

Docket NIOSH-047: Categorized Comments

About the Comments and Categories

[\(Select to skip to the comments\)](#)

Starting in May, 2005, NORA requested comments from stakeholders to identify important occupational safety and health issues, such as: diseases, injuries, exposures, populations at risk, and needs of the occupational safety and health system. Input was also requested on the types of research and partners needed to make a difference. Comments were received through this website, by E-mail and on paper. A court reporter provided transcripts of comments received during NORA Town Hall meetings.

Approximately 800 individuals submitted information through the website and the Town Hall meetings. Each submittal could include up to ten comments, since the comment form includes ten input boxes. Each comment was given a unique identification number, which is displayed in the search results.

Each comment was analyzed to determine if the text could be separated into distinct parts. Each 'unit comment' was then determined to be a "Comment on the NORA process" or a recommendation of a research priority. As a result, 1600 unit comments were categorized.

Each comment recommending a research priority was indexed by the terms listed below using the approach that such a comment could be characterized by a sentence of the form:

"I recommend as a priority these 'sectors' having these 'populations' experiencing these 'health effects' due to these 'exposures' where these 'approaches' will be most useful in reducing the problem and these organizations/people should be engaged as 'partners'."

Each of the words in single quotes is a category. For each comment, none or some of the items in each category were selected as search terms. The search terms are not exhaustive but were selected primarily to reflect the programs in the NIOSH Program Portfolio. Where additional terms were needed to capture the range of comments offered, terms were taken from the 21 priority areas of the first decade of NORA. A few more terms were added to cover large gaps; these tended to be broad terms, for example, exposures to "chemicals/liquids/particles/vapors".

Non-obvious aspects of the categorization criteria are indicated below:

Sectors:

The eight NORA sector groups are defined in terms of the Census Bureau's North American Classification System (NAICS) codes. [Click here for more information.](#)

- Agriculture, forestry, and fishing
- Construction
- Healthcare and social assistance
- Mining
- Manufacturing
- Services
- Transportation, warehousing and utilities
- Wholesale and retail trade

Unspecified – This term was chosen when a comment recommending a research priority did not specify any sector(s).

At least one of the nine terms in the sector category was chosen for each comment recommending a research priority. (This is not true for any of the other categories.) When the comment implicitly included all workers but gave examples in specific sectors, both “unspecified” and the sector(s) mentioned in the examples were chosen.

Population:

A term describing a population was selected when a comment described a group of workers that could not be characterized by their employers’ sector or sub-sector or their occupation.

Youth – Typically, teenage or younger.

Older – Typically, workers were described as aging or older.>

Language/culture/ethnicity – Typically, workers were described as immigrants, minority, Hispanic, Black, etc., or were characterized as having a distinguishing culture.

Disability – Physical or mental.

Small business

Other – Some examples are: women, workers who live in rural areas, pregnant workers, diabetics, part-time workers, workers in the informal sector, Generation X workers, shorter stature workers, and low wage workers.

Health outcomes; diseases/injuries

These terms were selected using their “common” definitions rather than strict medical definitions.

Cancer – Includes mutagenicity and other pre-cancer indicators.

Reproductive – Defined broadly as effects on the reproductive health of prospective parents as well as effects on fetuses leading to the birth of an unhealthy or deformed baby.

Cardiovascular disease – Typically, hypertension.

Neurological effect/mental health – Includes effects on nerves, headaches, pain, effects on nerves (including white-finger syndrome), depression and other mental health issues.

Renal disease – Any kidney or urological effect

Hearing loss – Includes noise exposures that might lead to hearing loss.

Immune disease – Includes any mention of the immune system. Does not include asthma.

Dermal disease – Typically, skin disease or chemical exposures of the skin.

Infectious diseases – Includes exposures to infectious agents that might lead to an infectious disease.

Musculoskeletal disorders – Soft tissue and joint disorders, most often caused by repetitive motions, especially repeated heavy lifting.

Respiratory disease – Includes asthma and other lung diseases as well as other conditions of the respiratory tract, for example, rhinitis.

Traumatic injuries

Mortality

Exposures

Infectious agents – Selected only when the exposure to the infectious agent was implicated in some other disease than an infectious disease, for example, cancer.

Chemicals/liquids/particles/vapors – Includes pharmaceuticals.

Work organization/stress

Heat/cold

Noise/Vibration – This term was not selected when noise exposure was a risk factor for hearing loss. It was selected when a noise exposure was a risk factor for some other effect, for example, injuries due to difficulty in communicating. Vibrations include all frequencies.

Radiation (ionizing and non-ionizing) – Includes sun and UV exposures of skin, radioactivity, and electromagnetic radiation of any frequency.

Indoor environment – Typically, exposures associated with office buildings described as sick-building, mold, ventilation system effectiveness or vapors released from materials.

Motor vehicles – Any mobile, motorized machine, including forklifts, farm tractors and other self-propelled farm machinery and ATV's.

Violence – Physical or verbal.

Work-life issues – Selected when issues originating outside work were mentioned as risk factors, including obesity, physical conditioning, and stress due to family relationships. Also selected when work exposures could harm family members or communities.

Approaches

These terms reflect answers to the question “What types of research will make a difference” and broadly reflect the public health model. “Research” is taken very loosely and includes any types of studies, better understanding and improved implementation.

Surveillance – Typically, surveillance systems, but also includes worksite surveillance of risk factors. Does not include worksite medical surveillance to identify early disease; that was categorized as “Health service delivery.”

Hazard identification – Narrowly defined as laboratory studies to determine what health effects exposure to a chemical (or a physical hazard) is capable of producing, without necessarily obtaining any dose response data relevant to worker exposures.

Etiological research – Field or laboratory studies relating health effects to worker exposures.

Exposure assessment – Includes worksite measurements as well as improved analytical methods and instrumentation.

Risk assessment methods – Narrowly defined as formal risk assessment (usually quantitative).

Engineering and administrative control/banding – Any engineering solutions, e.g., better design of machinery and buildings, engineering controls, process improvement, and substitution (with less hazardous chemicals). Also includes specification of allowable worksite procedures to reduce hazards (administrative controls) as well as control banding (relatively new administrative procedures to achieve worksite hazard identification, exposure assessment and control without measurements at the worksite).

Personal protective equipment

Training – Selected when improvements in training workers, supervisors, employers, engineers, architects and others were recommended. Improved education of occupational safety and health specialists and professionals was categorized as “Capacity building.”

Intervention effectiveness research – Broadly defined to include laboratory or field studies of the effectiveness of a workplace intervention designed to reduce risk.

Work-site implementation/demonstration – Selected when employers/workers control the adoption of interventions or programs and researchers have, at most, a facilitation and evaluation role. Typically, the comment recommends assistance in implementing a proven intervention within a population of worksites or recommends community-based, participatory research.

Economics – Selected when a comment cites financial, profit, or productivity issues as factors in worker safety and health. Includes issues of the business case for occupational safety and health and return-on-investment.

Authoritative recommendation – Includes policies, recommendations, standards and regulations applicable to a population of worksites, typically generated by corporate occupational safety and health professionals, NIOSH, consensus standards groups and government agencies.

Marketing/dissemination – Making information widely available.

Capacity building – Education of occupational safety and health specialists and professionals

Health service delivery – Occupational health medical services, including medical monitoring, diagnosis, and treatment as well as the payment for such services, especially workers' compensation systems. Includes return-to-work issues following a disabling injury or illness.

International interaction – Selected when the comment recommends collaborating with, learning from or sharing solutions with other countries.

Emergency preparedness and response – Includes natural disasters, terrorism and single-person emergencies.

Work-site occupational safety health system/record keeping – Selected when a comment recommends improvements in work-sites' occupational safety and health system or the safety culture. Also selected when a comment recommends improvements in governmental systems at the local, state or national level including improvements in the handling of information or records.

Partners

When a comment explicitly recommends future work with a named partner or a class of partners, the partner's name or class description was placed in a "partner" field. Select "Partner recommended" in the search criteria to find only those comments for which an entry was made in the "partner" field.

List of all categorized comments

Use the search capabilities of the file viewing software to locate comments of interest. Search for key terms listed above or for any term in the text.

The number before the comment ID indicates the submission identifier and the number after the ID indicates whether entries were made in more than one of the ten comment boxes offered. When a comment was categorized as multiple “unit comments,” the same comment ID occurs multiple times.

Five areas that need attention:

1) There is a need to identify effective methods to positively protected workers who are exposed to leading edge operations ie; precast decking, metal decking, wood decking. Many contractors currently use a Controlled Access Zone as their sole means for protection. While this may meet their obligation under the law it does little to protect workers from fall hazards. The issue is the surface material which often is not adequate to use as an anchorage. (light gauge metal decking will not support arresting forces). Additionally, non-movable anchorage connections seemingly prohibit worker movement as the leading edge progresses. Mobile anchorage connectors have been used (cast concrete deadmen with anchorage imbeds) but testing of such anchorages is non-existent.

2) In the residential construction industry a method of providing fall protection during truss setting and roof sheathing needs to be addressed. The issue is not having a sufficiently strong anchor point until trusses are properly secured. Limited testing on some products has shown limited use of trusses as anchor points (safety-strap) but more testing is needed. Perhaps technology can be used to further reduce MAF's below 900lbs and thus allow for the use of trusses as anchorage support.

3) There is a real need for a study on the cost effectiveness of fall protection. Many contractors view fall protection as a burden that will inhibit production. A study comparing multiple projects that use 100% fall protection (including the use of lifts) during all phases verses projects that only follow OSHA

guidelines would be helpful to safety professionals in convincing contractors that fall protection makes good business sense.

4) The post rescue of fallen workers needs to be addressed. OSHA requires it but little information is available on how to perform a rescue. Many contractors will use ladders, aerial lifts and manbaskets for rescue but most have no knowledge beyond calling 911 on how to go about safely rescuing a fall victim. Much information has been published on suspension trauma but only limited information on how to address it on the jobsite. A research program that can identify the methods to use for simple to complex rescues would be helpful

5) NORA has produced and currently is involved in research that is important to this industry. Unfortunately there is not a central location (at least not that i have found) where all completed research is published. If the individuals who would benefit the most from this research cannot easily access the information, the research, while excellent, is wasted.

Categorized comment or partial comment:

Once again, in giving a recent legal deposition, I wondered about what is being done with regard to insurance carriers and related activities. All too often, it seems to me, large corporations settle (out of court) occupational safety and health liability case without making suitable changes in the workplace. Why do they do this?

I suspect they do this because the underwriting is such that it is cheaper to settle than it is to improve workplace health and safety. Perhaps we need a renewed new effort to educate and train insurance underwriters as to what they should be considering when they set rates and provisions. In some cases, "loss prevention" programs have been cut, and few appear to be well staffed with well trained occupational health and safety professionals. Perhaps what we need is better informed brokers, rather than educational programs for customers.

Categorized comment or partial comment:

We are performing routine halogenated anesthetic waste gas exposure monitoring for Anesthesiology and other Operating Room staff. OSHA does not have PELs for the two halogenated gases that we use the most, Sevoflurane and Desflurane. NIOSH has an REL of 2 ppm for all halogenated anesthetic gases, which is widely used by health care safety professionals in several countries as the limit they want to keep their exposures under. This REL was developed in the late 1970's which was before Desflurane and Sevoflurane were even produced. What is really interesting is that the producer of Sevoflurane, Abbott Laboratories, uses an occupational exposure limit of 60 ppm over an 8-hour TWA at their factory. Our anesthesiologists' exposures and several published exposures for Sevoflurane have indicated that levels exceed the REL of 2 ppm fairly often. My concern is that we do not have OSHA PELs for Desflurane and Sevoflurane to use and that the only other published limits, the NIOSH REL of 2 ppm and the Abbott Laboratory limit of 60 ppm for Sevoflurane, are in such disagreement that we cannot determine an appropriate limit to compare our exposures to. I would like to see NIOSH develop specific RELs for desflurane and sevoflurane (isoflurane should be considered also) which hopefully would lead to specific OSHA PELs.

We need to design warm-up, stretching and flexibility exercises that can be used by workers in the different occupations to help prevent strains and sprains. This is especially true for repetitive injury and heavy labor type of activities. This could be used in any of the 8 categories above.

Residential Fall Protection - it has taken OSHA 35 years to get a safety handle on commercial construction, especially in the area of fall protection. It is my hope that it won't take another 35 years for the residential contractors. The industry badly needs ideas on how to work safely during stick frame construction, especially during exterior wall framing/installation and truss installation. Thank you, Garry.

Ground control is still the number one fatality problem. Whyatt and Iverson 2004 identified that burst prone mines have a four time greater risk for mortality than normal underground mines. This matches data from South Africa where the fatality rate below 2400 meters is three times the fatality rate of the underground gold rate.(Leger 1991). Coal and trona mines which have a propensity for having bumps would also have the same high risk factors for injury and mortality.

According to published surveillance from Jensen 2004, 70% of all injuries occur on the deck with upper and lower extremities accounting for 66% of all injuries. A 40 year study of Polish fisherman by Jaremin 2004, said boats less than 13 meters in length have significantly higher mortality rate. Therefore, one can conclude small boats which are usually independent operators have the biggest problems and most problems occur on the deck.

Partnership with a key player in each industry appears as the only valid way to conduct the research. The partnership brings credibility to any type of solution which government researchers might come up with because the solution can be tested and verified by the industrial partner. Other industrial non partners are more likely to adopt the solution if one of their peers has been part of the solution.

I think an area that has not been sufficiently addressed or evaluated is that of nutrition and the potential effect it has on injuries. Much research has been conducted showing a variety of injury factors but mainly machine-environmental based. In a study published in JOEM May/June 2003 by Huang and Hinze "Analysis of const. worker fall accidents" it was noted that most falls occur between the hours of 10am-11am and 1pm-2pm. It would be relevant to evaluate the extent that proper or improper nutrition has on how the worker makes choices, maintains balance, critical thinking ability, etc., to determine if poor nutrition has an effect on injury. Donuts and coffee for breakfast will no doubt affect blood sugar and may be a factor in many injuries.

Community-based Participatory Research (CBPR), education research and outreach is needed to be funded on a larger scale than before.

CBPR needs to be addressed and included as an important research method. Traditional university research has gone into the agricultural community, has done its research and left the community without much visible impact. CBPR has been shown to have a more positive response from the community.

The agricultural community is a diverse community and will only change slowly on any health and safety issue. But it has been shown that the CBPR creates the needed trust and knowledge necessary for the population in question to take charge and change from the ground up.

Scientific review panels need to gear up to review these kinds of proposals more favorably.

It is excellent that you are revisiting the original NORA topics. This action demonstrates your attention to the field and responsiveness to changes in the world of work. It is also nice that you are using web technology to collect input, but I hope that you will also use the "townhall" meetings for face-to-face interaction. Web based collection will certainly give a wider range of comments, but meetings will show the depth and intensity.

The sector structure is logical and inherent to the world of work. The different ways that people work cause different kinds of work problems. However, it is clear that there are a variety of cross-sector issues that do not fit well into the sector structure.

In particular, human factors, the person considered alone or in groups, clearly is a crucial element in workplace health and safety, yet it cannot be easily fit into a sector structure. Work organization, stress, interventions, education and training, economics, and communication basic and applied are historical topics of interest for NIOSH, yet in the sector structure, they must be subordinated or ignored.

I would strongly encourage NIOSH to create a new NORA topic on Human Factors that would operate at the same hierarchial levels as any sector and warrant the same resource and policy commitment.

Failure to include human factors would disarm NIOSH of one of the most powerful tools available for understanding and creating changes in workplace health and safety. The huge improvements in the workplace in the past 100 years and especially since the passage of key workplace legislation in the 1970s have come largely through hard science and engineering approaches. Less well understood and applied to the problem of workplace health and safety are human factors.

Consider this claim: NORA is a successful government program largely because of human factors. That is, the creation of NORA and its application as a program in NIOSH occurred through the skillful and continuing use of human factors like communication and education. If NIOSH had tried to "engineer" NORA, it could not have happened. If NIOSH had tried to lab test NORA, it would have never happened. NORA came about through human factors. It attracts funding support from Congress through human

factors. It generates industry and labor commitment through human factors. NIOSH needs to create a human factors sector in the new NORA.

I look forward to seeing the progress of the evolution of NORA and wish you success. If I can provide additional information, please contact me.

Home Health Care worker safety is an area about which I have found little to no research. Our employees work independently in homes which are frequently cramped and often impossible to set up in a manner appropriate to the care needed. They work with patients who have varying degrees of disability (from independent in ADLs to bedbound). We struggle on a daily basis attempting to determine the safest ways in which to provide the necessary care knowing that we are unable to refuse care in most cases. Even if we don't get bedbound patients out of bed, we are tasked with turning and positioning with a single employee to do the work. Our injury rates reflect overuse, awkward postures, and repetitive strain as well as specific incidents.

I would encourage you to consider research related to the provision of home health care.

I am afraid that with the sector approach we will lose the accomplishments and hard work that went into creating the 20 NORA-1 priorities. As you might expect, I have parochial interest in mixed exposures. Without a focus group for this topic, I really doubt that there will be a place for emphasis on this topic in the new structure. It would seem that somehow, the advances achieved by the NORA-1 teams should be captured better as a springboard for these NORA-2 program groups. That isn't evident in the current plan. I don't think we need to start NORA-2 from scratch. Let's make sure we use and incorporate the agendas that have been already created.

Categorized comment or partial comment:

Inhalation exposure to particulate, long accepted as a cause of fibrotic lung disease is increasingly recognized in the air pollution literature, both epidemiologic and mechanistic, to be a risk for inflammatory pulmonary disease as well as acute and chronic heart disease. Given the high levels of particulate exposures in various sectors (mining, construction, welding, transportation, and any industry that uses diesel powered equipment) this cross-cutting exposure deserves prominent consideration. It may also interdigitate with the nanoparticle issue.

Categorized comment or partial comment:

Musculoskeletal injuries and pain from patient handling continue to plague healthcare workers. Musculoskeletal disorders (MSDs) shorten the careers of registered nurses (and assistive personnel), leading to insufficient numbers of these knowledge workers at a time that the aging US population is increasing the demand for them. MSDs have a multifactorial origin. The current emphasis is on reducing physical load through the use of equipment, but psychosocial factors, such as stress, also contribute to pain and disability. The second decade of NORA should focus on this important problem.

Categorized comment or partial comment:

NIOSH has to be careful not to dilute the emphasis on the needs of special populations within the new sectoral organization of NORA for the second decade. I am particularly concerned with the emphasis on research about the health and safety hazards affecting immigrant and minority workers.

It would be important for NIOSH to make sure that all sectors where there is a significant participation of immigrant and minority workers in the labor force- such as the construction and service sectors- dedicate enough attention (i.e. money and human resources) to research the formerly called Priority Populations.

Although in theory there is no contradiction between the new organization of NORA and the former agenda for researching Special Populations, there should be a concerted effort from all NIOSH partners to make sure that these hard to reach, hard to study, but growing working populations are not excluded from future sector-oriented research programs and initiatives. Therefore, I suggest that all relevant sectors include Special Populations as a particular item in their research agenda.

One of the most pressing issues of workplace safety and health for farmers is locating the reasonable financial resources to fund changes. Many, if not most of the farmers I work with KNOW what the safety and health issues are in regard to the agricultural workplace. What they lack are practical solutions and funding. In addition, farmers with disabilities (especially with the graying of this workforce) need to be considered by the engineering, technological, and occupational health resources of our public/private/government organizations.

Respirator Protection

Construction workers need respirators for a variety of exposures over which they have little control- welding fumes, asbestos, concrete dust (silica). Often they are bystanders and can therefore not control ventilation, work practices, etc. Many go from one job to another. There needs to be a model for providing a respirator program that could be taken from one employer to the next. Could be provided by a union, contractor association, private party, etc.

Research should be done on developing and testing such a model.

Interventional studies for MSDs....see below, on cross-sector issues.

Editor's note: comment on cross-sector issues is reproduced below:

We were successful in getting large scale cohort studies listed at the top of the list in the first NORA session in Chicago. We then got those studies started and now are getting extraordinarily valuable results. The next phase is to get detailed data on interactions of risk factors for MSDs from Epidemiological studies. Immediately after that, will come the need for demonstration of successful multi/transdisciplinary intervention studies. The successful integration and addressing of psychosocial factors is likely to be a critical variable, in addition to both personal risk factors (e.g., DM, obesity) as well as ergonomic factors. The other issue is actual implementation of such research into the classroom, CE and into practice, which while r2p is working on it to some extent, we still have problems with the translation from research to practice/classroom settings.

Much as I like the speed of this approach and the ability of folks from numerous distant locales to participate, which is a huge plus, I still think that this sort of agenda development needs some face to face time in group settings to help think about problems and discuss them for a longer period of time than most participants are likely using going through this approach. I will use the example of cohort studies for MSDs in Chicago. Initially, it was not on the list at all. I suggested it be on the list, and then it gradually moved up the list as topics were discussed. I clearly have a biased view, but feel obligated to point out that I believe that that topic will have proven the most valuable of the topics from that agenda setting session if reviewed retrospectively in terms of total pubs and impacts in another 5-10 years. I would project that transdisciplinary interventional studies for MSDs would have a similar impact projecting into the future. Yes, there is more work to be done in so many areas (e.g., Infectious diseases, sharps, accidents/trauma), but MSDs cut across all work sectors.

Categories of care giver services are at risk for physical hazards such as lifting, sprain/strain, slip and fall, and assaults: for example, Home health workers, especially personal care providers; Residential care personnel for mentally ill and developmentally delayed, Non-nursing personnel such as recreational assistants, drivers, and respiratory services providers. There is little information and less safety and health enforcement for these workers. Research could focus on epidemiology of work related conditions for these groups and also on methods for effectively preventing injuries in these spread out and varied environments.

In my view, the largest risk facing workers is the lack of public and policy-maker concern about their safety and health (lack of resources, under-recruitment of motivated professionals, lack of public interest, low and often inappropriate media coverage, inability to create standards and improve policy, inability to enforce penalties, inability to prevent businesses from putting costs onto workers and the public, marginalization of the issue in public health, etc.)

We need more research to document the need for and benefits from investment and policy-making to protect workers` health and safety, and to evaluate current interventions and policies. While some of this research can be done sector by sector, some should take a broader scope. Unifying this work across sectors would really help to improve priority setting and coordination.

Categorized comment or partial comment:

I have concerns about incorporating the education sector with the services sector for several reasons.

1. We have found that K-12 schools are mainstreaming medically fragile students as well as students with severe emotional and social problems. As a result many workers in these schools are defacto healthcare/social services workers - they perform tasks that put them at risk of ergonomic injuries, infectious diseases and violence. Therefore, I advise that when there is sector overlap, education workers be considered in NORA deliberations for healthcare.
2. Communicable and infectious disease concerns are heightened for both education workers and corrections workers and again there may be an overlap with healthcare. Education and corrections institutions are more some of the most densely populated institutions in our society and we have not explored sufficiently the impact of infectious disease exposure on these workers - especially children of child bearing age (fifth`s disease, chicken pox-varicella etc.) and other vulnerable workers (diabetics, workers on chemotherapy etc.)

3. The education sector is somewhat like the healthcare sector twenty five years ago - the work-related exposures are ignored and not well studied. I would like to see more studies in areas that are crucial to these workers such as:

1. voice disorders - research indicates that teachers have a disproportionate rate of voice disorders - besides over use of the voice, we don't know what other factors may be contributing to this - indoor environment - inadequate air quality and/or acoustics? - it's anybody's guess.

They may share this problem with service people who are on the phone - reservationists etc. This is a critical problem because many teachers have to leave the profession involuntarily because they cannot use their voices adequately.

Do not swayed by the view or idea that NIOSH should move towards `private consultancy` of safety and health research.

This would be more harmful in longer term when compared with short term benefits.

Keep the NIOSH Mining researchers (health and safety) alive and well supported for their research proposals.

Going private consultancy has destroyed the South African mining research which is now trying re-build. Hope you don`t follow that route...

Safety Compliance has to be one of the greatest setbacks for the construction industry, Polluting our air, waters, land and workers, there seems to be no advocates for having the bigger companies comply with regulations and standards set out by the laws in this country. Safety Consultants are turning there heads and looking the other way in hopes of retaining there jobs which we may also refer to these people by the name of Yes Men, and the Safety professionals who are few and far between, that are there for the workers and the law, get blackballed from the industry in which they became a professional in. And also what about when a complaint is phoned in with a promise to investigate OH@S don` t show up meanwhile workers have been contaminated. Alot more can be said but its what can be done is what my question is. I think 8 years of being fired because you uphold standards and policies and without backup from the people you are actually working for is enough. Scared Yet? I seem to be the only one who isn` t.

Accomplishments from NORA-1 emphasize the public health relevance of studying workplace reproductive hazards. Since nearly 55% of children are born to working mothers, and 62% of working men and women are of reproductive age, there continues to be great potential for exposure during critical reproductive windows. Furthermore, only about 5% of 84,000 workplace chemicals have been evaluated for reproductive toxicity. It is important that NIOSH continues to promote and evaluate reproductive health issues in NORA-2.

Within specific industries and occupations, research should compare immigrant rates of injuries/illnesses/deaths to others.

Besides the hazards of particular industries/occupations, research should investigate what else causes higher rates of injury/illness/death: training, PPE, language barriers, etc.

What happens to health and safety as immigrants enter an industry?

What are the obstacles to having good health and safety conditions for immigrants:

In general

In specific industries

What policies, factors would improve immigrant health and safety?

Exposure to air pollutants emitted from building products and materials is a major concern. Installers of floor and wall coverings, roofers, painters, and other workers dealing with wet-applied products are subject to substantial exposures which later, usually at lower concentrations, affect building occupants. Research is needed on the emissions from building products and on alternative ways to protect construction workers. Building maintenance products are also a significant source of exposure.

Categorized comment or partial comment:

Indoor Environmental Quality should be a high priority for NORA2.

Indoor environmental quality, especially indoor air quality is a major concern that remains largely unaddressed due to the lack of regulation and, to a certain extent, the lack of knowledge about the exposures, the sources of those exposures, and the most effective means to control them.

We know that indoor air is the dominant concern among the public requesting health hazard evaluations. NIOSH should take the lead in developing a research agenda that places indoor air near the top where it belongs on the basis of public concern and an apparent real need for an enhanced understanding of the indoor environment.

People`s exposures to air pollutants are dominated by indoor air exposures, and in the indoor work environment, most people have little to no control over the air quality, ventilation, or sources of pollutants. It is well-established that the non-industrial indoor air exposures dominate people`s exposures to air pollutants, far more than in outdoor air. The service sector, office and retail workers, educators, health care workers, professionals of many types have little control over their exposures at

work in spite of the fact that these exposures can be substantial. this affects productivity and health care costs and should be an important NIOSH NORA priority.

NAICS 62549, I have found that there is a real need to help the residents of a community with their indoor air quality. Most people that are elderly, immunocompromised, pregnant, etc. do not have the financial resources to properly address their indoor environment with regards to microorganisms and VOC contamination. I would like to see more Community Development Departments, or an agency, offer some sort of financial assistance so these individuals so they can have their indoor environment inspected and if necessary sampled for contamination. We have done some pro bono work but, we can not afford to work for free either.

With indoor environmental awareness ever increasing, realtors need to be knowledgeable about what types of testing can be easily and affordably performed prior to the sale of property. Nobody wants to purchase another person's environmental issue. Simple sampling can be conducted that gives the prospective buyer microbial and chemical information about the structure prior to purchase. This may also provide some protection from liability to the seller down the road. If the structure is found to be devoid of various environmental issues at the time it is relinquished, and then a problem develops later, the new owner cannot falsely accuse or try to litigate against the previous owner since there is documentation to substantiate that the structure did not have that problem at the time of sale. Education about this type of sampling (e.g. fungi, bacteria, VOCs, toxins) is also necessary for tenants of condominiums, apartments, and public housing.

Workers manufacturing a variety of products are potentially exposed to materials of unknown toxicity, particularly through skin and inhalation exposures. The systemic as well as the local effects of representative agents of specific classes of agents (e.g. carbon nanoparticles, diketones, long and thin slowly dissolving organic fibers, etc.) should be investigated. Priority should be given to agents where workers, their physicians, or surveillance indicate exposure and unexpected disease trends, and where there is a paucity of data on the safety of these agents or close structural relatives. Laboratory studies should be a part of such investigations as they can reveal potential hazards where epidemiology studies are not possible and can help guide the design of epidemiology studies.

For many individuals in NAICS code 81 such as garage attendants and dry cleaning workers and in code 56 such as janitors the top problems are (1) inadequate health care due to lack of health insurance because of classification as "part-time" workers or because the employer is so small health insurance coverage is not mandatory and (2) lack of knowledge about the chemicals with which they work. The former problem is shared by others in this sector, particularly in code 72. Code 72 workers are most likely to be exposed to secondhand smoke at work.

For chronic diseases, particularly cancer, we need studies that document the links from exposure to disease. We need studies that collect enough information (biological and historical) on each individual so as to be able to attribute diseases to occupational exposures or rule out such attribution. Ambiguous results due to study limitations do not move the science forward or, in the case of occupational exposures that do lead to increased risk of disease, provide enough solid evidence to back up regulations increasing restrictions on exposure

Rogge Miller

Categorized comment or partial comment:

I hold memberships in the Environmental Education Foundation and the American Indoor Air Quality Council. I am involved in many types of indoor air quality issues but usually in the sense of finding and determining a remediation process for existing problems. This issue needs continual attention but another area we feel needs attention is prevention. One area where NORA could excel would be in the area of preventive IAQ inspections which would provide businesses a green light sticker for indoor air quality that would tell their employees their work environment was being scrutinized by the owners to ensure a safe environment. The investigation should include testing for particulates, volatile organic compounds, mold, CO₂, CO, and pressure relationships between inside and outside and specific higher risk areas within the building. Other areas can be added as needed. Once given the green light, results can be posted for employee review and a NORA IAQ certification sticker can be applied to the front lobby area. The certificate would be good for one year. Please consider taking a more active role in the IAQ of our buildings from a preventative standpoint. If our company can be of any assistance in this or other matters, please feel free to contact as at any time.

Sincerely,

Rogge Miller

Our understanding of the potential adverse health outcomes due to exposure to engineered nanomaterials, and the mechanisms underlying these responses, is essentially unknown. Basic toxicological studies need to be conducted to address this knowledge gap. This data will also contribute to later risk assessments of engineered nanomaterial exposure.

Inhalation exposures to agents, old and emerging, will remain a constant problem for workers in many industries. It is essential to conduct laboratory-based hypothesis-drive studies to identify the hazards, the levels at which agents cause disease, and the mechanisms involved in the etiology of the diseases, to protect workers from the threat of diseases.

Editor's note: The comments in the Construction section are reproduced below:

I am particularly concerned about the abuse and misuse of migrant/immigrant laborers (mostly Hispanic?latino) doing a variety of tasks without sufficient training or personal protective equipment. I have seen it in my community where stonemason work is being performed without even eye protection, much less hearing or hand protection. I have heard about it from some of the massive and deadly exposures to lead of transient (migrant/immigrant) laborers doing sandblasting of bridges for highway departments. I think that the exposure to a variety of problems in the construction industry, as experienced by largely untrained and unprotected (and not fluent in English, and certainly afraid to complain) hispanic (and sometimes others) is a crime. Even government entities are using these immigrant laborers.

I would be interested in research regarding how often young workers, age 13-19, experience workplace discrimination and harassment in this sector, and how such victims handle this occupational safety hazard, including whether most incidents are or are not reported to employers, parents, or appropriate government agencies. Many recent workplace discrimination claims filed by young workers involve severe and/or violent conduct, including, in some instances, rape.

Applying construction principles with indoor air quality in mind

Jeff Cavin, CMR, CIE, CMRPT, ASCS, RIAQM, WRT

Designers of modern structures give little thought to contributing factors of poor indoor air quality and the resulting health implications. Some of these factors consist of inadequate or improper drainage installation, HVAC design, or installation of roof flashing. Even though there are poor health repercussions associated with poor indoor air quality, consideration during design and construction of modern structures is minimal.

Drainage

Although we understand that water intrusion can be detrimental to structural stability and contributes to the proliferation of mold, amazingly, I often observe many if not all of these contributing factors on inspections. Improper land slope, downspout installation allowing water to stand next to the foundation, French drain construction, drainage of HVAC condensation lines, and installation of vapor barriers are usually present.

By applying principles for better drainage design, we could possibly eliminate some of the major causes of water intrusion. In turn, we could significantly reduce the potential for poor indoor air quality due to fungal growth.

The following solutions will dramatically reduce the amount of water intrusion issues discovered during inspections for mold.

Sloping ground away from the structure or in an instance where this is not possible, installing strategically placed ground drains to carry the water away from the structure minimizes water intrusion. Also, installing gutter drains that will carry rain water away from the structure and French drains complete with clean outs are procedures conducive to water intrusion reduction. Furthermore, connecting condensation lines with existing drainage lines and installing vapor barriers so water vapor cannot penetrate the structure during the evaporation process are other strategies implemented to reduce the intrusion of moisture.

HVAC Design

Designing air handling systems in accordance with ANSI/ASHRAE standard 62.1-2004 offers solutions for indoor air quality relating to HVAC systems design while adhering to local, state and federal building codes. Further, HVAC systems without the use of internally insulated ductwork or fiberglass duct board are less susceptible to fungal growth.

Flashing

Implementation and enforcement of strict building codes significantly reduce the chances of water migration through roofing systems. Governmental officials need to organize contractor licensing committees to increase construction competency for industry professionals and inspectors.

Moisture

After the building is closed in, many contractors recognize the benefit of drying down structural framing material. This assists in preventing conditions conducive to fungal growth. By lowering the moisture content of the framing members below 20 % and relative humidity below 50%, structural drying brings structural material out of the optimal range for mold growth.

There are a myriad of other factors contributing to poor indoor air quality. However, the preceding factors, if eliminated, would considerably lower the chances of poor indoor air quality.

