or any group of individuals, of primary importance would be the answers to the following questions:

Does he or she have any chronic conditions or impairments?

If so, what are they?
How severe are they?

Some chronic conditions are acquired early in life while others are acquired at a much later stage. Because of the recurrent nature of chronic conditions, many of those that are acquired early in life are carried into middle and old age. As a result, the older population ( 45 years and over) is much more affected by chronic conditions and impairments than the younger population (under 45). Table 1 shows this quite clearly.

These three questions become even more relevant when discussing the health of nursing home residents, since most nursing home residents are of this older population and more prone to chronic ailments. For example, there were an estimated 815,130 residents in nursing homes in 1969. Almost 90 percent ( 88.6 to be exact) were 65 years of age or older and only 2 percent were under age 45.

Accordingly, these questions were asked (using different wording) of the nursing home residents in the 1969 Resident Places Survey-3. When it. was discovered that 98 percent of the residents had chronic conditions or impairments, the responses to the second and third questionswhat are they and how severe are they-took on added importance. This report deals with those responses.

## BACKGROUND

The data presented in this report are based on the third Resident Places Survey (RPS-3) conducted by the Division of Health Resources Statistics. The survey was conducted in cooperation with the U.S. Bureau of the Census during June-August of 1969.

RPS-3 is the fourth in a series of ad hoc surveys of institutional health facilities which are part of the National Health Surveyprogram to
provide current health statistics on the Nation. ${ }^{1}$ The first of these surveys was conducted in April-June 1963 and collected sample data on nursing homes, chronic disease and geriatric hospitals, and nursing home units and chronic disease wards of general and mental hospitals. Further information on the Resident Places Survey-1, including a description of its design and methodology, may be found in several previously published reports. ${ }^{2-6}$ The Resident Places Survey-2, which was conducted in May-June 1964, is the second of these ad hoc surveys; it concentrated mainly on a sample of nursing homes and geriatric hospitals. This second survey collected more detailed information about each institution, its residents, and its employees? ${ }^{-15}$ The 1968 Nursing Home Survey, conducted during April-September 1968, was the third survey. It was a census of all nursing homes in the United States. It collected detailed information on the characteristics of the facilities. ${ }^{16-21}$ The fourth survey-RPS-3-was multipurpose, collecting information about the nursing home, its residents, and its employees. This report is one of several on the data collected in RPS $-3.22-26$

This report deals with the chronic conditions and impairments that afflicted nursing home residents in 1969. The conditions and impairments of each resident were reported by a member of the nursing home staff who was familiar with the resident.

One of the chronic conditions listed on the questionnaire is "other mental disorders," which includes mental illness or retardation and excludes senility. Because of the wide range of symptoms covered under this heading, comparisons between the nursing home population and the general population are virtually impossible. Therefore "other mental disorders" will not be discussed in the text of this report but will be included in the detailed tables.

Although RPS-3 obtained diagnostic information, the results indicated an apparent underreporting of chronic conditions and impairments. One explanation for this underreporting can be found in a publication which compares reported conditions to diagnosed conditions and concludes that a physician will list on a patient's record conditions that are active but may not list other conditions that are present but inactive at the
time of the visit. ${ }^{27}$ Thus reported rather than diagnosed conditions are used in the present report. The conditions and impairments are classified according to the Eighth Revision International Classification of Diseases, Adapted for Use in the United States (ICDA), ${ }^{28}$ with certain modifications. The chronic conditions and impairments and their codes are listed in appendix II.

## SOURCES AND QUALIFICATIONS OF DATA

Nursing homes, homes for the aged, and similar facilities of this kind were included in RPS-3. Two basic criteria for including a facility in the survey were (1) it must routinely provide some level of nursing or personal care and (2) it must maintain three beds or more. Thus homes providing only room and board or domiciliary care to aged people were not within the scope of the survey.

A description of RPS-3, the sampling frame used, the sample design, and the survey procedures are presented in appendix I. Appendix I also includes imputation procedures, estimation techniques, and estimates of sampling variation. Since the data in this report are national estimates based on a sample, they are subject to sampling errors.

Appendix II presents definitions of termsand the procedure for classifying establishments. Reference to the definitions is essential to the interpretation of data in this report. Special attention is called to the procedure for classifying institutions by level of nursing service. The classification of establishments as nursing homes, personal care homes with nursing, and personal care homes is based on the services provided in the home rather than on what the home may be called or how it may be licensed by the State.

Facsimiles of questionnaires and forms used in the survey are shown in appendix III.

## PREVALENCE OF CONDITIONS

Table A lists the 10 most common types of conditions suffered by nursing home residents in 1969. (Table 2 gives the prevalence figures for these conditions by age and sex of the residents.)

Table A. Percent of residents in nursing homes with reported chronic conditions: United States, 1969

From table A it is apparent that arteriosclerosis and senility were the two most prevalent conditions, occurring in more than half of the residents. Heart conditions and arthritis or rheumatism were the next most commonly occurring conditions, with each being prevalent in approximately one-third of the residents.

It should be pointed out that if senility and advanced senility were separated the percents would be 34.2 for advanced senility and 22.2 for senility. They have been combined because of the difficulty in many cases of determining the resident's degree of senility.

The bulk of this report will deal with only six of the 10 conditions listed in table A. These six are arteriosclerosis, senility, heart trouble, arthritis or rheumatism, cerebrovascular diseases, and diabetes. The remaining four conditions will be shown in some detailed tables, but because of their complexity and the difficulty in comparing them with other surveys, they will not be discussed.

These six conditions probably are the most studied and publicized of all chronic conditions.

The reason for this can be traced to the thousands and in some instances millions of people in the United States affected by these conditions. For instance:

- An estimated 27,130,000 people in 1969 were afflicted by cardiovascular diseases. ${ }^{29}$ This included heart conditions, arteriosclerosis, and strokes.
- An estimated 4.4 million people had diabetes. ${ }^{30}$
- An estimated 50 million people suffered from arthritis or rheumatism; 17 million suffered severely enough to require medical care. ${ }^{31}$
- In 1969, 739,265 people died from heart diseases, the number 1 cause of death. 39
- In 1969, 33,063 people died from arteriosclerosis. ${ }^{39}$
- In 1969, 207,179 people died from cerebrovascular diseases (the number 3 cause of death). ${ }^{39}$
- In 1969, 38,541 people died from diabetes mellitus. ${ }^{39}$

The sheer magnitude of these numbers ilIustrates the problem these conditions represent for the people in the United States. Add to it old age and institutionalization and you have the even bigger problem faced by residents of nursing homes. As evidence, table 1 shows that older people were more likely to have these conditions than younger people, and table B shows that nursing home residents were more likely to have the conditions than noninstitutionalized people. In fact, 65 percent of the residents had three or more conditions. ${ }^{32}$

The table shows marked differences in rates for the noninstitutional population (which were based on household interview responses) and the rates for the nursing home population. The ratio of rates ranged from about 2.1 for arthritis and rheumatism to 35.1 for senility.

Table B. Number and rate of selected chronic conditions in limited persons aged 65 years and over in the noninstitutionalized population and in the nursing home popu1ation: United States, 1969

| Selected chronic conditions | Civilian noninstitutionalized population 65 years and over limited in any activity ${ }^{1}$ |  | Nursing home population 65 years and over |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

${ }^{1}$ See reference 51 at end of text.
${ }^{2}$ Includes other types of mental and nervous conditions.
${ }^{3}$ Includes other conditions of the circulatory system.

## MALE - FEMALE COMPARISON

A comparison of the prevalence rates of male and female residents in nursing homes for each of the six conditions is shown in figure 1 .

The figure shows that women had significantly higher prevalence rates than men for arteriosclerosis, arthritis or rheumatism, and senility. Although the women also showed higher prevalence rates for heart conditions and diabetes, the rates were not significantly higher. Men, on the other hand, had significantly higher prevalence rates than women for effects of a stroke.

