Utilization of Short-Stay Hospitals
Summary of Nonmedical Statistics
United States - 1970

Presents statistics on the utilization of short-stay hospitals, based on data abstracted by the Hospital Discharge Survey from a national sample of medical records of discharged patients. The report is in two sections—one by detailed ages of patients under 15 years of age and the other by four broad age categories. Discharges, days of care, and average length of stay are reported by age, sex, and color of the discharged patients and by geographic region, bed size, and type of ownership of the hospitals. Some comparison of data for 1970 are made with those for 1969. Detailed tables for 1969 data are included.

COOPERATION OF THE BUREAU OF THE CENSUS

Under the legislation establishing the National Health Survey, the Public Health Service is authorized to use, insofar as possible, the services or facilities of other Federal, State, or private agencies. In accordance with specifications established by the National Center for Health Statistics, the Bureau of the Census, under a contractual arrangement, participated in planning the survey and collecting the data.

UTILIZATION OF SHORT-STAY HOSPITALS: SUMMARY OF NONMEDICAL STATISTICS

Evelyn W. Gordon, Ph.D., Division of Health Resources Statistics

INTRODUCTION

The year 1970 is the sixth successive year of the National Center for Health Statistics' collection of short-stay hospital utilization data in the Hospital Discharge Survey. Results of the survey permit generation of four basic types of reports: (1) nonmedical, (2) diagnostic, (3) surgical, and (4) patient charges. For each of these, information is available by patient characteristics and by the characteristics of the hospitals in which patients were hospitalized. Reports are published in Series 13 of the Vital and Health Statistics reports and as selected supplements of Monthly Vital Statistics Reports.

The hospital utilization study surveys a representative sample of noninstitutional, non-Federal hospitals with six beds or more and with an average patient length of stay of less than 30 days. Although the survey samples from among all discharged patients, this report excludes all newborn infants as defined by the survey.

Approximately 7,000 hospitals are represented in the sample of 465. Of these, 395 hospitals located in four geographic regions participated. These regions are composed of the 50 States and the District of Columbia.

This report will present nonmedical statistics for 1970 in terms of the numbers and percentages of patients by sex for various age groups in conjunction with patient characteristics of color and discharge status; with hospital characteristics of bed size, geographical location, and ownership; and with days of care and average length of stay. Detailed tables for 1969 data are included (tables 11-28), but analysis of 1969 data is found in a report by Gary E. Blanken of the Division of Health Resources.

In the first section of this nonmedical report emphasis will be placed on patients under 15 years of age, by the age intervals of under 1 year, 1-4 years, and 5-14 years of age.

The second section will be concerned with a brief summary comparison of data for 1969 and 1970 and with a more detailed analysis of 1970 data by the broad age categories of under 15, 15-44, 45-64, and 65 years of age and over. Information from this latter section can be compared with that of reports of previous years in this series for which similar data were given.

---

bPatient charges data were collected for 1968-70 and the first half of 1971.
cSee appendix II for definition of newborn and other terms used in this report.

dSee appendix I, table 1.
SECTION 1: PATIENTS UNDER 15 YEARS OF AGE

Age and Sex Comparisons

Discharges

Patients under 15 years of age accounted for an estimated 3.9 million or 13.4 percent of all discharged patients from short-stay hospitals in 1970. Of these, 2.0 percent were less than 1 year old, 3.8 percent were from 1-4 years of age, and 7.6 percent were from 5-14 years of age (table 1).

There were more males than females in each age bracket under 15 years of age (figure 1). Within the respective sex groups there was a higher percent of males under 15 years of age (19.2) than of females (9.7). This was reflected in over twice as high a percent of male (8.7) as of female patients (4.0) 4 years of age and under and in slightly less than twice as high a percent of males 5-14 years of age (10.5) as of females (5.7, table 1).

Discharge rates for each sex showed that as age increased, the difference in rate between the sexes narrowed from 194 per 1,000 males and 145 per 1,000 females under 1 year of age to 58 for males and 51 for females aged 5-14 years (table 2).

Days of Care and Average Length of Stay

Days of care for those under 15 years of age were an estimated 19.2 million, of which over half were utilized by males (10.9 million). Average length of stay was 5.0 days for males and 4.8 days for females (table 3). Patients less than a year old had an average stay almost 2 days longer than that of those 1-14 years of age, regardless of sex.

Regional Comparisons

By region the age group under 15 years ranged from a low of 12.6 percent of the discharges in the West to a high of 14.7 percent of the discharges in the North Central Region (table 1). Discharges in the North Central Region for this age group numbered about 26 times the number for the West. In each of the four regions the percent of discharged patients 1-4 years old was about twice that of those under 1 year old and the percent of those 5-14 years of age was approximately twice that of those 1-4 years old. In other words, in each region the relative increase in percent of patients in each of these age groups in the less than 15 years of age category was consistent among regions (figure 2).

Between regions, however, there were differences. For example, in the North Central Region, the number of patients under 1 year of age was about 2 1/3 times that of the West; 1-4 years old, approximately 2 1/3 times; and 5-14 years old, 2% times the West's. So, as age increased, the respective proportional differentials between the West and North Central Regions did not change appreciably (figure 3).

For patients under 15 years of age, there were more days of care in the North Central Region than any other region and, in fact, over three times as many as in the West Region (table 3). The Northeast Region had the longest length of stay for all three age groups, and the West Region had the shortest average length of stay. In all
regions patients under 1 year of age had the longest average lengths of stay, and those both 1-4 and 5-14 years of age had about the same lengths of stay.