The German Statutory Accident Insurance (BG) based on a sector structure is very successful with research related to sectors and branches. About 37 percent of BG-research projects in 2003 were sector projects. A considerable percentage of the others was primarily initiated in one sector and then generalized to cover more sectors. We learned from our experience that employees and employers are more interested and get more involved in sector projects than in general projects. So, the priority of projects with co-workers in industry and commerce is always classified as very high in our approval system because the achieved solutions can be tested and verified by the partners. This principle facilitates the adoption of solutions by all stakeholders. A common language and a specific technical terminology can often be identified as the key to success of sector projects.

Thank you for the opportunity to provide a comment. NIOSH has been a national leader in hearing conservation (HC) education/management. One area within HC where guidance/standards are almost non-existent is Fitness for Duty Evaluations - how best to make recommendations on a persons ability to function in a given work environment that has hearing loss. How much hearing loss is too much? There has been some work in this area mainly with police/firemen but more objective testing along with guidance would be money well spent.

Noise continues to be a chronic exposure issue across manufacturing, construction, mining, and other workplaces. We rely on hearing protectors to save hearing, but the analyses used to determine the attenuation and level of protection they provide are fraught with problems. Research should focus on how to make hearing protectors that are better embraced by noise-exposed workers, and how to determine how well those hearing protectors actually work on the people who use them.

The sector approach seems to make sense for R2P at first, but there are serious practical issues. The manufacturing sector is so diverse from an exposure standpoint that it should be subdivided. A proposed subdivision could be as follows:

Food and beverage;

textiles, apparel and furniture;

primary metals, machines, equipment, and motor vehicle manufacture;

chemicals, rubber, plastics and pharmaceuticals;

concrete, clay, and glass;

computers and electronics.

In addition, emerging hazards and exposures deserve new research that will not come out of a sector by sector approach.

A dual NORA approach may be needed: sector by sector to implement what we already know, and a focus on key exposures to promote new or additional research in the most important areas.

NIOSH should look at old NORA program and continue with what worked well and what makes sense to continue. The rest can be discontinued and replaced. The new program should build upon and supplement rather than completely replace the prior program.

The goal of R2P is admirable and a sector approach may make sense for that, but NIOSH should not abandon the focus on new research. In particular, a focus on musculoskeletal disorders makes sense in light of the fact that about half of workplace injuries and 2/3 of workers compensation costs involve soft tissue injuries.

Research on the effect of early education about workplace rights and safety on youth. In particular, are recipients of such training/information better equipped to respond appropriately, if necessary, to discrimination, harassment, and/or dangerous work conditions? Are teens likely to share this information with others: family and friends, co-workers and employers, and (eventually) subordinates? Are these teens less likely, in the future, to discriminate against or harass others, or to expose others to dangerous work conditions?

A cross-cutting issue is "solution resources". While a research agenda is being developed, we should be careful to not "reinvent". Much excellent work is now available from international colleagues, especially accomplishments in small-scale industries and the unorganized sectors. As "small business" becomes a more dominant component of each US sector, I urge that we learn lessons from these international colleagues. We may need research in the efficient application or the evaluation of applications to US workers/workplaces.

Advances here among small businesses may have application across sectors, and internationally.

Transition to NORA-2

Feedback from the NORA1 Reproductive Health Research Team

September 29, 2005

1. How can Reproductive Health Research continue into NORA 2?

o RHRT topics fit most directly into the Cancer, Reproductive, Cardiovascular, Neurologic and Renal Diseases Cross-Sector program (Terri Schnorr and Doug Trout manage this program).

o Hazardous Drugs activities may fit into the Healthcare Sector.

o The team's MSDS activities may fit into Chronic or Communications Cross-Sector programs.

2. What are the legacy issues/activities identified/started by the team that need to move into the future?

o Many of the team's general recommendations for occupational reproductive research are contained in its Reproductive Agenda and NORA@9 papers.

From the Reproductive Agenda paper (Lawson CC, Schnorr TM, Datson GP, Grajewski B, Marcus M, McDiarmid M, Murono E, Perreault SD, Shelby M, Schrader SM. An occupational reproductive research agenda for the third millennium. *Environ Health Perspect* 2003; 111:584-592.):

o Prioritization of research needs

-- New toxicology studies should be prioritized based on chemical structure and volume of use.

-- Field studies should be prioritized based on toxicologic studies combined with human exposure information.

- o Research results should be communicated to the policy makers and affected public through widely accessible, nontechnical reports and summaries.
- o Improved communication among research disciplines and should be encouraged through
 - Interdisciplinary research protocols
 - Organized collaborative teams
 - Shared scientific meetings/workshops
 - Dissemination of results to wider audiences.

From the NORA@9 paper (Lawson CC, Grajewski B, Daston GP, Frazier L, Lynch D, McDiarmid M, Muroso E, Perreault SD, Robbins W, Shelby M, Whelan EA. Implementing a national occupational reproductive research agenda: Decade one and beyond. Submitted for publication, 2005):

In this report, we describe progress made in the last decade by the RHRT and by the others in this field, including prioritization of reproductive toxicants for further study; facilitating collaboration among epidemiologists, biologists, and toxicologists; promoting quality exposure assessment in field studies and surveillance; and encouraging the design and conduct of priority occupational reproductive studies. This paper also describes new tools for screening of reproductive toxicants and for analyzing mode of action. We recommend considering outcomes such as menopause and latent adverse effects for further study, as well as including exposures such as shift work and nanomaterials. This report describes a broad domain of scholarship activities where a cohesive system of organized and aligned work activities integrates ten years of team efforts and provides guidance for future research.

o Pesticide prioritization NIOSH internal RHRT members plan to conduct an expert panel in FY06 to prioritize pesticides for reproductive research. The purpose of this NORA team project is to prioritize qualitatively ranked pesticides on the basis of overall risk of human reproductive toxicity, taking into account usage and exposure information. The team has previously been involved with prioritizing chemicals considered reproductive toxicants by the National Toxicology Program. With the help of an expert panel, a short, qualitative list of the highest priority chemicals was published (Moorman et al., *Reprod Toxicol* 2000; 14:293-301).

o RFA to Office of Extramural Programs for reproductive studies of priority toxicants and/or pesticides: Based on the prioritization of NTP reproductive toxicants described above, the NORA team sponsored several successful RFAs for occupational reproductive health effects research on prioritized chemicals. Internal NIOSH RHRT members are interested in using the results of the pesticide prioritization expert panel to develop a similar RFA for occupational reproductive health effects research with prioritized pesticides.

o Material Safety Data Sheet (MSDS) writing for reproductive hazards: Several RHRT members are planning to coauthor a publication to develop elements of the team's session on MSDS writing at this year's Society of Toxicology annual meeting.

o MSDS working group: Team members were interested in holding a meeting on MSDS writing for reproductive hazards, possibly leading to a more generalized working group (e.g., similar to that for Hazardous Drugs). This plan could not be carried out within the RHRT's lifespan, but would be a useful contribution to occupational reproductive health with relatively minor resources.

o Continue nominations of potential reproductive toxicants for expert panel evaluation to the Center for the Evaluation of Risk to Human Reproduction (CERHR).

o Encourage communication/awareness of occupational reproductive hazards during the preconceptional period. Two team members who attended a recent CDC conference on this topic alerted the team to increasing interest in this area. This objective was removed from Healthy People 2000 because its success was not readily measurable. Preconceptional attention to workplace exposures should become part of the ERC curricula. The team recommends that occupational issues be kept on the radar of the CDC groups interested in this topic by representation in any meetings or working groups which are developed. Ultimately, to make a difference in primary care, managed care organizations and the US Preventive Services Taskforce would need to engage in this issue.

o Team members were somewhat dismayed to see a large number of cross-cutting sectors and emphasis areas which incorporated a number of NORA1 teams, but no individually identified opportunities for reproductive health. One possible remedy would be an annual meeting of reproductive epidemiology and toxicology contacts from EPA, NIOSH, NIH, NIEHS, CDC, FDA, USDA in which each contact paid their own way and one agency hosted the meeting each year, with a subcommittee to plan an agenda of interest to all. The recurrent theme could be the national research agenda, and include updates on what's going on in each agency.

The National Agricultural Safety Database (NASD) is a valuable resource for researchers, educators and practitioners involved in agricultural health and safety. Because of the importance of NASD, I feel that those who rely on the database as a resource would benefit by having it moved and funded within NIOSA as a whole. I am concerned that in its current setup NASD is dependent on the ability of a Regional Ag Center to successfully compete for resources. I want to clarify that in no way do I feel the Southern Coastal Agromedicine Center is incapable of maintaining NASD, and in fact think that they should continue to take the lead in maintaining the database. However, I do think that NASD would benefit from all Regional Ag Centers participating in maintaining, upgrading and enhancing the database.

Occupational injury/illness surveillance, particularly in relation to chronic illness conditions, and linkages to interventions. We need to better understand what are the most useful metrics and techniques for tracking trends, adjusting for under-reporting, identifying emerging conditions, standardized metrics (such as the occupational health indicators project), and effective ways to intervene on growing and emerging conditions. These could be used in concert with systematic exposure surveys (such as regularly scheduled NOES).

I would like to see more focus on catastrophic injuries as part of the research agenda. This crosses all sectors. Loss of an eye or limb is catastrophic, but my particular interest is in seeing more focus on research addressing the prevention and treatment of neurotrauma - brain and spinal cord injuries. These are the most costly injuries to the individual and society.

I have a workers compensations case ongoing since 1984, for stress and injuries due to toxic chemical exposure. I have written to OSHA on several ocasions as well as some phone calls to inspect this chemical with the number 8493001, containg 16oz., called trichlofluouroethane as I learned from Dr. Halderman, a workers compensation doctor. The can did state "vapor Harmful" but when I complained by filing a grievance and verbal concern to my supervisor when she asked me why was I stressed I received know reaction from them or OSHA. I have been diagnosed with respiratory problems, toxic encephalopathy, toxic peripheral nueropathy, reactive airway desease. I have been declared totally disabled by social security and I receive long term dis. as well as life time medical, but know settlement or personal injury was filed. What other rights do I have and what can you do to stop the use of harmful chemicals on the without training or instruction. I have recently spoken to Mark, manager, at OSHA for records from my job of deaths and injuries but there was know report given them in regards to my case. What can my health results be in the future? Is this a slippery slop? Thank you,

The proposed, court-imposed OSHA standard for hexavalent chromium (as Cr), could be a significant impact in many settings where welding of stainless steel is performed. My main concern is the "one standard fits all" approach, wherein every form of hexavalent chromium is considered equivalent in terms of exposure limit (and by inference, health risk). In other words, the health benefits and risk reduction for a lower Cr PEL in say, electroplating, are assumed to apply to stainless steel welding, even though the chemical form of Cr (acid mist vs. particulate fume) is quite different.

The assumption that all forms of CrVI have the same type, location and severity of health effects as say, chromic acid, can--if unfounded--lead to overly conservative standards. I would like to test that assumption. I believe we'll find that chromium compounds will have a spectrum of health effects, in the same way that research has shown different forms of asbestos have vastly different long-term health risks [By the way, asbestos toxicity is another topic for research and standard setting].

In summary, I would like to see a `reality check` on the toxicity of CrVI compounds to categorize them in terms of health risk. This would require research that provides data to show whether there is a significant difference. This information should be provided to guide funding for control strategies and impact the standard-setting process to logically tailor the PEL to reflect the different health effects and feasibility of controls.

I am hoping NIOSH will do more research on the difference between patient safety and safe patient handling for bariatric vs. non-bariatric patients in LTC and acute care.

With 12 years in this area, I know without doubt, that bariatric patients are risky more for their body mass distribution than for overall weight, and require a distinctly different set of practices and device. I hope you will do a study on this.

The greatest area of need for our profession is training the next generation of qualified Occupational Health and Safety Professionals. The numbers of students in Masters programs at ERC is down.

I think a major focus area that needs to be addressed is how to get qualified students into Occupational Health and Safety.

I teach at ECU, which is the biggest program and the considered, the best. At ECU recruitment is constant. We will recruit waiters, delivery people, etc. We love our field and thoroughly enjoy talking about our career. When talking to students we stress the variety of careers available, the exciting career the number of jobs available, the opportunity to make a good living and the opportunity to go to attend graduate school in industrial hygiene for free.

The biggest problem with recruiting is that people do not know who we are or what we do. Once they find out or become involved in the field they love it.

- Have Introduction to Environmental Health Science or Introduction to Occupational Health Science fulfill a General Education Requirement

* ECU has two half semester classes that have over 200 students in each

- Develop a relationship with the Biology, Chemistry, Environmental Science and Physics professors at your University

* ECU gets a number of new EHS majors from Forensic Science

- Develop a relationship with local community colleges

* Biology, Chemistry, Environmental Science and Physics majors

- ECU has developed a DVD/Video on what EHS is

- * Send copies of the video to local community colleges
- * Send copies to local science teachers
 - o Middle school science teacher
 - o High school biology, chemistry and physics teachers
- ECU has developed a self scoring questionnaire for students to utilize to see if they would potentially like EHS as a career
 - * Send copies of the video to local community colleges
 - * Send copies to local science teachers
 - o Middle school science teacher
 - o High school biology, chemistry and physics teachers

As a Safety, Health & Environmental professional of 25 years experience, one of the areas needed is in the education of Management Professionals understanding the role of EHS professionals in the corporate setting. This was tried by The National Safety Management Society, under the heading of "Project Minerva", not one business school or undergraduate school would allow the EHS professionals to address the students? How can business & EHS professional work together, when they know nothing about each others contributions to the corporate setting. I would be happy to follow up concerning this concern with anyone from your organization, please contact me if you have any questions.

Thank you,

Patrick J. Brennan

I recently saw a presentation by "Safe Encasement" on a "biofilm removing coating" that reportedly passes ASTM mold resistance tests without a pesticide/fungicide additive. The secret was an anatase form of titanium dioxide that forms a photocatalytic surface, producing oxygen and hydroxide (OH) radicals in the presence of UV light to oxidize all things organic. Presumably, the product prevents future mold growth by destroying both the mold and its food source. I don't have any experience with the ASTM testing, but the supplier also offered results of tests they had arranged. I was not quite as impressed as the presenters by the test results, primarily because I didn't see any comparison to traditional products or placebos under similar conditions of natural or artificial lighting.

However, because of the promise of such a material in a variety of settings--restaurants, hospitals, locker rooms, restrooms, etc.--I would like to see results from more definitive testing, either through literature review or NIOSH funding for a MS or thesis project somewhere (e.g., at the University of MN).

The primary problems in education include indoor air contamination, including the lack of intelligent and enforceable standards. The contaminants of concern include mold -- but other issues are important, such as the use of appropriate cleaning substances and the use/abuse of pesticides. On the horizon is the spectre of infectious disease, always a problem at some level, but avian flu may present a new and special problem.

Behavior-based safety programs have spread like wildfire, but I have been unable to find independent and objective evaluations of such programs. There has been no study that I have been able to find of the impact of such programs on reporting behavior. There is anecdotal evidence of a "culture of guilt" rather than a culture of safety being established. I have observed in at least one industry the use of "negative reinforcement" -- disciplinary procedures -- to discourage injury reporting. This flies in the face of BBS system advocates of positive reinforcement techniques. Effective, un-biased evaluation of BBS programs should be a top priority.

Research institutions such as those at universities face an increasing challenge in determining risk to workers in laboratories. Topics of concern include nanotechnology, emerging and mutating infectious diseases, experimental configurations involving electrical, mechanical or similar hazards and long term exposure to very low levels of various chemicals. Safety and industrial hygiene professionals who are familiar with the research laboratory setting will likely have many more examples. Many universities have limited resources including inadequate indirect cost grant funding and aging facilities that were not designed to accommodate these research related risks.

I believe that we need to seriously address personal health if we are to continue to reduce workplace injuries. Many injuries are directly related to poor physical conditioning. How many employees don't know their blood pressure, blood sugar, cholesterol, etc. We still have too many workers who smoke, drink too much, and use illegal drugs. These issues contribute to workplace injuries and illnesses. I recommend that health promotion become a major NORA initiative.

Healthcare is a very heavily regulated profession--JCAHO, HHS, and multiple state agencies are very prescriptive. However, rarely do these agencies address the need to recognize work schedule related sleep disorders. Reduction of medical errors is one of our nations greatest concerns; a great number of errors are likely do to healthcare worker sleep deprivation. It is also quite likely that employee health (including weight loss) can be improved with better sleep health.

Let`s not study and rework regulations for the sake of doing work. I believe a few pressing issues in industry are:

1.Hand held cell phone/blackberry usage while driving. I believe gov`t should issue a standard on banning/partial banning its use while opertaing a vehicle. The studies are there. We in industry are not responding to a ban or limited ban, etc. Therefore gov`t should regulate; the ROI is there in injury prevention.

2. Avian flu preparedness. WHO and NIOSH have come out with planning checklists, but most in industry need actual sample procedures, guidelines, etc.

3. Let's put money in where the return makes good business sense. Nanotechnology is a great buzz word, but OSHA and state compliance agencies will never get involved in nanotechnology implications. Here's another example. In WA. State there is a 2006 heat stress proposal for general industry. This is ridiculous waste of time. The people who possibly need heat stress regulations in WA State are in agriculture and this proposed reg does not apply to agriculture. I am a former compliance person with OSHA and am a believer in gov't oversight. Please help out in the two areas I have listed.

How prevalent/how severe is PTSD, depression, alcohol/drug abuse ("burnout") among health care workers, and what are the social and economic consequences of these problems in the workplace? Do these conditions contribute to increased sick time/high turnover/errors in patient treatment/employee shortages? What can be done to screen/prevent/treat/minimize these conditions in healthcare workers? Are other direct service occupations (law enforcement, social services, firefighters, etc.) also at higher risk and if so, what are the consequences? After Katrina we saw police officers committing suicide, health care workers in need of grief counseling. In a catastrophe these needs are, perhaps, predictable and understandable, but what about the every-day job stresses that healthcare workers, et. al., endure? As a registered nurse for 20+ years, I can say that from a personal anecdotal perspective, these problems are more pervasive, more widespread, more persistent, and more severe than is acknowledged, and growing worse. The emotional and economic price we pay as individuals and as a society is very high, and the hidden price our younger children pay when their parents suffer from these problems is also high.

Categorized comment or partial comment:

I'd like to suggest that research involving occupational musculoskeletal disorders (MSDs) be conducted within meat and poultry processing plants (311611 and 311615). For example, a USDA (FSIS) food inspector will perform between 1818 to 2100 hand motions per hour while inspecting poultry carcasses. Additionally FSIS issued a directive, 6550.1-Line Speeds for Heavy Young Chickens, in 1993, however FSIS management will not permit the IICs to enforce this directive. The inspection process involved with viscera trailing requires that the inspector use their left thumb to reflect the left fat pad of the carcass in order to adequately view the abdominal cavity of the carcass. The inspector's right hand is used to lift the viscera. The opposite hands are used when the viscera leads. As the carcass increases in weight, the fat pad also increases in weight thus increasing the force required to adequately reflect this pad. The rapid repetitive hand motion in conjunction with inspecting chickens greater than 6 pounds can result in serious if not permanent disability to the tendons and nerves in the wrists and hands of the inspectors and their supervisors, the veterinarians/IICs. From my experience when performing inspection of viscera trailing carcasses, the flexor carpi ulnaris muscle of the left hand is primarily affected, and the ulnar nerve may become involved due to the resultant tenosynovitis/tendinosis of this particular tendon/muscle. I have spent a great deal of time researching this problem, and have found that there has been little research performed in this particular environment. In addition, many poultry plant employees have suffered from MSDs while working in either the evisceration or further processing areas.

The following comment was recently submitted concerning increasing the line speeds in turkey plants:

RE: Docket number 04-033P, Allowing Bar-type Cut Turkey Operations to Use

J-Type Cut Maximum Line Speeds; FSIS Proposed Rule

The proposed rule's objective is to increase line speeds in establishments that use specific shackles in conjunction with the Bar-cut opening of turkey carcasses. This proposed rule states that the IIC can reduce line speeds when, in his or her judgment, the prescribed inspection procedure cannot be adequately performed within the time available because of health conditions of a particular flock or because of other factors. Such factors include the manner in which the birds are being presented to the inspector for inspection and the level of contamination among birds on the line.

This proposed rule states that the preamble to the final NTI system regulations explains that the maximum inspection rates in these regulations were established by work measurement calculations and were based on the amount of time necessary for an inspector to properly perform the correct inspection procedure (50FR 37511). There isn't any mention as to whether or not studies pertaining to the resulting musculoskeletal disorders (MSDs) of those who work on the evisceration line were performed or even considered. According to the January 2005 GAO Report, *Safety in the Meat and Poultry Industry, While Improving Could Be Further Strengthened*, states that some experts believe, for example that faster line speeds increase workers' risk of injury (page 4). Were baseline studies performed as to the safety of those who work on the evisceration line when these initial NTI regulations were proposed? If studies such as these were performed then why are they not mentioned? Who performed these studies, and when were these studies conducted? Where is the documentation for these studies? If indeed these studies were performed then what conclusions were drawn as to the inspectors' and plant employees' safety concerning the effects of this highly repetitive, forceful, and static position job task? Were baseline studies performed to ascertain at what level of repetition and force an inspector could safely sustain these hand motions so as to adequately inspect the turkey carcasses? Although OSHA's proposed Ergonomic rule of 2000 was never enacted, it does provide valuable information. Was this proposed rule reviewed to ascertain what detrimental effects might be encountered by the inspectors and plant employees? The proposed rule states that indeed those who work the evisceration line can perform the work, but it fails to adequately address and assess the cumulative, detrimental effects that this fast-paced task places on those workers.

As there is not any information available concerning the particular hand motions currently employed by FSIS turkey inspectors, I will assume that this inspection task is performed in a fashion similar to that performed on young chickens (I refer you to pages 15 and 16 of the Employee Development Guide, Revised 1990 and to pages 1 to 3 of the SIS Procedure guide of 1986). For young chicken inspection the inspector is required to use both hands to inspect each carcass. If this is indeed the case, then turkey inspectors currently are required to perform 1050 hand motions per hour for bar-cut opened heavy turkeys (> 16 pounds) and 1350 hand motions per hour for bar-cut opened light turkeys (< 16 pounds). This proposed rule wishes to increase these hand motions by 180 per hour, to 1230 for heavy turkeys and 1530 for light turkeys. Have studies been completed so as to determine what effect this increase in line speed will have on the upper extremities of FSIS inspectors and establishment employees?

The rule states that FSIS may realize benefits because the inspectors would not be required to perform this extra hand motion (required for bar type openings). It further states that the elimination of this extra hand motion may reduce undue fatigue among turkey inspectors. So to put this in perspective, for a bar-cut opening, FSIS inspectors are required to perform 1050 to 1350 hand motions per hour in addition to the aforementioned hand motions. This proposed rule will eliminate this additional hand motion, but will add 180 hand motions per hour, thus increasing hourly hand motions to 1230 to 1530 for heavy and light turkeys, respectively.

The proposed rule further states that no difference was observed in processed turkey attributable to line speed changes during the period of study, or between the test week and the previous week. FSIS concluded that establishment employees and FSIS inspectors are able to perform as well as they did using the slower, regulatory maximum Bar-cut line speeds. Again, what studies were performed to ascertain the effect of this increase in repetition on the upper extremities of those who work on the evisceration line?

FSIS increased line speeds for poultry in the mid 1980s. This increase in line speeds was in addition to the already highly repetitive nature of the assembly line work of the evisceration line. Both FSIS inspectors and establishment employees who work on the evisceration line have been adversely affected. Data from the Bureau of Labor Statistics (BLS) for 1982 through 1993 showed a dramatic increase in total illness cases due to disorders associated with repeated trauma, from 21% to 63% for all private industry. In 1994 BLS began compiling this data from specific sectors. At that time 65% of all illness cases in the poultry processing and slaughter sector (SIC code 2015) were due to disorders associated with repeated trauma. In 2000, disorders associated with repeated trauma accounted for 67% of the total illness cases within the poultry processing and slaughter sector. In 2001 data collection again changed within BLS so these particular figures cannot be followed. Industry contends that there has been a decrease in these types of injuries. However one must wonder about the validity of this statement upon reviewing the 2005 Wake Forest University study that contends that the number of work-related injuries may be underreported. Additionally the 2005 Human Rights Report, Blood, Sweat, and Fear, stated that even OSHA-supported research confirmed assertions that there is substantial underreporting of MSD injuries. According to a May 2004 memo from Dr. Barbara Masters FSIS costs alone for OWCP were 15.9 million in (FY) 2002 and 18.5 million in (FY) 2003 for work-related disorders. A breakdown of the particular injuries was not provided in her memo. Presently there are approximately 11,000 employees in FSIS, with approximately 8700 working daily in poultry and meat plants. Dr. Masters encouraged bringing these injured employees back to work, but there was not any mention of ergonomic changes to facilitate their permanent reentry. In fact FSIS has not addressed these work-related MSDs in its wellness program nor in its Health and Safety meetings. Presently FSIS employees are ignorant as to the debilitating and potentially disabling effects that increasing line speeds have on the muscles, nerves, tendons, joints, and ligaments of their upper extremities. There is no excuse for these omissions as FSIS was informed of these potential problems as recently as August and October 2004 but has failed to enact any safeguards for its employees.

The proposed rule further states that the IIC can reduce line speeds. Such factors as manner of presentation and contamination were cited as factors that an IIC can use when, in their judgment, the line speeds should be reduced. However, what concrete guidelines are given so that the IIC can make an objective decision, 50 percent of a ten-carcass sample, 75 percent? There aren't any. In fact in 1993 Directive 6550.1, Line Speeds for Heavy Young Chickens, was issued and it directs the IIC to reduce line speeds when carcasses are greater than 6 pounds. VIII A of that directive states "IIC's must adjust line speeds as necessary to allow for proper inspection of heavy young chickens." VIII A 2 (Responsibilities of IIC) states "Adjust line speeds according to the weight of the birds." Yet, there was not one IIC in the Jackson Mississippi circuit who could enforce that directive. In March 2004 when the District Manager of Jackson Mississippi was questioned as to how to enforce that directive, the IICs were informed that presentation and disease incidence would have to be considered when reducing the line speed, it could

not be based on weight alone. There's nothing in the directive that states that presentation or disease incidence must be considered. In addition there's not any objective criterion given as to what disease incidence should be used in such an instance. Reduction of line speed using one's judgment is precarious and subjective, and it will be called into question by establishment personnel. From experience it will result in an immediate phone call by plant management to the Front Line Supervisor or the District Office and the line speed will be mandated to be returned to its `normal` rate.

FSIS will also counter these arguments saying that the presentation tests could be used. Presentation tests are performed by both establishment and FSIS personnel. It is rare indeed for these tests to fail for two reasons. First, in most plants the arranger is stationed adjacent to the inspector so when they see the `tester` approach, they can easily arrange adequately to pass the twenty carcass test (10 inside errors plus 10 outside errors). After the `test` is recorded they can easily revert back to inadequately arranging the carcasses. Speaking to plant management at the weekly meetings does little if nothing to alleviate this problem. Second, these presentation tests are generally only performed by FSIS personnel twice a shift. If the FSIS `test` fails, plant personnel will immediately follow with their own test, and in my experience, the majority of these `tests` always `pass`. This holds true for any test performed by FSIS, such as prechill and post chill tests. In my experience it was rare indeed to ever see plant personnel `take control` of the line or even of a process unless FSIS threatened to `tag` the product.

Before this proposed rule is accepted, there are several issues that must be resolved. The first is a baseline must be established at which the inspectors and plant employees can work safely. Criteria must be established as to what rate of repetition and force (weight of carcass) is `safe` for the FSIS inspector and plant personnel. Next, studies must be conducted to ascertain what effect this increase in line speed will have on their safety? The third issue that must be resolved is at what level of disease incidence/contamination will the IIC be able to reduce line speed. Finally, presentation checks are relatively useless, and need to be re evaluated.

Sincerely,

Christina Dumas, D.V.M

Categorized comment or partial comment:

Approximately 15% of the work force is engaged in night or rotating shift work. New data suggests these work schedules can prematurely age the cardiovascular system (with increased heart morbidity and mortality and at an early age) and in WOMEN (nurses and air stewardesses thus are researched) increase the risk of breast, colon and rectal cancers. I am not aware of studies of male workers, for example, regarding colon and rectal or prostate cancer and these studies are needed. The question is do night and shift work schedules, which cause disruption of the body's circadian rhythms on a frequent basis, through the work life contribute to cancer -- not only in women but men. European animal studies and US epi studies on women suggest this to be the case.

Moreover, I am concerned about the role of rotating shift and night work on injury risk (relating to fatigue plus deficits in eye-hand coordination and cognitive functioning). In particular, more needs to be learned about the effects of night and shiftwork on men, and especially women particularly those who have responsibilities for young children or elderly-dependents -- who are essentially working double jobs and double shifts almost daily. Early small scale studies show such women are quite sleep-deprived and stressed with the possibility of negative health effects.

Research may include: Epidemiologic research and coordination of field studies of Wild Land Fire Fighters (NAICS 115310) for better identification and understanding of respiratory exposures to air contaminants such as particulates or carbon monoxide among others; development of respiratory protection practices and administrative controls for hand crews and fire camps based on air contaminant research; similarities and differences between structural fire fighters' exposures and wild land fire fighting; fitness standards and screening that account for the effect of underlying cardio-vascular health, conditioning and age; the impact of "stress" related to fire fighting on the development of cardio-vascular disease.

Submitted by

Kate Wood, Safety and Risk Unit Manager

Kathleen.M.Wood@state.or.us

Oregon Department of Administrative Services-Risk Management

With support of members of the Oregon Department of Forestry

Massive wild land fires have swept western states for the past decade. Increasing population in these same states has contributed to the need for aggressive fire management. More lives and high-value personal property than ever before are at risk of loss. The public - and public policy - calls for protection. Interstate Mutual Aid Agreements have created a virtual guarantee of fire fighting work from May through November each year. Continued population growth, high value property construction and continued fuel build-up in forested wild lands will result in this work continuing for many years to come.

The wild land fire fighters are often young and physically fit. The work is seasonal; jobs viewed as "temporary". But increasingly, anecdotal reports indicate this may be changing. If the workforce is returning to this work over many seasons, the effect of the intense, but episodic, risks may result in unanticipated disease development.

Wild land Fire Fighter safety practices and personal protective equipment have improved dramatically over the years. Most attention is focused on injury prevention. But the Occupational Safety and Health community may wish to attend to issues related to health conditions - specifically: do work exposures cause or contribute to the development of cardio-vascular and pulmonary diseases. Research may include: a better identification and understanding of respiratory exposures to contaminants such as particulates or carbon monoxide among others; development of respiratory protection practices and administrative controls for hand crews and fire camps based on air contaminant research; similarities and differences between structural fire fighters' exposures and wild land fire fighting; fitness standards and screening that account for the effect of underlying cardio-vascular health, conditioning and age; the impact of "stress" related to fire fighting on the development of cardio-vascular disease.

For western states, wild land fire fighting is an increasing issue for the safety and health management. Solid safety practices and worker health protection needs to be based on the best science available. Inclusion of these safety and health issues in the 2006 National Occupational Research Agenda will bring focus to the work being done by various groups. The populations that will benefit are primarily young and at the beginning of their working years. Many will move on to other careers, but many more will remain involved in the Forestry industry.

We have recently conducted a survey of tractors in Washington State. Over 500 farms were sampled across types of farming and asked for detailed information about their equipment. The results showed that tractors used in orchard/hops/vine crop farming had ROPS less than other types of tractors. This is due to the possible presence of overhead obstacles. The other significant finding was that less than 20% wore seatbelts regularly. I would recommend research funding into development of low-cost, feasible ROPS for tractors operated under overhead obstacles. I would also recommend research and education funding to the farming community on ROPS and seatbelt use on tractors.

The SHARP Program in Washington State has been working with the trucking industry to develop a systematic injury reduction program. As part of the background work we completed a survey of all trucking companies in Washington to assess the safety and health needs and priorities for the industry. Overexertions/sprains/strains were ranked as the number one injury of concern in the industry, followed by slips/trips/falls. The greatest areas of concern as they related to profitability were 1) fuel costs, 2) increasing costs of labor/workers` comp, and 3) finding and keeping drivers. This is a vital industry for our economy that has been hit with increasing cost pressures and high injury rates. I strongly recommend funding to work with this industry to develop feasible strategies to reduce injuries and implement interventions to help protect workes and aid the industry in reducing costs and keeping drivers.

I would like to thank NIOSH organizers of the Town Hall Meetings for including input from the Pacific Northwest as the occupational research agenda is designed for the next decade. I appreciated being a part of the discussion

My suggestion is that NORA include basic research addressing the latent health effects of fetal exposures to agrochemicals, metals and solvents. These low dose, chronic exposures may heighten susceptibility to diseases such as cancer, infertility, neurological disease later in life. The emerging area is termed "fetal basis of adult disease". Increasing evidence suggests that these exposures may contribute to heritable, transgenerational deficits. Some environmental agents, especially those with hormone-like activity may alter developmental programming and yield functional changes rather than overt malformations. The injury manifests later in life as increased susceptibility to disease. The mechanism proposed for this phenomenon is epigenetic alterations in gene expression, through abnormal methylation (silencing) of DNA. In some instances these exposures may result in persistent, heritable changes, affecting future generations by somatic and germline damage. Therefore, my recommendation is to examine in utero, low-dose occupational exposures for increased risk of cancer, infertility and neurological disease (epidemiology) and laboratory studies to better understand the molecular basis of injury.

Categorized comment or partial comment:

In discussions with beef producers and veterinarian dairy consultant working in the NE corner of Oregon and SW Idaho, the top injury and safety concerns stem from the interactions of human workers with animals and machinery. Moving animals, heavy equipment/tools/yard maintenance. Farm worker safety may be challenged by difficulties in human communication, long hours, personnel turn-over, harsh conditions and training that may or may not result in durable behavior changes. The lack of program review may contribute to complacency.

These topics are too familiar. They suggest a remoteness of the work site and poor accessibility to interventions that may be currently available through NIOSH Ag Center activities. So, my suggestion is to promote efforts to extend the safety message/interventions to the frontier districts of Oregon and Idaho.

Nationally, tractor and machinery related incidents account for the largest segment of agricultural work related fatalities. Research needs to focus on engineering controls and improved "system safety" design. Outreach programming should be implemented to increase worker training and education.