Perhaps the most striking characteristic in figure 1 is the difference in the number of men and women with arthritis or rheumatism. The women's rate is 105 per 1,000 female residents higher than the men's rate. In terms of numbers, 205,401 women had arthritis or rheumatism while just

65,586 men had it-a ratio of more than 3 to 1 . Is this characteristic. unique to nursing homes or is it a characteristic of the population in general?

Looking again at table 1 we find that there is in fact a rather substantial difference between the number of women and the number of men affected by arthritis and rheumatism. Of the $3,265,000$ noninstitutionalized people who had to limit their activities because of arthritis and rheumatism, $2,170,000$ of them were women-almost twice as many as men. The prevalence rate for men 65 years and over was 144 per 1,000 men, and for women 65 and over it was 271 per 1,000 . Although these rates were not as high as the corresponding rates in nursing homes, they reflect the same picture-that many more women than men suffer from arthritis. Arthritis and rheumatism are discussed in greater detail in the next section of this report.

Figure 1. Prevalence rates per 1,000 residents of nursing homes for six chronic conditions, by age and sex: 1969

## THE SIX MAJOR CONDITIONS

In this section each of the six major conditions will be defined and discussed. Statistics are presented showing the impact these conditions had on nursing home residents in 1969 and whenever possible their impact on the population of the United States in general. Because of the interrelationship that exists between heart conditions, stroke, and arteriosclerosis, a brief discussion
will be presented for each; followed by a more detailed analysis of the three together.

## Heart Trouble

The term "heart trouble" is so broad it must be defined by ICDA codes. "Heart trouble" and "heart conditions" are used synonymously in this report. The codes for this and other conditions used in this report can be found in appendix I. In general, in this report "heart conditions"
refers to rheumatic heart disease, hypertensive heart disease, and ischemic heart disease. These are all cardiovascular diseases (diseases of the blood vessels of the heart) and are defined as follows:

Rheumatic heart disease occurs when rheumatic fever causes heart damage by scarring and deforming the valves of the heart.

Hypertensive heart disease occurs when high blood pressure (hypertension) persists at such a high level that the heart, which must now pump harder to push blood through the circulatory system, grows larger and weaker from the demands put on it and loses its efficiency.

Ischemic heart disease occurs when there is inadequate blood supply to certain areas of the heart due to blockage in the coronary arteries. If the blockage is slight, the result could be angina pectoris or "angina" (pains in the chest). If the blockage becomes more severe the result could be coronary insufficiency. However, if the blockage becomes complete and the blood supply cut off, the result is a myocardial infarction, more commonly referred to as a heart attack.

The mortality and prevalence figures intable $C$ show the magnitude of these three diseases in 1969. ${ }^{29}$ The 669,829 deaths for ischemic heart disease-the largest number of deaths for any single cause in 1969-were primarily the result of heart attacks.

Table C. Mortality and prevalence figures for rheumatic, hypertensive, and ischemic heart disease: United States, 1969

| Heart diseases | Deaths ${ }^{1}$ | Prevalence |
| :---: | :---: | :---: |
| Rheumatic <br> 'heart dis -ease------ | 15,432 | 1,670,000 |
| Hypertensive heart disease--- | $\stackrel{\iota}{24,712}$ | 21,790,000 |
| Ischemic heart dis-ease----- | 669,829 | 4,040,000 |

${ }^{1}$ See reference 39 at end of text.

Although data are not available on the prevalence of heart conditions in older people for 1969, evidence has shown that older people ( 65 and over, for example) have higher rates of heart conditions than younger people. According to information reported in household interviews, for instance, in 1967 approximately 1 percent of the noninstitutionalized population under 45 years of age had heart conditions, while 7 percent of those 45 to 64 and 19 percent of those 65 years and over had heart conditions. ${ }^{33}$

Having established the magnitude of the problem of heart conditions in the general population, the next step is to compare these statistics with the statistics on heart conditions for the nursing home population.

Detailed table 2 shows that in 1969 over 296,000 nursing home residents were reported to have heart conditions. That was more than a third of all nursing home residents. Of those residents 65 years and over, approximately 39 percent had heart conditions, a higher rate than the 19 percent that was experienced by the general noninstitutionalized population in 1967. Some of the difference between these two figures may be explained by the differing procedures that were used in collecting the data for these surveys. Therefore, in order to substantiate that heart conditions were more common to nursing home residents than they were to the noninstitutionalized population, it is necessary to consider those persons who were limited by heart conditions.

Table 1 indicates there were approximately $3,148,000$ noninstitutionalized persons 45 years and over who were limited in activity in 1969-70 partly or solely because of heart conditions. Roughly speaking, that was about 5 percent of the noninstitutionalized population 45 years and over. Of the residents in nursing homes ( 98 percent of which were 45 years and over), 173,653 , or about 24 percent, were limited partially or solely because of their heart conditions (table 3). Although the figures for nursing home residents' limitations were based on mobility and those for the noninstitutionalized population's limitations were based on activity, it must be remembered that for older people activity and mobility are often synonymous.

Before leaving this discussion on heart conditions, there is one other area that bears mentioning. In discussions of the various heart
conditions in medical literature, a basic concept that is repeatedly brought out is that heart attacks are primarily the result of heart diseases becoming severely worse (i.e., heart attacks are fairly slow in developing). But what about the deaths from heart attacks that frequently happen to people who had no known history of heart conditions-the sudden cardiac deaths. The following discussion sums up what has generally been learned about this medical phenomenon:

By sudden cardiac death is meant death occurring within one hour from the onset of a sudden and unexpected acute cardiac event. Because of the time element involved in the definition, such an event obviously requires a witness....
Subsequent anatomic studies have amply demonstrated the prominent place of coronary artery disease in patients dying suddenly. The recent data, chiefly derived from the experiences of medical examiners, show that coronary atherosclerosis is present in the overwhelming majority and that it is diffusely distributed.... In the patients in whom death was actually witnessed and could be judged to be instantaneous, the infrequency of fresh or recent thrombosis has been confirmed. ${ }^{\text {a, }} 34$
Hence most "sudden cardiac deaths" are not as abrupt as they appear but instead are often caused by atherosclerosis (the most common form of arteriosclerosis). The next two topics deal with cerebrovascular diseases and arteriosclerosis and how they affect nursing home residents. Stroke

Cerebrovascular diseases and vascular lesions affecting the central nervous system are the technical terms for what most people refer to as "stroke." Cerebrovascular diseases are diseases affecting the blood vessels in the brain (cerebro meaning brain and vascular referring to blood vessels).

A stroke occurs when the blood supply to a part of the brain is cut off depriving the nerve cells in that area of the blood they need to function. Since those nerve cells control body movements, the part of the body they control may become paralyzed or otherwise unresponsive. A stroke can also occur as a result of hemorrhage.

[^0]In 1969, over 207,000 people in the United States died from strokes and another $1,620,000$ people were afflicted by them. ${ }^{29}$ Although it is not known how many nursing home residents died from strokes, it is known that one-fourth $(204,655)$ of the residents were afflicted by them (table 2). These afflictions took the form of paralysis, speech defects, and other ill effects of a stroke.

These figures show that almost 13 percent of those persons afflicted by strokes resided in nursing homes. (By comparison, less than onehalf of I percent of all the people in the United States resided in nursing homes.) Further analysis shows that the $1,620,000$ afflicted persons in the United States represented less than 1 percent of the total population. In fact, even if every one of these afflicted persons were over 65 (it is not known how many actually were), they would only make up 8 percent of the population 65 years and over. In nursing homes, by comparison, 25 percent of all the residents and 25 percent of those 65 years and over were afflicted by strokes.

It seems quite apparent from these figures that nursing homes play an important role to the stroke patient. A look at table 3 helps to explain why. This table shows that of the nearly 205,000 residents suffering from the effects of a stroke, less than 22 percent were able to move about freely: In fact, more than half of these 205,000 residents were confined or restricted to bed. The remaining 27 percent were either confined to the premises or needed a wheelchair to get about. Thus of all the conditions listed in table 3, stroke appears to be the most limiting.