In sum, although there were more patients under 15 years of age in the North Central Region than in any other, the relative increase in proportions of patients from one age group to the next older one was consistent for each region. The West had the shortest average length of stay for all age groups under 15 years, and patients under 1 year of age had the longest lengths of stay in all regions (figure 4).
Size of Hospital

Hospitals of less than 100 beds and those of 500 beds or more had the same percent (12.6) of their patients in the age group under 15 years. Hospitals in the middle-size range (100-499 beds) had 14.0 percent of their patients in this age group. When this group was further differentiated it was found that, for both males and females under 1 year, as the size of the hospital increased the relative percents of their patients increased (table 4).

This did not follow for patients 1-4 years of age, for although the smallest relative percent (3.4) was found in the small hospitals, the largest percent (4.0) was found in the medium hospitals. The largest relative percent of patients 5-14 years of age was again found in the medium hospitals (7.9), but the smallest relative percent (6.7) was discharged from the largest hospitals.

Small hospitals at each age group up to 14 years of age had the least number of days of care of all hospitals, and in addition, they had the shortest average length of stay, ranging from 5.1 days for those under 1 year to 3.6 days for those 1-4 years old. Medium and large hospitals showed the same tendency to decrease their average lengths of stay as age increased in the age brackets under 15 years, but this was not true of the small hospitals. As hospital size increased, however, length of stay for each age group under 15 years of age increased (figure 5). This same pattern was repeated when each sex was observed separately (table 5).

Type of Ownership of Hospital

Government and voluntary hospitals had the same percent (13.5) of their discharges in the age group under 15 years, although there is not much difference between this proportion and that of the proprietary hospitals (12.9). Although differences were slight, government hospitals had a higher percent of their discharges in the age group under 1 year (2.5) than did voluntary (1.9) or proprietary hospitals. For each older age group in voluntary hospitals the percent of discharges tended to double, but did not quite do so in government hospitals. This trend was more pronounced among females than among males (table 6).

Figure 5. Average length of stay of patients under 15 years of age discharged from short-stay hospitals, by bed size of hospital and age of patient: United States, 1970.

For patients under 15 years of age, voluntary hospital patients had an average length of stay of 4.8 days. Average length of stay, however, was longest (5.4 days) in government hospitals (table 7).

Color

Color was not stated for over 13 percent of discharged patients under 15 years of age. Since this percent is a little higher than that for those patients who were classified as being of a color other than white (12 percent), estimates regarding color must be viewed cautiously. Unlike some prior years, color data for this calendar year showed a significant difference between the

Percent distribution

age distribution of the white group and the group for whom color was not stated. Of all patients under 15 years of age, there were approximately the same percents of each age subdivisions of this broad age category for whom color was not stated (table A).

Considering an age group as a base, it was found that there was a smaller percent of white patients in the group under 1 year of age (71.3) than in the groups 1-4 years (74.0) or 5-14 years (75.2). In comparison, the highest percent (15.4) of patients other than white was found in the group under 1 year old (table A).

When data were examined as percents of a color group, a slightly larger percent of patients under 5 years of age was found in the all other group (7.5) than in the white one (5.7). For those 5-14 years of age there was no appreciable difference between the percent of white patients and all other patients in their respective color groups (table 8). Among males the percent of patients 5-14 years of age in the all other group was 11.7 percent compared with 10.4 percent for the white group. Among females the difference was very small between the two color groups at all age levels under 15 years (table 8).

The average length of stay for white patients under 15 years of age was 4.7 days and for all others 6.6 days (table 9).

In sum, of the patients under 15 years of age for whom color was stated, white patients accounted for 86.1 percent and all other patients for 13.9 percent. In the 1 year and over age groups there was a larger relative percent of white patients than of all other and the reverse was true for patients under 1 year of age.

Discharge Status

Over 96 percent of all patients for whom discharge status was stated were discharged alive, but for those under 15 years for whom discharge status was given, the percent rose to 99 percent. When the number of deaths per 1,000 discharges is considered, however, the rate of 15.3 for those under 1 year was 2.4 times as high as for those 1-4 years old (6.1) and four times as high as for those 5-14 years of age (3.6). In fact, those 5-14 years of age had the lowest rate of deaths per 1,000 discharges of all age groups (table 10).

Average length of stay for males discharged dead was almost 1% times that for females, males having had about 3½ days' shorter average length of stay than females (table 10).

Thus the older the patient in the bracket under 15 years, the more likely he was to be discharged alive and the shorter his average length of stay. Nevertheless all patients in this age category discharged dead had longer lengths of stay than those discharged alive. Males, however, were over 1½ times as susceptible as females to being discharged dead.
Discharges and Their Proportionate Days of Care
Comparisons by Age and Sex Groups

As a group, discharged patients under 15 years of age constituted just over 13 percent of the total discharges, but utilized even a smaller percent (8.2) of the total days of care. For instance patients under 1 year of age who were 2.0 percent of the discharges used 1.6 percent of the days of care; those 1-4 years old accounted for 3.8 percent of the discharges and 2.2 percent of the days of care; and those 5-14 years of age accounted for 7.6 percent of the discharges and 4.4 percent of the days of care (table B).

Where the rate of discharges per 1,000 population less than 1 year of age was over twice as high (170.4) as that for those 1-4 years of age (81.3), the corresponding rate of days of care per 1,000 population for the younger group was about three times as high (1,109.9 and 379.7, respectively). These proportions of discharges and days of care within these age groups held true for males as well as for females. In turn the discharge rate for patients 1-4 years old was 1\% times the rate for those 5-14 years of age and the rate for days of care was also 1\% times as high (figure 6). By sex, however, the rates of discharge for males and for females 1-4 years old were 1 2/3 times and 1 1/3 times, respectively, those of males and females 5-14 years of age (table 2 and figure 1).