Tractor Overturns (both rearward and side) account for a significant number of occupational fatalities each year in agriculture across the US. These fatalities can be practically eliminated by the presence of a tractor Roll Over Protective Structure (ROPS). New tractors have these structures, while many older tractors do not. Retrofit ROPS kits should be installed onto older non-ROPS tractors.

Animal related events continue to be a leading cause of work related injuries across US agriculture. Animals have unique characteristics that result in unique safety hazards. Since animals (especially large) do not respond well to the typical guarding and shielding solutions for other hazard types, targeted research needs to look at this issue and possible solutions. Animal handling techniques should be explored that minimize the potential for injury, followed by investigation of more effective training methods for workers employed in the animal husbandry industry.

Migrant and seasonal worker issues in agriculture are not confined to one type and are often related to culture, background, and work history. Cultural diversity within the migrant population should be recognized in respect to research and programming. Farm workers in the US come from many different countries and include many varying languages. Often the non-Spanish speaking segments are overlooked in migrant safety and training activities. Workers from all represented countries, and additional cultures such as Mennonites and Amish, present unique issues and should be included in farm worker research topics.

Agriculture as an industry experiences one of the highest occupational fatality rates of any industry. Examination of these fatality events nationally, shows a predominance occurring to middle aged Caucasian males. Additional significant spikes are present in the very young and older populations as well - a uniqueness to agriculture. Research needs to correlate with the issues impacting the most workers and work related fatalities.

The National Health and Nutrition Examination Survey has provided invaluable population based data for researchers. With the addition of biomonitoring data this publically available data set provides a unique opportunity for researchers to test and generate hypotheses with sufficient sample size and a representative population. However, occupational data in NHANES is limited. I think a nationally representative cross-sectional study of worker across all industries covered by NIOSH would be a real asset to researchers, industry and the general public. Exposure assessment data could be combined with personal interview information to create an important data set specifically geared to address the needs of occupational and environmental researchers.

An area of research need that does not seem to be well addressed by NIOSH is in the area of exposure of agricultural workers to potential pathogens in the animal production environment. There have been some studies that indicate that workers on farms and in abattoirs are more likely to be colonized with potential human pathogens such as *Campylobacter* and other enteric organisms. These organisms that most likely arose from workplace exposure can lead to a source of infection for family and community members outside of the workplace environment as well. In addition, many of the pathogens that are present in the agricultural environment are resistant to the effects of many antimicrobial agents, which allows for a potentially bad problem (spread of pathogens) to get even worse (spread of pathogens that are resistant to treatment). There is a definite need to more fully understand the extent of the problem of workplace exposure to pathogens and better understand the ecology of pathogen transfer in the agricultural (and related) workplace. Additionally it will be important to understand what interventions can be done to limit the transmission of the potential pathogens from the animals to the workers in agriculture.

Could not find where to make a suggestion for Hearing Conservation concerns.

Currently we are testing at 500Hz and not testing at 8,000 Hz. A noise induced hearing loss does not effect 500 Hz but it might effect 8,000 Hz. Providing a quiet test environment is often difficult at 500Hz. If we were not required to test at 500 Hz, environmental attenuation concerns would be mostly eliminated, especially for mobile test facilities. I think the main reason we continue to test at 500 Hz is that OWCP and other Dept of Labor type compensation formulas require this frequency as part of the compensation formula. The question we should ask about this requirement is why? If Noise induced hearing loss doesn't effect 500 Hz, why is it part of the compensation formula? The only reason is to cut the employer some slack at the employees loss! In America, that is wrong, however, I'm reminded that OSHA won out over EPA action level recommendations that I think allow 20% of Americans exposed to 90dBA 8 Hr TWA using a 4 dB Exchange rate (not the scientifically proved 3dB ER) to possibly acquire NIHL. But I guess that is ok because corporations will also benefit from testing a 500 Hz. Bottom line, stop testing at 500 Hz and start testing at 8,000 Hz.

Noise induced hearing loss is a large concern in mining. The general population probably does more damage to their hearing at home than in the workplace. NIOSH should study the effects of non-occupational induced hearing loss, that manifests itself as an occupational induced hearing loss. Powered tools used at home, auto racing and extremely loud stereo music are just a few of the non-occupational noise exposures

I agree that the healthcare field is heavily regulated and it does not take care of it's own. No lift policies should be federally mandated. It would increase recruitment and retention. It would allow for the increased amount of healthcare workers needed to care for the aging population of patients. It would also protect healthcare workers young and older. Employers would have decreased costs and injuries.

Verbal Comment 2005/12/05: So good morning again. Actually now I'm representing another faculty member at the School of Public Health at Harvard, that's Robert Herrick, and he's asked me to present to you and present to NORA in terms of -- in terms of the town hall meeting today an unrecognized source of PCB exposure in the workplace.

We know PCBs are a set of persistent organic chemicals, and there's clear evidence that PCBs cause cancer in animals and they're considered a probable human carcinogen (sic), according to the United States Environmental Protection Act. The human and animal data provides evidence that PCBs have significant toxic effects on immune system, the reproductive system, the nervous system and the endocrine system. So -- so it -- we know of -- about its health effects for a long, long time.

But the four points I want to make today is construction materials to this day contain PCBs in substantial quantities. These PCBs can contaminate buildings and the surrounding soil. And occupants of these buildings can have elevated serum PCB levels. Removal of these materials in construction can -- can cause widespread contamination and worker exposure. This is based on a couple of studies that have taken place in Europe, primarily in German, Sweden and Finland. And they've demonstrated

relationships between PCBs in sealants, mainly caulking, and levels of indoor air and settled dust, as well as in the soil around the foundation of buildings containing these materials.

Now one source that's really hidden and it's probably in -- even in our own homes. I have an old 19th century home that I've been rehabbing and every time that you're peeling off the caulking, that caulking actually contains PCBs, and often it just drops into the soil next to it. And this caulking is used mainly when there's dissimilar materials, like brick next to concrete, or metal window framings and the like, and it often after time wears off and just falls into -- to the soil. And often there's workers that need to remove these materials -- or homeowners -- so there's tons of exposure to -- to workers involved in the removal of these sealants and the Finnish -- there was a Finnish study that looked at this. Mainly the grinding of old seams of -- of buildings, we've seen that a lot, exposes workers to high concentrations of PCB-containing -- contained in the dust of the -- of the grind material from -- from these sealants.

So they've done some bio-mark-- they've looked at serum levels of PCBs in these workers and find that they're about four times larger than a reference group and way above the recommended levels for PCBs.

This plays also a role in our schools and in our communities. One thing is -- is, you know, often in schools the -- the ground around the buildings are contaminated, and what we do know is there's also been measurements in these -- in these Finnish studies about the PCB levels next to the building. And you can see sort of an exponential decay as you move away from the building, and what we see is that you almost have to be almost two meters away, almost six feet away from the building before the PCBs in the soil are -- are below the federal guidelines for PCB materials.

So -- and this has been demonstrated in the United States, as well. There was 13 buildings out of 24 where the caulking had detectable levels of PCBs. Of these, eight buildings contained caulking that exceeded the 50 parts per million EPA criteria, in some cases by a factor of nearly 1,000 times the recommended level. And so these levels of PCBs in these materials are quite high.

I want to conclude with a story of a school in Westchester County, New York -- which is in between our two districts. And this was published in the New York Times. There was a school in Yorktown Heights. In what state health officials can call the first clean-up of its kind in the state, a school district in Westchester County is planning to remove soil next to the elementary school in Yorktown Heights because the soil is contaminated by PCBs from caulking in the school's windows. Dr. Daniel Lefkowicz* requested tests on scraps of caulk left after maintenance at French Hill Elementary School where his son Evan is a student. Tests found that PCBs at 350 times above the federal limit. So this is definitely an unrecognized source.

So let me in conclusion say that while EP regulations specify procedures by which PCB-containing materials must be handled and disposed, there is no requirement that material such as caulking must be analyzed for PCB content.

And finally, workers are removing PCBs with no precautions taken to protect themselves or to prevent environmental contamination.

And so with that, I want to thank you.

Problem: In the United States there is no performance-based certification for protective clothing for pesticide applicators. Testing and certification by NIOSH would allow individuals to select appropriate protective clothing based on the level of exposure.

Comments: PPE used by pesticide handlers is broadly divided into whole body garments and accessories such as gloves, respirators, masks, face shields and aprons. Performance-based selection criteria are available for the respirators and gloves. However, body garment recommendations are based on the garment design rather than the performance. In the last decade significant work has been done to standardize test methods and to develop performance specifications. For example, performance specifications for pesticide applicators are being developed by ASTM International and ISO. When approved, these specifications could potentially be used for testing and certifying protective clothing. It is proposed that NIOSH work closely with standardization agencies, researchers, and the industry to develop testing and certification based on the selection, use, care and maintenance of the protective clothing. As considerable work has been done on development of an online data entry and selection system, it is suggested that NIOSH review the current capabilities, and if acceptable, build on existing research in the area of PPE. It is envisioned that NIOSH certification would take a more holistic approach of testing and certifying protective garments and accessories.

Verbal Comment 2005/12/05: My name's Dave Madaras. I'm the President of the Chesapeake Region Safety Council, which is a local chapter of the National Safety Council. I'm a certified safety professional. I've spent most of my professional career in the construction industry. I've worked as a field laborer, carpenter, estimator, assistant project manager, corporate safety director and risk management specialist. My safety concerns result from more than 20 years of involvement in the industry. The construction industry employs approximately five percent of the working population, and it's consistently responsible for about 20 percent of the workplace fatalities.

On February 6th, 1995 OSHA's fall protection standard became effective. The Agency estimated the rule would prevent about 79 fatalities, 56,400 injuries annually. In 1992 the construction industry accounted for 275 deaths from falls. In 1997 falls accounted for 380 deaths. In 2001 over 400 deaths. Why is the number increasing? Is the standard flawed?

Why do accidents occur? Some of the common contributing causes as to why accidents happen are mistakes, absent-minded, risk-taking, fatigue, lack of concentration, didn't follow procedure, misjudged, over-exertion, shortcut, jury-rigged, careless attitude, et cetera.

Now the following is a list of the -- following is a list of effects of marijuana: Impaired brain function, relaxed inhibitions, confusion, fantasizing, memory loss, dulled attention, altered senses, exhaustion, disorientation, recklessness, poor judgment, loss of depth perception, lowered motivation and impaired coordination.

The Substance Abuse and Mental Health Services Administration conducted a survey of construction workers from the ages of 18 to 49. Twelve percent admitted illicit drug use in the last 30 days; 21 percent in the last year; 13 percent admitted to heavy alcohol use. Construction industry has the highest combined total of drug and heavy alcohol use, 15.6 percent for drugs, 17.6 percent for heavy alcohol. Most construction companies are small businesses. Small and medium businesses are where most substance abusers work.

Why have falls from elevations increased after the adoption of a new standard? Is there a strong correlation between substance abuse in construction and the industry's high fatality rate? Are falls from elevations the number one hazard in construction, or is it substance abuse? What's the best way to deal with the problem of substance abuse in the construction industry? What have private companies done to address the problem? What are some best practices? And is there hard data to support the best practice? What is organized labor doing about substance abuse with construction trades? How are the workers responding? Do they have best practices supported by data showing that they were successful with some of their -- their activities?

Just one brief comment. As a working -- during my period of time as a corporate safety director, sometimes one of the biggest challenges that I was faced with was conveying information to people, having them think it through and then apply it into the field. And a lot of times you look at what they do and you think why in the heck are they doing it that way? Would a logical person think through this and come up with the same conclusion? I can tell you from my experience, the substance abuse problem is enormous in the industry.

I heard a doctor one time talk about the workers who perform heavy labor, and he described them as industrial athletes. Industrial athletes that stay involved in an activity for a lengthy period of time, if they abuse their bodies with substances, will eventually break down.

So those are my comments. I appreciate your time, and thank you. Note: Verbal testimony provided to NORA Town Hall meeting in College Park, MD, 2005/12/05

Verbal Comment 2005/12/05: Good morning. My name's Katherine Kirkland. I'm with the Association of Occupational and Environmental Clinics. We deal a lot with health professional education, outreach, education to primary care physicians. And so one of the primary concerns that I am involved with is training of occupational safety and health professionals. And what has happened -- you know, we've got a couple of different models. We're -- we're still sort of looking at the traditional model of training. People are making some innovations, but right now I'm the executive secretary of another NIOSH group. It's a working group looking at the current NIOSH training programs and how they're functioning, what changes need to be done. I can't tell you what the conclusions are because we've had two meetings and haven't come up with a whole lot of answers yet, but a lot of questions.

One of the things that I think we need to do is to look at some new and innovative ideas and to get input from everyone who's currently working in the field. There's on-line case studies. There's some really great work being done in Europe by the University of Munich and the European Union looking at on-line training and how it can work with lower income developing nations who don't have the resources to put together a training program like our education and research training. Looking at distance* learning, we've all been looking at that. I don't think there's a single group of educators in the country, regardless of what their training program is, that aren't looking at distance learning.

But we need more. We need each sector that is part of this NORA training group to kind of look at what they're looking at and say okay, what are our training needs? What -- what sort of occupational safety and health professionals do we need to carry out the work that we are doing? We're looking at all these different fatalities, we're looking at injuries, we're looking at prevention. What are our training needs? What sort of people do we need coming through? And I'm looking at -- you know, what's working? You

know, we've got a lot of people coming through at various professions, but are they trained the way they need to be trained when they hit our field, when they hit your particular group? You know, are you getting what you need to out of the training that's currently existing?

And I'm talking about all the training needs. I'm talking about the occupational physicians, the nurses, the industrial hygienists, the safety professionals, the psychologists, everybody. Are their fields that we should be training that we're not training?

So I'm not up here to give you any answers. I'm up here to ask questions. And I think that in order to do this we need input from all the NIOSH stakeholders. We need all of you to be thinking about, you know, what are your needs, and give them both to the NORA -- and at this point, you know, I'm perfectly willing to take questions and comments about what -- what you think are needed so I can take it back to the occupational working group.

And I'm real simple to reach if you have any ideas for me, as well as for NORA. My e-mail is kkirkland@aoec.org, or just send them to the NIOSH -- you know, to John Howard's e-mail address. I'm sure he'll send them on to me. Thank you. Note: Verbal testimony provided to NORA Town Hall meeting in College Park, MD, 2005/12/05

Verbal Comment 2005/12/05: Thank you. Good morning. I appreciate this opportunity to describe the need for ongoing research regarding mental health issues in the workplace. As a mental health professional I've heard numerous complaints from individuals about the impact of stress on their ability to function and aggravating their underlying disease.

In preparing for today I spoke with a number of colleagues in the northern Virginia area regarding what job stress or complaints their patients were experiencing, and the following were the responses I received: A lack of flexibility by management, especially in the service industry, regarding child care and transportation issues; perceived lack of empathy by management regarding the effects of mental illness on job performance by government service workers; under-utilization of their skills and being bored as having chosen a less stressful occupation due to the severity and reoccurrence of their illness; an increase in workload without due compensation and the unvoiced expectation by management that this is acceptable; difficulty navigating the insurance and short-term disability system, and not knowing how much to disclose to the employer and peers upon returning to work; ineffective interpersonal communication with management, especially when receiving a punitive attitude to mistakes; and not obtaining treatment due to concern for job loss when working in the corrections field, but especially in this area, for fear of jeopardizing one's security clearance.

Mental illness is on the rise worldwide, and one of the leading causes of disability in North America. The global burden of disease study unveiled that mental illness, including suicide, accounts for 15 percent of the burden of disease in the United States, which is more than the disease burden caused by all cancers.

Mental disorders are common in the United States and internationally. An estimated 22 percent of Americans ages 18 and older, which is about one in five adults, or 44 million people, suffer from a diagnosable mental disorder in a given year, with less than a third receiving treatment.

The cost of mental illness in both the private and public sector is -- is -- in the United States is \$205 billion; \$92 billion is for direct treatment costs, \$105 billion is due to low productivity, and additional \$8 billion results from crime and welfare costs. It costs another \$113 billion annually for untreated and mistreated mental illness to American businesses, the government and families.

Despite these statistics, there are some U.S. employers who have been cutting back on mental health services as a means of cutting costs, with an eight percent reduction of employers offering mental health benefits from 1998 to 2002. This results in an increased cost for the organization or society as a whole.

For example, there was a Connecticut corporation that made a 30 percent cost reduction in mental health services, which triggered a 37 percent increase in their medical care use and sick leave by the employees who used those mental health services. Health plans with the highest financial barriers to mental health services have higher rates of psychiatric long-term disability claims compared to companies with easier access.

And lack of access to care results in increased substance use and incarceration rates. Correctional facilities which now house a large proportion of the severely mentally ill who don't have a place to stay - the cost of correctional facilities is four to five times higher than community-based treatment of mental illness.

There continues to be stigma and discrimination regarding mental illness despite scientific research supporting the biologic nature of these illnesses. There is a substantial proportion of Americans who view mental illness as a self-induced weakness, thus not seeking treatment. At times the person does not even have the awareness that they are ill, and this is part of the neurochemical changes that happen in the brain from the illness.

If mental health treatment is delayed, there is decreased productivity, greater absences and longer durations of disability. It impacts not only the individual, but their coworkers around them who have to compensate for the uncompleted work. When individuals with mental illness return to work, an additional five to nine hours of time is needed from supervisors and coworkers to help them return to their previous level of functioning.

Current concern in occupational health is the effect of downsizing on the mental and physical health of employees. In the past decade there have been hundreds of U.S. businesses that have downsized in order to reduce costs and improve efficiency. A number of studies have looked at the effects of downsizing on those who remain -- a survivor syndrome, as they put it. Those survivors, especially those who were more directly involved with the downsizing process, either giving notices or losing a job and then being rehired, have been found to experience worsening mental and physical health, increased stress, increase in job insecurity or an increase in alcohol use.

Organizational factors that have been identified as negatively impacting employees' mental health are increase in role ambiguity, role conflict and lack of effective communication from management. Employee attributes have been negative affect, an external locus of control or perceptions that management is not being supportive or interested in them. These individuals tend to be less likely to accept organizational changes.

In conclusion, focus of ongoing research should include evaluation of effective ways of disseminating current findings, especially to management and policy-makers, to improve the mental health of all U.S. workers in all sectors. Ongoing scientific research is needed in the cause and effective treatments of mental illness, collaboration between occupational health, mental health, public health, advocacy groups, the insurance industry, labor industry is encouraged to educate the public about mental illness and encourage a business culture that promotes mental health. Of particular interest is the effect of the organizational restructuring and the mental health of aging American workers, who are more at risk for depression and the onset of chronic medical conditions.

I thank you for your time. Note: Verbal testimony provided to NORA Town Hall meeting in College Park, MD, 2005/12/05 Expanded written comments submitted as w4617.

Verbal Comment 2005/12/05: Good morning. I'm here -- my name is Jane Lipscomb from the University of Maryland Center for Occupational and Environmental Health and Justice. I'm here to support NIOSH's approach to the second phase of NORA by focusing on sector-specific research.

I'm strongly in support of the focus on health care and social assistance sector. University of Maryland Center for Occupational and Environmental Health and Justice has been conducting research in these sectors over the past six years, and I've personally been focusing on health care worker health and safety research for the past 25 years.

As many of you know, more than ten percent of workers in the United States are health care workers, characterized as people committed to promoting health through treatment of the sick and injured. Health care workers ironically confront perhaps a greater range of significant workplace hazards than workers in any other sector. Hazards facing health care workers include biological hazards, chemical hazards -- especially those found in hospitals, which include anesthetic waste gases, sterilant* gases, hazardous drugs, industrial strength disinfectants and cleaning compounds; physical hazards such as radiation and ergonomic hazards; violence, psychosocial and organizational factors.

Of great concern are the many health consequences associated with changes in the organization and financing of health care. The social service work force, although much more poorly characterized, is a source of exposure to many of these same psychosocial and organizational factors that impact health care worker health and safety. Research is desperately needed to begin to understand the risk factors and control strategies for preventing injuries among the large and diffuse social assistance work force.

In the limited time allotted here I will provide a brief overview of hazards and research needs associated with the health care and social assistance sector, while my colleagues, Dr. Johnson and McPhaul, will focus on the hazards of occupational stress and workplace violence, respectively. We will all speak to the need for support for intervention effectiveness research within these sectors.

In 2004 the BLS injury and illness rate among hospital workers was nearly double that for the overall private sector, and higher than rates for workers employed in mining, manufacturing and construction. Although injury and illness rates have been declining among all private sector workers, the ratio of hospital worker injuries to the overall private sector rate has increased over the past eight years.

The home health care industry, the fastest-growing segment of the health care, has rarely been the subject of occupational health and safety research. Risk for injury and illness found in the home care work environment are poorly understood. Hazard controls widely used in other health care work environments are often unavailable or infeasible in the home.

It should be noted that in health care, workers as well as patients are affected when occupational safety and health threats are not adequately identified and addressed. There is an inextricable link between staff safety and the quality and safety of client care. Physical or psychological injuries to direct care staff directly impact the quality of client care and client safety. Optimal staffing levels and staff performance are essential to providing high quality care. The quality of health care is severely compromised when staff become injured, and supervisors and administrators are required to replace experienced staff with new hires or staff assigned from other units and therefore unfamiliar with the clients' highly individual needs and behaviors.

Despite this, the health care industry is decades or more behind other high risk industries in its attention to assuring basic safety. And I think this link between health care worker health and safety and patient quality of care really requires NIOSH to continue to and enhance a collaboration between NIOSH and other agencies within Health and Human Services, and also with regulatory agencies.

Musculoskeletal disorders rank second among all work-related injuries, and the highest proportion of these disorders occur in health care. Among all occupations, hospital and nursing home workers experience the highest number of occupational injuries and illnesses involving lost work days due to back injuries.

In a recent survey of nearly 1,200 registered nurses employed across health care practice settings conducted by Trinkoff et al at the University of Maryland, nurses reported -- reporting highly physical demanding jobs were five to six times more likely than those with lower demands to report a neck, shoulder or back MSD. Our team has also reported that the risk of MSDs increased when nurses worked greater than 12-hour shifts and on weekends and non-day shifts.

The health care industry spends billions of dollars each year in Workers Compensation premiums, even though there is strong evidence that reducing back -- low back load by implementing engineering and

administrative controls such as safe staffing levels, lifting teams and the use of newer mechanical patient-handling devices reduces the risk of injury to both patients and workers.

The most prevalent and least reported and largely preventable serious risk health care workers face comes from the continuing use of inherently dangerous conventional needles. Such unsafe needles transmit bloodborne infections to health care workers employed in a wide variety of infections (sic). Eliminating unnecessary sharps and the use of safer needles can dramatically reduce needle-stick injuries. Use of conventional needles in the health care environment today has been compared to the use of unguarded machinery decades ago in the industrial sector.

Is that -- do I have a minute left? Let me just -- by saying the health care sector also leads other industry sectors in incidents of non-fatal assaults. Most research to date has focused on the high risk injury of -- high risk setting of psychiatric facilities, but we've done research and we really recognize the need for more study of this hazard in social service workplaces.

Dr. Johnson's going to provide testimony on the importance of occupational stress, but as a segue to his comments, and in conclusion I want to point out that many of the hazards that I've discussed can only be prevented by strategies which address the organization of modern health care work across practice settings. Support for rigorous intervention research targeting the impact of changes in the work organization on health care and social service work is desperately needed. Our experience in conducting intervention effectiveness research over the past six years has taught us that it must be done within the framework of community-based participatory research if the intervention is to be accepted and sustained.

I also urge NIOSH to recognize that the time involved in conducting rigorous intervention effectiveness research and to provide a mechanism for longer periods of research support to allow for this critical type of research.

Thank you for the opportunity to have a voice in the development of NORA 2. Note: Verbal testimony provided to NORA Town Hall meeting in College Park, MD, 2005/12/05 Expanded written comments were submitted as w4618.

Verbal Comment 2005/12/05: My comments are directed at multi-sectors, and I'm going to be talking about occupational stress and new forms of work organization.

Work stress is one of the most widely-reported occupational health problems in the United States, Canada and Europe, second only to low back problems. Large population surveys of the working population in these countries indicate that from one-quarter to one-third of all working people are experiencing serious levels of occupational stress. These surveys also suggest that self-reported stress is increasing, nearly doubling in the last decade.

Stress has been shown to have an enormous impact on health and wellbeing of workers across all industrial sectors. Recent studies indicate that from 50 to 60 percent of all lost work days are due to stress, and that stress-related disability claims are frequently the longest-lasting and most expensive. Although detrimental in and of itself, work-related stress also contributes to the risk of premature death and disability from serious chronic diseases, such as hypertension and coronary heart disease.

The United States continues to lag behind the rest of the advanced industrial world in terms of research and intervention efforts that target work-related stress. Most notably, we have failed to implement earlier calls to investigate the serious occupational health problem by undertaking the kind of nationally representative longitudinal cohort studies that have been instrumental in developing scientific knowledge on the causes and consequences of work stress in Europe, Canada, Japan and other countries, now including Korea and China.

Today there is an even more pressing reason to advance our knowledge in this area, for evidence acquired in other countries strongly indicates that the fundamental employment relationship, the social contract between employees and employers that has governed much of what occurs at work, has undergone a transformation in the past decade or more. According to many scientists, the emergence of an increasingly global economy is changing not only the workplace but the very life course of workers themselves.

The demands of firms for maximum flexibility has resulted in widespread precariousness for many employees. While the threat of job insecurity as an episodic stress is well known, the impact of chronic, even permanent, precariousness may be much more stressful. European research suggests that precariousness threatens the basic notion of career development, and has profound implications concerning significant life course decisions, including marriage, and even the decision to have children, which are increasingly delayed among those with precarious employment.

Precariousness as work organization exposure represents a fundamental loss of occupational self-determination and work control. Employees in precarious employment may be faced with overriding pressures to work longer, faster and harder, even under conditions of seemingly high levels of micro or task level control.

Precariousness can mean a fundamental loss of control over many of the most essential components of the employment relationship. Loss of access to a job, control over future earnings, control over work schedule, location, use of skills, et cetera.

And even more importantly, precariousness may have significant impact on the stress experienced by all workers, not just those in the contingent work force. Researchers suggest that when temporary workers are desperate to achieve targets that will secure their future work, they may violate protective practices, and even erode the solidarity of the community among permanent employees.

Perhaps one of the most fundamental questions we need to address now and in the future concerns how precariousness and other forms of work organization restrict or limit the possibilities for employees to have a genuine voice in the work organizations of the future.

Many research studies over the past 50 years have underscored the critical importance of worker control and genuine employee participation in occupational and organizational decision-making. But what is happening today? New forms of lean, high-performance, continuous-improvement organizations are being presented as the solution to the routinized, tailored and stressful work organizations of the era of mass production. These new forms of work organization involve practices such as teamwork that, while eliciting greater employee involvement, also involve an intensification of work performance.

Organizational restructuring in many industries, including the health care sector, has applied the Japanese production management design. This has involved increased responsibility and accountability for production management, increased problem-solving demands, increased peer monitoring, and increased role demands including a blurring of manager and worker roles. Is this management by stress, or simply the freedom to do an impossible job, as some observers have suggested? Or rather do these changes reflect a need for a flexible, high-skilled worker who will ultimately benefit from greater responsibility? We simply don't know.

Although there have been calls to investigate these new forms of work organization for the past decade or more, there continues to be enormous uncertainty and debate concerning the impact of these new forms of work on employee health and wellbeing.

To conclude, stress is one of the most important occupational health problems in all industries. We need much better scientific knowledge about the relationship between new forms of work organization and stress. Future research should specifically focus on two areas: The impact of precarious employment on worker health; and the impact of lean or high-performance work systems on stress health and the possibility of genuine worker voice. Thank you. Note: Verbal testimony provided to NORA Town Hall meeting in College Park, MD, 2005/12/05

Verbal Comment 2005/12/05: I'm going to talk about microbial hazards so I wanted to borrow somebody's glass of water. So my name is Lance Price. I'm from Johns Hopkins School of Public Health, and the faculty in my department, Environmental Health Sciences -- which also has the division Occupational Health -- asked me to come speak about the microbial hazards that people employed in the industrial animal sector are exposed to, and to make a plea for more research in this area.

So industrial animal production, you probably know it as, you know, thinking of CAFOs and AFOs -- concentrated animal feeding operations, animal feeding operations. In the U.S. we produce over nine billion animals every year for human consumption, and there are a large number of people employed in this sector. And some of the methods used to produce these animals put these employees at risk.

And so if you think about a normal poultry CAFO, that's a -- this giant barn that holds 25,000 birds, and during that bird's life, that chicken's life, they're fed antibiotics to promote growth, to control infections, but throughout their life they're given these antibiotics. That selects for this large population of antibiotic-resistant bacteria in these birds.

It happens in swine, and also in cattle, as well. And so it -- the union of concerned scientists estimates that between 60 and 80 percent of the antibiotics used in the U.S. are used for animal production. And a large proportion of those are used for non-therapeutic uses. So this is not to treat sick animals; this is to make them grow faster. And so that leads to a rapid selection of antibiotic-resistant bacteria.

Now if you look at the problem of emerging infectious diseases in the U.S., we see that last year over 20,000 people died of drug-resistant infections in the U.S. We have -- and the excess cost of treating

these infections are estimated to be between \$5 billion and \$30 billion. And now we have these drug-resistant infections -- drug-resistant bacteria that we're running out of -- we're running out of antibiotics to treat these things, so they're resistant to seven or eight antibiotics sometimes.

And so we're concerned about the people that are going in and being exposed to these animals on a daily basis. And when we go in and we do some monitoring inside a house, we find, not surprisingly, antibiotic-resistant bacteria everywhere. So when we look in the litter, we find antibiotic-resistant bacteria. There's published papers on this.

But recently Kellogg Schwab* and Amy Chapin* from our school started monitoring the air in these facilities -- in a swine facility -- and they found in every sample that there were drug-resistant enterococci, staphylococci. So you've heard of VRE, vancomycin-resistant enterococci. These are important medical -- or important pathogens.

And so we're concerned about the people that are going in and, you know, I don't know if you know how chickens are -- are brought to the slaughterhouse, but somebody goes in and actually catches these birds. And so these people are going in and catching thousands -- literally thousands of birds a day. And so besides the repetitive stress injuries that these people are facing, they're also facing risks due to the antimicrobial-resistant bacteria.

And some of our own studies -- we've started some studies on the eastern shore where 860 million chickens are produced on the Delmarva Peninsula, and we -- we are starting to see evidence that these -- that these chicken workers are actually -- have an excess risk of carrying drug-resistant bacteria.

So I want to talk a little bit about the different potential outcomes, so there is the obvious -- there is the obvious outcome of somebody could have a drug-resistant infection, say a respiratory infection, a GI infection, but also infected cuts, wounds, so you could imagine that you could get scratched a bit when you're out there catching these birds. But there -- we're also concerned about a carrier state, so some of these aren't frank pathogens, but these are bacteria that are part of our normal flora, and so we could be carrying around drug-resistant bacteria that then are just sitting in their resident -- residence in our -- in our normal flora. And then when we come -- when we go to a hospital and we're treated with antibiotics, they could become a big problem. And they could also be -- so -- so the employees of these -- or the people working in these facilities could be part of -- you know, become part of a -- the carriers that we're seeing in the community.

And just a bit of evidence, Dr. Myers* from the University of Iowa found that farmers -- swine farmers had a 35 times the risk of carrying swine influenza, so when we talk about avian influenza, that's a -- it's an important thing.

So what do we need? We think we need -- we need to know what's in the feed. What are the antibiotics? We don't know. The industry says that they don't have to tell us. We need active monitoring. We need to -- I mean these people -- not only their own health, but our health as a society, we need to know whether these antibiotic-resistant bacteria and -- and flus are moving from the animals to the people and at what rates? Do they become long-term carriers or are they short-term carriers?

I'm supposed to stop very soon. And so we need cohort studies, and we need to know what kind of protective devices to recommend to these people. Thank you. Note: Verbal testimony provided to NORA Town Hall meeting in College Park, MD, 2005/12/05

Verbal Comment 2005/12/05: I appreciate that. Good morning. My name is Kelly Castellan, and first I would like to say thank you for allowing the Center for Business and Public Policy to participate in this forum. On behalf of our Executive Director, John Mayo, I am very happy to be here today.

The Center was started as part of the McDonough School of Business at Georgetown University, with the hope of fostering dialogue and debate in several key areas including workplace safety and health. Over the past four years of our existence we have posted and participated in numerous events, and have been fortunate to get to know some of the true experts in this field.

I would like to share with you today some of the research needs that we have found in the course of those interactions, and I will share three research needs.

As a business school our initial approach to looking at workplace safety and health has been through an economic lens. While a great deal has been done to create an academically vigorous account of the business case for safety, more research needs to be done to establish this link. We here can all agree that work-- caring about workplace safety and health is the right thing to do. However, the truth of the matter is, that message is much more powerful to CEOs and companies when it's attached to saving hard dollars.

Enough research has shown that there is a positive link between spending on workplace safety and health and saving money on health care, lawsuits and many, many other areas to know that we need to find the exact extent to which these linkages exist, and the research needs to be done to do that. Also this research needs to be boiled into easily-digestible formats for CEOs and stockholders, whether their business is small, medium or large, so that they can use it to protect their workers in the best way.

Another area that deserves more research attention is looking at the relationship between workplace safety and health protection and promotion. Preliminary data suggests that companies that take care of their employees' health, anything from having a smoking cessation or weight loss program to simply ensuring that their employees have access to high quality health care, those companies also have employees who are more likely to be safer on the job. While powerful in and of itself, the preliminary data in this area needs to be expanded upon. Not only do we need to look at more companies in this area, but we also need to see the extent to which this linkage exists. And we need to include research topics such as employee turnover rates, absenteeism and many others.

We also believe this data will tie closely back to the business case for safety that I have already mentioned. If we can prove that a healthier cafeteria program can help employees not only stay safer on the job, but also save a company money in long-term health care benefits, we will have a powerful tool to go to CEOs with.

The last research area I will mention today is that of the organization's behavioral decisions that impact the safety and health arena. This is a wide area, and one that's somewhat difficult to get a good grasp on. It could include anything from scenarios such as examining a manager who pushes her employees to get a job done quickly, and thereby might necessitate that a few safety corners are cut. Is that manager more likely to get promoted for consistently coming in ahead of schedule, or reprimanded for sacrificing safety, even if no incidences occur?