As with heart conditions, multiple disease factors must be considered when discussing the patient who has had a stroke, for risk of stroke has been found to be higher in persons with a history of hypertension ( 2.1 times as high), coronary heart disease ( 2.4 times), diabetes ( 1.9 times), or angina pectoris ( 2.3 times). ${ }^{35}$

Nursing home residents with multiple diseases is one of the subjects covered in the following section on arteriosclerosis.

## Arteriosclerosis

Heart attacks and strokes have much in common. In addition to the crippling and deadly aspects of each, they can both be caused when a
blockage occurs in the arteries and the blood supply is cut off. If the blockage occurs in the arteries leading to the heart (coronary arteries), a heart attack results; if the blockage occurs in the arteries leading to the brain, a stroke results.

The blockage referred to is usually caused by arteriosclerosis. Actually the term arteriosclerosis is very general and refers to all types of degenerative changes in the arterial wall. The most common type of arteriosclerosis is ath-erosclerosis-generally known as "hardening of the arteries." Atherosclerosis is the process by which the inner linings of the arteries become thickened and roughened by deposits of fat, fibrin, cellular debris, and calcium, thus interfering with both the smooth flow of blood and the amount of blood carried through the artery. The inner walls become thick and heavy, lose their ability to expand and contract, and may eventually block the channel completely. (To avoid confusion, arteriosclerosis will be used throughout this section.)

As mentioned before, when the arteries are completely blocked, heart attacks and strokes occur; when they are partially blocked, the lesser (but still painful and dangerous) heart and cerebrovascular diseases occur.

As an indication of its prevalence, it is estimated that arteriosclerosis, as an underlying cause, contributes directly to more than 850,000 deaths a year from heart attacks and strokes. 29 It is not known how many millions of people are afflicted with arteriosclerosis, but because of the nature of the arteriosclerotic process elderly people usually experience it the most.

This relationship that exists between arteriosclerosis and aging is one of the most written and talked about aspects of the disease. It is generally agreed that arteriosclerosis is not necessarily a process of aging. ${ }^{36}$ Nevertheless, all experience tends to show that the number of arteriosclerotic patients, the severity of the disease, and its fatal complication all increase with age. On the other hand, these relationships are not linear (though these relationships show a general increase with age, they do not increase at each age level) as would be expected in a normal natural occurrence. ${ }^{37}$

Though prevalence figures are not available for the general population, they are available for
the nursing home population. As mentioned earlier in this report, in 1969 arteriosclerosis was the most prevalent condition in nursing homes, affecting more than 469,000 residents (over 57 percent of all the residents). Of those residents 65 years and over, almost 63 percent had arteriosclerosis.

In 1969, 293,330 residents of nursing homes died. 25 Unfortunately neither the cause of death nor the conditions these residents suffered from before death are known, but many of these residents were surely among the aforementioned 850,000 deaths a year from heart attacks and strokes due to arteriosclerosis.

Equally apparent is the fact that the 469,000 residents with arteriosclerosis were in a high risk situation because of the disease and their age. In addition, to make matters worse, many of them were also suffering from heart conditions and the effects of a stroke (table 4).

From table 4 it can be found that 261,917 ( 56 percent) of the residents with arteriosclerosis also suffered from either heart conditions, the effects of a stroke, or both. Table 4, in conjunction with table 2, can also be used to determine how many residents had either heart conditions, stroke, arteriosclerosis, or any combination of these. Appropriate manipulations will reveal that more than three-fourths ( 76.7 percent) of the residents had one, two, or all three of these conditions.

One can see from table 4 the extent to which nursing home residents had multiple disorders. Considering the fact that this table includes only the six major conditions, it is not surprising that 65 percent of the residents had three or more of any type of chronic condition. ${ }^{32}$ However, because of the effect multiple disorders had on residents, it is difficult to determine which of the disorders was most responsible for the residents' mobility limitations.

Table $D$, which is derived from table 4, shows combinations of the six major conditions crossed with the two severest mobility limita-tions--restricted or confined to bed. This table indicates that whenever the condition effects of a stroke are present, the percentage of those residents severely limited is between 55 and 60 and that whenever this condition is not present, the percentage drops to about 30 . This informa-

Table D. Number of residents in nursing homes having specified multiple chronic conditions, and number and percent with mobility status D or E: United States, 1969

| Multiple chronic conditions | Residents | Residents with mobility status D or E ${ }^{1}$ |  |
| :---: | :---: | :---: | :---: |
|  |  | Number | Percent |
| Stroke, heart trouble, arteriosclero | 37,390 | 21,996 | 58.8 |

| Stroke, arteriosclerosis, arthritis-rheumatism--- | 29,481 | 17,377 | 58.9 |
| Stroke, arteriosclerosis-- | 74,848 | 42,777 | 57.2 |
| Stroke, arthritis-rheumatism | 36,502 | 20,556 | 57.2 |
| Arteriosclerosis, arthritis-rheumatism- | 195,816 | 58,741 | 30.0 |
| Stroke, heart trouble, diabete | 6,809 | 3,650 | 53.6 |
|  | 45,634 | 26,101 | 57.2 |
| Stroke, diabetes----- | 14,411 | 8,084 | 56.1 |
| Heart trouble, diabete | 42,108 | 12,220 | 29.0 |
| Stroke, arteriosclerosis, diabetes--------------- | 9,203 | 5,260 | 57.2 |
|  | 74,848 | 42,777 | 57.2 |
| Stroke, diabetes------.. | 14,411 | 8,2084 | 56.1 |
|  | 56,404 | 16,810 | 29.8 |
| Stroke, senility (including advanced), |  |  |  |
| arteriosclerosis-------------------- | 57,079 | 34,540 | 60.5 |
| Stroke, senility (including advanced) | 73,239 | 43,399 | 59.3 |
|  | 74,848 | 42,777 | 57.2 |
| Senility (including advanced), arteriosclerosis | 334,064 | 115,022 | 34.4 |
| Heart trouble, arteriosclerosis, diabetes-------- | 30,854 | 9,444 | 30.6 |
| Heart trouble, arteriosclerosis, senility (including advanced) | 159,245 | 58,733 | 36.9 |
| Heart trouble, arteriosclerosis, arthritis-rheumatism | 100,234 | 30,653 | 30.6 |

[^1]tion combined with that in table 3 demonstrates fairly conclusively that the condition most prominent in causing mobility restrictions is the effect of a stroke.

The prominent role played by arteriosclerosis in heart disease and stroke has been discussed. The next two sections reveal two
more conditions which can be caused or aggravated by arteriosclerosis.

## Diabetes

Diabetes mellitus is the technical term for what is generally referred to as diabetes. It is defined usually as a chronic disorder of car-
bohydrate metabolism characterized by hyperglycemia and glycosuria. ${ }^{38}$ It is also defined in terms of a deficiency of insulin.

Although the exact cause of diabetes has not been found, contributing factors such as heredity and obesity have been recognized.

It has been estimated that approximately 4.4 million people are diabetics, with females having a higher prevalence than males. ${ }^{30}$ In nursing homes in 1969, approximately 12 percent of the residents of each sex were diabetics (table 2).

Of major concern in the study of diabetes is its association with arteriosclerosis. Findings indicate that together with hypertension, diabetes mellitus is the principal precursor to arteriosclerosis. It has been said that there is no other disease with which arteriosclerosis is so frequently associated and that there can no longer be any doubt that arteriosclerosis, with its resulting diseases, is the main cause of death to diabetics. ${ }^{37}$

Indeed, studies have shown that the incidence of death from cardiovascular complications has risen from 32 to 65 percent among diabetics. ${ }^{52}$ However, in addition to diabetics dying from heart conditions, many die from diabetes itself, as evidenced by the fact that in 1969 over 38,000 deaths were attributed to diabetes mellitus. 39

Although no cause-of-death data are available for nursing home residents, figures are available on the numbers of diabetic residents with arteriosclerosis and/or heart conditions. Tabulations show that 67,658 ( 70 percent) of the residents with diabetes also had either arteriosclerosis, heart conditions, or both (table 4). Similar tabulations for residents 65 years and over revealed a percentage (73) of diabetics having one or both of these disorders. Based on the above incidence of death figures, if an actuarial table of diseases were drawn up, these residents would undoubtedly fall into the highest risk category.