Thus, patients under 15 years of age at all age levels used less than their proportionate share of days of care, but the youngest group had a disproportionate rate of days of care compared with the rates of older groups among the discharges under 15 years of age.

Comparisons by Hospital Ownership

Patients under 15 years of age in voluntary hospitals constituted 9.7 percent of the total discharges and accounted for 5.9 percent of the days of care; in government hospitals, 3.0 percent of the discharges who used 2.0 percent of the days of care; and in proprietary hospitals, less than 1 percent of the total discharges (table B). In other words, in each age group constituting the category under 15 years, there was a larger proportion of discharges than there were days of care.

Comparisons by Color

Patients under 15 years of age for whom color was stated used an estimated 16,821,000 days of care (table 9). White patients in the same age group used 5.9 percent of the total days of care,

</table>

but represented 9.9 percent of the discharges. All other patients in this age group, or 1.6 percent of the total discharges, used 1.3 percent of the total days of care (table C). Both color groups at all age levels below 15 years used the same or less than their proportionate share of days of care, but the percentage differences for white patients were greater than those for all other. For instance, for white patients under 1 year old the difference was 21.4 percent, but for all other there was no difference; for white patients 1-4 years of age the difference between discharges and days of care was 46.4 percent, but for all other 1-4 years of age the difference was only 20.0 percent (table C).

**Summary of Section 1**

Of an estimated 3.9 million discharged patients under 15 years of age from short-stay hospitals, within each age group, the proportion of males was about twice that of females, and rates of discharge decreased as age increased. Males

</table>
used 58 percent of the days of care and constituted 56 percent of the discharges of those under 15 years of age, but had about the same average stay as females. Patients under 1 year of age, like all subgroups in the age category under 15 years, used less than their proportionate share of days of care, but had a discharge rate two to three times higher than those patients 1-14 years of age. No matter in which region they were found, the youngest group had the longest lengths of stay. The North Central Region had 2½ times the number of discharges as the West and the latter had the shortest average length of stay.

As the size of the hospital increased, the relative percents of those under 1 year of age increased, but this was not true of other age groups. Regardless of the type of hospital ownership, patients under 15 years of age used less than their proportionate share of days of care.

White patients used proportionately fewer days of care than all other patients, although both color groups used proportionately fewer days of care than their number of discharges would have indicated.

Only 1 percent of patients under 15 years of age was discharged dead, and the older the patients in this group the less likely they were to be discharged dead. Males, however, were over 1½ times as likely to be discharged dead as were their female counterparts.

After discussing patients under 15 years of age in three age subdivisions of this group, the next step is to compare patients under 15 years old as a broad age group with older patients, that is, those 15-44, 45-64, and 65 years of age and over. It is this section which will be found to be more comparable with previous reports in the series on the Hospital Discharge Survey.

**SECTION 2: PATIENTS OF ALL AGES**

**Comparisons Between 1969 and 1970**

**Discharges**

The total estimated number of patients discharged from short-stay hospitals in 1970 was approximately 2 percent more than in 1969, representing an increase in discharges of approximately half a million from 28.5 to 29.2 million (table D). The increase in discharges was not consistent among age groups. In fact, the percent of discharges decreased by 2 percent for those under 15 years of age and increased for those 15-44 years by 4 percent, for the 45-64 year old patients by only 1 percent, and for those 65 years of age and over by slightly over 3 percent (table D).

From 1969 to 1970 the overall rate per 1,000 population increased by less than 2 percent. The rate of discharge for males, however, decreased by less than one person, from 120.0 to 119.1 per 1,000 population. The rate increased for females by four persons per 1,000 from 166.8 to 170.8 per 1,000. When deliveries were excluded, the rate increased by almost three persons, from 133.8 to 136.3 per 1,000 population from 1969 to 1970 (table D).

Despite the fact that deliveries were responsible for increasing the female rates of discharge from 132.4 to 216.1 or by 84 per 1,000 in the group 15-44 years old in 1970, the comparable difference was only 81 per 1,000 in 1969 (table D).

**Days of Care and Average Length of Stay**

Total days of care decreased in 1970 from 1969 by approximately 5.0 million days even though the estimated number of discharged patients increased by 651,000. This resulted in a decrease in average length of stay of almost half a day from 8.4 days in 1969 to 8.0 days in 1970.

The biggest decrease in average length of stay from 1969 to 1970 (half a day) was in the Northeast Region and the smallest decrease (one-fifth of a day) was in the South Region, although the South's average length of stay was 1.8 days shorter than the Northeast's in 1969 and 1.5 days shorter in 1970. The biggest difference by 2.4 days was found between the Northeast and West Regions in 1970, but this represented only one-tenth of a day shorter stay between these regions from 1969 to 1970 (table E).

Thus the main differences between 1969 and 1970 were that the estimated number of discharges increased by approximately 651,000, the number of days of care decreased by about 5,015,000, and the average length of stay decreased by almost half a day.

The remainder of this report will deal with data for the single year 1970.

</table>

Thus in 1970 discharge rates for those 65 years of age and over were higher than for those of patients under 15 years of age (table 2). The rate of female discharges was almost 1½ times the rate for males; but males 15-44 and 45-64 years of age had lower rates of discharge (89.8 and 157.3, respectively) than did females (216.1 and 165.1, respectively).
tively). On the other hand, males under 15 years of age and those 65 years and over had higher rates of discharge (74.7 and 327.7, respectively) than females (60.7 and 289.4, respectively). In other words, for males 65 years and over the rate was about four times as high, and for females 65 years and over it was almost five times as high as that for the youngest groups (figure 7).