Another example of a research topic in this area has to do with near misses. Georgetown University researchers have done work showing that many organizations, including NASA, can easily suffer from a near-miss bias. Essentially that means that it's easy for people and organizations to look at past experience as paramount to what they know to be factually true. For example, you might be late for a meeting while driving across town. You come to a very, very orange light. If you -- now if you've run through that light even just once or twice before and made it without getting hit or a ticket, you're much more likely to try it again. You can see how this bias would play out in the work force.

Organizations do, however, have the power to counter this tendency in their employees, to make them not run the orange light. But in order to do that, we need to know how, why and where the bias depends at all -- or where it develops, excuse me. By looking closely at how an organization's behavior impacts their safety culture, whether that culture is negative or positive, we will be able to uncover the best practices a company can use to ensure that valuing safety is imbedded in their organization.

I have just a couple of seconds left, and I'd like to -- I have one more quick point. There have been a lot of good attempts in the last ten years to get at good safety and health practices, and I think we can see a lot of progress made. We've used a lot of different ways to get at those safety and health practices. I think it's important to -- to note that a business perspective offers a unique way at getting at good safety and health. By allowing a business perspective to tackle this problem, we can show CEOs not only that safety -- the safety of their workers is the right thing to do, but it's also the smartest thing to do for

their company`s wellbeing. Thank you very much. Note: Verbal testimony provided to NORA Town Hall meeting in College Park, MD, 2005/12/05

Categorized comment or partial comment:

Verbal Comment 2005/12/05: Yeah. Hi, I'm Kate McPhaul from the University of Maryland, as Jackie indicated. And as a researcher and also practicing occupational health nurse, I wanted to talk a little bit about workplace violence, which -- according to the format -- is really a cross-sector issue, and is going to involve not only health care and social services, which is my primary focus and research interest, but would also cross into transportation, retail -- especially retail and service sectors.

I have quite a bit of data, and the issue of the epidemiology of workplace violence is fairly well established. The standard statistic that -- most recently that we have been using is that each year from

1993 to '99 there have been 1.7 million incidents of workplace violence or violence in the workplace, and many of these involve physical injuries.

But what I wanted to focus on today is the fact that now that workplace violence is no longer an emerging occupational hazard and much more established, unfortunately, we really need to focus on the barriers and challenges to implementing workplace violence prevention efforts, and to understand more what it takes at the level of individual workplaces to both implement and sustain this. So the lack of effective workplace violence prevention, intervention effectiveness data, and the overall culture of violence within our society presents sort of a formidable challenge to the prevention of this hazard in the workplace.

Generally, unless there's a tragedy, most employers are willing to allow the competing demands to take precedence over workplace violence. And in many industry sub-sectors such as health care, violence is imbedded in the workplace culture and considered part of the job. Regulatory solutions such as a standard, an OSHA standard that would require workplaces to institute effective workplace violence programming, would depend on solid cost and effectiveness data.

The workplace violence evidence base has broadened considerably in the last decade. But the basic information about situational environmental triggers, the characteristics of the perpetrators and the victims, and most importantly that conclusive data on effective prevention strategies, that's what's really lacking. For example, the true frequency of workplace violence, especially verbal violence, is just not known. We can't estimate the true incidence of violence directed towards staff by job title, by service setting, by client type, by time of day, that kind of thing.

Motivating employers, workers and policy makers to devote time and resources is made more difficult without these prevalence figures, especially those at the verbal threat end of the violence continuum. So there's a need to identify and describe successful management systems for tracking workplace violence and related follow-up actions. The systems really should be in place in all private workplaces, and may even be in place in many private workplaces. But because the information is considered proprietary, we don't actually have access to that on a national level, and that information is not shared. So we feel like NIOSH could include the development and testing of such tracking systems in its research grant programs.

All of the information -- not all of the information gaps represent gaps in basic research. Many elements of workplace violence prevention evidence base are available, but not widely or appropriately disseminated. For example, the definition of workplace violence is not universally understood by employers and workers, even though it's been published. And specifically, there's widespread misunderstanding of the nature of the type of violence we call Type II violence that we see mostly in hospitals, schools and social services. So employer and worker communities appear to focus more on worker-on-worker violence.

Strategies for the time-- so we feel like strategies for the timely translation of workplace violence research into occupational health practice must be better understood.

But unlike regulating other hazards, workplace violence in health care and human services has to require the involvement of probably the patient care quality community, such as the Joint Commission for Accreditation on Health Care Organizations, or JACO, and health care regulatory bodies within the Department of Health and Human Services. The patient safety and worker communities must also work

together. Crucial agencies include the National Institute of Mental Health -- this would be for research partnering -- Centers for Medicaid and Medicare; American Psychological Association, American Hospital Association, JACO -- as I already said.

So in summary I`m just going to ask the questions that I think really need to guide the research agenda for workplace violence. How prevalent is the full continuum of workplace violence, including verbal abuse, verbal threats and non-fatal assaults? What are the organizational attributes that contribute to successful workplace violence prevention? What training content, methodologies and intervals result in optimal staff and management knowledge and behaviors to prevent workplace violence? What are the direct and indirect costs of not implementing workplace violence strategy? And how can basic workplace violence research be translated in a timely and effective manner to occupational health practitioners, employers and workers? Thank you. Note: Verbal testimony provided to NORA Town Hall meeting in College Park, MD, 2005/12/05 Expanded written comments were submitted as w4612.

Verbal Comment 2005/12/05: Adele Abrams, I represent the American Society of Safety Engineers, and this was just more of a follow-up comment to Dave Madaras's statement concerning substance abuse in construction, as well as the people who have identified mental health, which can be related to substance abuse as well. And because many of the sectors that are addressed here are OSHA-regulated, it may be of interest to know that the Mine Safety and Health Administration within the U.S. Department of Labor is currently engaged in a rule-making to address substance abuse in the mining industry. And the comment period just closed on November 27th. There is a great deal of research data posted on the MSHA web site, as well as testimony from I believe it was five public hearings that were held in October and November on this subject. So those who are interested may want to take a look. There are a lot of programs for management of substance abuse that were submitted to the record by some of the companies within the mining industry. And ASSE also submitted testimony on this, but we agree that this is a subject of concern and would suggest that perhaps NIOSH also look at some of the research that's posted there for suggestions on where that could be taken to the next level by the governmental research programs. Thank you. Note: Verbal testimony provided to NORA Town Hall meeting in College Park, MD, 2005/12/05

Verbal Comment 2005/12/05: Thank you, Jackie. I usually don't read things, but I -- is this on? But because we're under these time constraints, I will read this.

I am here today to propose that problems faced by cancer survivors in the workplace be added to the NORA research agenda. The problems that cancer survivors experience at work represent a national burden in the American workplace. As the number of cancer survivors increase, a result of earlier detection and improved interventions, the number of cancer survivors who desire or need to return to productive work will increase. Currently there are approximately 3.8 million working-aged adults with cancer in the United States -- 3.8 million. This workplace public health problem will escalate over the next decade as treatment becomes more successful and the work force ages.

So what are some of the data on cancer survivors in the American workplace that signal a problem? One out of five cancer survivors who are one to five years post-diagnosis report cancer-related limitations in their ability to work. Nine percent were actually unable to work. Research indicates that labor force participation declines 12 percent immediately following diagnosis to follow-up.

Using another national database, the National Health Interview Survey between 1998 and 2000 research indicates that 17 percent of approx-- or approximately one in six -- workers with a history of cancer report they are unable to work. These employees attributed this work disability to physical, cognitive or

emotional challenges. Probably sounds a little familiar. An additional seven percent indicated that they were limited in the amount and type of work they could perform.

This burden does not rest solely on the cancer survivor or his or her family. As with any health problem that impacts work productivity, there is a cost to employers. Of course there are medical costs, of which a large portion are often covered by the employer. But there are also real costs related to lost productivity, turnover, family medical leave, and potential effects on coworkers.

Our culture continues to perpetuate the view that an individual with cancer is somehow now defective. While at this point limitations in function often represent the sequelae of cancer and its treatment -- and hopefully that won't be the case in the future, but at this point it is -- the question we need to be asking is not can he or she do the work, but rather can the cancer survivor perform the essential tasks of his or her job; and if not, can he or she be reasonably accommodated to minimize the impact of the illness on work productivity? Yet employers and supervisors continue to perceive cancer survivors as poor risks for advancement, and cancer survivors are at high risk for job loss. These outcomes can regrettably lead to a cascade of problems for the survivor, the workplace and society.

Accommodating workers with other medical conditions have been on the rise. However, a study completed by my research group using litigation data from 1990 to '96 indicated that cancer accounted for seven percent of all impairments involved in EEOC litigation related to failure to accommodate.

I am a 55-year-old full professor. I was brought to the Uniformed Services University to develop and direct the first and only Ph.D. program in the military in clinical psychology. This thing was proposed by the U.S. Congress and I followed through and developed it.

In the summer of 2002 I was diagnosed with a small -- with a -- not a small, with a malignant brain tumor. I had surgery to biopsy the tumor, maximum radiation and 12 months of chemotherapy, and I receive MRIs every four months. I am a cancer survivor.

I returned to work two weeks after brain surgery and worked throughout my radiation and chemotherapy. I myself experienced problems re-integrating into the workplace. The unexpected problem was my supervisor's reaction to me, not my health.

I returned to work to find out from a secretary that some research space and a part-time research assistant were no longer available. I went into my supervisor's office and asked why. He told me I didn't need these anymore because I was not normal. Fortunately I was able to resolve the matter through frank discussion and support of colleagues.

I also experienced a number of other workplace challenges following my diagnosis, including the denial of my request for an accommodation that I sincerely believe was reasonable.

Given the challenges that I and other cancer survivors experience at work, I recommend NORA add cancer survivorship and work to its agenda over the next decade. Specifically, research in the following areas should be seriously considered: Epidemiological studies of this burden at a population health level; identification of modifiable risk factors; detection and long-term surveillance of problems in affected workers; evidence-based cost effective approaches that address the problems cancer survivors experience in returning to work, work retention and work productivity; and lastly, national and state policy on more effective ways to address this problem at a systems level.

Thank you. Note: Verbal testimony provided to NORA Town Hall meeting in College Park, MD, 2005/12/05. Expanded written version was submitted as w4608.

Verbal Comment 2005/12/05: Good morning. My name is Cherise Baldwin Harrington. I`m speaking on behalf of Dr. Michael Feuerstein from the Uniformed Services University in Bethesda, Maryland. I`m a graduate student and member of his research group, here to discuss areas of importance to work disability.

Work disability is a source of significant cost to the worker, workplace and society. As a result of these problems, a worker can find it hard to cope with persistent pain and changes in function that accompany these disorders, while attempting to return to work or remain at work. This change in function and productivity can also exert a substantial financial burden. Costs to society derive from long-time wage replacement, disability settlements and health care. In addition there are indirect costs associated with training of replacement workers and lost tax revenues.

Also it is interesting to note that when Dr. Feuerstein developed the Journal for Occupational Rehabilitation over 15 years ago, he thought that perhaps the Journal would gradually lose its popularity as the problem of work disability was solved. Yet almost two decades later it is still stronger than ever,

with citations of research at its highest levels and submissions from around the world continuing to increase. Clearly work disability continues to be an important public health concern.

A major source of work disability is musculoskeletal disorders of the back and upper limb. While most workers return to work within a month from a claim musculoskeletal disorder, many who actually return to work continue to experience pain and disability. It is well known at this point that a small percent of these workers transition into prolonged disability, and account for a disproportionate share of the health care burden. Also in some cases back and upper limb pain can be recurrent, and those returning to work with pain are at increased risk for future problems.

Research from our group and groups from around the world indicate that recurrent and prolonged work disability are influenced by a number of factors including the medical status of the individual, their physical condition in relation to their work demands, various workplace and individual psychosocial factors and systems level variables.

Data also suggests that by identifying workers at high risk for disability and intervening within a few months from the time of the first report of the pain or injury, disability can be prevented. Our groups has also investigated such outcomes as function, patient satisfaction, perceived health and costs related to health care in acute low back pain, and have also identified a possible pathway for this prolonged pain and disability.

We first observed in over 10,000 cases that provider adherence to clinical practice guidelines suggested that workplace ergonomic evaluation and intervention, as well as psychosocial intervention, were associated with better outcomes and lower costs. In a prospective study on 368 participants to be published soon, we found that workers exposed to ergonomic risk reported greater job stress, which in turn was related to higher levels of emotional distress and increased likelihood of returning to the clinic with persistent back pain.

Future efforts need to investigate these relationships more closely and develop innovative approaches at the workplace to address these areas realistically and head-on. Currently this pathway is either ignored or held out as a possible explanation only months after persistent pain leads to prolonged disability, and a series of other problems for the worker and workplace emerge. It is time the integrative role of these factors is studied more seriously and cost-effective approaches are developed to mitigate them.

Another important concern is the risk of recurrent disability following return to work. In preventing reinjury, accommodations are often helpful. Work disability is further impacted by the complexities often involved in truly implementing these accommodations over the long run and assessing their impact. Research done by our group some years ago indicated that musculoskeletal disorders account for 23 of all impairments involved in litigation for failure to accommodate under the Americans With Disabilities Act. Have things changed?

The concerns associated with work disability do not discriminate in job type or setting. The prevalence of these problems emphasize that more attention be placed on identifying the relevant risk factors for onset, progression, maintenance, and the effects of innovative interventions. Also it is important to note that BLS data indicate that more workers return to work with pain than ever before. Is that the solution? Probably not.

It is recommended that NORA reconsider what needs to be done about work-related musculoskeletal problems and work disability in the following areas: First, well-controlled epidemiological studies on the interactions and pathways among multiple risk factors and their relationship to work disability. Second, randomized controlled trials based on work from recommendation number one to identify effective long-term interventions to work disability. And third, research on policy that helps facilitate the recognition and need for approaches that address the multiple factors involved in work disability that maximize the application of evidence-based policy. There needs to be a greater awareness that by focusing on multiple factors we are not blaming the worker or labeling the worker with psychological problems. Workers experience natural reactions to injury, pain and workplace stress that combine to create a situation that is often fueled by the way we look at the process and manage it. Armed with new data, it is time to seriously tackle the problem from a broader perspective. Thank you. Note: Verbal testimony provided to NORA Town Hall meeting in College Park, MD, 2005/12/05 Expanded written comments were submitted as w4614.

Verbal Comment 2005/12/05: Thank you. Good morning. I'm speaking on behalf of the American College of Occupational and Environmental Medicine, or MCOEM. We're pleased to submit these comments to NIOSH's National Occupational Research Agenda. MCOEM is a volunteer, non-profit association of over 100 physicians and allied health providers in the state of Maryland. Our members practice occupational medicine in factories, clinics, hospitals, military bases, academic centers, from shores to mountains. We collectively care for tens of thousands of workers who directly benefit from our professional efforts, and the efforts at NIOSH to produce quality occupational research.

We applaud NIOSH's solicitation of comments on such a significant pathway for guiding the agency for the next decade and beyond. We recognize the accomplishments from the first decade of NORA. And like aspiring athletes, we encourage NIOSH to excel further.

We fully ascribe to the proposition that NORA is setting an agenda, not only for NIOSH but for occupational and environmental evidence-based medicine. While there are many issues that deserve attention from researchers given the ongoing changes that we see in the workplace and the field of occupational and environmental health, we have identified several areas that we feel should be priority for national occupational health research in the coming years: Mental health and the organizational psychology; indoor environments; emerging diseases; emergency preparedness; delivery of occupational health services to small and medium-sized employers; cost effectiveness of occupational health services; vulnerable populations; and effects of chronic disease on work and working populations

The issue of mental health in organizations is large. We know the combination of effective and other disorders in the workplace have imposed a huge direct and indirect cost on many employers. In addition, the role of mental health and productivity is only just beginning to be appreciated. NIOSH

should seek the opportunity to partner with other federal and private research institutions to foster research in this area.

Similarly, we know that workers spend a sizeable amount of time indoors, yet the science of indoor environment is still fairly young, and at times chaotic. Much work is needed to understand the complex interactions between the indoor environments, work, physical and mental health, quality of life, and productivity. We applaud NIOSH's efforts in this area to date, but would still regard it as a need for further emphasis.

As demonstrated so sadly following 9/11 and the anthrax exposures, the nation looked long and hard for expertise in safe remediation procedures. This is an area where NIOSH has particular expertise and could identify and demonstrate appropriate remediation techniques, including worker protection. MCOEM urges NIOSH to consider that the threat of emerging infectious diseases require a reserve of resources and preparedness, while the nation's improvement in (unintelligible) conservation warrants applause more than further basic science research. Likewise, finding effective personal protective equipment such as respirators and gloves warrant more investigation than association of cigarette smoking and chronic obstructive disease.

That's the issue of the vulnerable populations. There have been tremendous changes in the work force, which continue today. These include the aging of the work force and increase of women in the work force, increasing number of migrant and non-English-speaking workers and dual working parents, workers with chronic diseases or permanent impairment. These shifts are important and NIOSH should promote research to understand these shifts, what they portend for the health and safety of the workers.

The other issue concerns the effects of chronic diseases -- asthma, diabetes, HIV, heart disease and cancer, for instance -- and their effects on safety, health, productivity in the workplace. As more and more workers with disability are staying in the work force, the effect of these disorders on safety, health and issues of management of illness in the workplace are more complex and deserving of special attention.

And I will close by saying that MCOEM appreciates this opportunity to comment on NORA, and we remind NIOSH that our patients and our nation's public health benefits from NIOSH's research, and we steadfastly support the quality improvement in NIOSH and believe that NIOSH should be provided with the resources necessary to carry out this vital public health research agenda. Thank you. Note: Verbal testimony provided to NORA Town Hall meeting in College Park, MD, 2005/12/05 Expanded written comments were submitted as w4616.

Verbal Comment 2005/12/05: Good morning. It's a pleasure to be here to provide some input to NORA. McCaffery & Associates, by way of background, is a historical document research firm. A large part of our research is in the field of toxic substance exposure. We regularly review the U.S. Navy Bureau of Ships files, which is Research Group 19, at the National Archives and Records Administration, NARA. After the Kennedy and Nixon files, the files that we review are the most often requested documents at NARA.

Our topic is the preservation of historical documents that contribute to the body of knowledge for occupational health and safety. And I have three issues to present this morning.

Issue one, although the National Archives and Records Administration exists to collect and maintain information from activities of the federal government, both in its headquarters in Washington, D.C. and at regional NARA sites, we have found instances of federal agencies holding archival data in-house long after the records were inactive, such as World War II, Korean War and Vietnam War eras.

Specific examples for the work we do in researching toxic substance exposure are the U.S. Navy and the U.S. Maritime Administration. The problems with federal agencies holding such information in house include: One, the lack of adequate data management, especially tracking and inventory control; two, the lack of security to protect the records from theft, from -- from autograph-seekers, primarily, and damage by other researchers; and three, the lack of open access to the public, especially researchers who might benefit from the historical perspectives and progress in occupational health and safety that was made by such agencies as the U.S. Navy and the U.S. Maritime Administration, going back to the 1930s. Freedom of Information Act requests are frequently required to access records that are held by the agencies.

Where NARA has obtained these records, it does a good job cataloging, safeguarding and maintaining the collection of information.

And our recommendation here is simply that we should ensure that federal agencies provide their records to NARA when these records are no longer in active use by the agency.

Our second issue is maintaining technology that supports reviewing and reproduction of archived documents. We have found instances of film archive materials being unusable due to the lack of technology to review and reproduce the documents to paper copies. Specific examples include 105 mm. and microfiche film records. The manufacturers of the viewing, scanning and conversion equipment stopped making and servicing this equipment, and by the time NARA gets these records, the creating agency's equipment is also either long-gone or unsupportable. Therefore one must find a contractor who has developed a work-around technology. In addition to the expense of conversion from film to paper, there is a chain of custody that, if broken, could result in a loss of records.

While we may not be able to resurrect the obsolete technology, we strongly encourage any federal agency that will generate archival records to not fall victim to assuming that today's technology for conversion from CD-ROM disks, thumb drives, et cetera, will always be available. Think eight-track tapes.

Recommendation two is to keep paper copies of records. While this is generally looked upon with disfavor, we find that it is the most reliable means of preserving documents. The other form of storage that has endured with adequate scanning and conversion technology is 35 mm. film.

Our third and final issue is that some offices in federal agencies fail to maintain records filed with a filing system that can be easily researched. The U.S. Navy did use a subject-coded filing system until the 1960s, which made its records very useful for researching and finding valuable history on its occupational safety and health activities. However, when it converted to a chronological filing system in 1962, the trail to the occupational safety and health system became much more difficult to follow if the chronological file index was not kept with the records.

And our specific recommendation here is that whatever system a federal agency uses to maintain its files, the subject, cross-index or correspondence logs must be kept with the files when they're turned over to NARA, the Federal Records Center, or any other archival facility.

Thank you very much for the opportunity to provide input to National Occupational Research Agenda.

- American Society for Safety Engineers

Categorized comment or partial comment:

Verbal Comment 2005/12/05: Thank you. My name is Adele Abrams and I am the national representative for the American Society for Safety Engineers in Des Plaines, Illinois. I'm also a professional member and certified mine safety professional. ASSE appreciates the opportunity to be here today to join in this effort to shape the future of occupational safety and health research. On behalf of ASSE's 30,000 members -- as well as the 13 practice specialties that ASSE has that include construction, transportation, mining, health care, et cetera -- we want to commend NIOSH and those involved in leading the National Occupational Research Agenda for taking a proactive approach in engaging those with a stake in helping NORA determine direction for occupational safety and health research in the coming decade.

The unprecedented openness and willingness to listen to those whose work and lives are affected by our nation's investment in occupational safety and health research marks what ASSE hopes can be a fully cooperative endeavor that lasts throughout this next decade and beyond.

The day-to-day work of ASSE members in helping employers and employees work safer and healthier is intimately connected with the decisions made by NIOSH in establishing the NORA for the next decade. ASSE's members recognize that without a vibrant, aggressive research agenda that addresses the risks workers face in a quickly-changing work force and workplace, their responsibilities would be difficult to

fulfill. Our members know that many of the tools they use to address or head off workplace hazards come from the research efforts that the NORA effort spurs on. They also know that their -- many of their tools come from the practical need to deal with risks in their day-to-day experience on the job floor, from talking to workers whose wellbeing our members strive to protect, from the exchanges they have with their fellow safety and health professionals, from applying strategies learned in one situation to a situation for which there may be no book-determined answer. Our members are masters of the practical. Ways to save lives, prevent injuries, keep workers healthy come from many sources.

That is why ASSE is pleased to be a partner with NIOSH in its Research to Practice, or R2P, initiative to close the gap between the job floor and the research that NIOSH so ably accomplishes. ASSE appreciates the revitalized recognition in recent years in NIOSH's leadership that the good work of NIOSH needs to be better known by the safety, health and environmental professionals responsible for applying the knowledge gained in safety and health research. At the same time there has been an appreciated recognition on NIOSH's part that safety, health and environmental professionals provide a wealth of knowledge and experience that can help inform and help provide direction to the occupational safety and health research agenda.

The ASSE partnership with NIOSH is helping to close this gap. NIOSH leaders and researchers have greatly increased their involvement in ASSE's professional development and educational opportunities, as well as in its professional publications. And while ASSE has long been an active participant in NORA, now Dr. Hongwei Hsiao, Chief of NIOSH's Protective Technology Branch, has joined the Research Committee of the ASSE Foundation to help bridge the efforts of both ASSE and NIOSH to support research activities. ASSE has increased greatly its dissemination of information on NIOSH publications and communications of its many activities, thereby bringing our members closer to NIOSH's work than ever before.

What we offer today is just the beginning of a process that we intend that will engage each of our 13 practice specialties, and also the leaders of ASSE's Foundation, our volunteer leaders in governmental affairs and the Society's policy process, and our members at large so that we can provide as much input into this process as possible. Our members have ideas that their knowledge and experience can offer to this agenda. Our next follow-up in this effort will be at the December 19th town meeting in Chicago, which is where ASSE's headquarters are located, and there a member of our construction practice specialty will offer specific ideas for NORA direction in the construction sector.

Due to their own generosity and that of corporations dedicated to safety and health, the participants in the ASSE Foundation have demonstrated a tangible commitment to supporting occupational safety and health research. And since 1998 the ASSE Foundation has funded 14 different occupational safety and health studies totaling \$95,000. Another foundation research committee approval will occur this week, and since 2000 the Foundation has funded eight fellows to study at the Liberty Mutual Safety Research Institute with grants totaling over \$50,000. All of these studies are published after peer review in ASSE's Professional Safety magazine, as well as being posted on our web site, and the link for that is included in the copy of the comments submitted.

So we appreciate the opportunity to bring this process -- or to be involved in this process and bring our members' views to you so that they can be put on the front line of protecting workers. And we are encouraged that, with the involvement of all stakeholders in this process, NORA's second decade will

achieve even better and more effective protections for the nation`s workers. Thank you. Note: Verbal testimony provided to NORA Town Hall meeting in College Park, MD, 2005/12/05

Verbal Comment 2005/12/05: Yes, I will. My name is David Goldsmith. I`m a member of the faculty at George Washington University in Washington, D.C. I want to start by commending NIOSH as an agency. They have provided support for me in my career, and I have been able to bring to greater focus something that`s an old concern in occupational health; namely the exposure to crystalline silica.

I basically have four topics I would like to generally share with you.

The first is that reliance on -- which is the standard procedure. Reliance on regular chest X-rays is really not sufficient for us to diagnose true cases of silicosis. We know that that`s true based on some research done in South Africa which shows that, comparing autopsies with chest X-rays, only one out of three true cases are actually diagnosed by the use of chest X-rays.

This suggests to me that NIOSH should provide some leadership to focus greater attention on PET scans and other kinds of new technologies for chest imaging. This is something that the agency can play a significant role in doing.

A second point I would like to share with you is that the silica issue as we see it in the United States today is much more focused on the health of minority and African-American and immigrant workers than it is on what used to be considered a relatively well-paying area of research for all groups in the society. That being the case, there needs to be health education research efforts directed to these communities, specifically the immigrant communities because of their lack of knowledge in English. This means that the agency has to find better ways of getting information that it has about silica -- and for that matter, all other hazards -- translated, particularly into Spanish and other significant languages of some immigrants.

The third thing I want to share with you is concern that the silica issues related to silicosis and silicotuberculosis and cor pulmonale have changed radically in the last ten to 15 years. We have a much greater awareness that silica exposure, like asbestos, produces multiple health effects, and we need to expand our research effort to look at kidney disease. We need to expand our research effort to look at cancer. We need to expand our research effort to focus on autoimmune diseases. All of these three areas are drawing much more research attention. That also means that we need to take the findings from these areas and translate them into expanded educational efforts and to look at other data that are relevant to these kinds of concerns

And lastly, I wanted to draw your attention to two sort of interlinked areas.

One is that we've tended to have a good background on the mining industry and the construction industry and its exposure links to silica. That emphasis needs to be expanded a great deal. We need to recognize that silica exposure is a significant factor when we're talking about agriculture, and it's also true when we're talking about maintenance of roadways, both on the construction side as well as the railroad side.

And there is a lot of silica dust exposure that is not being studied, and in that context there also needs to be technological developments that allow for improved means for detecting elevated silica levels. That is to say hand-held devices that might allow for managers and supervisors and workers in these industries and the traditional industries to know when they're faced with excess silica exposures so that personal protective equipment can be put into place and expanded health education can also be moved into this context.

In all of these we see that there has been a great deal of research exposure -- there has been a great deal of research conducted in these silica areas. But NIOSH is the one agency, in my opinion, that can lead some of these issues forward, and I would very much like to see NIOSH, in collaboration with some of its sister agencies, particularly the Mine Safety and Health Administration and NIEHS and the National Cancer Institute play a leading role in looking at some of these other -- these other new data.

Lastly, I just would like to say that the -- on the research side, on the cancer research side, there clearly is a desire to look at other cancers than lung cancer. Nevertheless, that does remain somewhat of a controversial area, but there`s new data on GI cancers, on kidney cancers and skin cancers. And for those health endpoints there needs to be a new focus on these kinds of problems and a new set of investigators to look at these things in a novel way.

So let me end by thanking you all and I appreciate the time that you`ve given me to share with you my concerns about this area. Thank you very much. Note: Verbal testimony provided to NORA Town Hall meeting in College Park, MD, 2005/12/05

National Safety Council

Categorized comment or partial comment:

Verbal Comment 2005/12/05: Good morning. My name is Mark Riso and I'm here on behalf of the National Safety Council's Washington, D.C. office. And we'd first like to express our appreciation for the opportunity to be here today, and of course our appreciation to convey our support of NIOSH and their execution of NORA, and from what we believe will be a continued strong relationship in each of our missions. The Council has been very supportive of NORA since its inception, and we look forward to our continued work.

By way of brief background, the National Safety Council is a Congressionally-chartered national safety and health organization with chapters in almost every state. The Council is committed to fulfillment of its mission and is always mindful of the benefits of working with agencies and other organizations to accomplish its goals.

I'd also like to note that our President, Mr. Allen McMillan*, will be present to speak at the town hall meeting I believe December 19th in Chicago, which is where the National Safety Council is headquartered. The Council will also seek further opportunities in the future at other meetings on other topics.

The Council views partnerships with federal and state agencies, other safety and health organizations, companies and federal and state legislatures as critical in its overall efforts to accomplish its mission. Sharing ideas, research, programs, initiatives and training is critical to the Council, NIOSH and the work conducted through.

As you all may well know, the Council has many strategic partnerships, cooperative agreements and working relationships with agencies and the like, which serve as a basis for its work. The Council understands that it cannot responsibly and effectively perform its work alone. In the Council's view, the work of NIOSH, through NORA, is a living cooperative relationship that, in essence, develops a

collaborative environment to work productively and share ideas. The significance of our relationship is crucial in that our mission is greatly enhanced with the dynamics of the objectives of cooperative relationships like these.

The benefits to the Council with regard to the work of NIOSH through NORA can be summarized by highlighting tangibles and intangibles. Tangibles include the development of initiatives, programs, information, research data and information sharing. The intangibles include a strong spirit of cooperation and mutual respect.

Though cooperation is often seen as political, the real truth is that a positive working spirit that is often established between organizations and agencies is the only way in which productive results are accomplished in the real world. Success cannot be responsibly measured on paper. It must be measured in concert with implementation.

Much of the work the National Safety Council performs is conducted within the public policy arena, which is what I do. The Council is deeply engaged in public policy, and we identify, develop and implement many initiatives, which must be supported by research and data. As such, the sharing of research and data, as well as the access to research, is of great value.

One of the greatest frustrations when working with public policy is -- is -- it's not necessarily that it's bad information that's out there; it's that there's no information out there. And it's not necessarily that the information doesn't exist, but it's just not visible.

Lawmakers and the public, though sympathetic to many of the causes that we advocate, are not informed or aware of the critical need for action on many important issues. Stimulating the need is greatly enhanced when research supports initiatives. When educated, we see dramatic results with the public, and even lawmakers, in terms of action on issues.

The Council will always encourage that research be conducted, be improved and updated, and be made available always. We encourage NIOSH to always be mindful of the value of the resources you provide, and to help the Council by supporting our public policy efforts by sharing your valuable research.

Again I want to thank you for your time. Thank you. Note: Verbal testimony provided to NORA Town Hall meeting in College Park, MD, 2005/12/05

We all share a commitment to improving the occupational health of worker's regardless of their country of origin. My experiences with workers in Mexico and the US, and my current location at the border, has underscored for me the importance of embracing a global and bi-national (US-Mexico) approach to occupational health. A variety of skills are needed to prevent occupational diseases among workers that contribute to the U.S. economy. Maximizing control of occupational health hazards, particularly in border communities, calls for us to diversify partnerships beyond our profession - reaching out to new partners in business and government.

Verbal Comment 2005/12/05: Good morning. I`m Debora Jones. I work with the Maryland Center for Environmental Training based at the College of Southern Maryland. I want to thank you for the opportunity to present some of the challenges and research opportunities for addressing the incidence of illness and injury in the health care industry.

As a nurse who has worked in a hospital, home care, nursing homes, and as a safety professional, this is a topic of personal and professional concern. For the purposes of my comments, I focused on nursing in residential care facilities and hospitals.

Employment in hospitals and nursing homes is estimated to exceed 7 million workers. While this number is impressive, it is far below the number necessary to serve the needs of our aging population. The U.S. Department of Labor estimates that we have over 100,000 vacant health care positions as we anticipate the beginning of retirement for 78 million baby boomers in the year 2010.

At the same time, our nurses are aging -- something I`m painfully aware of -- with an average age approaching 50. Estimates of the lack of availability of nursing care are astounding. The Department of Health and Human Services reported by 2020 we will need 2.8 million nurses, one million more than the projected supply.

Our health care work force crisis is not limited to nurses. The American Hospital Association projects severe work force shortages in both clinical and non-clinical workers, to include, yes, nurses, but also radiology techs, pharmacists, medical records personnel, housekeepers and food service personnel. It is most disturbing to recognize that the joint commission on accreditation of hospitals has identified thousands of hospital deaths each year related to the nationwide nursing shortage.

What does our health care work force crisis have to do with ergonomics and injury prevention, a question you might be asking at this point. The connection becomes quite clear when we acknowledge that health care workers are leaving the profession at an alarming rate, partly due to health and safety concerns, and continue to be injured at rates that far exceed our rate of injury in private industry.

A 2001 American Nurses Association survey confirmed that nurses are concerned about their health and safety at work. 88 percent of the responding nurses reported that health and safety concerns influenced their decision to stay or to leave nursing. 60 percent identified disabling back injury within their top three health and safety concerns.

Bureau of Labor Statistics data support the extent of our health care worker injury crisis. The rate of non-fatal occupational injury and illness in the private sector in 2004, as was mentioned earlier, is 4.8 per 100 full-time equivalent workers, while hospitals report a rate of 9.7 and nursing homes 8.3. Of particular note is the rate for what we call "all other illness" cases where the OSHA record-keeping standard directs us to record our cumulative workplace injuries. The private industry rate per 10,000 full time workers is 18, versus 54.3 in hospitals and 26.4 in nursing homes.