## Senility

Because of the difficulty encountered in classifying residents as senile or advanced senile, the two have been combined for the purposes of this report. However, for the benefit of the reader, they are defined separately here.

Advanced senility is the layman's term for senile psychosis and chronic brain syndrome-two terms which themselves fall under the overall heading of senile dementia. Advanced senility (using the definition for chronic brain syndrome) is a syndrome characterized by essentially irreversible impairment of cerebral functions, i.e., memory deficit (primarily for recent events), loss of orientation, affective disturbance, and decline of intellect and judgment.

Cerebral arteriosclerosis is the most frequent cause of chronic brain syndrome. It usually begins between the ages of 50 and 60 and is characterized by acute episodes of confusion and excitement followed by partial remissions, so deterioration progresses in a step-wise pattern. Senile dementia rarely occurs before age 60 and follows a steady progressive course. ${ }^{5}$

Senility is a shortened version of senility without mention of psychosis or presenile brain disease. Senility is a mental disorder associated with cerebral atrophy or degeneration which causes debility (feebleness) and aphasia (loss of the power to articulate speech). Both senility and advanced senility are known as diseases of old age. From here on, senility and advanced senility will be combined and referred to as senility.

Though prevalence figures on senility for the general population are not available, institutionalized population rates are moderately high for people over 60 . In nursing homes, for instance, 459,672 residents were reported as senile. That represented 56 percent of all the nursing home

Table E. Number and percent of nursing home residents with senility, by age: United States, 1969

| Age | Residents with senility |  |
| :---: | :---: | :---: |
|  | Number | Percent |
| Under 45 years------ | 1,020 | 5.6 |
| Under 65 years ------ | 14,333 | 15.4 |
| 65-74 years--------- | 62,518 | 45.1 |
| 75-84 years--------- | 197,435 | 61.3 |
| 85 years and over--- | 185,386 | 70.8 |

residents. Table E shows a steady increase with age in the percent of senility of nursing home residents.

Referring back to table 4, it can be seen that of the residents with senility, 73 percent alsohad arteriosclerosis. It should also be noted that of the residents with arteriosclerosis, 71 percent were reported as senile. Thus for nursing home residents, these two diseases seem highly associated with each other.

At the beginning of this section mention was made of the difficulty encountered between classifying residents as senile or advanced senile. It must also be mentioned that the classifying of a resident as senile or not senile is often just as hard, as noted in the following excerpt:

It is difficult to determine which aspects of the older person's behavior are the result of his aging and which are the result of his diminished social contacts, his relative lack of education, his loss of employment, or the poor state of his health. 40

Another factor to be considered is how physical changes that occur with age relate to behavioral changes occurring during the same period. For example, an older resident whose vision and hearing are beginning to fail may show marked behavioral changes which might be interpreted as signs of senility. This same incorrect interpretation might result from many kinds of physical changes that occur.

That old age and senility are very closely related can be witnessed by the following observation:

Psychologists and scholars in various fields have observed pronounced changes in the behavior of the aging organism. Among these are deficits in sensation and perception, in muscular strength, in the ability to react quickly to stimuli. . .and among persons over 60, deficits in the ability to remember, learn, and respond with intelligence. ${ }^{41}$

Many of the deficits mentioned are found in the definition of senility, in particular those involving perception and the ability to remember.

In the area of perception, however, old age and senility may not be the only factors present:

> Various experiments indicate a tendency for older persons to perceive time as moving more rapidly than it actually does. But this tendency appears to be at least partially a function of the environment and attitudes rather than simply a result of increasing age per se. 41

The nursing home environment along with the resident's attitude towards it might very well contribute to this loss of perception. One of the experiments conducted, for instance, indicated that older institutionalized subjects underestimated time intervals of 30 to 300 seconds to a greater extent than the older noninstitutionalized subjects did. At the same time, the study demonstrated there were no differences between young, middle-aged, and older noninstitutionalized groups. ${ }^{41}$

## Arthritis and Rheumatism

Arthritis is the inflammation of one or more joints due to infectious, metabolic, or constitutional causes. Rheumatism is a condition which causes inflammation or pain in muscles, joints, or fibrous tissue. The most common forms of these two related conditions are rheumatoid arthritis, osteoarthritis, and gout.

In terms of age distribution, rheumatoid arthritis (the most devastating and crippling form of arthritis) can affect both young and old alike, but usually occurs in later years. About five million Americans have it. Osteoarthritis is associated with aging and degeneration of joint tissue, thus affecting the older population. About 10 million people suffer from it. Gout affects about one million people and apparently can be acquired at any age. ${ }^{31}$

For simplicity's sake, the term arthritis will be used from here on to describe arthritic and rheumatoid conditions.

It is estimated that at least 50 million people in the United States have arthritis to some extent, of which 17 million have it severely enough to require medical care. ${ }^{31}$ Arthritis ranks second only to heart diseases as the major cause of
activity limitation, affecting over 3.2 million people (table 1).

In 1969 almost 271,000 nursing home residents had arthritis-one-third of the nursing home population. Depending on whether one uses the 50 million or the 17 million estimate, between onefourth and one-twelfth of the general population had arthritis.

In terms of mobility, approximately 58 percent of the residents with arthritis had some form of mobility restriction, with 28 percent confined to bed most or all of the time (table 3). However, it is difficult to determine how much of this restriction was due to other conditions being present.

## IMPAIRMENTS

## Vision Impairments

Before discussing vision impairments of older people, it should be mentioned that the aging process has a detrimental effect on vision. According to May's Manual of the Diseases of the Eye, the power of accommodation needed to bring near objects into clear focus gradually diminishes with age, due chiefly to.loss of elasticity of the lens. The physiological change becomes most pronounced when nearing the age of 45. Distance vision is not similarly affected. ${ }^{41}$

From 1960 through 1962, as part of the nationwide Health Examination Survey of noninstitutionalized people aged 18 through 79 years, visual acuity tests were administered. ${ }^{42}$ These eye examinations revealed, as May's Manual suggested, that visual acuity does decline with age from about 45 years on and that near vision tends to be more deficient than distance vision.

Eye examinations are the most accurate means of detecting vision deficiencies. However, the personnel and equipment that are necessary in administering these tests are usually not available. As a result, most surveys are forced to rely on other means of measuring vision deficiencies. This can be done through a series of questions.

For example, can this person readordinary newspaper print, can he see across the street, can he identify moving objects, can he see light,
and so on. These are typical questions that might be asked of a person concerning his vision. But even if these questions could be arranged in some logical order whereby "no" answers indicate an ever-lessening degree of sight, additional information would be needed in order to determine the extent of the impairment.

For instance, does this person wear glasses and, if so, were his answers based on his sight while wearing his glasses or while not wearing them? In other words, if a person has a vision impairment but his glasses correct the problem, is he still considered visually impaired?

If a person has impaired vision in one eye but has perfect vision in the other eye, is his vision impaired? What about the extreme case when a person is blind in one eye but can see perfectly with the other one?

These are just a few of the problems encountered when trying to measure vision impairment by means other than eye examinations. Although interviews may not be as accurate as actual eye examinations, they nevertheless produce valuable information of their own.

In a survey of the civilian noninstitutionalized population conducted from July 1963 to June 1964 the questions concerning vision dealt with the person's ability to read newsprint, see features and/or objects, see a friend across the street, and see light. ${ }^{43}$ The survey also determined whether one or both eyes were involved.

The results of the survey indicated that an estimated $5,029,000$ persons aged 6 and over were visually impaired in one or both eyes. Of these, $2,415,000$ were 65 years and over. For visually impaired persons aged 6 through 64 the rate per 1,000 population (noninstitutionalized) was 18.2 , while for the people 65 years and over the rate was 141.9. Table 5 gives the numbers and rates of visually impaired persons by various age groups.