The largest percent of discharges, 43.4 percent, was found in the age group 15-44 years. For males 15-44 years old the percent of discharges was only 30.4 percent, but for females it rose to 51.8 percent; when deliveries were excluded the average for females dropped to 39.8 percent, which was still higher than the percent for males.

For those 45-64 years of age the trend was reversed, for here the average percent of discharges was 23.0 percent, rose to 27.2 percent for males, and dropped to 20.3 percent for females. When deliveries were excluded the percent distribution for females rose to 25.4 percent, which was still lower than the percent for males (table 1).

**Days of Care**

Rates for days of care increased as age increased, the rate for those 65 years and over being 12 times the rate for those under 15 years of age. For males 65 years and over, the rate was 11 times higher than that for males under 15 years of age. Comparable figures for females showed the rate for the older group to be more than 13 times that for females under 15 years of age (table 2).

**Regional Comparisons**

The West had the smallest number of discharges (4,363,000) in all age groups (table 1); its rates of discharge for those 45-64 years old and 65 years of age and over (151.0 and 277.5, respectively) were higher than those of the Northeast Region (147.6 and 265.9, respectively). Nevertheless the West Region's rates for days of care were the lowest of all regions at all age group levels (table 2). For all age group levels the average lengths of stay were shortest in the West, ranging from 3.7 days for those under 15 years to 11.3 days for those 65 years and over, and longest in the Northeast, ranging from 5.4 days to 15.7 days from the youngest to the oldest groups (table 2).

**Size of Hospital**

Although the smallest (6-99 beds) and the largest (500 beds or more) hospitals had the same percent of their patients in the age group under 15 years (12.6), they differed appreciably in the percentage distributions for the three age groups 15 years and older. The smallest hospitals had proportionately fewer patients 15-64 years old than did the largest hospitals, but the largest hospitals had only 16.3 percent of their patients in the age group 65 years and older compared with 25.5 percent for the smallest hospitals (table 4).

Patients of medium-size hospitals were distributed by age between the distribution for the smallest and largest hospitals for all ages except those under 15 years. This age group rather than having the highest percent for the largest hospitals had instead the same percent as that for the smallest hospitals. By the same token, instead
of the percents of each size hospital's patients 65 years and over increasing as hospital size increased, the reverse was true. In other words, the smaller the hospital the more likely it was that a larger percent of its discharged patients would be found in the oldest age group. On the other hand, the larger the hospital the larger the relative percent of patients to be found in the age group 15-64 years.

These same directional age trends were true for males and, with the exception of the 45-64 year old patients, for females. Percents of females in the age group 45-64 were approximately the same (20.6, 20.2, and 20.3) for each size hospital. Only when deliveries were excluded did the usual trend of increasing percents of patients with increased size of hospital hold true for females in the 45-64 age group (24.7, 25.4, and 26.0, respectively) (table 4).

Average length of stay also increased as age increased and as hospital size increased. This was true for males in all age groups; for females without deliveries; and, with one exception, for all females. This exception was the fact that the average length of stay did not increase for patients from under 15 years old (6.8 days) to 15-44 years old (6.2 days) in the large hospitals.

Average length of stay ranged from 4.0 days for the youngest group to 11.2 days for the oldest group in the smallest hospitals, from 4.7 days to 13.6 days in the medium hospitals, and from 6.8 days to 14.5 days for these respective age groups in the largest hospitals (table 5).

For the oldest female group, the average length of stay not only was longer than that for males 65 years and over but also increased as size of hospital increased.

**Type of Ownership of Hospital**

Hospitals of all types of ownership did not show much difference in the proportions of their discharges for the youngest age group. However, there was a significant difference between voluntary and proprietary hospitals on the one hand and government hospitals on the other in the distribution of their patients 15-64 years of age (table 6). The government hospitals had a larger percent of patients 15-44 years of age (45.8) and a smaller percent of persons 45-64 years of age (20.8) and of persons 65 years of age and over (19.9) than did the other two types of hospitals.

**Color**

On the basis of the 86 percent of patients for whom color was stated, it was found that there were approximately seven times as many white discharges as all other.

There was a relatively lower percent of patients up to 44 years of age in the white group than there was in the all other group; after 44 years of age the reverse was true. This was the case for both males and females, including and excluding deliveries.

White patients had almost a half day's shorter stay than all other, but white males had over 1 day's shorter stay than all other males. When deliveries were excluded, white females also had a half day's shorter stay than did all other females. But when deliveries were included, white females had approximately the same length of stay as all other females. This overall similarity in length of stay was seen primarily in the childbearing ages of 15-44 years. Because this age group represented 49.3 percent of the total number of white female discharges and 65.8 percent of all other females, the experience of such large segments of the discharges would tend to heavily weight the average length of stay for all ages (table 8).

**Discharge Status**

Deaths per 1,000 discharges for patients over 14 years of age increased as age increased for both males and females, but for males the rate was higher than for females at each age group level (table 10). The biggest difference in these rates was seen at ages 15-44 years where the males had almost double the rate of deaths (10.0) per number of male discharges as had females excluding deliveries (5.4). When deliveries were included, the rate for males 15-44 years of age almost tripled that for females. It was almost 1 ½ times the rate for females at ages 45-64 years and almost 1 1/3 times the rate for ages 65 years and over (figure 8).