The Maryland Center for Environmental Training recently completed an ergonomics "train the trainer" program funded by an OSHA Susan Harwood grant, in cooperation with the Johns Hopkins Bloomberg School of Public Health Education and Research Center. Development and delivery of the train the trainer curriculum allowed us entrance into 13 Maryland-based nursing homes. Delivery of the curriculum with the support of Maryland Occupational Safety and Health facilitated our interaction with representatives of an additional 27 Maryland-based health care facilities. Anecdotal data collected through the delivery of the training is indicative of how far we have to go to improve the health and safety of this critical working population.

Of the 195 attendees from our site program, only one had read or reviewed OSHA's ergonomics guideline for nursing homes. Pre-planning site visits identified care givers working without the benefits of electric beds and assisted resident-handling devices while we are preaching and teaching concepts of neutral body postures and zero lifting policies. Ancillary department staff, including laundry, housekeeping and food service, are consistently left out of injury prevention initiatives, while being exposed to significant risk for injury, especially in manual material handling.

Certified nurse assistants and nurses that teach nursing assistants, when asked, admit that prevention of work-related injury is not currently included in their training. Registered nurses describe working in a, quote, patient-focused, unquote, environment with little room for worker focus and the prevention of worker injury.

The answer to our health care staffing crisis is not recruitment and training alone, but should incorporate strategies for keeping our existing workers at work, and those entering the health care work force safe and injury-free in the future. We think some of these areas of future research may include injury prevention strategies for an aging work force; economic models for justification of patient-

handling and material-handling equipment; exploration of our educational system for certified and licensed health care professionals, with consideration of opportunities to incorporate concepts of injury prevention and ergonomics; methods for evaluation of current injury-prevention training; and effective means for dissemination of injury-prevention information within the health care industry. Thank you.

Categorized comment or partial comment:

Verbal Comment 2005/12/05: Thank you very much. I'm Sheila Fitzgerald from the Johns Hopkins Education and Research Center, and I direct the occupational health and environmental nursing program. I'm pleased to present information at this town hall meeting to describe the need to -- for research regarding the employment of individuals who are born with a disability or who acquire a disability over the course of their working life, a NORA vulnerable population.

As a woman who was diagnosed with a chronic disease in 1984, during the early stages of my career, my work life did not end for the following reasons: I have a slowly progressive disease that has been managed well by me and my health care providers; an employer who has made accommodations for me, on request; and family, friends and coworker support. Since 1984 I have also benefited from a stimulating work environment, a good salary and generous benefits that have been -- allowed me to escape the cycle of marginalization, poverty and social exclusion that so many individuals with disabilities experience. I happily have been a contributing member of society and a taxpayer, and not on the roles of Social Security Disability.

The passage of the Americans with Disabilities Act in 1990 provided that individuals with a disability were legally entitled and not to be discriminated against during any stage of the employment process. However, selective demographic, economic, occupational, physical, psychosocial and environmental factors continue to hamper the process to enable individuals with disabilities to achieve employment. Data from the National Health Interview Survey conducted in -- between 1983 and 1985 found that 79 percent of adults without disabilities were working, and only 37 percent of those with disabilities were employed. Those individuals who reported work disability, defined as an inability to perform work resulting from physical, mental or other health conditions of six months or more duration, included 12.8 million persons aged 16 to 64 years. About 12 percent of conditions identified in the NIHS case activity limitations, the broadest measures of disability. Of the conditions reported by the NIHS that cause

activity limitations, heart disease ranks first, followed by back disorders, arthritis, orthopedic impairments to the lower extremities, and asthma. I would also like to add to this list of diseases and conditions a major risk factor for multiple chronic diseases, obesity, which has reached epidemic proportions in the United States, and will have implications for worker health and risk of injuries. I would also like to emphasize the frequent association between mental health disorders -- namely depression, as discussed earlier by Martina Lavrisha -- and chronic disease.

The indirect and direct annual costs of disability is estimated to be greater than \$170 billion. Of note are interesting Department of Labor statistics that reported that the working disabled have high productivity rates, better safety records, that they do not escalate insurance rates for companies, and have comparable attendance records to the working well.

As we age, our likelihood of having a disability of some kind increases. With the baby boom generation approaching later life, there will be more individuals at risk for disability, which will have implications for employers and the workplace environment.

Studies conducted by Cornell University to examine employer practices in response to the employment provisions of Title 1 of the ADA report these results. Topical areas identified by those surveys included lack of related experience with the hiring process, lack of required skills/training, supervisor knowledge of accommodation, attitudes/stereotypes, cost of accommodation, cost of supervision, and finally cost of training.

This brief overview highlights important areas for researchers, policy makers and employers to investigate in order to bring the unemployment rate for persons with disabilities in line with that of the general public, and to improve integration of persons with disabilities into the work force.

Thank you very much. Note: Verbal testimony provided to NORA Town Hall meeting in College Park, MD, 2005/12/05

Verbal Comment 2005/12/05: Good morning, everyone. I am Lisalyn Jacobs, vice president of government relations for Legal Momentum. Legal Momentum is the new name of the NOW Legal Defense and Education Fund, and is a 35-year-old organization with a history of advocating for women's rights and promoting gender equality. As I begin I'd like to thank NIOSH and both the Johns Hopkins and Harvard Schools of Public Health for holding this important forum and for allowing us to appear here and speak today.

Legal Momentum chairs the National Task Force to End Sexual and Domestic Violence Against Women, a coalition of over 2,000 groups under whose umbrella we are currently working on the second reauthorization of the Violence Against Women Act. From the Task Force's standpoint, workplace safety and the economic independence that goes along with it is a crucial necessity for victims of sexual and domestic violence seeking to escape abusive situations.

And in the interests of time, I just want to say two things. One is that I will be making numerous references to a number of attachments which I have in my bag, most of which can be found on our web

site, legalmomentum.org. And also, when I use the words "sexual and domestic violence", those are a shorthand for the four issues that we are working to eliminate when we're working on the Violence Against Women Act. And those would be domestic violence, sexual assault, dating violence, and stalking. But you will hear me, for the remainder of my time, refer to them again in shorthand as sexual and domestic violence.

So again, from the standpoint of the Task Force, workplace safety and economic independence are crucial linchpins for victims of sexual and domestic violence seeking to escape abusive situations.

Legal Momentum has worked to secure this goal at the federal, state and local levels by working with employers to create workplace policies on domestic and sexual violence, advocating for legislation that affords victims of violence in the workplace the opportunity for unpaid leave to attend to safety planning or legal issues caused by the violence, and by advocating that unemployment insurance be available to victims and their family members if they need to relocate in order to escape the violence. Attached to my testimony are a number of fact sheets that we produced in this regard, as well as excerpts of our testimony in support of the economic security provisions that were included in the Senate version of the reauthorization of the Violence Against Women Act.

Next I think it will be helpful to talk about sexual and domestic violence in the workplace in the abstract, and also quite concretely. On the abstract side of the equation, some statistics will help illuminate the magnitude of this issue.

Between one and three million Americans are physically abused by a current or former intimate partner each year.

Approximately ten million have been stalked at some point in their lives, and 80 percent of these victims are women.

The Bureau of National Affairs has estimated that domestic violence costs employers between \$3 billion and \$5 billion annually in lost time and productivity, while other reports range significantly higher, between the figures of \$6 billion and \$13 billion annually.

Studies indicate that between 35 and 56 percent of employed battered women surveyed were harassed at work by their abusive partners. Such harassment can also include their partner's interfering with their ability to work, preventing them from going to work, harassing them at work, limiting their access to cash or transportation, and sabotaging their child care arrangements.

Domestic violence also affects the perpetrators' ability to work. Nearly 50 percent of abusers report having difficulty concentrating at work, and 42 percent report being late to work because of the abuse.

The General Accounting Office has found that between one-quarter and one-half of domestic violence report losing a job due to -- losing a job, due at least in part to domestic violence.

More than 35 percent of stalking victims report losing time from paid work due to stalking, and seven percent never return to work.

Almost 50 percent of sexual assault survivors lose their jobs or are forced to quit in the aftermath of the sexual assault.

For additional documentation of this phenomenon, again, I have attached some materials which can be found on our web site.

I'd now like to take a moment to talk about just one of the victims whose story is inadequately captured by the statistics I just provided. Those of us who live in the Metropolitan Washington area may have heard or read about the woman who sought and received a protective order from the courts here in Prince Georges County, only to have the judge subsequently lift that order, over her objections. Several weeks later the woman, Yvette Cade, was critically injured when her husband allegedly doused her with gasoline and set her afire. Because the media's coverage -- as in the Washington Post article I've also enclosed -- has been heavily focused on the inappropriateness of the judge's actions, the fact that Ms. Cade's husband committed this grievous act in her workplace, a T-Mobile store in Clinton, has gone largely overlooked. I am here to ask that you not overlook the totality of Ms. Cade's story, and of others like her, as you shape the National Occupational Research Agenda.

As we've worked on these issues in the context of the Violence Against Women Act, we've been privileged to work with and have the support of some simply fabulous employers, both state and private, including Harman International, Liz Claiborne and Altria, and the governors of Arizona and Wisconsin, among others. Again, more information is attached to my remarks.

The statistics I've provided, the story of Yvette Cade and the countless others that she represents, and our work with employers paints a vivid picture of the problem we face. What we desperately need as we struggle to assure that victims of domestic and sexual violence in the workplace can maintain their economic independence and thereby escape their abusive situations is a more concrete notion of which approaches work to improve their safety. It will be key in the pursuit of such research to focus on the hardly incidental consequences, for both employers and employees, of supporting victims of sexual and domestic violence in the workplace, including decreased absenteeism, improved employee satisfaction, and decreased health care costs for both employers and employees.

With all the foregoing in mind, I'm pleased to present our suggestions for the type of research we urge NIOSH to pursue in the context of domestic and sexual violence in the workplace.

We have about five suggestions, and I will sort of encapsulate them in one big picture -- one, since I realize I have gone over time.

Among the suggestions we have is that some research be devoted to assessing the impact and effectiveness of workplace domestic violence and sexual assault programs, including how helpful these programs are to victims and employers; the effects of programs on batterers or perpetrators; the effect on workplace fatalities; and the effects on job retention and employee safety and satisfaction, as well as cost savings to employers.

This research is also needed in the area of already-existing state and local legislation to figure out whether or not those types of legislation have had any appreciable impact in reducing workplace violence and improving safety from both the worker standpoint as well as the employer standpoint.

Once again I'd like to thank NIOSH and the Johns Hopkins and Harvard Schools of Public Health for holding this important forum, and for allowing us to appear here today. Thank you. Note: Verbal testimony provided to NORA Town Hall meeting in College Park, MD, 2005/12/05

Verbal Comment 2005/12/05: Good morning, and thank you for this opportunity. I`m Ron Jester with the University of Delaware, and I`ve been asked to make some comments on behalf of Farm Safety for Just Kids -- the founder, Marilyn Adams, who lost a son in 1989 in a farm accident. And also I`m going to make a few comments as Executive Director for the DelMarVa Safety Association, started back in 1975 -- older than some of you are -- and I`ve been involved in safety in the workplace.

Incidentally, as a member of the University, I work with ASSE and a lot of safety organizations in promoting safety and health, and I`ve got a keen concern in NIOSH taking the research data and getting it into the workplace.

Let`s start with the agricultural safety. Most of you probably know that farming is the most hazardous industry in the United States. The death rate is up above 31 per 100,000. It`s followed -- or preceding that is mining, where the death rate is about 28; and preceding that is construction, where the death rate is about 15 per 100,000. So farming is the most hazardous industry in the U.S., and probably the least regulated.

Just to put it in perspective, if you worked for the DuPont Company, the death rate is about one per 100,000. For any of you into skydiving, the death rate is about 22. So it's more dangerous to jump out of an airplane than it is to jump on a tractor.

Now Farm Safety for Just Kids tries to address the issues with adolescents and children in the workplace. And farming is the only industry, of course, that permits children in the workplace. In some industries where you would not be permitted to take a tour unless you're 18 or older, yet in farming children well under ten are operating farm equipment. So it's a serious issue. It's a culture that, unless you are exposed to it or you come from that culture, you don't really understand the risk and issues that are involved.

At the same time, it's the most hazardous industry in the United States, and yet USDA recently has failed to provide financial support to land grant institutions to promote agricultural safety and health. So we appreciate the effort that NIOSH has put into ag safety and health research, and we at the University have certainly benefited from that.

Farm Safety for Just Kids has provided some comments. Number one, they are involved in community involvement and feel that that's where a lot of effort should be directed. They've established a chapter network of community people to deliver important farm safety and health messages, consequently they're able to reach tens of thousands of people with injury prevention information. They also seek youth representation, grass root volunteers, community leaders and safety specialists from North America in this effort, and they will continue to foster relationships that help spread the farm safety messages.

One example, at Delaware we had two farm safety day camps. Farm Safety for Just Kids provides the leadership. In one of the day camps it's a school-based program and the other one we actually targeted at-risk populations, specifically migrant children. And in a lot of these efforts you look at at-risk populations, and that is certainly one of them.

Three of their concerns is, number one, ATV safety, and they give some statistics relative to the injuries and fatalities, but it's sort of the vehicle of choice in agriculture. 95 percent of the injured drivers under the age of 16 were riding on adult-sized vehicles.

Tractor safety continues to be the leading cause of fatality in agriculture. And of course most of the children and adolescents that die in agriculture, it's a result of incidences with tractors.

And then the third issue is rural health, and Farm Safety for Just Kids has put together a health safety kit to talk about sun safety, food safety, water safety and respiratory health. So those are some of their concerns.

Relative to the DSA, some of the things that we see, number one, the aging population; number two, safety in a multi-cultural work environment; and number three, small employees -- employers and the challenge that they are facing. Thank you very much. Note: Verbal testimony provided to NORA Town Hall meeting in College Park, MD, 2005/12/05

Categorized comment or partial comment:

Past research by the NIOSH Alaska Field Station into fishing vessel safety has yielded important and impressive results. Key areas which are of particular note include:

- Characterization & quantification of fleet effort and risk exposure, especially as it relates to fishery species and gear types.
- Characterization of accident types and causes as it relates to gear and species, followed on by development of specific intervention strategies (such as deck safety on crab vessels).
- Determination of key factors to survive accidents.
- Measuring accident / fatality rates between rationalized and open access fisheries (Ongoing).

I would recommend two separate avenues to continue this body of research. The first avenue is to continue funding of items (1) & (2), however, the focus of future research should be expanded past the borders of Alaska to include other areas of the country where high accident rates exist. A particular focus should be on those fisheries in Washington, Oregon, California & New England.

The second avenue of research is an expansion of research into new areas, which haven't been previously studied to my knowledge.

While NIOSH has done a considerable body of work into examining types of casualties, etc. There has been little work undertaken which examines which is the most effective type of regime to ensure compliance with the fishing vessel safety regulations. Research should be conducted to determine whether the current dockside exam program, the fix it program, safety compliance examinations (such as safe crab), or mandatory dockside exams are more effective as a service delivery model.

Another area of research should be in regards to recovery of fishermen at sea, and whether current equipment and training on board federal rescue platforms is sufficient to meet the typical SAR victim needs. In particular, should there be defibrillators on board CG helos.

Verbal Comment 2005/12/05: I'm Dave LeGrande, director of occupational safety and health for the Communications Workers of America. I want to congratulate NIOSH for having the -- you might say the guts to develop this agenda and move forward, along with the School of Public Health at Johns Hopkins.

As a -- an original member of the first NORA work team back in the days of Dr. Donald Millar*, if those of you in the audience remember those days, I want to bring back the focus for just a moment in -- in more of a general sense to a topic that's been raised by a number of you, but particularly focused upon the health care industry. And I want to broaden that focus to include all workers in the U.S., and that is the issue of holistic ergonomics, or as we might refer to it in the United States, we still have this hang-up about thinking of ergonomics as it's defined in Europe to include both physical and psychosocial issues. So I would call it holistic ergonomics in the spirit of looking at, in an interactive sense, both physical and psychosocial issues related to ergonomic hazards in the workplace.

I would encourage the agency to move again on focusing on those issues. I just looked at the most recent BLS data and I was thoroughly amazed that OSHA has, in its unique way, pretty much eliminated musculoskeletal disorders as an issue of concern in the American workplace. Indeed, we see every day musculoskeletal disorders occurring, as well as very high stress rates in the telecommunications

industry. Those of you who are familiar with customer service work know how stressful that work is and the very high rate of MSDs and stress-related health problems in those work environments.

I also want to point out a study that was recently conducted in North Carolina among poultry workers that found MSDs occurring at catastrophic rates. In addition, some of the work that we have done, as well as work that the Telecommunications International has done in a study just recently published conducted in Europe, which also find catastrophic rates of MSDs and stress disorders among telecommunications and customer service workers within that group.

So again I want to look at an issue that really affects the largest number of American workers, and that is a holistic ergonomics and would encourage NIOSH to revisit that issue. NIOSH, again to its credit, has stood on both feet and -- and has tackled these issues in a somewhat precarious position. That is, they've put themselves in somewhat of a precarious position. Unfortunately, the folks at OSHA have moved into the Department of Commerce and have jumped in bed with all the employer communities and have pretty much given up their concern about workers' rights. Their concern now is employer rights.

Another issue that I would suggest focusing on, many of us work on a daily basis with a set of guidelines. They're standards developed in 1989, guidelines developed by the American Society of Heating Professional -- Heating, Refrigeration and Air Conditioning Engineers, ASHRE. OSHA tried, somewhat haphazardly, to initiate an indoor air quality standard-setting process. Did that, and unfortunately tried to include environmental tobacco smoke and the Tobacco Institute came through the wall in opposition to that.

I would again encourage the agency to look at IAQ-related issues and health problems. Indeed, the majority of U.S. workplaces -- indoor workplaces are not in conformance with those 1989 ASHRE guidelines. Every study that's been done by engineers in that field have shown widespread violations of the ASHRE guidelines, again an issue that affects very large numbers of people.

Again I want to congratulate Jackie and all of you for attending, but also NIOSH for stepping forward and moving forward with this very important agenda.

Many of -- and another area that is emerging, too, that we're very -- getting more and more concerned as the national pandemic plan and some of the influenza concerns that we have and other new health problems that have been arising really globally. We have concerns about respirator use, that the health care workers are protected with various respirators and the N-95, the fit testing, and I think everything that's impacting in that area. I think we need to offer as many options as we can in the fit testing, be sure that the fit is -- is protecting the nurses and other health care workers, so I think there's some opportunity there in -- in light of the recent developments that are going on with respiratory protection for health care workers.

And as I said earlier, many of the nursing safety initiatives and interventions impact the quality and safety of patient care as well. For example, like our handle with care campaign that has shown differences in reduction in the lifting injuries and the short staffing concerns with the -- like there -- two times the number of needle stick injuries where there was short staffing involved. There's some research along that line, but I think we can't stress enough about the link and I guess the synergy that can be developed when you look at the patient quality of care issues and the health care safety issues.

Thank you.

Verbal Comment 2005/12/05: Good afternoon. Thank you very much. My name is Robert Clarke. I'm the President of the Truck Manufacturers Association. We represent the major manufacturers of medium and heavy duty trucks manufactured here in North America. These are trucks that weigh 19,500 pounds and above.

Before I begin, if you all will allow me just a personal note, I would like to thank NIOSH because more than 30 years ago I had the opportunity to take an engineering short course at the University of Michigan and was introduced to some folks who were involved in the then-very early NIOSH trainingship program. And they offered me an opportunity to go to graduate school that I don't think I would have had otherwise, and so I went to graduate school at Michigan on a NIOSH trainingship. And I've always been very thankful for that and it had a big impact on my life, so thank you.

With that in mind, let me -- there's just three quick points I want to make. It's obvious -- you've seen from these statistics that in the transportation arena, in the truck transportation arena, the single largest fatality risk that truck drivers face is of course highway crashes. Those statistics that you're seeing up there are a direct reflection of crashes involving trucks. And notwithstanding what the causes of those crashes may be or the precipitating factors, the fact remains that in certain kinds of truck accidents, certainly single vehicle accidents involving rollovers particularly, truck drivers are extremely vulnerable. People don't think of truck drivers as being vulnerable in these big vehicles, and -- and

typically think of the risk to other road users, but as an occupation, driving a truck unfortunately can be relatively hazardous. And the biggest hazard they face is crashes.

It's -- this is old news, but something that we need to continue to focus on, and that is the single biggest and best thing we could do to help truck drivers survive crashes is to get seat belt use rates up. This is old news, but it's still relevant today. Unfortunately, among truck drivers, despite the fact that car driving population is up I believe in the 80 percent range of seat belt use, truck drivers are still down below 50 percent. And thus -- and the proportion of drivers who die in crashes is way out of proportion to those who are not belted. I forget what the statistic is, it's like 70 percent or something. It's way, way up there. So seat belt use clearly is the -- one of the keys to surviving a crash, and ways to get drivers to wear them I think is a challenge that we continue to face.

For our part, we continue to do work on restraint system design with our suppliers to try and make the systems as comfortable and usable as possible. And additional research support in that area from NIOSH or DOT would be helpful, in addition to the age-old problem of behavioral programs to convince drivers that, unlike old-time steam locomotive, jumping out of the cab is not the best thing to do when faced with a imminent crash situation.

Along those same lines I'd like to encourage NIOSH to fund something that they did years and years ago and has been extremely helpful to our industry, and that's anthropometric data, basic anthropometric data. It's used in all our cab habitability studies. It hasn't been brought up here today, but we use that information, and the truck driving population long ago -- I think the last time this was done was 25 or 30 years ago -- was shown then and I'm sure is still the case now -- is not the typical population as a whole. So -- and now it's even more so I think with more females and others coming into the arena.

Last but not least, I'd like to focus on the issue of diesel emissions. There's a lot of interest in health-related issues associated with diesel emissions. I would remind and ask folks to keep in mind that the industry has been on a continuing -- increasing -- severity -- severity, that's not the right word -- stringency of emissions standards from EPA, and diesel engines in the 2004 and now again in 2007 and 2010 time period are going to be extremely clean mode of power equipment. So issues arising from research studies pointing out that older vehicles that -- I'll call them legacy vehicles and/or poorly maintained vehicles represent health hazards of one way or another are probably not as useful in terms of making decisions going forward about -- about those same kinds of effects on the newer vehicles. So I would ask that you keep that in mind as you frame studies, that studying yesterday's technology in many cases is not a good road map to what the future may hold.

Thank you very much.

Verbal Comment 2005/12/05: I`m not Brenda Cantrell, I`m Ruth Rutenberg. Brenda has the misfortune of being on vacation in Cancun and missing all our snow, so I`m stepping in for her. I`m also from the National Labor College, and Brenda is the Director of the Railway Workers Hazardous Materials Training Program. I`ve been associated with it along with her for the last 15 years.

I just want to thank NIOSH for the opportunity to share some views today about the occupational safety and health needs of rail workers, and it is railroad workers that is my focus. And over the next decade we hope that NIOSH will continue its intervention-oriented research because that research really truly does save lives and the health of workers.

The research that might be associated with rail worker safety and health we believe is sorely needed, and I`ll give you some examples as I go through.

The railway workers hazardous materials training program is 15 years old. It has formally trained approximately 20,000 railroad workers in every state of the country, and it also has an active peer

training program so that, beyond the 20,000 very formal students that have been through the program, there are hundreds if not thousands of other contacts a year because when the peer trainers go back onto the work site, we've documented how often they -- they teach their fellow workers, either formally or informally, about how to use resource guides like the NIOSH pocket guide or the ERG. Also how to -- how to get upwind and what first response ought to be and how important personal protective or chemical protective equipment is so that the spread has -- has been tremendous. In the last year alone our peer trainers were working in 33 states of the country. So it's a fairly broad network.

The program is funded by the National Institute of Environmental Health Sciences. It's run by the National Labor College, but it's also associated with a number of other groups. These include the AFL/CIO Department of Occupational Safety and Health, the AFL/CIO Department of Transportation and Trades, North American Railway Foundation, and seven rail unions -- the Brotherhood of Locomotive Engineers, the Brotherhood of Maintenance of Way Employees, the Brotherhood of Railroad Signalmen, the International Brotherhood of Boilermakers, the National Conference of Firemen and Oilers, the Brotherhood of Railway Carmen, and the Transport Workers Union. You can see from this one of the side benefits of this program has been that government funding has brought these seven unions together. They're seven different crafts and they've -- they've found that they have clearly common interests.

The program also works in conjunction with the ARC faculty from Johns Hopkins University to do medical testing before trainees don their self-contained breathing apparatus, chemical protective equipment, and also to teach a module on toxicology to all the students. Our trainees work on major railroads and also on commuter and short-line railroads.

And I just want to give you a quick overview of sort of the size of the rail industry in terms of its potential impact on health and safety. There are approximately 160,000 railroad workers. Freight revenue alone in 2004 was \$40 billion. There are approximately 500,000 rail freight cars, with about 30 million carloads annually. Each car weighs about 60 tons, with the average train carrying well over 3,000 tons. And in terms of hazmat danger, that's pretty powerful, what a 3,000 ton explosive speed down the track can -- can do. In 2004 railroads carried 1.8 billion tons of freight, and that totaled about 1.7 trillion ton miles. So we're talking about a lot of activity.

And I'd like to first address the health risks that face worker-- rail workers, and then something about the injury.

Our workers -- our trainees alone have listed over 200 hazardous materials that they're exposed to, many of them on a very frequent basis. The one that probably folks are the most familiar with in the health and safety area is chlorine, because the railroads carry 85 percent of the country's chlorine, and it's one of the most dangerous chemicals and I'll -- remember chlorine, because I'm going to come back to it in a minute with some examples.

But other highly dangerous materials that are regularly transported include anhydrous ammonia, sulfuric acid, nitric acid, methanol, phenol -- the list is -- is very long. The railroad workers like to talk about the "dirty dirt" that they transport, which -- they can't tell you what's in it, but they know it's bad. Sometimes it glows green and yellow, so that -- there's radioactivity in it, but it's usually stuff from hazardous waste sites that are full of a huge soup of chemicals.

During the course of the training sessions, trainees share information with the class about work colleagues who have become ill and who've sometimes died from diseases that they assume are work-related. Sometimes it's only when they hear the health risks of some of the materials that they work with, like silica and benzene, that they begin to make the links between exposure and possible illnesses. Here are just a few of the illnesses that have been documented to be related to exposures rail workers face: Asbestos-related diseases, asthma, brain damage, brain cancer, chest pain and tightness, colon cancer, dermatitis, dizziness and other equilibrium disabilities, headaches, kidney cancer, leukemia, liver diseases, lung cancer and other severe lung diseases, lymphoma, multiple myeloma, pancreatic cancer, silicosis, stomach cancer, skin cancer, testicular cancer, and throat cancer.

Now -- I mean that's pretty horrible when these folks first learn how really serious some of their exposures are, and one -- one example here are the folks who work in the shops and on the train gang have gotten cancers at very early ages. It's one of the things we wish NIOSH would look at, actually. Many of these people dying in their 30's and 40's or being on kidney dialysis in their 30's and 40's, and the fear that folks live with of getting cancer almost any time.

The track workers, for example, come in contact with every hazardous material that drips on the track. And there's a very complex soup of chemicals that that involves. The BMWs, the track workers, have actually very few retirees because most of them die, actually, before they reach that age.

The injury risks are also huge, and in 2004 in Ohio alone there were over 100 accidents, more than a quarter including hazardous cargo. With all due respect to BLS survey data, I could list by name over 100 rail workers who died last year alone, and that's only from partial lists, so the under 20 is just totally flawed and I -- new data would be -- would be better.

There were two accidents in 2005 that I think are really critical to mention quickly, one was -- that both involve chlorine. In January of this year a puncture in a rail car in Spartanville, South Carolina killed an engineer and eight other people. In June a train accident in Bexar County, Texas left three dead from chlorine, a conductor and two local people. The transportation industry is a sector where accidents and diseases are really just very strong.

The railway workers program has consistently used their evaluation research to intervention strategies and improving worker safety and health. And just real quickly, some of the examples of that. When the Bexar County, Texas disaster happened, it turned out that the dispatchers, both in the Sheriff's Office and in the Fire Department, really didn't know how dangerous what they were facing was. And so the railway workers program provided their on-line training course to the dispatchers in the San Antonio area, and in fact all of the dispatchers were required to do this -- this training.

Another is the Navaho workers who we train who asks -- asked for joint work between -- between rail workers and the community emergency response people, so courses were held in Chinle, Arizona. And also in New Jersey emergency responders and rail workers have come together in classes to help -- to help coordinate the -- and I'm really almost done.

The third example that I'd like to just mention is in this whole new area of security and potential terrorism, the rail training program has taken on a whole new focus on that. And besides doing a simulation for like Level A dress-out, they also do a full simulation on incident command, teaching folks how to be skilled support people in an emergency.

So just in closing, NIOSH research findings are widely disseminated. We use them in training all the time. They pave the way for safer and more healthful workplaces, and we hope you'll continue it.

Verbal Comment 2005/12/05: I`m sorry? Yeah, I got it. Thanks.

Good afternoon, everybody. I`m Judith Murawski. I`m an industrial hygienist with the Association of Flight Attendants labor union, and thank you very much, NIOSH, for inviting this input. I must admit that, representing workers who are covered by the Federal Aviation Administration, we`re not used to being asked for input so this is very welcome.

In the past ten years NIOSH has funded a series of flight attendant health studies, but for the most part this is a research area that`s largely been ignored, perhaps partly because flight attendants aren`t covered by OSHA. And perhaps partly, in my opinion, because in many people`s views, flight attendants are just waitresses that fly -- right? -- so what could possibly be hazardous about that.

There are so many research gaps in this industry. I know I have less than five minutes now so I will keep this as short as I can, but the three that I want to describe all relate to this hazard of exposure to partly-combusted and aerosolized engine oil. And that may sound like a hazard that`s specific to maintenance workers. It`s not. We know that engine oil gets in the air supply system on commercial aircraft because aircraft mechanical records confirm it, and because the ventilation ducts are coated with oil afterwards. We know that these oils contain up to three percent of the neurotoxic tricresylphosphates, or TCPs, and that upon heating these oils, carbon monoxide gas can also be generated. This is supplied to the passenger cabin and cockpit, so we`re clear here.

We know that TCPs get distributed to the cabin air because they`re on the recirculation filters, and we know significantly that crew members around the world report significant neurological damage that is

consistent with exposure to tricresylphosphates and carbon monoxide gas. I wish that I had time to give you a real world example of that. I'd be happy to afterwards for anybody who's interested. We also know that this happens about one in every 1,000 flights on more problematic aircraft types.

But despite what we know and despite the hazard being recognized by two National Research Council committees, most recently in 2002, there are three big unanswered questions, and we're hoping that NIOSH research can help answer these questions.

The first two questions are about exposure. What level of TCP exposures are we talking about during these events? And how can a crew member -- or passenger, come to that -- prove that they were exposed? The third question is about health effects. What scientific, systematic studies address the chronic central nervous system effects of inhalation exposure to aerosolized engine oil?

On the first question, biosensor research that's intended to protect against bioterror attacks has very exciting potential for commercial airlines, and any other workplace. Animal antibodies that only react to particular chemical agents -- for example, in the case of research that's already been done, this has been done for ricin and anthrax -- these antibodies have been identified and isolated. They are housed in sensor equipment, and upon exposure they bind to the specific chemical agent at a rate that can be quantified and converted into a concentration at ppb level in real time monitoring. These units are apparently the size of a child's lunch box and they cost about \$25,000. TCP-specific animal antibodies do exist, but they need to be isolated and identified. Ambient TCP levels could then be quantified on a real time basis with this technology in the aircraft cabin and cockpit, addressing the obvious research gap for TCP exposure monitoring on commercial aircraft that was recently recognized by an NRC committee. Workers need proof of exposure.

To address the second gap for -- research gap for TCP-specific blood tests for workers who may have been exposed, TCP has already been demonstrated to modify a commercially-available pig liver enzyme in a way that's not only detectable but, again, quantifiable. So research funds are needed to apply this insight to worker -- to develop a human blood test. Workers need proof of exposure.

In terms of research partners, I'll submit that information to the docket, given time limitations.

And on the third research gap, health effects, there are published studies that describe how when test animals ingest these engine oils, they show delayed effects to the peripheral nervous system, problems with gait and balance. But existing studies are inadequate for a number of reasons, the main reason being that workers are not ingesting these oils. They're inhaling them, and there's evidence that inhalation may have very different toxic effects. Crew members need NIOSH to take the lead in funding inhalation research with these engine oils, with a focus on damage to parts of the brain involved in cognition.

In closing, these three projects -- the biosensor to detect TCPs in real time in the cabin and cockpit, the blood tests, and the inhalation research -- could each be funded well within typical NIOSH grant levels, and are estimated to take one to two years to complete, depending on the available funds. NIOSH would be filling major research gaps by answering questions that have been left unanswered for decades, with obvious benefits for workers in the aviation sector and beyond.

Thank you for your time.

Verbal Comment 2005/12/05: It's okay. I'll use Bob Clarke's unused two minutes.

I'm Gary Donaldson. I'm the senior research director for Advocates for Highway and Auto Safety. What's the average life span of a professional over-the-road truck driver? I know a lot of people in here by name, including Roger. What is it, Roger? UNIDENTIFIED: (Off microphone) I don't know, I'm going to guess -- DR. DONALDSON: Don't make it too good. UNIDENTIFIED: -- (unintelligible) years old?

DR. DONALDSON: It's between 50 and 55, and there are several people in the room here who know that. If you're an over-the-road professional truck driver, your health is at risk. And the health of professional truck drivers, specific health pathologies, are at virtually epidemic proportions and have been for many years -- cardiovascular disease, insulin-dependent diabetes. Obesity is at astronomical levels. Sleep apnea is probably virtually -- or legitimately to be termed an epidemic among professional truck drivers. And we know now, with research that was done in the last several weeks that was released, that it probably has a causal relationship with the onset of stroke and perhaps heart attacks, as well.