The 1969 RPS-3, on which this report is based, used the following set of questions to determine the vision impairment of nursing home residents. The questions were directed to a member of the nursing home staff who was familiar with the resident in question.

Does he USE eyeglasses? yes no
How well can he see?

Table F. Number of nursing home residents with ability to see with and without glasses, by age and sex: United States, 1969

\hline Blind------------------- \& 36,086 \& 3,445 \& 32,641 \& 2,139 \& 8,965 \& 1,306 \& 23,676 <br>
\hline
\end{tabular}

(a) Can read ordinary newspaper print with or without glasses
(b) Can watch television across the room (8 to 12 feet) yes no
(c) Can recognize the features of people he knows if they are within 2 to 3 feet
(d) Is blind

For the second question, the interviewer proceeded from (a) to (d) until a "yes" answer
was obtained. A person's vision was considered to be seriously impaired if a "yes" answer was given to either (c) or (d).

Approximately 22 percent of the residents had seriously impaired vision. The 487,421 residents who wore glasses represented 60 percent of all residents. (It was also discovered in the 1963-64 survey that 60 percent of all nursing home residents wore glasses. $)^{13}$

Table $F$ shows the results of combining the answers to the questions, some of which are as follows:

- That 487,421 residents wore glasses.
- That 489,619 residents could read ordinary newspaper print with or without glasses.
- That 149,718 residents could watch television across the room (8 to 12 feet).
- That 139,707 residents could recognize the features of people they know if they were within 2 to 3 feet.
- That 36,086 residents were blind.

When discussing blindness it should be remembered that there are two definitions of blind-ness-the medical definition and the legal definition. According to the medicaldefinition blindness is the lack or loss of ability to see, lack of perception of visual stimuli due to disorders of the organs of sight or to lesions in certain areas of the brain.

The legal definition of blindness represents an economic definition derived from Title X of the Social Security Act which is based on an arbitrary point below which individuals are presumed to be unable to perform economically. ${ }^{31}$

Using this legal definition, an estimated 435,000 Americans were legally blind in 1969, 34,200 of these were new cases of blindness which occurred in 1969. On the average this meant that 94 times every day of the year an American man, woman, or child lost his or her sight. ${ }^{31}$

The most common causes of blindness are senile cataracts ( 15.6 percent of all blindness), glaucoma ( 13.5 percent), diabetes ( 11.2 percent), and the vascular diseases hypertension, arteriosclerosis, and nephritis (combine for 7.6 percent). ${ }^{31}$

The 36,086 blind nursing home residents shown in table $F$ were classified as such based on the nursing home staff's definition of blindness, which more than likely corresponded to the medical rather than the legal definition. For this reason, it is possible that some residents who might have been legally blind were placed in answer category (c) rather than (d) because (c) best described how well they could see.

## Hearing Impairments

Aging has a detrimental effect on hearing as well as vision.

The increasing age of our population is probably the greatest single factor for the in-
creased incidence of hearing loss. People developing the sclerotic changes of old age have a far higher incidence of sensorineural deafness than people in the younger groups. The degree of hearing loss seems proportional to the degree of the aging process. ${ }^{31}$

Deafness is defined as a lack or loss, complete or partial, of the sense of hearing. Similarly, a deaf person is someone lacking the sense of hearing or not having the full power of hearing. For this reason, to state that a person is deaf is not enough, instead it must be stated whether he is partially or totally deaf. As might be expected, the difference in prevalence between the two is tremendous. Approximately 236,000 Americans are totally deaf, and an estimated $20,000,000$ Americans are partially deaf. ${ }^{31}$

The two major types of hearing loss are 1) middle ear or conductive hearing loss and 2) sensorineural hearing losss. The first one usually occurs early in life (at birth or early school age), when children are subjected to upper respiratory infections. The second one is associated with the dangers of being brought into the world or the degenerative changes of old age and as such, occurs at the beginning and near the end of life. ${ }^{31}$

In the survey of the civilian noninstitutionalized population from 1963 to 1965 in which hearing impairments were defined as "deafness or serious trouble hearing with one or both ears," it was found that over 8.5 million persons were so afflicted. ${ }^{44}$ Table 6 indicates the numbers and rates of these people by age groups. The table shows the marked increase in the rates in the older age group.

The RPS-3 used the following set of questions to determine hearing deficiencies of the residents in nursing homes. Again these questions were directed to a member of the staff who was familiar with the resident.

Does he USE a hearing aid? yes no
How well can he hear?
(a) Can hear a telephone conversation on an ordinary telephone (no amplifier) yes no

Table G. Number of nursing home residents with ability to hear with and.without hearing aid, by age and sex: United States, 1969

(b) Can hear most of the things a person says yes no
(c) Can hear a few words a person says
(d) Can hear only loud noises
(e) Can't hear anything

Once again the interviewer proceeded in the second question from (a) to (e) until a "yes" answer was obtained. Persons whose hearing ability fell within answer categories (c), (d), or
(e) were considered to be seriously impaired. Table $G$ indicates the extent to which the nursing home residents had hearing problems.

Table G indicates that approximately 35,000 residents used hearing aids, which was 4.3 percent of all the residents. (In 1964 virtually the same percent (4.4) of nursing home residents used hearing aids. ${ }^{13}$ ) Most of the residents had little or no trouble hearing. Over 688,000 (84.4 percent) heard sufficiently with no hearing aid to be grouped in answer categories (a) or (b). Only 14,546 ( 1.8 percent) of the residents could not hear anything, i.e., were totally deaf.

## OTHER FACTORS

This report has demonstrated the high occurrence in nursing home residents of arteriosclerosis and its associated cardiovascular and cerebrovascular diseases. Certain outside factors are known to aggravate these diseases; among them are stress, lack of exercise, smoking, and obesity. Smoking and obesity are individual rather than group oriented and as such cannot be related to the nursing home population. Stress and lack of exercise on the other hand are factors which can be related to the nursing home population.

Lack of exercise is a common problem for nursing home residents. Although exercise is a difficult factor to measure, it has been found that:

In general it appears that moderate activities exert a favorable influence upon heart disease and that inactivity may have some deleterious effects. ${ }^{\text {b, }}$, ${ }^{5}$

Stress is generally accepted as an important factor in the arteriosclerotic process. It has been the subject of considerable discussion in the medical literature:

There seems to be evidence that individuals living under constant stress and tension are subject to more frequent heart attacks than those with well-regulated lives. ${ }^{5}$

In many instances institutionalization creates stress.

Life in an institution-any institution-has a profound effect upon the resident. Human experiences take place within its walls which are helpful or harmful to recovery. For most it was neither choice nor wish to establish residency in the institution. Yet thousands, young and old, face the prospect of spending years, perhaps even a lifetime in an institution. . . .

The person who newly enters into situations where others have been before him, tends to

[^2]feel lonely, isolated. often unwanted and generally endangered. ${ }^{46}$
While some new residents may react calmly in these situations, others may show signs of stress, anxiety, tension, and perhaps even fear.

A number of investigators have studied the effects of radical environmental changes on the psychological well-being and physical survival of the aged. Many of these studies have involved changes from community living to life in an institution; others have studied relocation from one institutional setting to another. . . . The majority of these studies . . . showed that changing the environment of elderly persons sharply increased the death rate. Although more precision is required in understanding which conditions and what types of aged will experience such environmental changes as severe crises, overall the evidence suggests that radical environmental change for the aged leads to destructive physical processes and has noxious psychological effects. ${ }^{47}$

The foregoing discussion is not meant to downgrade nursing homes. Indeed, nursing homes are extremely valuable and have much to offer the elderly. The purpose of the discussion was to point out that certain factors which might exist in nursing homes could have potentially dangerous side effects on the nursing home resident. An awareness of this could in time be beneficial.

## SUMMARY

This report dealt with the chronic conditions and impairments which affected nursing home residents in 1969 and related the prevalence figures for the nursing home population to the figures for the noninstitutionalized population. The six basic chronic conditions discussed were heart trouble, stroke, arteriosclerosis, diabetes, senility, and arthritis or rheumatism. The impairments discussed were those of vision and of hearing. The conditions and impairments of each resident were reported by a member of the nursing home staff who was familiar with the resident.