Average length of stay for all discharges was longer for those discharged dead (13.6 days) than for those discharged alive (7.8 days). Among
males, as age increased, the difference in average length of stay decreased between those discharged dead and those discharged alive. It ranged from a difference of 5.1 days for all patients under 15 years of age to a difference of only seven-tenths of a day for those 65 years of age and over. For females, the difference in length of stay between alive and dead discharges increased from 3 days' difference for those under 15 years to 6.4 days' difference for those 45-64 years of age and then decreased to the smallest difference of all age groups of 1.4 days between discharge statuses for patients 65 years of age and over. The difference in length of stay was the same (5.6 days) between males 15-44 years of age discharged alive and dead and between their female counterparts without deliveries. However, for this age group, males both alive (7.1 days) and dead (12.7 days) stayed approximately 1 day longer than females (6.0 and 11.6 days, respectively, table 10).

Females 45-64 years of age discharged alive had approximately the same length of stay as males, but when discharged dead, they had a 3-day longer stay than males. Females 65 years and over, on the other hand, had 1 day's longer stay than males when discharged alive and over 2 days' longer stay when discharged dead (figure 9).

discharges and their proportionate days of care

comparisons by age

Patients 65 years and over represented 20.2 percent of the discharges but 33.0 percent of the days of care; those 45-64 years of age represented 23.0 percent of the discharges and 27.5 percent of the days, while those 15-44 years old accounted for 43.4 percent of the discharges and 31.3 percent of the days of care; and those under 15 years of age represented 13.4 percent of the discharges and 8.2 percent of the days of care. Clearly, the older the patient group, the disproportionately greater were their days of care to their number of discharges (figure 10).

comparisons by hospital size

Patients in all age groups in large hospitals used a larger percent of the days of care than their percent of discharges would indicate to be their proportionate share. In medium and
Figure 10. Percent of total discharges from short-stay hospitals and percent of days of care, by age of patient: United States, 1970.

large hospitals patients followed the same age pattern as for other variables which have been discussed, that is, patients 45 years of age and older used more than their age group's proportionate share of days of care (table F). Therefore, it is interesting to note that the only exception to

this general trend occurred in small hospitals where all ages used less than their proportionate share of days of care (table F).

Comparisons by Color Groups

In considering each color group as a percent of the total number of discharges in a particular age group, it was found that at all age levels below 65 years of age, the percents of white persons' discharges exceeded their respective percents of days of care by from 1.2 to 3.0 percentage points. White patients 65 years of age and over had the same percents (80.0) of discharges as days of care. For all white patients regardless of age, the percent of discharges and days of care were approximately the same (table G).

Conversely, all other patients in all age groups had a slightly higher proportion of days of care than discharges, ranging from less than 1 percentage point of difference for those in the oldest group to more than 4 percentage points difference for those under 15 years of age (table G).

These, then, were the relationships within their respective age groups between discharges and days of care for white persons and all other.

When each age group was considered as a percent of a total color group, it was found that

Among both color groups those under 45 years of age used less, and those 45 years of age and over used more than their proportionate share of days of care (Table H). Even though white patients as opposed to all other in one age group category used proportionately the same or less and all other patients used more than their share of days of care (Table G), within each color group patients aged 45 years and over used a number of days of care disproportionate to the number of discharges and patients under 45 years of age, regardless of color, used less than their share (Table H). Tables G and H suggest that although white patients are more likely to use less than their proportionate share of days of care, age is a more important determinant of the proportionate number of days of care.

### Summary of Section 2

The year 1970 saw an approximately 2 percent increase over 1969 in the estimated number of patients discharged from short-stay hospitals, the highest percentage increase being among those 15-44 years of age. Although the overall discharge rate increased only slightly, it increased a bit...
more for females since 1969 but decreased even more slightly for males.

Since 1969 the number of days of care decreased by over 5 million days and the average length of stay decreased by about half a day.

In 1970 the discharge rate for males 65 years and over was about four times and the days of care rate 11 times the rates for patients less than 15 years of age. Among females 65 years and over the discharge rate was five times and the days of care rate 13 times as high as those for the youngest group. The largest proportion (43.4 percent) of the discharges were among those patients 15-44 years of age. The biggest difference in average length of stay between regions was found between those of the Northeast and West, the latter having the lowest days of care rates of all regions and the shortest average length of stay.

The smaller the hospital the greater was the likelihood that it would have a higher proportion of its patients in the 65 years and over age bracket. As age and hospital size increased, the average length of stay increased,

There was a significant difference in the distribution of patients 15-64 years of age in government hospitals compared with those of hospitals under other forms of ownership.

Of patients for whom color was stated, white patients in a single age group used less than their proportionate share of days of care and all other used more. Patients under 45 years of age in both color groups used less than their color group's share of days of care than did those 45 years of age and over.

White males had a shorter average length of stay than either all other males or all females.

The fatality rate of discharged patients increased as age increased, but the male rate was higher than that of females at each age level. Average length of stay was higher for those discharged dead than for those discharged alive.

TECHNICAL NOTES ON METHODS

Statistical Design of the Hospital Discharge Survey

Scope of the survey.—The scope of the Hospital Discharge Survey (HDS) encompasses patients discharged from noninstitutional hospitals exclusive of military and Veterans Administration (VA) hospitals which have six beds or more for inpatient use, are located in the 50 States and the District of Columbia, and have an average length of stay of less than 30 days. Although all discharges of inpatients from these hospitals are within the scope of the survey, all newborn infants are excluded from this report.