I have to cover a lot of terrain in a very short amount of time. You're talking about a professional work force in the United States, here in the beginnings of the 21st century, that is essentially an early 20th

century professional labor force. Some of you in the room may not know that this is the largest labor pool in the United States that exempt from the Fair Labor Standards Act. Because of that exemption that was put on the record in 1938 and consummated in legislation in the Roosevelt administration in 1939, truck drivers are not subject to the 40-hour week for overtime pay. As a result, hours of service since 1939, with one major change in 1962, has drivers, under the rule that was finally superseded in the spring of 2003, working and driving 60 hours in seven days or 70 hours in eight days.

That rule, after rulemaking that was initiated in 1997, was changed by the Federal Highway Administration and then by the Federal Motor Carrier Safety Administration, the new agency of jurisdiction. In that final rule, despite the protest of labor organizations and major safety organizations and people concerned with health and safety effects of shift work and excessively long working hours, the agency made the working hours much longer.

You now no longer have a fixed work week for professional truck drivers. You have a floating work week, and under that floating work week you can now accrue 98 hours of work in eight days and drive 88 hours in that eight-day work day -- work week. And as a result, you have driving hours which are now up to 28 percent longer than under the former rule, and working hours that are now 40 percent longer than under the old rule.

Think about the ordinary American workers, who works about -- take away his two hours of vaca-- two -- two weeks of vacation in a year, about 2,000 hours a year. Professional truck driver can accrue up to 3,900 hours a year legally under this rule. So we have a rule where the context for adverse health insults for disease pathologies is sitting there as a fermenting brew, waiting for the kinds of diseases and health problems which are, as I say, virtually epidemic among truck drivers.

That rule was challenged. It was challenged when it came out in April of 2003. My organization and several others filed suit against the Federal Motor Carrier Safety Administration. We won. They threw the rule out in its entirety in a scathing decision, which said that the agency had not had adequate evidence in the record for a single feature of the final rule, and that they had also failed to uphold their statutory obligation to protect the health of truck drivers.

The agency came back and entered a new phase of rulemaking after the adverse court decision in which, in the final rule, they now made one sector of the trucking industry work longer hours than they did in the original rule. The short-haul sector now can work under an eight-day regime, which is not very common, 102 hours in eight days. So we now have a condition out in the trucking industry where, despite the protestations of the Transportation Research Board's oversight committee and excellent comments that were filed with the docket by NIOSH -- which made them very, very popular with the Federal Motor Carrier Safety Administration about truck driver health and safety -- this agency denies that there is any causal relationship with the excessively long shift work and health outcomes -- adverse health outcomes for truck drivers. And I would hope that the NORA will have a exceedingly stronger emphasis on worker health and safety, particularly in the areas of truck driver health and safety. The agency has denied that any of the studies tell them what they need to know, and as a result, having long-term epidemiological studies and long-term studies that have prospective and longitudinal design with very large populations of truck drivers are absolutely crucial. Thank you.

Verbal Comment 2005/12/05: Good afternoon. My name is Joe Myers and I'm an engineer, a risk analyst in the Office of Design and Engineering Standards at U.S. Coast Guard headquarters. The observations I'm going to share today are my own, and are not yet official Coast Guard input. It's in process.

That said, I think I will offer you some very fertile ground in the water transport sector for some areas for research.

Just a brief background. The Coast Guard is a small, multi-mission organization with regulatory authority across several of the NORA research sectors. These include fishing, mining -- in terms of oil and gas extraction in the off-shore, construction and transportation. While our primary focus has been on safety related to preventing maritime casualties such as sinkings, collisions, fires, groundings, we also have authority for the workplace issues on vessels which we inspect. There are two broad classes of vessels, inspected and uninspected vessels. Smaller vessels, vessels that may be engaged in the inland marine transportation, tugboats and those sorts of things are currently -- are typically uninspected vessels. These authorities are provided both through legislation and court decision, as well as cooperative agreements and memorandums of understanding between the Coast Guard and OSHA.

For those vessels that are inspected, these would include passenger vessels, maritime mass transit such as Washington State and Staten Island ferries, inland and coastal tugs and barges, oil and gas off-shore production, and marine cargo transportation ranging from container ships to (unintelligible) -- to tankers for both petroleum and chemical products.

Some of the issues that we're wrestling with are the numbers of workers at risk. We know how many documented, licensed mariners there are. We have some estimates as to the numbers of unlicensed deck hands, but we don't have a firm number on that. We're also lacking firm numbers on the number of commercial fishermen, people engaged in commercial fishing industries. BLS statistics provide us a number of fishermen that is actually less than the number of documented fishing vessels that we know about, so there's some real discrepancies in those areas. We're looking at about 204,000 licensed mariners.

Other problems are the under-reporting of injuries. We have a pretty good feel that we're getting the fatalities when they occur, but the occupational type injuries that occur are supposed to be reported, but there is more disincentive to report than there is incentives to report.

Other issues concern the unique nature of the maritime industry. It's a 24/7 operation. The workers live where they work. There's a strong tendency for a lot of extra hours, once you go off your standard-duty watch, to turn to ship's work -- scraping and painting and those sorts of things, a very complex set of hazards. It's a dynamic, moving environment. You're looking at noise, chemical exposures, heat stress, very strenuous activities. All of those things combine, as well.

And it's a very compartmented industry sector. As I mentioned, there are different aspects of it, each with its own unique set of hazards.

There are diet/exercise/wellness issues, as well. Shipboard cooking is probably not the most nutritious and healthful. Everything is fried 'cause that's quick and easy to do. Lots of -- lots of caffeine abuse to -- to maint-- you know, in order to maintain vigilance and alertness during these long work hours.

Some other issues would be the traumatic and -- versus repetitive injuries. A lot of the ship work is very -- very strenuous, line handling and those sorts of things. We suspect there's a lot of musculoskeletal injuries that go unreported.

Two other interesting aspects would be infectious disease exposures. It's an international industry, and not only are U.S. workers exposed, but we have foreign workers coming in -- foreign nationals coming in, so we have to look for things like SARS and perhaps avian flu and those types of issues, as well. Plus the ship is living in close quarters, so there are some infectious issues there, as well.

The last point is the human and organizational factors -- training, education, and turnover, language and literacy issues. As I mentioned, you may have a multi-national crew, so there are some communication and crew resource issues, as well.

It's a very demanding environment with high demands for vigilance and high performance, and we think that some of those issues would be useful, as well. Thank you.

Verbal Comment 2005/12/05: Good afternoon. My name is Ray Alexander. I'm with Liberty Mutual Insurance Company, and Liberty Mutual is a very large insurance company, the largest writer of Workers Compensation insurance in the country, and also I think the fifth largest writer of auto liability insurance in the country.

We've been involved in transportation safety for many, many years. Back in 1959 and 1961, I believe it was, we built two safety cars with a lot of the safety features which are on automobiles today.

One of the areas that we're very much interested in in transportation has to do with driver training, particularly with tractor-trailer drivers. As you know, or some of you may know, we have 44,870 transportation-related deaths in 2004, and of those, 5,190 fatalities from large trucks. It's interesting that number really hasn't changed much over the last several years. The frequency, when you take accidents per million miles driven, has come down significantly. But the actual number of fatalities really hasn't changed much. It's stayed right around that 5,200 point, and that hasn't changed a lot.

Liberty is very interested in driver training and how we can train drivers to drive safely. And we're not necessarily talking about new drivers. We're talking about experienced drivers who have been driving for five, ten, up to 30 or 40 years. If you go back and look at a lot of these drivers, where did they learn to drive? Generally on a farm, from a brother or father or someone who taught them, and their driving habits may be good or bad -- who knows? And a lot of these people need some type of driver training.

A study that was done a number of years ago showed that less than 20 percent of the commercial motor vehicle drivers had had any type of good, formal training. So a lot of these drivers out there need some type of training.

Now, there are four different types of training that's being used today -- classroom training, in-vehicle training, some computer-based training now, and also simulators that are being used to do driver training. The question is, are any of these effective? When you go back and look at a lot of the training that's being done, it's very questionable. Nobody really knows how effective this training is.

So Liberty Mutual would like NIOSH to do a study on the effectiveness of driver training programs. Does company-sponsored driver training programs really work? Nobody really knows.

How can the effectiveness of training be measured? Is there a way to do that? How can a trainer determine if the trainee really gets it, does he really understand what he's doing? Are there ways to do that? Can we empirically measure changes in driver behavior after the training is done? And finally, can we see a change in driving habits by the driver, and how long do those changes work?

We drive by habit. We have driving habits. We all do, some good, some bad. This is where the driver trainer comes in, and an experienced driver trainer, one who's been trained -- and this came out at the International Truck and Bus Symposium which was held just about two weeks ago. They were talking about what are the qualifications of that driver trainer, who's doing the training? Do they have any qualifications? So -- but the driver trainer's job is to look and observe that driver and see what are his driving habits and how can they be changed, and to make the driver aware of them and try to teach him how to change those driving habits. But we need to find some way to be able to go back and measure those habits and measure those changes and see did the driver in fact change his driving habits.

So driver training is very important. Liberty Mutual, like I say, has been involved in driver training for years. We did our first driver training class I think back in about 1960. We have seen some very effective training programs take place.

I'll give you one example. We had a -- one company, we trained their driver trainers and they in turn went back and trained all of their drivers. And at the end of the first year after the training took place, they had reduced their accidents by 50 percent and their auto liability loss by 62 percent, I believe it was. So we -- we have seen some very effective methods.

But that's only one case. We need a study to go back and see what's really happening in the industry and can we make changes to improve driver training to reduce the accident frequency and the number of fatalities.

Categorized comment or partial comment:

Verbal Comment 2005/12/05: Thank you. Good afternoon. My name is Scott Madar and I'm the assistant director of the Safety and Health Department of the International Brotherhood of Teamsters. Thank you for the opportunity to present today on behalf of the hundreds of thousands of teamster drivers who make their living driving our nation's roads. The types of drivers that we represent include long-haul, short-haul, automobile transporters, tank haulers, construction drivers, delivery drivers, waste transport drivers, and utility drivers whose driving is incidental to non-driving job tasks.

It is important to have a frame of reference when looking at the hazards associated with the transportation industry. Historically truck drivers have had among the highest fatality rates of all professions. According to the Bureau of Labor Statistics, fatal highway incidents increased -- increased to 1,374 in 2004, after decreasing for the previous two years. This equates to one of every four fatal work injuries in 2004 were the result of highway incidents.

In addition, the injury and illness rates have also been among the highest of all professions. The incident rate of injuries and illnesses in transportation and warehousing declined in 2004 from 7.8 to 7.3 cases per 100 full time employees. This is in contrast to the 4.8 cases in all of the private industry. BLS attributes the decline in truck transportation, which is the NAICS code 484, from 6.8 in 2003 to 6.1 per 100 full time employees in 2004 to decreases in the numbers and rates of both cases involving days away from work, job transfer or restriction in cases away from -- sorry -- cases involving days away from work.

The Teamsters Union is interested in any research that can help reduce both the fatality rate and the injury and illness rate among drivers. We're committed to working with all interested researchers on

this endeavor. And if we had more time, I would talk to you about some of the research opportunities that we have actually undertaken.

General wellness issues are also of interest to the Teamsters Union. Due to the general sedentary lifestyle of a truck driver -- as Jerry Donaldson mentioned, you're behind the wheel anywhere from -- up to 11 hours a day, theoretically -- there is a tendency for drivers to become overweight, and the use of tobacco products and caffeine is rampant. From these lifestyle-related issues, drivers often develop medical conditions such as hypertension, weight-induced diabetes and heart disease.

Work/rest cycles for transportation workers, and all workers in general, are also problematic. As forced overtime and work stress become more predominant in our economy, the adverse health effects of extended work cycles and chronic fatigue should be examined since more workers in all sectors of the economy are faced with these stressors.

As the controls of the motor vehicle increase in technical complexity, the driver is required to process ever-increasing amounts of data. This information overload can significantly increase driver distraction and may create a more stressful work environment.

One issue that NIOSH has looked at is the distraction that drivers face -- are faced with from cell phones. Now imagine a multitude of other devices in the cab, all beeping and blinking at you while you're trying to drive and navigate the roads with a lot of people who don't know how to drive.

The drivers are also faced with constant monitoring, using technology such as global positioning systems, which is an enormous change from the historical autonomy that drivers have enjoyed. NIOSH should examine the stress and other psychological effects of electronic monitoring in this industry.

Verbal Comment 2005/12/05: Hot-dang, Leroy, it's open pulpit time. No. I would like to thank NIOSH and NORA for providing this opportunity. I am a recipient -- active recipient of NIOSH activity at the present time. Our association represents 350,000 people who own and operate their own trucks on America's highways, and we're in the midst of doing a retroactive mortality study on about 130,000 names in our membership base who are inactive. That means that we haven't heard from them for three years. It is my suspicion that some of them are very inactive, as in laid out flat and about six feet lower than everybody else.

In looking back at mortality studies, the -- there was a California study done -- oh, gosh, what was it; it was in '82 on 1965 data -- for all the occupations in California. But of the groups, truck driving was the largest sample. It had 3,000 people in it, and the average age was 54.

I didn't know that at the time, but five years ago Dr. (Unintelligible) came out -- the sleep doctor -- and said oh, well, it's 61. So I called him and said where'd you get that? He said I got it from a friend of mine, so I called him and said where'd you get it? He said well, I got it from a conference I went to and I wrote it down. It came from a Teamster. I said great, who was it? I don't know. What was the name of the conference? I don't remember. So I called Scott and said Scott, back this up, and he says I can't do it. But what the man said was that the Teamsters average getting out 18 months of checks. Thinking that they retire at 60, that makes it 61 and a half, so 62 was the age (unintelligible) came out with.

So I started looking at the obituaries in our magazine. Our magazine goes out nine times a year. It has obituaries every -- every other one, and I started adding those up and -- and the average was 56.

And so I told my boss, and my boss says well, that doesn't count all the ones that retired. And I said name a retired trucker. And he said well, there's this guy, and I said yeah, he's terminal. Well, there's that guy; well, he's got a colostomy bag. Well, no, all the old ones are all gone. And I -- I think that -- there -- there's not a lot of truckers in Florida basking in the sun.

And looking at -- after -- after I -- I got this preliminary information and finally got tied up with John Cistito* and NIOSH, I started looking at other things, so I asked for height and weight on our membership profile survey, found out that only 12 percent of our members are at their optimum or below their optimum weight. That makes 88 percent of them heavier than their optimum weight. Our mean is right on the body mass index line between overweight and obese. And of course on the other end of obese you've got mortally obese -- morbidly obese. Really big. Some of those guys have got three people on one skeleton. Really. And when you think about hauling around three people's weight, for their height and weight they've got three people all in one skin. It's a -- it's a bad thing.

One thing that we found that the California thing didn't -- oh, I'm going to go way beyond that time. You can go now. Your services have been fine up to this point. If this is on your evaluation, you're in trouble.

UNIDENTIFIED: (Off microphone) (Unintelligible)

MR. SIEBERT: California said that suicide was not a really big thing in their 54 years of age. But in mine, I only -- when I looked at -- when I was -- when I came up with that 57, I on-- I had 1,200 -- 1,200 in my population, but I -- of those, 485 I knew the cause of death, and I had 14 suicides out of 485. The national average is 27 out of 100,000. Oops. You want to talk about some stress. Jerry put it out there.

We actually sued a carrier, and in the suit we asked the judge to put a cease and desist against them, and we quoted the Fourteenth Amendment. The Fourteenth Amendment outlawed indentured servanthood and slavery. By signing the contract this company had, the people were automatically indebted to the company store so far that they had zero percent -- zero percent -- people who had actually paid off the lease and walked off with the truck. They had 100 percent failure. And not only were they taking back the truck, they were taking back these people's homes and putting them out on the street. This is the business environment in which these workers are working.

So much of the stuff that I heard about the agricultural workers, the nurses -- truck drivers are right in there with them. The precariousness of the employment. We have very good trucking carrier companies who have a average turnover of employees of 135 percent. Now do you feel secure working for somebody who's turning over their entire work force 1.3 times a year? Do you have a job that you want to stay with, because a lot of them are voluntarily leaving; they're not being fired. They're looking for a greener pasture. They're actually looking for a job that pays them for the hours that they work. They can legally work God only knows how many -- 82 in eight, 102?

DR. DONALDSON: (Off microphone) (Unintelligible) 88 (unintelligible) 98 (unintelligible) work (unintelligible).

MR. SIEBERT: But that's just the start. They wait at docks for 40 hours a week, and they don't get paid for that. That's work. They cannot go to sleep. They're waiting for free for another 40 hours. So now we're up over 100 hours -- 120, somewhere around that -- for \$35,000 a year. This is not the America that we all know and love.

I was blown over the other day listening to NPR coming in. And someone was talking about the new worker program. Well, we will have immigrants come in and do work that American workers just won't do. And the -- and they guy that was playing devil's advocate said yes, but what you're -- what you're asking for is a slave class in our -- in our society. And the lady that was -- lady that was defending our current administration's stand said well, would you rather have a servant class that is illegal or a legal servant class?

Can we economically compete on a global basis and compete with political prisoners in China, with slavery in China? Is this what our society says is okay? There are enough people in this country to drive trucks. They have the skills. They have the experience. They refuse to work that hard for that many hours for that small amount of money. And it's not happening just in trucking. It's happening in nursing and it's happening in agricultural work, too.

Tyson had a plant in Wisconsin. They renegotiated the contract. The entire work force went out on -- on strike. The new contract offered a beginning wage that was nine cents an hour below the old -- no, offered a top wage that was nine cents below the old -- let's get this straight. The new top wage in the contract was nine cents below the old entry level. That was as high as you could get. You could get nine cents below what you used to start at. And when asked why should the American public subsidize Tyson's payroll, the man said what do you mean? The reporter said you are offering a top wage that makes these people all qualify for food stamps if they have one kid. He said I don't offer wages; I offer work. But the work he's offering is for illegal aliens, because folks who are used to getting an honest day's dollar for an honest day's work still deserve that today, even though we're in a global economy.

I'm almost through. When we -- we have a lot of -- lot of talk about fatigue in trucking. And I will -- I suspect that there are a lot of fatigue fatalities that are marked down as fatigue that are not fatigue. They're death fatalities. Well, of course he died, he had a wreck. No, he died before. Because when you see a trucker who does not make any steering correction and no braking and goes off and hits a tree or a bridge abutment, that's called fatigue. He was asleep. I'm saying that a lot of those are really asleep; they died and the -- the same thing happened. There was no -- there was no corrective move. He was already dead in the saddle.

NIOSH has -- has talked earlier about -- and I'd like to encourage them to continue -- they talked about funding a center of excellence for transportation workers. And I've been to the Center for Production Workers Rights and seen the work that those folks are doing there, and if we had such a thing for our sector, I think that would be a great thing. And I've heard -- oh, I don't know -- rumors that perhaps this center of excellence may become virtual. And if that's the case, I want to be first in line to bid for the job of cleaning the windows on the virtual headquarters. Thank you.

Dick Collins of National Postal Mail Handlers Union

Categorized comment or partial comment:

Verbal Comment 2005/12/05: Good afternoon. My name is Dick Collins. I serve as assistant to the president of the National Postal Mail Handlers Union, and I wasn't planning on speaking, but I heard a lot of comments, primarily this morning, about ergonomics. It just made me rethink the idea of sitting here and not sharing.

Three years ago the Mail Handlers Union, the American Postal Workers Union, the Occupational Safety and Health Administration and the Postal Service joined together in a partnership. That was a term I heard a lot this morning, partnerships, so that's one aspect I'll be talking about. And we decided to attack the risk factors that lead to musculoskeletal disorders.

So the Postal Service approached the unions, with OSHA's help, and suggested this partnership. And what we came up with was something we called the ergonomic risk reduction process. To those from business that wonder about the cost effectiveness of ergonomics, I will tell you, after three years of considerable personal involvement, ergonomics will save you a ton of money. For the people that worry about stress in the workplace and workers that feel disenfranchised from their employee, I will tell you -- or from their employer, rather, I will tell you that ergonomics, when properly structured -- involving the workers on the floor, giving them the knowledge and the power to make the changes that

they need to make to eliminate the risk factors that they encounter every day -- will help you to reduce worker stress.

We came up with a model where we put an ergonomist in one of our large mail processing facilities for 90 days. And the purpose is to transfer knowledge, to make the people in the facility aware of the risk that they face in the performance of their duties, to provide them with the knowledge to both identify and eliminate those risks, and to build teams to go around that plant to identify those risks in every area and come up with the solutions to implement to eliminate those risks.

We were skeptical, I guess would be a good word -- it'd be a Christian word -- initially when the company approached us. But I have to tell you that this process has far exceeded anybody's expectations.

We currently have 93 large processing facilities involved with this ergonomic risk reduction process. The goal -- the objective ultimately is to bring all 400 of our major processing and distribution plants on line with this. Those plants that are currently in range in size from 800 employees to 2,500 employees. Actually I guess I'd have to go a little higher on that top end. Morgan Station in New York, which takes up four city blocks in Manhattan, I believe they employ somewhere around 12,000 or 13,000 employees in that facility alone. That's the downtown plant for Manhattan that takes care of all of Metro New York and the surrounding area.

What we've seen -- going off the top of my head for the metrics -- the lost workday injuries, we took the facilities in the first seven phases, we rolled out in anywhere between eight and ten facilities in a phase. We compared phases one through seven against the rest of the nation. That group comprised about 66 of these large plants. The lost workday injuries were down somewhere in the neighborhood of 34 or 36 percent, I believe, compared to the rest of the nation. The lifting and handling MSDs, the lost -- lost work -- light duty workdays where someone would get hurt and come back was down close to 70 percent, if I remember the slide. Larry Liberatore is here from OSHA, he's one of my partners so I'm asking him for a little help here 'cause -- all I remember were the numbers were staggering.

If anybody's seriously interested in an ergonomics program, I have some business cards with me. I'd be happy to give them to you and give you some more precise information later, but the ergonomics works. I don't care what your goal is. You know, I took some heat from people who thought that, as a union, we shouldn't embrace this because they said well, one of the byproducts is that management gets a more efficient operation. And that's true. But my reason for becoming involved was to keep people from getting hurt. If the company can do it a little bit safer and get a little -- I mean a little faster, get a little more out of it, that's okay because one of the realities of the Postal Service is that they are beginning to shed workers. They're down approximately 100,000 employees in the last three years. They're going heavily to automated operations, and that's inevitable. We're not going to change that. But what we can change is the way people do the job, the way people are approached and given the ability to both do their job and to make sure that job is done safely, and to protect the people we represent. And if the company benefits from that, that's okay because that means that people that come after me are going to have a job, too. So if you'd like to see me on the way out, I'd be happy to give you a card and share some more information. Thanks.

Verbal Comment 2005/12/19: Thank you for allowing me to discuss the National Occupational Research Agenda. My name is Rochelle Davis and I'm the founding Executive Director of the Healthy Schools Campaign, the primary advocate for school environmental health issues in Illinois. Our mission is to advocate for policies and model programs that allow students and staff to learn and work in a healthy school environment.

We have two program areas, environmental health and school food. My testimony today will address what we see as the important role that NORA can play in promoting healthier staff and students.

An estimated 20 percent of the population spends their days in elementary and secondary school buildings, yet this critical component of our national infrastructure is crumbling. School buildings in every state, county and city in the country have environmental problems that adversely affect the health, well-being and productivity of staff and students.

One important component of school environment affecting health and productivity is indoor air quality. Studies reveal an alarming percentage of schools with facility problems that relate to indoor air quality. Sources of indoor air quality problems include VOCs emissions from furnishings and materials, mold infestations, chemical emissions from improper use or storage of maintenance products or educational supplies, insufficient fresh air due to poorly designed or maintained ventilation systems or to overcrowding, the entry of pollutants from outside due to improper siting or design of ventilation

systems, and high radon levels. Indoor air quality problems can also result when asbestos or lead in building materials is distributed during repair or renovation activities.

In 1995 the U.S. General Accounting Office survey of 10,000 schools found that approximately 27 (sic) reported unsatisfactory ventilation, and almost 22 percent reported unsatisfactory indoor air quality generally. With about 20 percent of the U.S. population spending their days in elementary and secondary schools, the potential health, comfort and productivity impacts of poor indoor air quality are considerable.

The effect of poor indoor air quality on health, learning and general well-being are wide ranging and include allergies, asthma, increased rates of infectious disease, chronic headaches and a variety of respiratory diseases. Asthma, a condition that can be triggered by mold, cockroach dander and a number of environmental conditions in schools, has become the leading cause of school absenteeism due to chronic illness.

There are existing best practices to address poor indoor air quality. Green Cleaning can reduce the use of toxic chemicals in cleaning programs. Integrated Pest Management protocol reduces the use of pesticides in schools` environment. Anti-idling procedures reduce the toxic exhaust caused by the idling of diesel buses. Safe chemical management protocol can reduce the use of toxic chemicals used in curriculum. The USPA (sic) has taken the best practices and developed Tools for Schools. The EPA will soon launch a new tool called "Healthy Seat", which provides a more sophisticated management tool.

However, few schools employ these best practices. Research dollars should be spent addressing the research to practice gap. While much is known about why schools do not embrace best practices, little has been done to explore effective strategies for bridging the research to practice gap. A couple of examples of particular interest to us is to examine the role that school nurses can play in promoting indoor air quality-related best practices.

Also of interest to us are projects which examine the effectiveness of school/community partnerships in improving the school environment. Currently Healthy Schools Campaign is engaged in an NIEHS-funded project which explores the role that community organizations can make in improving the school environment. The research aims of the project include the development of a common language between "professionals" and "community members and parents" that will be used to motivate school administrators to take action to improve the school environment.

Thank you very much for the opportunity to share our perspective with you. If you want more information, we`re available to share our research ideas with you in greater detail.

Verbal Comment 2005/12/19: Good morning. My name's Tim Leahy. I'm the Secretary-Treasurer of the Chicago Federation of Labor, AFL-CIO. On behalf of our President Dennis Gannon, our executive board, the 321 affiliated unions and more than 500,000 union members of the Chicago Federation of Labor, it is a pleasure to be here before you today and offer some public comment on NIOSH -- NIOSH's role and mission.

I would like to thank our Chicago and NIOSH partners -- Lorraine Conroy, Dr. Rose Sokas, Leslie Nickels, Joe Zaroni -- they do a great job here in Chicago and we're very proud to work with them.

In the Chicago Federation of Labor we're not just a casual stand-by observer. The Chicago Federation of Labor, through our affiliates, raised -- we raised a significant amount of money to create an endowment on behalf of our former president, Michael Bruton*, that yearly -- every year hands out grant money to do research in occupational health and safety.

I come here today simply to comment on the scope and breadth of NIOSH. Simply put, I believe NIOSH is not looking far enough, deep enough, and in many cases is missing entire segments of the working population. The world we work in has changed dramatically. The look, the complexion of our workforce is also changing. While there remain many, many good ethical, successful employers who choose the

high road, there remain far too many employers who, through their sheer greed, simply choose the low road to conduct their business.

The benchmarks of a high road employer would include the following characteristics. He's aware of the community in and around where he does -- he or she does business and invests in that community; provides health care for employees and their families. Of course I know -- the labor -- we know how difficult this is. It's how we end up striking over every contract negotiation, it's health care. But as long as an employer is constantly attempting to provide some type of realistic health care coverage, then they're trying. Stays out of decisions that are solely made by employees when it comes to a decision to form a union, and provides some type of pension/retirement benefits.

Benchmarks of a low road employer would be provides no health and welfare benefits for employees. At the expense of his employees he is constantly contracting out, continuing to hire temp workers, workers from day labor agencies; interferes unlawfully with union organizing drives.

Why is this important? Because unfortunately in this current economy we are seeing a disturbing growth of low road employers. Between perma-temping, day labor, privatization, growth of illegal and unethical use of immigrant labor, the workforce that we see today works in a much more dangerous environment. And if our government statistics on safety in workplace do not corroborate this, then I strongly suggest they're looking in the wrong places.

Organized labor has long been an advocate for a safer work environment, not just for union members, but for every worker. The Chamber of Commerce is not going to sit up and stand up for a safe workplace, but the labor movement will. Every single law ordinance that pertains to protecting workers on the job was pushed by -- advocated for the labor community. The inertia, (sic) momentum and pressure put forth to pass safety laws in our country did not come from the business community; rather from organized labor and the communities where work takes place.

While scientific research on how chemicals, toxins, air qualities are important to protecting our environment, I believe NIOSH must be much more diligent in reaching out to labor community groups to study what exactly is happening in the immigrant worker population. Whether the sector is manufacturing, construction, transportation, hospitality or retail, I believe the injuries and industrial disease affecting our workforce are dramatic and unreported. Between the pressures on employers from insurance companies not to report, aligned with the fear of a worker, especially an undocumented immigrant, to report an extremely dangerous -- to report a disease or an injury makes for an extremely dangerous environment, an environment that promotes not reporting making a work-- an environment that makes not reporting commonplace in our workplaces. This makes our workplaces more dangerous.

This is a complex and dangerous situation and will require time and resources to set it straight. But more importantly, it will require the will to do what's right. It will require a will to begin asking more questions and questioning basic assumptions. It will require the will to begin reaching out to the labor community, immigrant community, the religious community, the civil rights community. This problem will not be solved by one entity alone, but rather from a true partnership of the above organizations.

The business community must once again take ownership of how it operates in our communities. Why is it when we have an exculpulous (sic) day labor agency that provides no health care insurance that it provides -- that it sets up a dangerous work shop, that it's only the labor and religious community that stands up and protests. Where is the business community?

Once again, to fully attempt to make our workplaces safer, NIOSH must step up and more fully reach out to the labor and communities. Through NIOSH's efforts, if more low road employers become high road employers, then you will see a dramatic turnaround ensuring the safety of our workplaces.

Thank you for the -- the opportunity to comment publicly.

Verbal Comment 2005/12/19: Thank you. I'm Mike Perry, Director of Education and Employee Involvement for AFSCME Council 31. Occupational safety and health for the public sector, particularly state and local government workers, continues to be a major area that does not receive the attention it needs and deserves. Nearly 20 million workers are employed by state and local governments, roughly 15 percent of the non-farm, civilian workforce in the country. According to the Bureau of Labor Statistics, there were 5,703 fatal workplace injuries in 2004, of which 525, or nine percent, involved state or local government workers. Thousands more die each year from occupational disease, and hundreds of thousands suffer injuries that result in time away from work -- in all too many cases, permanently.

Despite doing some of the most hazardous work in this society, public employees were excluded from the Occupational Safety and Health Act when it was passed 35 years ago. Today only 24 states have federally-approved state OSHA programs that cover state and local workers.

Categorized comment or partial comment:

Today I want to bring just a few of the serious hazards facing our members of public service workers generally to your attention. There's an epidemic of workplace violence in this country. The public is aware of the risks to law enforcement personnel and late-night retail establishments, but there's an unseen war going on in workplaces where our members work, as well. In correctional and mental health facilities assaults are a daily occurrence. As government budgets get squeezed ever tighter, staffing shortages increase the danger to the workers. In addition to the staffing issues, the reasons for violence are already well-known.

What's missing is a solid body of research that documents the efficacy of various solutions. There are many strategies and workplace violence prevention guidelines that have already been developed by federal and state OSHA programs, such as in California and Washington. However there has been a lack of research to evaluate what works best. Intervention research to assess the impact of workplace prevention guidelines is a glaring topic in need of further study.

Ergonomic problems continue to top the list of workplace risks. Patient lifting and moving puts direct care workers in nursing homes and other direct care settings in the unenviable position of having the highest rates of musculoskeletal disorders year after year. Adequate staffing, lifting equipment, no-lift policies are all known to dramatically reduce and even eliminate these preventable injuries. Yet despite the evidence of cost effective injury prevention measures, employers too often fail to take appropriate measures.

Back and other injuries are an important cause of the high turnover. If there are tried and true methods to control ergonomic risk factors that also save large sums of money, the question that remains to be answered is why are these recognized injury prevention strategies not being implemented? It would be instructive to know why there is such resistance to adopting ergonomic programs. Besides the lack of strong federal or state mandates, what other factors are at work?

A long-neglected occupational group in terms of research is sanitation workers. They face a wide spectrum of biological and chemical exposures in the refuse they collect. They're exposed to extremes of heat and cold, UV radiation and other physical hazards. They are maimed and killed by faulty equipment. Some are killed when falling off the truck, by passing traffic or crushed by their vehicles.

I'd like to point out that there's an ever-growing number of workers in non-traditional jobs who all too often never appear on the research radar screen. These are home health care workers who work in the homes of the elderly; personal assistants who provide vital support to individuals with disabilities in their homes, at school, in their jobs; and family child care providers who care for the children of others in their homes. These workers are too often injured due to the physical strains of their job. They are at particular high risk for back injuries, as well as repetitive motion injuries and falls. There's a critical need for research into the causes of the health and safety hazards such workers confront and what can be done to reduce their risks.

Finally I want to mention another pressing area of research. The nation is facing the possibility of an avian influenza pandemic, yet our health care workers and emergency responders have still not been provided with the equipment and resources they need to protect themselves to avoid -- and to avoid infecting their families at home. For example, the Health and Human Services Pandemic Influenza Plan recommends a surgical mask for respiratory protection. Its recommendation is based on the assumption that transmission is primarily via large droplet nuclei. However, the plan admits it does not have definitive scientific evidence to support this claim. It does not address the issue of the evaporation and breakdown of droplets into respirable-sized particles within matters of seconds, or even fractions of seconds, after they are expelled through sneezing, coughing or even in talking. Surgical masks are not respirators. They cannot filter out droplet nuclei, and they cannot achieve the tight seal against the wearer's face. More research is needed on the airborne risk of transmission of influenza and other potentially lethal pathogens.

In conclusion, I mentioned just a few of the many serious hazards that are taking a huge and unnecessary toll on state and local government workers. Research is important not only to quantify the nature and magnitude of the problem. Documenting hazards and solutions provides workers and this union with the evidence we need to obtain stronger health and safety rights through laws, government policies, collective bargaining, labor management committees, in arbitration and other forums.

Thank you for this opportunity to express our concerns.

Verbal Comment 2005/12/19: My name is Jim Buskus, a retired member of UAW, Local 719, and previously a UAW health and safety rep for General Motors, electromotor division, outside of Chicago. I have 19-plus years of safety experience in the manufacturing environment and have held a CSP for the past ten years.