Since it would be impossible to present all of the findings within the contents of this summary, only one or two important findings for each condition and impairment are presented here.

- Of the nursing home residents in 1969 who were 65 years and over, 39 percent had heart trouble. Of the noninstitutionalized population 65 years and over in 1967 (the closest prevalence data available) about 19 percent had heart trouble.
- About a fourth of all nursing homeresidents in 1969 were afflicted by strokes. These afflictions took the form of paralysis, speech defects, and other ill effects of a stroke. In 1969, less than 8 percent of the total United States population 65 years and over were afflicted by strokes, whereas 25 percent of the nursing home residents 65 years and over were so afflicted.
- It is estimated that arteriosclerosis, as an underlying cause, contributes directly to more than 850,000 deaths a year from heart attacks and strokes.
- Arteriosclerosis and its cardiovascular complications are highly prevalent among
persons with diabetes. Approximately 70 percent of the nursing home residents with diabetes also had either arteriosclerosis or heart trouble or both.
- In 1969, 56 percent of all nursing home residents were reported as senile. Age seemed to be a definite factor among nursing home residents reported as senile. Only 15 percent of the residents under 65 years of age were senile, whereas 71 percent of the residents 85 years and over were senile.
- Almost 271,000 nursing home residents (a third of all the residents) had arthritis or rheumatism in 1969. More women than men suffered from arthritis or rheumatism in both nursing homes and the general population.
- Approximately 22 percent of the nursing home residents had seriously impaired vision in 1969.

Approximately 16 percent of the nursing home residents had seriously impaired hearing in 1969.

## LIST OF DETAILED TABLES

Page
Table 1. Average number of civilian noninstitutionalized population with limitation of activity due to selected chronic conditions, by sex and age: United States,  ..... 22
2. Number of nursing home residents with selected chronic conditions, by sex and age: United States, 1969 ..... 23
3. Number and percent distribution of nursing home residents with selected chronic conditions by mobility status: United States, 1969 ..... 24
4. Number of nursing home residents with specified multiple chronic conditions by  ..... 25
5. Number and rate per 1,000 persons in total population, and number and percent distribution of visually impaired persons aged 6 years and over by degree of im-  ..... 26
6. Average number of persons with hearing impairments, percent distribution, and rate per 1,000 persons in total noninstitutionalized population, by age and sex: United States, July 1963-June 1965 ..... 28

Table 1. Average number of civilian noninstitutionalized population with limitation of activity due to selected chronic conditions, by sex and age: United States, 1969-70

| Persons limited in activity | Both sexes |  |  |  | Male |  |  |  | Female |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

${ }^{1}$ Mobllity status categories are as follows:
A = Capable of going off the premises with or without assistance.
B = Confined to the premises but does not use a wheelchair.
$\mathrm{C}=$ Needs a wheelchair but requires minimal help in getting around.
D = Generally confined to bed but is in wheelchair for at least a few hours a day.
$\mathrm{E}=$ Restricted to total bed rest.

Table 5. Number and rate per 1,000 persons in total population, and number and percent distribution of visually impaired persons aged 6 years and over by degree of impairment, according to sex and age: United States, July 1963-June 1964

Data are based on information reported in household interviews of the civilian noninstitutionalized population during the Health Interview Survey of July 1963 to June 1964]

| Sex and age | Total population | Total visually impaired persons ${ }^{1}$ | Degree of visual impairment |  |  |  |

## APPENDIX I

## TECHNICAL NOTES ON METHODS

## Survey Design

The Resident Places Survey-3 (RPS-3) was conducted during June-August 1969 by the Division of Health Resources Statistics in cooperation with the U.S. Bureau of the Census. This was a sample survey of nursing and personal care homes in the conterminous United States which provide care to the aged and infirm. Data about the sample establishment itself, about the health of a sample of the patients or residents, about the administrator of the establishment, and about a sample of the employees were collected in the survey.

Sampling frame. - The universe for RPS-3 consisted of all institutions classified as nursing homes in the 1967 survey of the Master Facility Inventory (MFI). A detailed description of how the MFI was developed, its content, maintenance plans, and a procedure for assessing the completeness of its coverage has been published. ${ }^{48,49}$ The MFI includes the names, addresses, and certain descriptive information about "all" hospitals and resident institutions in the United States. It was originally developed by collating a large number of published and unpublished lists of establishments and surveying these establishments by mail to obtain information on their nature and status of business.

Since the MFI serves as a sampling frame for institutions within the scope of the various health facilities surveys, it is imperative that it be kept as current as possible. To aid in accomplishing this purpose, a mechanism known as the Agency Reporting System (ARS) has been developed to provide information on new institutions. This information is incorporated into the MFI at regular intervals. A report on the origin and development of the ARS has been published. ${ }^{50}$

Although it was conducted in 1969, it should be noted that estimates from RPS-3 will not correspond precisely with figures from the 1969 MFI survey. This is because the two surveys used different data collection mechanisms; RPS-3 data are subject to sampling variability, and the RPS-3 universe did not include all MFI facilities. In general, however, the data from the two sources are compatible.

Sample design. - The sample was a stratified twostage probability design; the first stage was a selection of establishments and their administrators and the
second stage a selection of residents and employees of the sample establishments. In preparation for the firststage sample selection, establishments listed in the MFI wexe sorted into three types of service strata: nursing care homes, personal care homes with nursing, and personal care homes. (The classification scheme for homes is described in appendix II.) "Births" (newly opened homes identified by the Agency Reporting System as not in the MFI) were treated as a fourth type of service stratum. Each of these four strata was sorted into seven bed-size groups, producing the 28 primary strata shown in table I. MFI establishments were ordered by type of ownership, State, and county. The sample of MFI establishments and the "births" were then selected systematically after a random start within each primary stratum. Table I shows the distribution of establishments in the sampling frame and the final disposition of the sample with regard to response and inscope status.

The second-stage selection of residents and employees was carried out by Bureau of Census interviewers at the time of their visit to the establishments in accordance with specific instructions given for each sample establishment. The sampling frame for residents was the total number of residents on the register of the establishment on the day of the survey. The sampling frame for employees was the Staff Information and Control Record (HRS-4e, appendix III), on which the interviewer listed the names of all employees of the establishment; he sampled only professional and semiprofessional employees, using predesignated sampling instructions that appeared at the head of each column of this form.

Survey procedures. - The Bureau of Census collected the data according to specifications of the Division of Health Resources Statistics. The initial contact with an establishment was a letter (HRS-4g-1, appendix III) signed by the Director of the Bureau of the Census and mailed prior to a personal visit to each sample facility. This letter was accompanied by the facility and administrator questionnaires (HRS-4a and HRS-4b, appendix III). The respondent for the facility questionnaire was usually the administrator or another member of the staff designated by the operator of the establishment. The administrator questionnaire was self-enu-

${ }^{1}$ The universe for the RPS-3 sample consisted of the nursing and personal care homes included in the Master Facility Inventory and the Agency Reporting System.
""Births" consist of homes which were assumed to be in scope of RPS-3 but for which current data were not available.

3"Births" of unknown bed size were inadvertently excluded from frame.
merative, and it was completed by the person who was designated as "administrator" by the owner or operator of the sample facility. These two forms were later collected by an interviewer during the personal visit to the facility and were edited for completeness and consistency at that time. The resident information was obtained during the personal interview at the sample establishment. The sample of residents within an establishment was selected systematically according to predetermined sampling schemes. The interviewer was asked to list on the back of the Current Patient Questionnaire (HRS-4f, appendix III) all the residents, or patients, in the sample and to complete the health information for each of the sample patients from the patient's medical record and/or from the personal knowledge of a staff member of the establishment who had close contact with the resident and firsthand knowledge of the resident's health condition.

Staff information was obtained by means of a selfenumerative questionnaire (HRS-4c, appendix III), which the interviewer left at the facility with instructions for return by mail.