Sampling frame and bed size of hospital.—The universe (sampling frame) for the Hospital Discharge Survey consists of the short-stay hospitals, exclusive of military and VA hospitals which are included in the Master Facility Inventory of Hospitals and Institutions (MFI). A detailed description of how the MFI was developed, its content, plans for maintaining it, and procedures for assessing the completeness of its coverage is published in an earlier report.5

There were 6,965 hospitals in the universe. The distribution of short-stay hospitals by bed size and region in the universe and in the HDS sample is shown in table I. The samples for 1969 and 1970 consisted of 465 hospitals, of which 21 were ruled out of scope of the 1969 survey because they failed to meet the definition of a short-stay hospital and of which 42 refused to participate. For the 1970 survey, corresponding figures were 24 out-of-scope hospitals and 46 refusals. Estimates are based on 208,000 abstracts received from the remaining 402 hospitals that participated during 1969 and 205,000 abstracts from the remaining 395 hospitals participating during 1970.

Sample design.—All hospitals with 1,000 beds or more in the universe of short-stay hospitals were selected with certainty in the sample. All hospitals with less than 1,000 beds were stratified, the primary strata being the 24 bed-size-by-region classes, as shown in table I. Within each of these 24 primary strata, the allocation of the hospitals was made through a controlled selection technique so that hospitals in the sample would be properly distributed with regard to ownership and geographic division. Sample hospitals were drawn with probabilities ranging from certainty for the largest hospitals to 1 in 40 for the smallest hospitals.

The within-hospital sampling ratio for selecting discharges varied inversely with the probability of selection of the hospital. The smallest sampling fraction of discharged patients was taken in the largest hospitals, and the largest fraction was taken in the smallest hospitals. This was done to compensate for the fact that hospitals were selected with probabilities proportionate to their size class and to assure that the overall probability of selecting a discharge would be approximately the same in all hospitals.

In nearly all hospitals the daily listing sheet of discharges was the frame from which the subsamples of discharges were selected within the sample hospitals. The sample discharges were selected by a random technique, usually on the basis of the terminal digit(s) of the patient’s medical record number—a number assigned when the patient was admitted to the hospital. If the hospital’s daily discharge listing did not show the medical record numbers, the sample was selected by starting with a randomly selected discharge and taking every kth discharge thereafter.

Estimation.—Statistics produced by the HDS are derived by a complex procedure. The basic unit of estimation is the sample patient abstract. The estimating procedure used to produce essentially unbiased national estimates has three principal components: (1) inflation of reciprocals of the probabilities of sample selection, (2) adjustment for nonresponse, and (3) ratio adjustments to fixed totals. These components are described in appendix I of two earlier publications.1 2

Data Collection and Processing

Data collection.—Depending on the study procedure agreed on with the hospital administrator, the sample selection and the transcription of information from the hospital records to the abstract forms were performed by either the hospital staff or representatives of the National Center for Health Statistics (NCHS), or by both. In more than half of the hospitals that participated in

Figure 1. Medical abstract for the Hospital Discharge Survey.
the HDS during 1969 and 1970, work was performed by the medical records department of the hospital. In the remaining hospitals, nearly all the work was performed by personnel of the U.S. Bureau of the Census acting for NCHS.

For nearly all survey hospitals data were transcribed from hospital records to the form shown in figure I.

Data processing and editing of data.—Shipments of completed abstract forms for each sample hospital, along with sample selection control sheets, were transmitted to NCHS for processing. Every shipment of abstracts was reviewed; each abstract form was checked for completeness; and when necessary, problems were referred to the hospitals for clarification and correction.

The demographic data in sections I and II of the Medical Abstract form were converted to tape, and all abstracts were assigned one of five category codes: (1) deliveries, (2) newborn infants born outside the hospital, (3) well newborn infants, (4) nonwell newborn infants, and (5) all other discharges not included within (1)-(4) above. This report excludes all discharges assigned category codes 3 and 4.

Final editing was done by computer inspection of the demographic data compared with the category code assigned each abstract. If the patient's sex was left blank, it was imputed and tabulated as "not stated," except in those cases known to be deliveries (category code 1).

Very few rejects were encountered; those found were corrected by inspection of data on the computer tape. If age was left blank, it was imputed by assigning the patient an age consistent with the ages of other patients with the same category code. If the dates of admission or discharge were not given, and if they could not be obtained from the monthly sample listing sheet transmitted by the sample hospital, a length of stay was imputed by assigning the patient a stay consistent with the stays of other patients of the same age. Other missing demographic items were coded and tabulated as "not stated." A few abstract forms with missing category codes were discarded.

Population Estimates

The base populations used in computing rates are unpublished estimates for the U.S. civilian, noninstitutionalized population as of midyear 1969 and 1970 (July 1) provided by the U.S. Bureau of the Census.

The population estimates for the United States by age and sex (tables II and III) and by age and geographic region (tables IV and V) are consistent with the estimates of the civilian population published by the U.S. Bureau of the Census in Current Population Reports, Series P-25. However, they are not official population estimates of the U.S. Bureau of the Census. Estimates of the regional populations by age and sex were provided by the U.S. Bureau of the Census specifically for use in the HDS for computing rates.

General Qualifications

Rounding of numbers.—Estimates of the number of discharges and number of days of care were rounded to the nearest thousand for tabular presentation. Per cent and rates were calculated on the basis of unrounded estimates. Due to rounding, detailed figures within tables do not always add to totals.

Patient characteristics not stated.—Sex was not stated for less than 2 percent of all 1969 discharges and for less than 1 percent of all 1970 discharges. However, color was not stated for approximately 14 percent of the patients discharged during each year. The proportion of sample hospital records with color not stated varied considerably among the sample hospitals.

Reliability of Estimates

Estimates from sample surveys such as the Hospital Discharge Survey are subject to two types of errors—measurement or nonsampling errors and sampling errors. Measurement errors can occur in a complete count or census as well as in a sample survey. Sampling errors, on the other hand, occur because a sample instead of a complete count is taken.