First let me say the UAW supports NIOSH in its efforts to protect workers against hazards. I'm here to speak about priorities for the occupational health and safety research in the manufacturing sector. First let me say the UAW -- oh, I'm sorry. I'm here to speak about the priorities for the occupational health and safety based on the experiences of the UAW at the national and local levels.

The UAW has put our money where our mouth is in the support of research. We have negotiated and jointly administered research funds in the U -- in General Motors, Ford and Chrysler starting in 1984. Millions of dollars were spent and around 100 publications produced. We also launched small efforts at International Truck, NUMI* and other locations.

The most important goal of research is to identify gaps in protection, situations where workers are getting sick or getting injured under current conditions. This can be done -- this can be because an exposure permitted by standards is making people sick. As a health and safety representative out on the plant floor, I can tell you how often my own eyes burned, heads ached, skin became irritated, and then the industrial hygienist came and said that the exposure's within the OSHA limits.

Health effect research, including injuries, is the most important thing NIOSH can do, and it is something only NIOSH can do. Industry only pays for health effect research after some other investigators have found a problem and the industry is convinced it will make costs go away. Sometimes there's a gap in protection because the methods of controlling exposure is unknown or a more efficient method of controlling is needed. But this is much less a priority than showing an exposure is causing people to get sick or injured.

Verbal Comment 2005/12/19: Hi, I'm Myra Glassman. I'm the Field Director with Service Employees International Union, Local 880. We're a union of home health care and home child care providers in Illinois, roughly about 30,000 members in home health care and about 50,000 in home child care in Illinois.

Most of our members that work in home care work through two state agencies, Department on Aging and the Office of Rehabilitation Services, Department of -- Department of Human Services. Roughly -- between the two, probably 40,000 to 50,000 workers that care for elderly and people with disabilities that get those services by being Medicaid-eligible.

Our members -- Helen will explain in more detail, but our members do a variety of home tasks and personal care tasks -- you know, anything from cooking, cleaning, shopping, to giving baths, changing diapers, coming in a lot of contact with bodily fluids -- and Helen can detail. We see as probably some of the top problems is that there's really nobody taking bottom line for training and providing equipment for these thousands of workers, so there is some training provided through in-services at private companies that contract with the Department on Aging, some companies that are taking on more responsibility for doing that and providing equipment, but we've had to organize to get those things. So when we started there was really no such thing as giving out gloves or maybe even talking about universal precautions and, through organizing, we were able to get that going. It always seems to be a problem of funding mainly, like who's going to pay for those kind of trainings. And a lot of the in-services, if the speaker doesn't provide that service for free, they're usually not invited. So sometimes the quality of that training is a problem.

And a lack of equipment is also a funding issue. I mean our members a lot of times provide their own out of their average wages, which before we started organizing was minimum wage -- some were making as little as a dollar an hour because they were considered independent contractors -- to an average wage now of \$7 to \$9 an hour. So to have to provide your own gloves and other equipment is a real issue.

There`s no health insurance for a majority of the workers, so that is something we`re organizing to win, and have won it for some small amount of workers. But for the majority of workers, there`s no access to health insurance. So to get hepatitis shots or other kind of things that can keep them healthy, that`s a real struggle. And a lot of times workers go to work ill because they`d lose a day`s pay if they don`t.

And probably, you know, the biggest issue is just that this workforce just has not been studied. And we`re very fortunate to be involved with Dr. Rosie Sokas and Joe Zandoni and Leslie Nickels in the home care bloodborne pathogen study which is now underway to really study this workforce and see what the exposures are because there`s really -- literally, if you put home care workers and the people they assist together, there`s hundreds of thousands of people that are at risk every day. So we appreciate being part of that and we`re looking forward to the results of that study.

Verbal Comment 2005/12/19: Well, Myra almost told you who my name was. I'll just say it again. My name is Helen Miller and I've been a home care worker for 25 years, and I want to tell you a little bit about what I did as a home care worker. And when I say what I did, 'cause I just lost my last client in October.

So the first thing you do when you go in in the morning, you have to get them up out of bed and get them to the bathroom and get them dressed. And I'm kind of -- I'm going to kind of talk like two different clients. Okay.

The first clients, when I was there with her, she was a diabetic so she had needles. So you was always conscious of where the needle are and she was partially blind so you have to watch out for where she put her needles or how you dispose of her needles. And I had to give her a bath. And as the time went on, her disease got worse, so she had a major stroke. So when she came home she had no control. So you understand what I'm saying, no control? So I -- she couldn't furnish the gloves, so I had to furnish my own gloves.

And I don't know what kind of mask would -- I didn't know exactly what the safety of masks was, but I used to use the one that I used to clean my house with. I used those masks to kind of protect myself and I bought my own gloves.

So that was one patient. Then I had another patient that I just lost. She was a patient that -- she wasn't completely bed rest, but I had to go in and first thing I had to do was to wash her up. I also had to clean her mouth, you know, because she couldn't -- she had no incentive (sic) of doing anything for herself.

Also -- and she also wore Depends so I had to do that. But I -- and I had gloves for -- I -- you know, the family did support gloves for that. And she was a patient that I had to take her to the bathroom. I had to get her up off of the bed. She could walk, so I had to walk her to the bathroom, but then you got to help them get on the stool, off the stool, on the bed, so you have a chance of hurting your back. And at that time they didn't have Hoyer's, so you know, it's difficult to lifting a patient up and down from one place to the other one.

Let me see what else I could think of. And I think that's about -- I think that's about it as the work I did.

Verbal Comment 2005/12/19: Good morning. My name is Linda Forst. I'm currently a practicing physician and associate professor here at UIC School of Public Health. I'm a long-time fan of NIOSH, having done my occupational medicine training at an ERC in the 1980s consulting on projects while practicing in my first job in Cincinnati. And becoming a faculty member within the Illinois ERC in 1991, I directed the occupational medicine core training program here at UIC for seven years. And I've been a beneficiary of NIOSH research funding through its extramural programs.

I have been a program evaluator and grant reviewer for NIOSH, and I've been on the receiving end of those activities, as well. I greatly appreciate your giving me and my midwestern colleagues the opportunity for input into the National Occupational Research Agenda for the next decade.

My research interests lie in the areas of occupational injury, injury and illness surveillance, and vulnerable populations. First, occupational injury.

I was recently at the APHA, American Public Health Association, conference in Philadelphia where I heard Dr. Hunt and others from the CDC injury prevention group talk about their response to Katrina. They talked about the impact that they had on citizens, and specifically relief workers. On asking what role NIOSH had in their work, Dr. Hunt responded that after they wrote injury prevention documents for New Orleans, they gave them to NIOSH to review.

Clearly NIOSH has a long history of expertise in workplaces, and in addressing worker efforts in the aftermath of unexpected disasters. I heard an anecdote about the Exxon Valdez oil spill near Alaska. NIOSH's evaluation of the rock cleaning activity after that disaster led to the recommended use of techniques from roofing operations where it was deemed best to clean from the top downward,

collecting oil and debris at the bottom of the rocks. This adaptation prevented slipping on the part of the cleanup workers.

Dr. Hunt`s response at APHA made me concerned about turf being more important than prevention. I`d like to see NIOSH better recognized within the CDC, and nationally, for its expertise. Better publicized research in the area of injury control during disasters, or maybe simply getting in their face, is important.

Next I'd like to talk about occupational surveillance. Clearly NIOSH should be on the cutting edge, promoting higher quality data collection, analysis and dissemination in the states, and facilitating efforts on the part of state health departments and workers compensation commissions. NIOSH could explore and assist in data linkage techniques, and in addressing confidentiality concerns in a global way that can be helpful to getting data from state databases into the public domain.

At present NIOSH requires a competitive application for funding of surveillance projects, looking for creativity and grantsmanship to decide which of these programs is worthy. If the goal of NIOSH is to summarize surveillance results from the 50 states, NIOSH should provide a template and support to the states on a non-competitive basis, in much the same way that infectious disease divisions prioritize data collection on infectious sentinels.

A third area that I believe requires intense focus is that of vulnerable populations. Immigrant workers in agriculture, construction, manufacturing and service appear to be at tremendous risk, with numbers and rates of illness growing dramatically, demonstrating a clear occupational health disparity as rates appear to be declining the U.S. workforce overall. The informal sector which overlaps immigrant workers is also an employment setting that requires intense scrutiny for ways to make inroads into injury and illness prevention.

The proposed NORA agenda to focus on single economic sectors, like construction, may obscure the global issues for vulnerable populations since their problems cut across economic sectors. In general, I'm concerned that listing single sectors as NORA agenda items will create inefficiencies and barriers to studying these cross-country occupational health sentinels in worker categories.

I want to commend NIOSH's work on the research to practice and intervention effectiveness. Your clear guide -- this clear guide sits on my top shelf, ready for use when I'm planning a project, teaching a student or writing a manuscript. I support continued refinement of techniques to research, publicize and disseminate interventions that work, and I look forward to more of this from NIOSH in the new NORA initiative.

I also want to thank NIOSH for the NORA pilot projects program which has launched research careers for many trainees and junior faculties at our institution. I encourage continuation of this form of extramural funding.

Thank you for allowing me to testify today.

Verbal Comment 2005/12/19: My name is Brian Devlin and I'm a registered physical therapist that consults to the long-term care industry. I've consulted the long-term care industry for the past ten years, and my wife is a PT in long-term care industry, so we -- we've lived and breathed this industry for the past ten years.

And the long-term care industry is in a crisis mode right now in the area of employee safety. I've been formally trained in ergonomics. I've been formally trained in the science of patient and resident handling. And I can tell you that I can't go onto a long-term care facility floor at any given point and use proper body mechanics 100 percent of the time. It is a impossibility, physiologically and anatomically.

And there's many reasons why, but the most important reason to realize is that residents and patients are dynamic weights. It requires the caregiver or the direct care person to constantly assess or change the process by which they handle and lift residents. And coupled with the fact that there are resident diagnosis issues, there's hygiene issues, there are many issues that prevent a person from using proper body mechanics or ergonomics all the time.

That aside, my son asked me a very poignant question. He's six years old and he had to prepare what his mother and father did for -- for their jobs. Well, my wife being a physical therapist, it was a very easy conversation. But for myself, I had to explain to him why I go into businesses and health care facilities to try to prevent workers from being injured. And he asked a very good question: Why do these people have the opportunity to be injured? And if a six-year-old can ask that question, it begs -- it begs us to ask the same question and come up with a rational answer. And I couldn't -- I started listing out all the answers, but him being six, he of course couldn't understand that. This will all make sense why I have no hair, I'm sure, now. But he -- aside from that, we -- we ended the conversation -- he said I think I'll just be a farmer and wear a hard hat.

And I wish it was that simple for the long-term care workers that are exposed to an increase in the acuity levels of the residents dramatically over the course of the past ten, 15 and 20 years, but the education and training that the CNAs and direct care workers have had to go through during those same changes have not kept pace with the acuity changes for residents and patients in long-term care. So we have a very unrealistic expectation for these workers to use proper body mechanics at all times.

I'm an advocate of a limited lift program. I don't believe that we can create a no-lift environment in health care because we are in the business of providing care for individuals, and that comes with the element of touching and caring for people. But we do have to engineer out the heavy lifting that these individuals do because it's not like we are lifting a widget or a product all the time. We are lifting patients, and they're humans. And with that comes an area of misunderstanding -- not only from the employees, but from the residents -- of what the expectations are.

I wanted to also talk to you a little bit about what is contributing to this environment, which is the long-term care industry as a whole. The market conditions right now are such that the operators have to worry about reimbursement issues, staffing issues -- because the turnover rate is so high within the industry that this strips away the opportunity for the operators to put a lot of resources into training and prevention programs because they allocate those resources and then two weeks later 20 percent of the staff may be gone already. So it really creates a difficult atmosphere for the operators to provide these safe work environments, and the only way we can do this is to engineer out the risk and the opportunity for heavy lifting to occur in health care.

Thank you for the opportunity to address the panel, and we look forward to working with you in the future.

Verbal Comment 2005/12/19: Good morning, and thank you. I am here today in the presence -- or to take -- in the place of Alan McMillan, the president and CEO of the Council. I sit on his executive board as finance chairman. I was told this morning on my way down Alan has recently had a death in his family which he just finished dealing with, and now the flu. So maybe there`s something to personal stress and lowering your immune system and all of that, so I guess it`s -- it is making sense.

What Alan`s cause was today was to explain the theme of what the Council is all about. But also in our recent world congress in Orlando we saw that there are -- 111 nations were represented in Orlando, Florida to see what the world had to say about safety. And there was a very common theme in that saying, and that was that it`s not just workplace safety, it`s not just driver safety, it`s off-the-job safety. So as I go through this brief presentation, allow me to give you just a little bit of that information.

As we saw the hurricanes come through this last fall, the congress in Orlando started just after Hurricane Katrina. The year before we were chased out of New Orleans with Hurricane Ivan. While we were there, Hurricane Rita was coming up the Gulf. So the world leaders that represented this -- this congress that was represented in the United States for the first time in 50 years were very attuned to what we`re doing in emergency preparedness and in workplace safety.

It should be noted that when we expand the profession of safety, we need to extend it beyond the roles of the workplace. And in that I mean that when we find workplace numbers are dropping, as we know injuries and illness and death is dropping, I would say that that's an obvious result of the extensive work of NIOSH and OSHA, and all of their activities over the last 30 years have made safer places for us to work. But as we get into the mobility of the next generation, the Generation X, as we get into the older workforce that is causing the Baby Boomers to get toward retirement, we're finding whole new elements of safety needed by the professionals out there today.

I wanted to explain just briefly that the reduction in this -- in these incidents has shown that not only have they gone down and injuries have been minimized, but the workforce has quadrupled during this same period of last two decades. As well as we are now producing nine times the goods and services during a period prior to two decades ago. We still have sustained 4,500 to 5,200 workplace deaths each year since 1992. And of those, nearly half result in motor vehicle collisions. While deaths of motor vehicle are down 15 percent, motor vehicle crashes remain the leading cause of work-related deaths, with over 2,000 each year.

A primary concern in this country's changing workforce again is the demographics that we talked about. A huge segment of our workforce, Baby Boomers, are now moving toward retirement. This is going to cause safety professionals to take a hard look at the way we train and educate our employees, but also that we should be taking on a mentoring role that we look forward to research and data from NIOSH in order to grab ahold of that mentoring process and make this next generation safer than the one that preceded it.

I would say that in -- the National Safety Council statistics say that death from accidental injury is the fifth leading cause of death in the United States, following heart disease, cancer, stroke and lower chronic respiratory diseases. However, among Hispanics in our U.S. workforce currently, the accidental injury rate ranks third, only after heart disease and cancer. And the highest rate of deaths from occupational injuries between '95 and 2000 was among Hispanic workers, with the greatest number of occupational injury and deaths occurring among Hispanics employed in the construction industry.

Now although I represent the Council on their board, it is -- I am also the vice president of safety and health for Kenny Construction Company based here in Chicago. And we are seeing, within our own ranks of employment and our subcontractors, that the need to educate -- not just train, but to educate - - and to communicate with the Hispanic workers in our industry is increasing exponentially every year.

Today's safety professionals have a challenge, and they're not limited to the workplace. We are taking - - we are recording, I'm sorry, a striking increase in the level of injuries occurring among workers who are off the job. This was I think the one theme that came from the congress this past year, and it's not just to workers, it's to their dependents. When a worker is home working on something in the garage, putting up Christmas ornaments outside, working from a ladder, operating a saw, it's all off-the-job injuries that are now rising to huge numbers. And when these people are injured, they do miss work but they're not compensated as they would with injuries that they occur while on the job. So last year 61 percent of injury-related deaths occurring in and around the home involved either workers who are off the job or their family dependents. Annual costs related to accidental injuries, including wage loss, medical expenses, property loss and direct employer costs exceeds \$600 billion. The cost of doing business alone is more than \$200 billion a year.

DR. CONROY: Okay. If you could finish up briefly --

MR. ZARLETTI: Okay.

DR. CONROY: -- you can submit -- I'll remind everyone again that --

MR. ZARLETTI: Okay, this will all be available if you need it afterwards, and I guess I would just conclude by saying that we cannot train and educate our people on the job to be safe and leave it at a 9:00 to 5:00 opportunity. We need to take that opportunity beyond and show them, with management support, how to be safe at home, how to teach their families to do the same so that they can return to work and become in the environment that we've already made safe for them. Thank you.

Verbal Comment 2005/12/19: Thank you. I'm -- appreciate the opportunity to appear before you today and before NIOSH to give our input with respect to the new NORA priorities. I'm filling in for several people here today. The first is Dr. Rachel Rubin, who is the head of the division of occupational medicine at Cook County Hospital, Stroger Hospital of Cook County; second of all for Dr. Daniel Rahorchik*, who is the head of our Great Lakes Centers for Occupational Environmental Safety and Health, which the educational resource center -- research center, rather, that Dr. Conroy is the head of, and our other activities are under the umbrella at the School of Public Health. I myself am a physician practicing here. I'm professor at the School of Public Health and I direct the Occupational Health Services Institute within the School of Public Health, and I would like to underline one last thing and that is that our center here is a World Health Organization collaborating center, along with NIOSH and the University of Texas and a few others in this country.

I want to welcome you all here and welcome NIOSH here, utilizing all of those hats. We -- again, we appreciate your coming and we appreciate the NORA process of listening to those of us in the field of -- as to the creation of priorities for research and education within NIOSH.

I would only content-wise raise one general area for your consideration. I want to raise the issue of safer substitution within our general increasing concerns about chemical security, both for -- both to avoid acute catastrophic events, either intentional or due to natural -- natural events, as well as to avoid the chronic long-term effect of toxins. And I would urge NIOSH to consider the enlarging of the research

agenda with respect to safer substitution, for safer, less toxic chemicals, both with respect to their toxicities and the economics of the transfer of these technologies to assure both a just transition as well as reduction in toxic exposures.

I would only underline that this is one of the topics that makes the link between the workplace and the community that's so important to us in the Great Lakes Center, and we think makes so much sense for the occupational agenda. It also is a topic that has international ramifications and is immediately of use internationally within the WHO's sphere, as well as others.

One particular example that I would link to bring to NIOSH's thinking in the matter with respect to the safer substitution is the problem related to ethylene oxide in its use in the health care industry as a sterilant when steam and Autoclaving is not effective or not usable. This is an area that cries out to us for safer substitution. It is an area that probably cannot be made safe, or actually I feel cannot be made safe within its current methods of usefulness with this known human carcinogen and neurotoxin.

So with that, I thank you again for hearing me and I beg your indulgence that the others are not here. Dr. Rahorchik is out on the highway somewhere trying to get his car operating, so there's an excuse for you for today. Thank you again.

Verbal Comment 2005/12/19: Good morning. Thanks for having me. It's my pleasure to be here. I've not been to one of these before. I am impressed with the eloquence with which people preceding me have spoken, and have some scribbled notes here to try to match those presentations.

I'd like to make three points today.

Number one, I'd like to reinforce the direction that NIOSH has taken with research to practice. I think that's exactly the route to take and I think it's deserving of increased emphasis. Those of us practitioners working out in industry benefit, researchers benefit, and of course ultimately workers on the shop floor benefit from that emphasis on practical, implementable solutions for workplaces. So I commend NIOSH and encourage that continued direction.

Categorized comment or partial comment:

Secondly, I want to make sure that we don't lose track of the importance of NIOSH's educational resource centers, not only in general the importance of those centers to increasing protection of workers through the product that they put out -- basically well-trained occupational health and safety professionals -- but also to recognize the importance that those educational resource centers play in research to practice. We are one of those employers that I hope achieves the high road, as was described by a previous speaker, in approach. And as an employer striving for the high road, we often bump into the edges of the envelope of understanding in the occupational health and safety area. And we rely very heavily on our colleagues in the educational resource center that -- that is -- is we're very lucky to have one located in the Twin Cities with us, and we rely very heavily on our colleagues there as we work to really break through those barriers and understand the practical approaches that we can use moving forward.

The ERCs are the place where we grow our professionals. We grow and encourage dialogues that are really going to be the seeds from which future ideas and practical research efforts emerge, and we must not lose track of them. And in fact should increase the funding that goes to those ERCs as very practical hotbeds for increasing the practice, the practice and science of occupational health and safety.

Categorized comment or partial comment:

And third, I want to make an appeal for a pretty focused area of research, and that is the area of exposure assessment and management. We have continuing opportunities to improve the -- both the effectiveness and the efficiency of those exposure assessment strategies, really in two ways.

One -- one at a high level in terms of the overall strategies, working to develop techniques to understand how effective those strategies are. And by effective I mean how well do those strategies identified at-risk employer -- employees so that we can introduce management techniques in order to reduce their risk. And secondly, we need to do it in an efficient mechanism as we can.

So we need research into better understanding the efficiency and effectiveness of overall exposure assessment strategies so that they can be improved and we can better protect our workers.

The bottom line is that prevention starts with a good understanding of exposure. And if we don't understand exposure, we can't do a good job of prevention and management. And secondly, the connections between exposures and disease, teasing out some of those finer relationships, and in particular teasing out synergistic relationships between multiple agents, is going to depend on better understanding of exposures. And today every time we misunderstand exposures, we misclassify an exposure, we dilute our ability to tease out those finer relationships.

So at a program level I think we need some research, and then down at a very specific kind of individual exposure characterization level we need research around techniques to improve individual practitioners' ability to make good exposure decisions. And this can be in the area of qualitative or semi-quantitative exposure assessments. Particularly, exposure modeling needs better research to understand and validate deterministic models that will aid practitioners in making good exposure assessments. And in the area of quantitative exposure assessment, better tools to aid the practitioner in making better decisions, given limited monitoring data. And I believe Bayesian statistics offer some exciting possibilities, not only in terms of those monitoring data interpretations, but also in terms of

systematically integrating, in a transparent way, qualitative judgment, modeling, and quantitative exposure assessment.

Thank you.

Verbal Comment 2005/12/19: Thank you. I'd like to talk just a little bit about a sector of the economy that is unlikely to receive much attention here at these hearings. Small and medium-sized businesses are a very important part of the U.S. economy, and a growing import-- they continue to grow in importance in terms of both the numbers and the number of people employed.

Right now there are about six-and-a-half million businesses -- business establishments that have fewer than 100 employees in the United States, and they employ approximately 17 -- I'm sorry -- 97 million workers. This is in a range of economic sectors, not just in manufacturing, of course, where there are import-- very important hazards in both the service sector and the manufacturing sectors. Many of these small business establishments in all of -- in all sectors have significant health and safety hazards. And if you look at the data, while the -- you do see the decreasing trend in injury rates in businesses overall, what you -- when you start to look more carefully at the injury rates by size of establishment, you don't see the decreases occurring as rapidly in the -- in the smaller and medium-sized businesses as you do in the larger ones. And in fact, injury rates are always highest in companies that are -- that

employ between 50 and 250 employees. So it's an area in -- and in manufacturing in particular, so it's an area where we still really need to pay some important attention.

Of course there are some important barriers that get in the way of accessing and helping small and medium-sized businesses. They have limited resources, and generally their staff have very minimal background in occupational health and safety.

I've met and worked with a lot of small business owners in the last decade. I've been doing intervention research in small businesses. And I've yet to hear any of them say that they don't care about health and safety. They all care a lot about it. But most of them -- and many of them admit that they don't really know what they should be doing, and they're skeptical many times when we make recommendations to them about what underlies those recommendations and why do we think something -- a policy, a program, an approach, a control -- why do those things matter and why will they make a difference.

And so the biggest issues have come -- I think really have to do with communication, as well as understanding the effectiveness of the things that we are recommending. They're not convinced, necessarily, and for good reason.

So I'd like to make a few recommendations to NIOSH in terms of putting -- first putting more emphasis on small businesses and helping them make the connection between health and safety and business productivity. That's the language they talk, especially in a small business where many of them go out of business within the first two or three years. And year to year it still can be hand-to-mouth in a -- in an economic sector where things are constantly changing. The sizes of businesses -- it amazes me from year to year -- can change dramatically from 50 to 100 to 200 and then back to 50. So they're always having to adjust.

What we need in order to be able to help them with health and safety are these things: First, we need simple, easy to use, valid measures of health and safety. For example, from the perspective of a small business, trying to do exposure sampling is almost impossible. They cannot afford it, and it isn't necessarily going to help them because it's so focused on one single exposure. They have a lot of issues. They don't -- and most of the hazards they have are not measurable as exposures.

We need easily understandable methods for us to be able to connect improvements to business outcomes and health and safety outcomes. So we need to be able to show them it matters to your business. Your productivity will improve and your costs will go down if you work on health and safety.

And we need to be able to help them figure out what we mean when we talk that very technical language that we all use in this field. What does that really mean when you're trying to solve problems? So we -- and I think there's much to be learned by health -- by communication from other public health arenas.

And finally, I think we should -- we need to identify a few key activities that really are associated with health and safety. We have a lot of things we expect, but we don't really know what exactly it is that means health and safety in a small business. I think the issues of management commitment and employee participation are all -- are both -- they need more focus and more research.

So I appreciate the opportunity to speak for a group of people that I think cares a lot about their employees, but doesn't really have a forum for sharing their interest and their needs. Thank you.

Verbal Comment 2005/12/19: Can you hear now? Okay. I feel like a commercial.

Thank you for letting me talk today. As Lorraine mentioned, I'm the director of the occupational health nursing program at UIC. My name is Shannon Lizer. I'm a family nurse-practitioner and also assistant professor in the College of Nursing. My dissertation work was about older farmers' health status and injuries, so I will direct the focus of my comments to sector 11, which is agriculture, specifically older farmers who are 55 and above.

As you all probably know, the number of older farmers is increasing. In 2002 the mean age of farmers were 55.3 years of age, and that does reflect a trend -- an older group of people. In Illinois currently the average age is 55.1, and over half of working farmers are over 55, which is unlike other areas of our workforce.

So while we know that farming is a very dangerous occupation to all age groups, it is very dangerous, it turns out, for older farmers, who suffer more injuries and fatal accidents in farming than other age groups. And there are many reasons for that. One of -- one reason might be physiologic changes of aging. We know these occur, but typically these may not affect workers over 65, 70, 80 years of age because they are typically retired. And as we know, farmers do not retire like other occupational groups.

Chronic diseases are also a problem. We know that chronic diseases increase as we age, in the general public. Many of these I believe are undiagnosed in older farmers, who do not seek health care and preventative health care as do other groups. They're typically self-employed and are not willing to leave their work setting to go seek preventative care. They go for treatment of things they see as needed.

So for example, in my dissertation I found -- which was a study in Illinois -- farmers reported hyperlipidemia, hypertension and diabetes at greater rates than the general public of the same age group, but much less heart disease, which may indicate that these diseases are not diagnosed but a factor in their illness -- or in their injuries.

We also know that medications play a role. There have been some studies that have looked at this, but not specifically in the older group. We also know that stress is a factor in injury, and we do not particularly have data to show why or how that happens. And also the effect of mental health disorders, such as depression, and the role of depression as related to occupational injury.

So finally, I would say that I recommend that we look at research aimed at older farmers 55 and older, looking at the relationship of physiologic status, their current health status, chronic disease status, mental health outlook, the role of stress and medications to injury and accidental death. I also think that we need to look at better tracking mechanisms for these injuries, which are grossly under-reported.

In doing this research I would recommend that we involve multi-disciplinary approach, including nursing, medicine, agricultural safety and health professionals, also agribusiness and the farmers themselves, who really need to be part of the process. So I would recommend that we use community-based participatory models to look at changes in health care delivery and assessment of injury and factors that are related to that.

And I would thank you very much for letting me have the opportunity to talk with you.

Verbal Comment 2005/12/19: Good morning. My name is Lezah Brown and I'm a doctoral candidate here in environmental and occupational health sciences department at the School of Public Health at UIC. And prior to returning to graduate school I practiced industrial hygiene in the governmental and private industries. Based on my exposure to the diverse occupational settings and populations during my 12 years of practice, I have chosen to concentrate my research on the impact of occupational exposures as they relate to the health outcomes in the family.

My current research is looking at psychosocial issues as predictors and antecedents of occupational injury, illness and assaults. The data for this project was collected by Dr. Kathleen M. Rospenda, who is an industrial psychologist here in the College of Medicine's department of psychiatry. The data was collected during a two-wave national random-digit telephone survey administered to over 2,000 working men and women in the 48 contiguous states, including Washington, D.C. Rospenda and colleagues collected information on many aspects of workers' psychological and social environments, both at work and away from work. The areas of interest that I feel are pertinent to this forum involve those variables possibly associated with occupational injuries, illnesses and assaults. The data collection tool captured information concerning the usual demographics of the workers, such as race, gender, age, highest educational level attained and type of job or profession, along with their income. Other personal information collected established marital status and whether or not there were children under 18 living with them.

The work environment topics that we're looking at, the workers were asked to document issues such as the number of hours they usually worked per week and whether or not they had experienced an occupational injury, illness or assault on the job within the last 12 months prior to their interview. Additionally they were asked about their perception of the presence of job pressure, job threat, generalized workplace harassment, and the status of their social support network at work. As far as the personal life aspects, the workers were asked to answer yes or no to questions about stressful life events such as did they lose a significant other through divorce or death, did they experience any financial difficulties such as bankruptcy, or did they have any other legal problems. As with the work environment questions, the study participants were asked about the status of their social support networks in away from work, but they could talk about work problems. The questions were designed to establish whether or not -- there were also questions designed to ask whether or not there were problem alcohol use issues, and whether they had sought services from any type of professional or clergy member to deal with the psychosocial needs.

The preliminary results show that in the cross-sectional data analysis for both waves that race was not significantly associated with reducing the risk of pre-- of -- of a occupational injury or illness; that older workers were not as likely to experience an occupational injury, illness or assault as were their younger counterparts; that gender was not a good predictor of -- in this population for occupational injury, illness or assault; and that stressful life events and generalized work harassment composites were significantly associated with an increased likelihood of having an occupational injury, illness or assault controlling for race, age and gender in both waves.

When we put the data into logistic regression analysis it showed that the older group was significantly associated with reduced odds of having a occupational injury, illness or assault. Along with that, the generalized workplace harassment composite showed a significant association with an increased likelihood of occupational injury, illness or assault in wave two controlling for race, age, gender in both waves, and that the stressful life events and problem drinking composites from wave one were not significantly associated with an increased likelihood of an occupational injury, illness or assault.

When we're looking at wave one and wave two, we're looking at the longitudinal information which shows that -- did these things exist before or after, we're looking for causation.

These preliminary results I suspect are the tip of the iceberg when considering important issues of the work environment and workplace.

Lastly, the types of partners that are needed to address the issues of psychosocial predictors and antecedents of occupational injury, illness and assaults should include academia in conjunction with all classifications of employers unions and employee groups.

Thank you for allowing me to testify today.

Verbal Comment 2005/12/19: Good morning. I want to thank NIOSH for the opportunity to speak this morning. My name is Tom Robins. I am the director of the education and research center, the ERC, at the University of Michigan in Ann Arbor. I guess I`m one of your hosts, as well. I also a member of the scribbled notes club, so bear with me and we`ll see how I do.

What I want to talk with you specifically about today is the role of NIOSH and NORA with respect to international global research in occupational health, over and above or beyond what we do directly here in the U.S. And what I`m going to do is first of all say a little bit about the key role NIOSH already plays in this area `cause I`m going to strongly advocate that they continue to do so. I`m going to tell you a little bit about my view of the kinds of problems that exist, especially in the developing world, in developing countries, that may be somewhat different than the problems here. I`m going to talk about what some of the specific research needs are in those countries. And I`m going to talk about why I think it`s important for all of us as Americans to support research in these areas.

So first of all, besides being the ERC director, I`m also the director of a grant from the Fogarty* International Center, which is in the U.S. National Institutes of Health. And the purpose of that grant is to support training and research in occupational and environmental health in southern Africa. Actually a 14-state area called the Southern African Development Community. We`ve been doing that for about ten years. And actually NIOSH plays a very important role in this. They`re one of the big indirect supporters. FIC doesn`t have its own money. They get money from places like NIOSH for this to happen.

In addition, NIOSH has played a leading role among the WHO, World Health Organization, collaborating centers in occupational health around the world. NIOSH is one of them, and a number of academic

institutions in the U.S., as well as in many, many other countries, are members, and NIOSH has played an absolutely key function in making this group able to address global health problems through funding and expertise, and essentially lending at some points some of their finest personnel for periods of a year or two to work mostly on WHO issues. So there's been tremendous support by NIOSH of that.

And a prime example of what WHO and the International Labor Organization are doing now that NIOSH is playing a major role in is a campaign around the elimination of silicosis, which is a lung disease that's caused by exposure to silica. Silica is present in many industries across the world. In many countries it's epidemic. Here in the U.S. we -- we've for the most part dealt with the major problems there.

So what sort of health and safety problems are maybe faced by developing countries like the ones I deal with in southern Africa that we may not see so much of here in the U.S.? Well, let me give you some examples that I've been directly involved with.

I went and toured a plant that was making paints and pigments, including lead-based paints and pigments, in what will be an unnamed country in Africa. And the management was very forthcoming about some of the issues they had, and there were many problems with exposure controls, and they had some people working there with blood lead levels that were twice the standard in the U.S. for immediate removal from work -- a symptomatic worker. So this is probably not an unusual situation. At least this company had actually measured blood leads. So that sort of gives you a sense of how things tend to look in the rest of the world.

Another example, I'm currently involved with a study of copper miners in Zambia who have silica exposure, in fact, as part of the ore. Now silica, besides causing silicosis, also weakens the immune system of the lungs. And tuberculosis -- TB is epidemic, or at least endemic. I'm going to have to be -- this is my last example. We professors can go on. Is epidemic in Zambia, and of course there's also HIV/AIDS is epidemic. And so the combination of high levels of HIV/AIDS with the silica exposure has put miners in Zambia at tremendous risk for developing active tuberculosis, by the ten-fold increase in the last decade.

So that just gives you a couple of examples. I'll skip the rest of them.

What needs to be researched? There are certain problems that have not been well characterized. A huge percent of the labor in these countries is in what we call the informal sector. And there's some of that here in the U.S., but in general the informal sector's been very poorly studied with respect to what are the major risks and what are the types of interventions that are effective when you have sort of a family level kind of employer situation.