The usual checks and followups were performed during the course of the survey. The completed questionnaires were edited and coded by the National Center for Health Statistics and the data were processed on an electronic computer. This processing included assignment of weights, ratio adjustments, and other related procedures necessary to produce national estimates from the sample data.

## General Qualifications

Nonresponse and adjustment for missing data.Statistics presented in this report were adjusted for failure of a home to respond. Data were also adjusted for nonresponse which resulted from failure to complete one of the questionnaires or from failure to complete an item on a questionnaire.

Estimating procedure. --Statistics reported in this publication are the result of two stages of ratio adjustments, one at each stage of selection. The purpose of ratio estimation is to take into account all relevant information in the estimation process, thereby reducing the variability of the estimate. The first-stage ratio adjustment is included in the estimation of establishment and resident data for all primary service-size strata from which a sample of homes was drawn. This factor is a ratio calculated for each stratum. The numerator is the total number of beds according to the Master Facility Inventory for all homes in the stratum. The denominator is the estimate of the total beds obtained through a simple inflation of the Master Facility Inventory data for the sample homes in the stratum. The effect of the first-stage ratio adjustment is to bring the sample in closer agreement with the known universe of beds. The second-stage ratio adjustment is included in the estimation of resident data for all primary strata.

For resident data, the second-stage ratio adjustment is the product of two fractions: the first is the ratio of the total number of residents in the establishment to the number of residents. for whom questionnaires were completed within the home; the second is the sampling fraction for residents on which the selection is based.

Reliability of estimates.-As in any survey, the results are subject to reporting and processing errors and errors due to nonresponse. To the extent possible these types of errors were kept to a minimum by methods built into survey procedures. Since statistics presented in this report are based on a sample, they will differ somewhat from figures that would have been obtained if a complete census had been taken using the same schedules, instructions, and procedures.

The standard error is primarily a measure of the variability that occurs by chance because only a sample, rather than the entire universe, is surveyed. It is inversely proportional to the square root of the number of observations in the sample. Thus as the sample size increases, the standard error decreases.

As calculated for this report, the standard error also reflects part of the measurement error, but it does not measure any systematic biases in the data. The chances are about 2 out of 3 that an estimate from the sample differs from the value which would be obtained from a complete census by less than the standard error. The chances are about 95 out of 100 that the difference is less than twice the standard error and about 99 out of 100 that it is less than $2 \frac{1}{2}$ times as large.

Relative standard errors of aggregates shown in this report can be determined from figure I. The relative standard error of an estimate is obtained by dividing the standard error of the estimate by the estimate itself and is expressed as a percent of the estimate. An example of how to convert the relative error into a standard error is given with figure I. Standard errors of estimated percentages are shown in table II and those of estimated numbers in table III.

To determine the standard error of a median value or of the difference between two statistics the following rules may be used.

Standard error of a median.-The medians shown in this report were calculated from grouped data. Approximate confidence intervals for these estimated medians can be computed as follows:
(a) Determine the standard error of a 50 -percent characteristic whose denominator is equal to the estimated number of persons in the frequency distribution on which the median is based. For example, the median age of males is 77.7 years. The estimated number of males is 193,784 (table 2). The standard error of a 50 -percent characteristic whose base is 193,784 is shown in table III, by interpolation, to be 1.13 percentage points.

Figure I. Approximate relative standard errors of estimated numbers of residents shown in this report.
Example of the use of figure I: An estimate of 100,000 total residents has a relative standard error of 2.8 percent (read from scale at left side of figure). The estimate has a standard error of 2,800 ( 2.8 percent of 100,000 ).

Table II. Approximate standard errors of percentages of residents: RPS-3, June-August 1969

| Base of estimated percent (number of residents) | Estimated percent |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| 800,000 $\ldots-$ - | 0.1 | 0.2 | 0.2 | 0.3 | 0.4 | 0.4 | 0.4 |

Table III. Approximate relative standard errors of estimated numbers of residents: RPS-3, JuneAugust 1969

| Size of estimate | Relative standard error in percent | Size of estimate | Relative standard error in percent |
| :---: | :---: | :---: | :---: |
| 100---- | 71.4 | 80,000-- | 3.0 |
| 500-.---- | 32.0 | 90,000 | 2.9 |
| 1,000- | 22.6 | 100,000- | 2.8 |
| 2,500-.-.- | 14.4 | 200,000- | 2.3 |
| 5,000----- | 10.2 | 300,000-2 | 2.1 |
| 10,000--- | 7.3 | 400,000-- | 2.0 |
| 20,000-..- | 5.3 | 500,000- | 1.9 |
| 30,000---- | 4.4 | 600,000-- | 1.8 |
| 40,000---- | 3.9 | 700,000-- | 1.8 |
| 50,000---- | 3.6 | 800,000- | 1.8 |
| 60,000---- | 3.3 | 900,000- | 1.8 |
| 70,000---- | 3.1 |  |  |

(b) Apply this standard error to the cumulative frequency distribution to obtain a confidence interval around the median. The steps are as follows: For the above example, using the 95percent level of confidence, determine the points on the cumulative frequency distribution corresponding to the 47.74 percent ( 50 percent minus two standard errors) and 52.26 percent ( 50 percent plus two standard errors). The points are $92,512(47.74 \times 193,784)$ and 101,272 ( $52.26 \times 193,784$ ). From table 2, determine the ages that correspond to these points. They are 77.1 and 78.3 years, respectively. Therefore the confidence limit for the estimated median age of 77.7 years is 77.1-78.3 years at the 95percent level of confidence.
It is possible to investigate whether the observed differences between two estimated medians can be attributed to sampling error alone by obtaining the upper 68 -percent confidence limit, $U_{1}^{\prime}$ of the smaller median, $M_{1}^{\prime}$, and the lower 68-percent confidence limit, $L_{2}^{\prime}$, of the larger median, $M_{2}^{\prime}$. These limits may be found by
using the method outlined above, but using one standard error instead of two. The square root of the sum of the squared differences between $M_{1}^{\prime}$ and $U_{1}^{\prime}$ and $M_{2}^{\prime}$ and $L_{2}^{\prime}$ is the standard error of the difference between $M_{1}^{\prime}$ and $M_{2}^{\prime}$; that is,

$$
s_{\left(M_{1}^{\prime}-M_{2}^{\prime}\right)}=\sqrt{\left(M_{1}^{\prime}-U_{1}^{\prime}\right)^{2}+\left(M_{2}^{\prime}-L_{2}^{\prime}\right)^{2}}
$$

For the purpose of this report, any difference between $M_{1}^{\prime}$ and $M_{2}^{\prime}$ greater than $2 S\left(M_{1}^{\prime}-M_{2}^{\prime}\right)$ has been considered a significant difference.

Standard error of a difference between two esti-mates.--The standard error of a difference is approximately the square root of the sum of the squares of each standard error considered separately. This formula will represent the actual standard exror quite accurately for the difference between separate and uncorrelated characteristics, although it is only a rough approximation in most other cases.

# APPENDIX II <br> <br> DEFINITIONS OF CERTAIN TERMS USED IN THIS REPORT 

 <br> <br> DEFINITIONS OF CERTAIN TERMS USED IN THIS REPORT}

## Terms Relating to Residents

Age.-Age is defined as age at last birthday. Resident, -A resident is a person who has been formally admitted to an establishment but not discharged. All such persons were included in the survey whether or not they were physically present at the time.