Measurement errors.—These include errors due to hospital nonresponse, missing abstracts, information incompletely or inaccurately recorded on abstract forms, and processing errors. Some of these have been discussed in earlier sections.

Sampling errors.—The standard error in this survey is primarily a measure of the sampling variability that occurs by chance because the estimates are based on a sample of short-stay hospitals rather than on all discharges from all short-stay hospitals. The relative standard error of an estimate is obtained by dividing the standard error of the estimate by the estimate itself and is expressed as a percentage of the estimate.

The chances are about 68 out of 100 that the value obtained in a complete enumeration is contained in the interval represented by the estimate plus and minus one standard error of the estimate, 95 out of 100 for two standard errors, and 99 out of 100 for 2½ standard errors. Applying the illustration at the bottom of figure II, the chances are about 68 out of 100 that the value that would be obtained in a complete enumeration is contained in the interval 2,018,000 ± 4.2 percent of 2,018,000 (between 1,933,244 and 2,102,756); 95 out of 100 for the interval 2,018,000 ± 4.2 percent of 2,018,000 multiplied by 2; 99 out of 100 for the interval 2,018,000 ± 4.2 percent of 2,018,000 multiplied by 2.5.

The standard error of one statistic is generally different from that of another even when the two come from the same survey. To derive standard errors that would be applicable to a wide variety of statistics and that could be prepared at a moderate cost, a number of approximations were required. As a result, figures II and III

¹Consistent with the estimates of the population by age for States published by the U.S. Bureau of the Census in Current Population Reports, Series P-25, No. 437.
Figure II. Approximate relative standard errors of estimated numbers of patients discharged for patient characteristics, by geographic region, size of hospital, and type of ownership and for all hospitals.

Illustration of use of figure II: As shown in table 1, an estimated 2,018,000 patients aged 45-64 years were discharged during 1970 within the South Region. The relative standard error of this estimate as read from the line "Region groups" is approximately 4.2 percent: the standard error of 2,018,000 is 84,756 (4.2 percent of 2,018,000).

cross-classified. The procedures that apply are as follows:

1. Approximate relative standard errors of estimated number of discharges are obtained from the curves shown in figure II.
2. Approximate relative standard errors of estimated number of days of care are obtained from the curves shown in figure III.
3. Approximate standard errors of estimated percentages of discharges when the characteristic(s) used to form the numerator of the percentage is a subclass of the denominator are shown in table VI.
4. Approximate standard errors of estimated percentages of days of care when the characteristic(s) used to form the numerator of the percentage is a subclass of the denominator are shown in table VII.

Approximate standard errors of average lengths of stay can be calculated as in the following example:

Suppose the standard error ($\sigma_{av}$) of the average length of stay during 1969 for males aged 35-44 years for all hospitals is desired. The estimated number of discharges for this statistic is 1,199,000.
Figure II 1. Approximate relative standard errors of estimated number of days of care for patient characteristics, by geographic region, size of hospital, and type of ownership and for all hospitals.

Illustration of use of figure II 1: As shown in table 27, an estimated 4,480,000 days of care during 1969 were provided to patients aged 15-44 years in proprietary hospitals. The relative standard error of this estimate as read from the line “Ownership groups” is approximately 17.0 percent: the standard error is 761,600 (17.0 percent of 4,480,000).

(table 12) and the estimated number of days of care is 9,633,000 (table 13).

Let

\[ R' = \frac{\text{Number of days of care}}{\text{Number of discharges}} = \frac{9,633,000}{1,199,000} = 8.0 \text{ days} \]

The relative standard error \( V_{R'} \) of 9,633,000 (from all hospitals curve in figure III) is 4.3 percent, or .043; \( V_{X'} = (.043)^2 \). The relative standard error \( V_{Y'} \) of 1,199,000 (from all hospitals curve in figure II) is 3.6 percent, or .036; \( V_{Y'} = (.036)^2 \). The sample correlation coefficient \( r \) which measures the closeness of the relation between the estimated number of days of care and the estimated number of discharges has been computed to be 0.75.

\[ V_{R'}^2 = V_{X'}^2 + V_{Y'}^2 - 2r V_{X'} V_{Y'} = (.043)^2 + (.036)^2 - 1.5 (.043 \times .036) = .00189 + .001296 - .002322 = .000823 \]

\[ V_{R'} = \sqrt{.000823} = .029 \]

\[ \sigma_{R'} = R' \times V_{R'} = 8.0 \times .029 = 0.2 \text{ days}. \]

Illustration of use of table VI: Table 11 shows that 28.3 percent of the 8,787,000 white male patients discharged during 1969 from all hospitals were aged 45-64 years. Linear interpolation between the values shown in table VI will yield an approximate standard error of 0.5 percent for an estimate of 28.3 percent with a base of 8,787,000.

Illustration of use of table VII: Table 17 shows that of the 21,921,000 days of care provided for males discharged during 1970 from hospitals with 500 beds or more, 25.7 percent of the days were utilized by patients 65 years and over. Linear interpolation between the values shown in table VII will yield an approximate standard error of 1.9 percent for an estimate of 25.7 percent with a base of 21,921,000.
DEFINITIONS

Terms Relating to Hospitalization

Patient.—A person who is formally admitted to the inpatient service of a short-stay hospital for observation, care, diagnosis, or treatment. In this report the number of patients refers to the number of discharges during 1969 or 1970 including multiple discharges of the same individual (if any) from one short-stay hospital or more. All newborn infants, defined as those admitted by birth to the hospital, are excluded from this report. "Inpatient" and "patient" are used synonymously.