## Classification of Homes by Type of Service

For purposes of stratification of the universe prior to selection of a sample, the homes on the MFI have been classified as nursing care homes, personal care homes with nursing, and personal care homes. The classification scheme for type of service was based on the following four criteria:

1. The number of persons receiving nursing care during the "past 7 days." Nursing care is defined as the provision of one or more of the following services:

Taking of temperature-pulse-respiration or blood pressure
Full bed bath
Application of dressing or bandages
Catheterization
Intravenous injection
Intramuscular injection
Nasal feeding
Irrigation
Bowel and bladder retraining
Hypodermic injection
Oxygen therapy
Enema
2. The presence or absence of nurses on the staff.
3. Whether or not the institution provides administration of medications or supervision over self-administered medications.
4. The number of activities for daily living for which the institution offers assistance. These include provisions of rub and massage, help with tub bath or shower, help with dressing,
correspondence, or shopping; help with walking or getting about; and help with feeding.
The type of service provided by a home might have changed during the 2-year interval between the 1967 MFI survey (used as the basic sampling universe) and the RPS-3. To produce reliable statistics by type of service from the RPS-3, the homes were reclassified by type of service on the basis of the data collected in RPS-3. This classification procedure is essentially the same as the MFI scheme. The three types of service classes delineated for RPS-3 are defined as follows:

Nursing care home.-Home in which 50 percent or more of the residents received nursing care during the week before the survey and in whicha registered rarse (RN) or licensed practical nurse (LPN) was employed at least 35 hours or more per week.
Personal care home with nursing. - Home in which either (a) some but less than 50 percent of the residents received nursing care during the week before the survey and at least one full-time RN or LPN was employed or (b) some of the residents received nursing care during the week before the survey, no RN or LPN was employed, and at least one of the following conditions was met:

The institution provided administration of medicine or supervision over self-administered medicines.

The institution provided assistance with three or more activities for daily living.

Personal care home.-Home in which one or more of the following criteria were met: (a) some of the residents received nursing care during the week before the survey, no full-time RN or LPN was employed, the institution did not provide administration of medicine or supervision over self-administered medicines, and the institution provided assistance with one or two activities for daily living; or (b) none of the residents received nursing care during the week before the survey, at least one full-time RN or LPN was employed, and at least one of the following conditions was met:

Table IV. Glassification of institutions by type of service

Dmpomiciliary care home (out of scope)
smoarding or rooming house (out of scope)

The institution provided administration of medicine or supervision over self-administered medicines.
The institution provided assistance with three or more activities for daily living.

Institutions which provided assistance with one or two activities for daily living or offered room and board as the only service were classified as out of scope of the RPS-3. Table IV shows in detail the scheme for classifying institutions according to type of service.

| Condition | ICDA Code Numbers |
| :---: | :---: |
| Advanced senility | 290.0 |
| Senility, not psychotic | 309.6, 794 |
| Other mental conditions (such as mental illness and retardation) | 290.1-309.5, 309.7-315, 790 |
| Cerebrovascular diseases |  |
| Speech defect or paralysis (palsy) due to a stroke . | 438,781.5 |
| Other ill effects of stroke | 430-436 |
| Hearț trouble . | 390-398, 400.1, 402, 404, 410-429, 782.1, 782.2, 782.4 |
| Hardening of the arteries . . . . . . . . . . . . . . . | 440 |
| Paralysis or palsy not due to a stroke . . . . . . . . . | 342, 343, 344, 348, 349.1-349.5, 350, 787.0, 780.3 |
| Arthritis or rheumatism | 710.718 |
| Diabetes . . . . . . . | 250 |
| Any chronic trouble with back or spine . . . . . . . . . | $353,722.0,725,726,728,729.0,729.1,731.0,735$, 756.1, 756.2 |
| Permanent stiffness or any deformity of the foot, leg, fingers, arm, or back | 722.1, 727, 729.4, 736, 737, 738.2-738.9, 754, 755 |
| Chronic conditions of digestive system (excluding stomach ulcer, hernia of abdominal cavity, liver or gallbladder trouble) | $\begin{aligned} & 530,535-537,540-543,560-569,577.1-577.9,750.1 \cdot 751.9 \\ & 754.1-754.5 \end{aligned}$ |
| Auditory impairments . . . . . . . . . . . . . . . . | 388, 389 |
| Vision impairments . . . . . . . . . . . . . . . . . | 370.9, 378.9, 379 |

Figure II.

## Coding Ranges for Chronic Conditions

The chronic conditions and impairments used in this report and their International Classification code
numbers ${ }^{25}$ are listed in figure II. (An explanation of the categories used in table 1 may be found in appendix II of Vital and Health Statistics, Series 10, Number $80 .{ }^{51}$ )

## APPENDIX III

# RESIDENT PLACES SURVEY-3: FORMS AND QUESTIONNAIRES 

Introductory Letter

U.S. DEPARTMENT OF COMMERCE

BUREAU OF THE CENSUS
WASHINGTON, DC. 20233
HRS -4g-1 (4-69)
OFFICE OF THE DIRECTOR
$\Gamma$
7

L
Dear Sir:
The Bureau of the Census, acting for the United States Public Health Service, is conducting a survey of nursing homes, homes for the aged, and other establishments which provide nursing care, personal care, or domiciliary care for the aged or infirm. The purpose of this survey is to collect much needed information about both the facilities and the employees and patients. This activity is part of the National Health Survey program authorized by Congress because of the urgent need for more comprehensive and up-to-date health statistics.

This letter is to request your cooperation and to inform you that a representative of the Bureau of the Census will visit your establishment within the next week or so to obtain the needed information. Prior to this visit, the Census representative will call you to arrange for a convenient appointment time. Meanwhile, to save time, I should appreciate your completing the two enclosed questionnaires which request some information about you and your establishment. Our Census representative will pick up these questionnaires when she visits you to obtain the additional desired information.

All the information provided on the questionnaires and given to the Census representative will be kept strictly confidential by the Public Health Service and the Bureau of the Census, and will be used for statistical purposes only.

Your cooperation in this important survey will be very much appreciated.
Sincerely,

A. Ross Eckler

Director

## VITAL AND HEALTH STATISTICS PUBLICATION SERIES

Originally Public Health Service Publication No. 1000

Series 1. Programs and collection procedures.-Reports which describe the general programs of the National Center for Health Statistics and its offices and divisions, data collection methods used, definitions, and other material necessary for understanding the data.

Series 2. Data evaluation and methods research. - Studies of new statistical methodology including: experimental tests of new survey methods, studies of vital statistics collection methods, new analytical techniques, objective evaluations of reliability of collected data, contributions to statistical theory.

Series 3. Analvtical studies. - Reports presenting analytical or interpretive studies based on vital and health statistics, carrying the analysis further than the expository types of reports in the other series.

Series 4. Documents and committee reports.-Final reports of major committees concerned with vital and health statistics, and documents such as recommended model vital registration laws and revised birth and death certificates.

Series 10. Data from the Health Interview Survev. -Statistics on illness, accidental injuries, disability, use of hospital, medical, dental, and other services, and other health-related topics, based on data collected in a continuing national household interview survey.

Series 11. Data from the Health Examination Survey. -Data from direct examination, testing, and measurement of national samples of the civilian, noninstitutional population provide the basis for two types of reports: (1) estimates of the medically defined prevalence of specific diseases in the United States and the distributions of the population with respect to physical, physiological, and psychological characteristics; and (2) analysis of relationships among the various measurements without reference to an explicit finite universe of persons.

Series 12. Data from the Institutional Population Surveys - Statistics relating to the health characteristics of persons in institutions, and their medical, nursing, and personal care received, based on national samples of establishments providing these services and samples of the residents or patients.

Series 13. Data from the Hospital Discharge Survey. - Statistics relating to discharged patients in short-stay hospitals, based on a sample of patient records in a national sample of hospitals.

Series 14. Data on health resources: manpower and facilities.-Statistics on the numbers, geographic distribution, and characteristics of health resources including physicians, dentists, nurses, other health occupations, hospitals, nursing homes, and outpatient facilities.

Series 20. Data on mortality. - Various statistics on mortality other than as included in regular annual or montnly reports-special analyses by cause of death, age, and other demographic variables, also geographic and time series analyses.

Series 21. Data on natality, marriage, and divorce. - Various statistics on natality, marriage, and divorce other than as included in regular annual or monthly reports-special analyses by demographic variables, also geographic and time series analyses, studies of fertility.

Series 22. Data from the National Natality and Mortality Surveys. - Statistics on characteristics of births and deaths not available from the vital records, based on sample surveys stemming from these records, including such topics as mortality by socioeconomic class, hospital experience in the last year of life, medical care during pregnancy, health insurance coverage, etc.