Patients under 1 year of age.—Includes infants admitted on the day of birth, directly or by transfer from another medical facility, with or without mention of a disease, disorder, or immaturity.

Discharge.—The formal release of an inpatient by a hospital, that is, the termination of a period of hospitalization by death or by disposition to place of residence, nursing home, or another hospital. In this report, "discharges" and "patients (or inpatients) discharged" are used synonymously.

Discharge status.—The condition (i.e., alive or dead) of a patient upon being discharged.

Discharge rate.—The ratio of the number of hospital discharges (inpatients) during a year to the number of persons in the civilian, noninstitutionalized population as of July 1 of that year.

Days of care.—The total number of inpatient days accumulated at time of discharge by patients discharged from short-stay hospitals during 1969 or 1970. A stay of less than 1 day (inpatient admission and discharge on the same day) is counted as 1 day in the summation of total days of care. For patients admitted and discharged on different days, the number of days of care is computed by counting all days from (and including) the date of admission to (but not including) the date of discharge.

Rate of days of care.—The ratio of the number of inpatient days accumulated at time of discharge by patients discharged from short-stay hospitals during a year to the number of persons in the civilian, noninstitutionalized population as of July 1 of that year.

Average length of stay.—The total number of inpatient days accumulated at time of discharge by patients discharged during 1969 or 1970 divided by the number of patients discharged. "Average stay," "duration of stay," and "length of stay" are used interchangeably.

Hospitals and Hospital Characteristics

Short-stay hospitals.—General and short-term special hospitals having six beds or more for inpatient use and an average (mean) length of stay of less than 30 days. Military and Veterans Administration hospitals and hospital units of institutions are not included. "Hospitals" and "short-stay hospitals" are used synonymously.

Size of hospital.—Measured by the number of beds, cribs, and pediatric bassinets regularly maintained (set up and staffed for use) for inpatients; bassinets for newborn infants are not included. In this report the classification of hospitals by bed size is based on the number of beds at or near midyear reported by the hospitals.

Location of hospitals.—See "Geographic region."

Type of ownership of hospital.—Refers to the type of organization that controls and operates the hospital. In this report the classification of hospitals by type of ownership is based on responses provided by sample hospitals. The hospitals are grouped as follows:

Voluntary hospitals.—Hospitals operated by a church or another nonprofit organization.

Government hospitals.—Hospitals operated by State and local governments.

Proprietary hospitals.—Hospitals controlled by individuals, partnerships, or corporations for profit.

Demographic Terms

Age.—Refers to age at last birthday prior to admission to the hospital inpatient service (newborn infants excepted).

Color.—In this report patients are classified into two groups, "white" and "all other." The all other classification includes all categories other than white, some of which are too small for statistical purposes to be
presented separately. White includes Mexican and Puerto Rican unless specifically identified as all other.

**Marital status.**—Marital status applies only to persons 15 years of age and over in this report.

**Geographic region.**—In this report hospitals are classified by location according to the four geographic regions of the United States which correspond to those used by the U.S. Bureau of the Census.

Series 1. Programs and collection procedures.—Reports which describe the general programs of the National Center for Health Statistics and its offices and divisions, data collection methods used, definitions, and other material necessary for understanding the data.

Series 2. Data evaluation and methods research.—Studies of new statistical methodology including: experimental tests of new survey methods, studies of vital statistics collection methods, new analytical techniques, objective evaluations of reliability of collected data, contributions to statistical theory.

Series 3. Analytical studies.—Reports presenting analytical or interpretive studies based on vital and health statistics, carrying the analysis further than the expository types of reports in the other series.

Series 4. Documents and committee reports.—Final reports of major committees concerned with vital and health statistics, and documents such as recommended model vital registration laws and revised birth and death certificates.

Series 10. Data from the Health Interview Survey.—Statistics on illness, accidental injuries, disability, use of hospital, medical, dental, and other services, and other health-related topics, based on data collected in a continuing national household interview survey.

Series 11. Data from the Health Examination Survey.—Data from direct examination, testing, and measurement of national samples of the civilian, noninstitutional population provide the basis for two types of reports: (1) estimates of the medically defined prevalence of specific diseases in the United States and the distributions of the population with respect to physical, physiological, and psychological characteristics; and (2) analysis of relationships among the various measurements without reference to an explicit finite universe of persons.

Series 12. Data from the Institutional Population Surveys.—Statistics relating to the health characteristics of persons in institutions, and their medical, nursing, and personal care received, based on national samples of establishments providing these services and samples of the residents or patients.

Series 13. Data from the Hospital Discharge Survey.—Statistics relating to discharged patients in short-stay hospitals, based on a sample of patient records in a national sample of hospitals.

Series 14. Data on health resources: manpower and facilities.—Statistics on the numbers, geographic distribution, and characteristics of health resources including physicians, dentists, nurses, other health occupations, hospitals, nursing homes, and outpatient facilities.

Series 20. Data on mortality.—Various statistics on mortality other than as included in regular annual or monthly reports—special analyses by cause of death, age, and other demographic variables, also geographic and time series analyses.

Series 21. Data on natality, marriage, and divorce.—Various statistics on natality, marriage, and divorce other than as included in regular annual or monthly reports—special analyses by demographic variables, also geographic and time series analyses, studies of fertility.

Series 22. Data from the National Natality and Mortality Surveys.—Statistics on characteristics of births and deaths not available from the vital records, based on sample surveys stemming from these records, including such topics as mortality by socioeconomic class, hospital experience in the last year of life, medical care during pregnancy, health insurance coverage, etc.