And then finally -- I'll have to close in about two sentences. The other thing I want to point out is there's a lot of need for intervention studies, which are also applicable to the U.S. What kind of interventions are effective in these situations, and a lot of times that information can also be applied to the U.S.

Finally, besides the fact that I think it's important, ethically the right thing to do, there's also other reasons we as Americans should be interested in this kind of work, because in fact when health and safety situations are poor in the developing world and is not being supported, it actually ends up being unfair competition for American business and it ends up moving jobs away from the U.S.

So for all those reasons, I strongly support NIOSH's continued emphasis on research in global health. Thank you.

Verbal Comment 2005/12/19: Hi. I'm from the University of Minnesota and the Midwest Center for Occupational Health and Safety. Thank you for this opportunity.

I'd like to recommend that NIOSH continue to include work organization as one of its NORA priorities. In the first decade of NORA, work organization was identified as a priority, and the term covered issues such as hours, schedules, job design factors associated with health. Continued research is needed with particular attention to the dual role many employees have tending to work and family commitments, and the implications for role conflict, stress and health.

Well, how many people are affected by these issues? Data from the Department of Labor for 2003 revealed the following: Among married couple families with children six to 17, two-thirds have both partners in the labor force. And among those with children under six years, half have both partners in the work force. But what about single moms? From -- women with children ages six to 17, three-quarters are in the labor force. And among those with children under six, 64 percent are in the workforce.

The potential work family stress and health effects is particularly acute for women, who traditionally shoulder more of the daily child care and home responsibilities. But why emphasize these issues for women; don't men also have work family commitments?

Yes. However, findings from time use studies show that women and men's paid labor time has become remarkably similar over the last decade, whereas the uptake of home chores has not been as similar. Moreover, the nature of home responsibilities differ by gender with implications for paid work. Time studies reveal men spend more time than women on activities that are discretionary in terms of scheduling, such as home and lawn maintenance and financial management, while women spend more time on non-discretionary activities like preparing meals and caring for children. It probably doesn't matter too much if you wait a few days to mow the lawn, but your kids are going to notice if you don't make the meal. Thus women's responsibilities have a greater potential for conflicting with paid work, as such tasks are not easily rescheduled. And these trends are only likely to be exacerbated by the data showing increasing annual work hours in the U.S.

Americans work 200 to 400 more hours per year than workers in western Europe. This translates into five to ten more work weeks per year, with implications for role conflict and stress.

But how do work hours and role conflict affect health? Studies from Sweden have documented that role conflicts and work overload are reflected in elevated stress at work and at home, which can induce symptoms of cardiovascular, musculoskeletal and immune system disorders, with implications for long-term health. Lundberg and colleagues from the University of Sweden report that female workers employed full time, in comparison to men in the same jobs of the same age, have a greater total workload and experience more stress and role conflicts than men. And this gender difference increases with the number of children. The difference between men and women's total workload increased to 20 hours per week in families with three or more children, with women approaching 90 hours per week.

What does this mean in real world terms? One example comes from one of my former research staff, who called me last week. She now works two part-time jobs and recently had a two-week spell where either one or both of her children were sick. Her one-year-old had diarrhea for ten days and her three-year-old simultaneously ran a temperature, had a respiratory infection and pinkeye, and her day care did not accept the children because of very appropriate policies on infection control.

What did this mean for her? She ended up putting together a patchwork of child care services so she could show up at work, and during this period rarely slept more than four hours a night due to her children's frequent nighttime awakenings. She too developed a respiratory infection, and by the end of ten days spoke of possibly quitting one of her jobs, if things didn't get better soon, due to fatigue and stress.

But what does work have to do with it? Aren't these problems the result of personal choices? The point of the story is that one of her part-time jobs is more flexible. It allows her occasionally to work at home to balance work and family. There's social support from other coworkers who are young mothers. And one of the jobs provides her autonomy to help work with her supervisor and set work priorities and work flow. These are all work factors that help her address the inevitable conflicts of paid work and family.

Now this story focuses on a woman who's well-educated, married and middle income. Now imagine a single mother with limited financial resources, an inflexible job or two -- how much; 30 seconds -- and a non-supportive supervisor. What is the potential for role strain and health effects for her?

So let's see, I'm going to skip to the punch line and just say that there's -- research is needed to identify the effects of work family conflict on the health of employees with children, and in particular to identify those work factors that can be modified to enhance health and positively affect productivity.

One last comment. Moreover, in a study underway right now, we're studying a cohort of about 800 women as they return to work after having their babies, and doing a longitudinal study of the first 18 months postpartum. What we've found is that total workload, perceived job stress, job flexibility and workplace support has significant effects on general mental health and postpartum depression scores. And so I think there's a continued need for work in this area and a focus on women from different racial and ethnic backgrounds and income groups. Thank you very much.

Verbal Comment 2005/12/19: Once again I see OSHA's loved -- I'm up here all by my (unintelligible). I'm used to it; it's okay.

Thank you for inviting us here today or giving us the opportunity. My name is Mike Connors. I'm the regional administrator for OSHA for the Great Lakes Region. And I have two issues that I would like to talk about, and they're local issues because I know that Washington is working with your national operation to talk about input on NORA, but these are local issues that we are working on.

The first one deals with isocyanate operations. We're seeing an increase in the number and uses of isocyanates in a variety of operations. We're particularly concerned about control technology and a number of other areas. Let me explain.

One of the areas that we did an emphasis program on was truck bed liners because we heard about the use of isocyanates in there and we were concerned about it that they tend to be very small operations. We've done about 80 inspections in the past year or so, and at least 50 percent of them have had overexposures, some of them up to 39 times the permissible exposure limit. We've had a death case in Michigan, and we've had people on the fringes of the so-called containment areas that were also exposed to pretty high levels, levels that we'd be concerned about.

Now we're also not comfortable that in walking away and doing the evaluations as to whether they're over the PEL or not that we've got a safe operation when they're under, because we're seeing more and more uses of mixtures with isocyanates, and mixtures for which we don't have clear-cut guidelines on the health effects, how to analyze it and things like this. We're seeing more and more uses of it in auto body shops, two-part paint operations using polyisocyanates.

NIOSH put out an excellent publication, a summary of the HHEs* involving isocyanates from '98 to '02, and there's a lot of good information in there. What I'm asking for hopefully that you could look at in NORA is continue to work on the sampling and analytical methods. There are two or three competing techniques on how to analyze it, what needs to be done in the field, working on training materials for employers, employees, and safety and health professionals. There's still a lot of confusion out there on how to do a good evaluation in this area.

While the medical surveillance issues that are there related to the respiratory problems, we think more information on skin exposures and its importance needs to be done.

And of course something on a standard for mixtures. We are kind of jealous at the U.K. model that looks at total reactive isocyanate groups, that that might be a model that we could use, but we need more information to make sure that the health effects are there for the mixtures. We are working with the polyurethane industries to get more information out there, but we could sure use help in some of these areas.

The other area I'd like to ask for some help on is in making the business case for safety and health. Years ago we had a Project Minerva study that went on, and it kind of died through neglect over the years. What that program did was try and get the word out on the need for safety and health programs in the business community. Well, we think we need a similar program for not only the business community, but for the business schools, for owners and operators of medium and small-sized establishments, and in fact for safety and health professionals because the schools do not seem to really be teaching safety and health as it relates to and the need to integrate it into the business process to make it an asset rather than always being thought of as a cost center.

We have developed, working with groups -- one of which talked earlier, Brian Devlin from Life Services Network. We've worked for a couple of years in Illinois, probably three years, with the home -- with the health care industry, focusing on nursing homes; working with UIC, Abbot Labs, the life services network, long-term health care, OSHA, consultation, nurses and therapists, we've developed examples of practical studies where people did invest in equipment for assisted lift programs, developed an assisted lift program, and then we looked at the business case. How much money did it cost and what was the impact? And we saw very positive results that we've seen over and over again in the nursing

home area, that a small outlier in investment can bring back big returns. Usually the return on investment is within a year or two. We also see improved morale, less turnover of nurses and nurses aides, and better resident care and that there are less skin tears and bruising as the equipment is used.

We think there`s a story there, to go out and talk to owners and operators and show them that you can and do need to invest the money and you`ll get the money back.

We`ve put a module on OSHA`s website and it contains some case studies addressing the need for safety and health programs, the value for safety and health programs, essentially the need to control risk and build your safety and health program around that. We have examples for foundries, construction, nursing home, pharmaceutical and auto industries. We need more.

What I`d like to see is that in the future when we talk about control technologies we always put it in some sort of context. What were the before and after conditions in terms of exposures, were there ergonomic problems, airborne exposures, safety issues; what was the investment, what kind of return on the investment was there and what were the improvements noted, so that when we go out to small and medium-sized employers that we can make this case and show there are practical examples out there and have this library there available to help people in the workplaces.

And that, in a nutshell, was what I had to ask for today, so I appreciate the opportunity. Thank you.

Central Brain Tumor Registry of the United States

Categorized comment or partial comment:

Verbal Comment 2005/12/19: Well, first of all I'd like to thank NIOSH for the opportunity to be educated here today, and also to develop some empathy for others who have concerns that they are addressing to NIOSH. I think that many of us think that our organization or our causes are the ones to put forth primarily, which is what we do. There is -- I have at least developed an awareness here and an empathy with -- with you all.

Our organization is the Central Brain Tumor Registry of the United States, and we are a surveillance organization. And I'm actually coming with a question and an offer to work with NIOSH. We receive requests from the patient community and from researchers who are investigating cancer clusters, and wondered what the surveillance policy for these is at NIOSH and how we can partner with NIOSH to help them or work with them to identify these clusters, especially with childhood brain tumors and childhood cancers. Is there --

DR. CONROY: But before you leave, could you tell us who you are? I'm sorry.

MS. KRUCHKO: Carol Kruchko, and I'm president and administrator of the Central Brain Tumor Registry, and we're located here in Illinois.

Verbal Comment 2005/12/19: Good afternoon. I'm actually here on two different role, to welcome you to UIC on behalf of Dean Scrimshaw*. My name is Shaffdeen Amuwo. I'm associate dean for the School of Public Health in urban health and diversity programs.

My second role here is to present a testimony, although I don't have a written one, in terms of some of the direction that I think NIOSH should go. As many of you may know, the face of this country is changing very rapidly (unintelligible) of immigrants, and they have to work. Well, you notice that immigrants generally take on some of the first jobs available to them that they are allowed to work, and some of those works are where you have very high risk exposures. For instance, when you look at cab drivers in any part of the major cities in this country, most of the ones you will see driving will be immigrants. When you look at the building industry, most of the builders, most of the carpenters, most of the brick layers, are immigrants. Then but what we don't attempt to do is to look at the contribution of this immigrants to the health disparity in the nation. Therefore I would strongly recommend that more and more research dollars should be devoted to looking at the contributions of immigrants to our health care disparity, given the fact that many of them get sick, many of them don't have insurance, many of them that does have insurance are not adequately covered. As a result, their morbidity increases the gap between -- between African-Americans, immigrants, as well as the general population. So it just makes a lot of sense to put more research dollars on the issue of exposure of immigrants in the workplace. Thank you.

Verbal Comment 2005/12/19: Okay. Thank you for giving me this opportunity to be able to give a short testimony, one that wasn't planned. My name is Adedeji Adefuye. I'm the assistant dean for Urban Health and Diversity Programs here at the UIC School of Public Health. I've listened to all the presentations in the morning and one thing we probably all will agree on is the fact that the -- there is disparities in the number of injuries when you look at the different parts of the U.S. populations. There are some groups that are affected more than others, and mostly minorities when you look at personnel injuries. And when we're trying to make sure that workplaces are much safer than they are, we cannot shy away from looking at the disparities actually in the training of health -- health care professionals, particularly those who are involved with occupational safety and health. Here at the UIC School of Public Health we are in the business of training these professionals, occupational health and safety professionals, among other public health professionals. And what I really think that both NIOSH and NORA should be considering as part of their research agenda is looking to how the disparities in the training of occupational health and safety professionals affects efforts to make the workplace safer.

Everyone here probably will agree with me that in designing interventions to reduce workplace injuries and diseases that actually occur as a result of exposures at places of work, people tend to a lot of times want to have interventions done by those who actually can associate with the kind of upbringing that they have, with the kind of environments in which they grow -- they grew up, and as such probably will be more willing to take part in intervention projects that are designed and also implemented by people of their -- of their kind, probably maybe people who look like them, who talk like them, who understand their sensibilities and everything.

And you just mentioned the question of research to service. I actually want to interject something between research and practice. Most policies are driven by research, and I really think that if we do not train enough minority professionals who will be part of the research enterprise because we know that

research actually drives policy and it's actually policy that leads to (unintelligible) design and practices that are actually effective. So my -- we -- also we need to look definitely into the training of minorities in occupational health and safety so they become part of the research agenda and actually have an impact on both policy and practice. Thank you.

National Roofing Contractors Association

Categorized comment or partial comment:

Verbal Comment 2005/12/19: Thank you very much. Can you hear me okay? All right.

So good afternoon. My name is Tom Shanahan and I represent the National Roofing Contractors Association. NRCA is one of the oldest construction trade associations, celebrating its 100th year this year. Roofing businesses are typically small family-owned businesses, as Matt had alluded to earlier. We were right in there with that. And from a personal perspective, you know, working with roofing contractors has been a fantastic experience. Not only are they incredibly intelligent, but incredibly warm people who care about what's going on with their workers because there's a very family feel to it.

But roofing work is very dangerous work and OSHA recognized this in its formation back in 1970 when it -- it was -- roofing was one of its five targeted areas. And with good reason. Like I said, the nature of the work is very hazardous.

So then it only seems natural that everybody involved would do everything he or she could to see that those hazards are controlled in some way. Interestingly, for one reason or another, that just isn't the case. And that's not to say that OSHA or insurance companies or roofing contractors or roofing workers aren't effective -- aren't affected by this or they don't care, because I can tell you first-hand that they really do care and they try to do a lot about it.

But safety solutions aren't easy in the roofing industry, and -- as it might seem at first blush. If you took the -- talked to some, they'll say well, if a roofing contractor will just do this, or if the workers would just do this, or if OSHA would do that -- and it goes on and on. I think we all know that. But that doesn't get anywhere.

So what's the difference? You know, what really gets through and what -- what is it that we need to do? In essence, it sets the stage for my comments here.

For the last 17 years I've had the opportunity to work in the roofing industry as its national risk manager, and in my experience it's become apparent that what needs to occur is effective training. And you might be thinking well, no kidding, Tom; of course. But I challenge you to really consider the numbers and the efficacy of training in the construction industry. They're not very good. And they're not very good in particular for small businesses, and if you look at the small business numbers in general, they're not very good. So something is missing, even though it's something that we all would consider very obvious.

So from an effective standpoint, I think what I'd like -- what we'd like to suggest is -- I'm concerned about my time here -- is that -- recently I've seen roofing contractors who, on an exception basis, have been doing some really cool things. And so I've asked them, from a safety perspective -- they've just made safety a part of who they are as a company, and that is a difference I see from typical. I've asked them why they've done that, and some of them say well, you know, we really could not take another serious accidents and look at our employees square in the face. Or they just say, you know, we finally figured out that it makes good sense from a business perspective. And of course, you know, I'm thinking well, aha, finally, you know, you're hearing something you really think makes a lot of sense.

The reality is, as obvious as it might seem, safety isn't as obvious as you think it is. So the questions that we believe need to get studied are to what extent is safe behavior affected by training; understanding in the construction workplace what type of training works and for what kind of behavior changes; what kind of training and education affects the long-term behavior needed to impact safe decisions on the job by employees every day. And I really believe that if you can get at the behaviors, change someone's behavior to tie off a ladder, you know, what training impacts that decision so somebody does it. And then finally, and I think importantly, you know, what changes small businesses owners' minds to see that business models that embrace education and training are successful ones. In other words, what's the business case for safety and education? And after talking to some people at NIOSH, I understand -- I think it's through the University of West Virginia -- they're working on some of that, and I think that's fantastic and we would love to be a part of that.

And so in the end, you know, the idea of affecting safe behavior and understanding how that works in the training scenario I think is very key. And although obvious, we spend millions of dollars every year training, and to what end? And getting at that and understanding it I think would be great. And if I was younger and wanted to go after a Ph.D., that's where I'd be -- I would be heading my degree on. Thanks so much.

Verbal Comment 2005/12/19: My name is Jim Platner. I'm with the Center to Protect Workers' Rights. Now for those of you that aren't familiar with our organization, we're a non-profit that's affiliated with the building and construction trades department of the AFL/CIO. And since about 1990 CPWR has been working closely with NIOSH on research related to construction safety and health. Now -- and you know, we're really committed to working with NIOSH and we appreciate the opportunity to comment.

First I wanted to suggest that there's a lot of different initiatives, it seems like, going forward at once that are complicated to understand. And it might be useful at the front of this NORA II effort to describe, in a paragraph or two in the -- what the difference is between the ongoing part performance criteria and this NORA II effort.

You know, in my mind there's really three things going on at once that are mixed between these efforts. One is NIOSH is developing performance metrics under the part requirements that are really going to be used as a proxy for research performance by the Office of Management and Budget. And I think that's very different than the research priorities, which should be driven by surveillance, by gaps in the research literature, by evidence-based science. And then the third, in my mind, which is sort of going on at the same time in this NORA II process, is the -- almost the development of new management structures as to how NIOSH will deal with each -- like sector councils, deal with each sector, and hopefully use those to continuously update its research objectives.

I think, given the -- how long it takes to get a group like a sector council functioning, I think NIOSH should consider whether it's worth abandoning this sort of ten-year time frame. It seems to me that it could take ten years to really get a new organizational structure functioning, and it doesn't seem to me that it's necessary to have a defined time frame on a management structure like that.

Just some of the other issues that I wanted to raise is that, you know, we certainly agree that our research priorities should be based on evidence and surveillance data that we have. But I think there's a concern that when -- when we have a cross-sector council that is seen as defining priorities across industry sectors, it's important that that council understand that they're not going to divvy up and share

the money or research projects equally. I think there has to be probably a specific process for targeting money at high-risk industries. And construction, in my mind, is certainly one of those.

Categorized comment or partial comment:

I'd also like to see the research priorities consider the hierarchy of controls. You know, we're in a difficult position in construction where we really want to see engineering controls for most of the exposures. But because it's dominated by small businesses and the decisions are often very scattered across the country where you've got thousands of small businesses that have to make decisions, we have to think about both the engineering controls and PPE and the efforts of groups like the National -- the NPPTL* research. We encourage and support the effort to go to research to practice, and I think those kind of applied projects are important to link to the engineering controls. And I think there's some real personnel and qualification issues that have to be dealt with from a management perspective to say we have the connections and the staff to deal with the engineering controls and the personal protective equipment in some sort of integrated manner rather than dealing with them separately, when hopefully the PPE is only going to be used until the engineering controls can be implemented.

So we've got a -- I've got a whole list of other comments, but they'll be submitted in writing. Thank you for the opportunity to speak.

Verbal Comment 2005/12/19: This is great. Now I can bore you with two microphones.

I'm Don Garvey. I'm the construction industrial hygienist with St. Paul Travelers. I'm also a past chair of the American Industrial Hygiene Association. Today, though, I just come as a grunt industrial hygienist who works down in the trenches, so I don't have the big global picture that a lot of other speakers have been coming with.

But what I would like to suggest with NIOSH is a stronger emphasis on researching noise in construction, and particularly impulse and impact noise in construction. Mark Stefanson* with NIOSH did a fascinating little study several years ago which indicated that, on average, the typical 25-year-old carpenter has the hearing of a 50-year-old person, which -- which would indicate an exposure or a repeated, consistent, constant exposure of upwards of 100 decibels on a daily basis. Which -- which just isn't happening out in construction. Certainly we have high noise levels, but certainly not 8-hour time-weighted averages on the order of 100 decibels. So it indicates that something else is going on there.

One of the things that construction is rife with is impulse and impact noise, whether we define it as the official kind of impulse or impact noise or the short, very high-intensity noise of brick -- cutting a brick with a chop saw. In the 2004 American Industrial Hygiene Association conference, during their noise symposium, one of the symposium sessions was on impulse and impact noise. And the one sentence synopsis of that presentation was we really don't know a lot about impulse and impact noise, what -- what parameters are important in deciding if impulse or impact noise is going to be detrimental to hearing. And even if we did know which parameters to look at, we don't really have either good methods or we don't know how to monitor and evaluate those exposures.

So I would like -- I would like to see NIOSH focus more on noise in construction in general, and particularly on impulse and impact noise.

The last thing that I would like to mention, I would like to emphasize what Tom had said. He brought up an interesting point on the efficacy of training. Again, another NIOSH study, and again I believe by Mark Stefanson. Something on the order of 90 percent of construction carpenters knew that noise was dangerous to their hearing. And something like 70 percent of those carpenters believed that noise was impacting their hearing. But only about 20 percent were actually wearing hearing protection on a continuing basis, which would tend to indicate that while we're getting the point across and while we're doing the training and while we're getting the knowledge to them, it's not taking hold, it's not taking root. So what Tom said, I'd like to back that up on research on the efficacy of noise training.

So thank you very much.

Verbal Comment 2005/12/19: Good day to everybody. I`m pleased to have been asked or been given the opportunity to speak today on this topic of fatalities from falls. I have personally seen and heard from many friends, coworkers and other craft`s families to have been devastated from this problem.

My name is John Shine. I have been in my trade, the insulators, since 1973. I have worked for the Local 17`s apprentice program since 1987, and I`ve been involved with the safety training, program development, and research since then.

I`ve worked in the field as a helper, an apprentice, journeyman, foreman. I worked around, saw and heard about many falls and the resulting injuries. I at first thought this was the chance that you took to be paid. As I went along from job to job, I noticed that the foremen in the companies that were interested to keep this to a minimum. These were and are motivated people. People would, could and did get hurt. These people said that there was a better way to do our job.

I have since then been teaching fall protection and prevention at our apprentice school. One day at work when I was in the field, I used the example of a painter I saw fall from a height. He had no fall protection on at all. It was not used then. I will not go into the details here, but his family should have never gotten that phone call that day. There were better ways to do his job that day.

I also know that there are better ways to protect all workers that I deal with. I`ve had two young apprentices fall at work from a scaffold, and another young man came -- was about to come into the apprentice program, fell from a pipe rack at work. These men were a terrible waste of excellent minds, who would have been a credit to our union and our craft. These are a few stories I hear about at work. I

listen to workers in the classes that I give. I give their stories back to the membership who attend our SMARTMARK program on construction safety, and the apprentice classes, also. These incidences I speak of come from them, as well as their own experiences.

When we reduce this injury and fatality rate we can keep smart, productive and interested people on the job sites. There are many directions that this study can go, and should each be addressed from all these instances.

My first one is training is for everyone, workers, safety directors, supervisors, superintendents, estimators and the owners. Each one of these people in the process needs to know what the other is doing and if they are doing it correctly. I think as I go through the other issues, this will become evident as to why it's important.

One of the big problems with fall protection from height is the anchorage point. You'd be surprised to hear and see what is done on the job sites, what workers are told to do. Some of it doesn't make sense. Electrical conduit, electrical light fixtures to be used as anchorages. How does a worker anchor to a 500-pound (sic) anchorage point when no one knows, nor will tell him, what constitutes a 5,000-pound anchorage point? Try to get an answer. This might be your fun for the day. Is it a 4-inch steel pipe sitting on a concrete beam? Could it be a 3-inch electrical conduit? Do not even think of the light conduit, which people have been told to anchor to. What do I do as a worker when there is nothing of substance to attach to? Do I put on a show, wrap the lanyard around the ceiling joist to make the safety guy happy? If I don't, I might get laid off for not following the safety rules. It might not make sense, but you do it anyway. If I do -- if I do say something, I'll be complaining. I might lose my job as a troublemaker; he asks too many questions.

The next issue could be preplanning for engineering stages. Anchorage points, as an example, have been put in place during the erection of floors and ceilings, and left in place for future use. This has been successful on many jobs lately. This will be -- put the anchorage points above the workers' heads, where they should be. This also minimizes the pendulum effect if the people fall, and minimizes swinging into stationary objects.

Next part is inconsistency of regulations, such as OSHA standard, which has two different heights that we can work from: six foot for fall, ten foot for scaffolds. I don't understand the differences, but that should be addressed. How about the inconsistency of one facility to another? One site goes to the extreme of have you in a harness on a six-foot ladder, while the other site lets you walk around 40 feet in the air on a beam.

The next one is lack of knowledge of what equipment is proper for the job at hand. There are many different types of harnesses that can be used. One type doesn't do it all. The various trades have harness types that they use consistently. This does not mean that every job is the same.

Let me continue on here. I think I'm running out of time.

DR. ALBERS: Yeah, you are out of time, I'm sorry.

MR. SHINE: Excuse me, I was almost there.

DR. ALBERS: All of your comments will be entered into the record. You know, we'll get a copy of his comments.

MR. SHINE: I'm a teacher; I guess I get too wordy.

Verbal Comment 2005/12/19: Yes, thank you. I'd like to thank NIOSH for the opportunity to come here this afternoon and address some of our issues that I feel are important for the research of the study that's coming up over the next ten years.

My name is Tom Kavicky. I'm safety director with the carpenter's union here in Chicago and the outlying 81 counties. I've been doing this now for about eight years. Previous to that I was like Jack Shine of the insulators where I was an instructor at the training center for almost 17 years. I've worked out in the field for quite a while before that, since 1970. So I've got a background in construction and dealing with a lot of the issues that we address every day on the job with workers.

Number one, we would like to see -- over the years the issue of fiberglass has been on the list, been taken off the list. We have a tremendous amount of carpenters that are involved in insulating homes, insulating commercial buildings with different type of insulating products such as fiberglass. And we'd like to see a study done and once and for all coming up with some kind of idea -- is it safe, is it not safe; what best practices to use when installing fiberglass.

Second issue, and I'm in agreement with Jack Shine from the insulators on this one regarding falls. I would like to see more data, more specific data. When we talk about falls in construction from elevated and same-level surfaces, but we don't get into specifics as far as what was the worker doing when he fell. What caused the fall? And causes aren't that important as to what was he doing or she doing when the fall occurred? Was it through a floor opening? Was it while they were installing a ladder or working from a ladder? What were they doing? Were they over-reaching? More specific information so we can utilize the information at our training centers across the country and specifically zone in as to where we're seeing these issues out in the field to help better our relationship with our members and contractors and reduce those injuries.

Another issue is the -- we provide a tremendous amount of training here in Chicago, both through the apprenticeship program and through the skill enhancement program where the journeyman has an opportunity to come back for training. In that training, specifically the skill enhancement training, we've got about 8,000 right now members that come in for training on an annual basis. Now that 8,000 equates to a membership of approximately 43,000 members here in Chicago. I would like to know why 8,000 members make it a point to come out just about every year, taking classes, and the other 32,000 you just can't reach. And we do all sorts of promotional -- things like that. But what makes the one person -- one individual want to take the training to better himself -- and it's not only safety, but as far as skills -- and the other, majority, not take the training?

We would like to see research done along with Mr. Garvey's comments. What is it that makes one worker at a job site stand up and say I'm not going to do this because it's an unsafe act, and the majority not take that stand? I know if we could all figure that out, we'd be rich or whatever, but I would -- just wonder if that would come into being in research and study.

Verbal Comment 2005/12/19: Thank you. Thank you for the opportunity to speak. I really appreciate it. Frankly, I'm humbled by the intellect and the credentials of the people that I've been listening to for the last four to six hours. It's incredible.

My name is Al Rexroat. I represent the Illinois Regional Insulation Contractors Association. I represent the National Union Insulation Contractors Alliance, which is a national organization that I wish I could say is 115 years old like the roofers, but it is only three years old. We just started it. And I represent Interstate Mechanical Insulation Contractors. So I wear three hats. I'm a businessman and I'm an association executive. And I am not an expert on musculoskeletal disorders by any stretch of the imagination.

From a businessman's perspective, though, over the years -- I started in the business in 1964 -- I know that I have had -- the largest single case I've had against my company was a musculoskeletal disorder. It was a back injury, and the man was doing nothing wrong except doing his job. And he got injured, and it was the largest single expense we had that year.

From a businessman's perspective, this is costly because we have men that can't -- or people, men and women, who can't work. Excuse me. I have three daughters; I should remember that. But we also -- when our people aren't working, our mods go up in our workmen's comp. So from a business perspective, this is very costly for us, as business people.

So we would like to see something on -- along these lines, with especially these insidious musculoskeletal disorder things. We have men working in our industry that are young, most of them, that are installing duct wrap around duct work in buildings. And they're -- the process is that they cut the material, they smooch it with this hand and close the gap, and then they use a plier-type device with

their other hand and they make -- every inch they make a staple to hold the stuff together. Well, they do it all day long, and then they do it the next day. And then they do it the next day.

The point is that these disorders -- they don't even know it's happening to them. It's kind of like the asbestos was in our business back when I started; we didn't know it was happening and all of a sudden we were whacked with it and we were sick. Well, that's what's happening to these kids, and we need to pay attention to it.

I would say -- I would agree with a couple of other issues. Mr. Connors from OSHA was up here earlier this morning. He talked about education -- educating contractors to understand that safety is a good policy for businessmen because it puts money in our pockets and keeps our men working and our women working. It's just good business. So we need that -- that's paramount importance, I think.

I also agreed with Jack Shine when he talks about education of the employees, of the foremen, of his contractors -- people like me -- that we need to know that these things are happening. We need to know what the best practices are to help our people, because we are there to do that. I don't want to see guys get hurt. I don't want to see people fall. I don't want to see people get hurt.

So with that, I'll -- again, I'll thank you very much for the opportunity to speak. I do present a little different perspective 'cause I am a businessman, and thank you again.

Verbal Comment 2005/12/19: Good afternoon. I'll keep my personal opinions to myself. I'm representing the American Society of Safety Engineers today. I'm in construction safety for 30-plus years, 17 of them as a compliance officer for OSHA. But I'm also a member now of the construction practice specialty, which has approximately 3,500 members of the 30,000 members from ASSE. We commend NORA and NIOSH for this effort.

ASSE's construction practice specialty is one of the largest and most active specialties. We have, within ASSE and the construction practice specialty, the NCA10* series for construction and demolition, which equates to 44 specific standards, that is to say, for construction and demolition subjects ranging from dredging to scaffolding. And similarly, we are a secretariat, as well, for an organization, NCZ15*, which are the safety requirements for the operation of motor vehicles, another key issue to construction.

There are two suggestions or I should say recommendations that NC-- or that ASSE would have, that being that within the construction sector research council that we would hope that NIOSH would have the chair or the A-10 committee closely involved, if not also chairing, the construction research sector. Similarly with respect to the Z-15 standards chairperson. Not that they necessarily have to be the chair for the transportation sector research council, but that we would urge you to actively involve them in any of your proceedings.

Cultural ambiguity. OSHA, IMSHA*, state safety and health agencies, unions, employers and safety and health professionals are all working diligently to communicate better with and to educate Spanish-speaking workers to help keep them safe and healthy on the job. Even when we develop appropriate language documents and we use effective visuals and further build our supervisors` language proficiencies, there is still the hurdle in the cultural differences we experience in working with Spanish speakers. It is now time to go, we believe, one step further in our efforts and to support research that examines cultural ambiguities that exist within the framework of what the construction industry currently uses as its methods for communicating and reinforcing hazard information. Translated, we believe that right now of course there are some moribund, age-old traditions within the construction industry, vis-a-vis the safety toolbox -- the weekly safety toolbox talk, et cetera, et cetera. And we`re wondering, in essence, whether or not these are effective. But beyond that, we`re wondering as well about the methods for communicating and reinforcing information about hazards.

For example, Spanish-speaking workers have an approach to authority that is different than the typical U.S. approach, and may lead them to saying yes when they mean no. We should know as much as we can to understand that orientation. I got to thinking about this when someone from ASSE was going to be putting on one of these conference calls and he himself is of Spanish descent, or of Mexican descent, and he indicated that it`s often the case that the messages that these hardworking individuals take when we give them a particular order or direction in terms of their work is something different apparently. And that when we similarly do this with respect to communicating hazard information that they as well take different messages along with that. So we`re close to the -- the point being that we need a better understanding of both the workers` and the employers` cultural assumptions and that they should be the next frontier of research.

I think -- I commend Tom Kavicky for his remarks on the injury and illness source database. That said, I second that, and that was one of our recommendations, the full record of which will be for your review. So I think we can skip over that one, except to say, if you don't mind, that we do know anecdotally that the majority, for instance, of disabling falls in your framework, Tom -- that is, framing carpenters -- from sheathing, roof on -- work on top plates and from (unintelligible). But we don't have that substantive database that gives us anything more than the very broad brush of fall from height, or fall from scaffold at the very least, in terms of really parsing it out. That specific information would be most helpful.

Beyond that, a greater focus on silica. We know that there is myriad literature out there on the subject of silica. That said, we don't ask that any further research be performed as to what the safe levels are. We have everything from the fables -- or not the fables, but the -- the tragedy of Hawk's Nest down to everything that you folks have most admirably done in the last ten years.

What we do need, however, we believe, are activity-specific pieces of information -- as one of the young presenters earlier this morning was suggesting -- for the small to medium-sized firm that's going to be able to use that information in the context of simple reading. We understand of course that there are variables, vis-a-vis, again, weather, environmental factors that go into that. But we urge you to consider at least a silica message in terms of silica information to the small to medium-sized firm with an eye toward giving them some things as to what's the most effective controls for the short duration exposures.

Thank you very much.

Verbal Comment 2005/12/19: Good afternoon. Thank you for the opportunity to address the committee regarding the National Occupational Research Agenda construction sector issues. My name is Michael Watson and I am a certified industrial hygienist and representative of the safety and health department, International Brotherhood of Teamsters. Our building material and construction trade division is comprised of approximately 102,000 building material supply and construction members who may be impacted by decisions regarding the agenda.

According to data published by BLS for 2003, construction, sector transportation and material moving drivers experience 5,800 non-fatal occupational injuries and illnesses involving days away from work. These drivers perform work in highway and steel construction, water and sewer and utility line construction and repair, heavy construction and excavation work, ready-mix concrete, refuse, and construction material and pipeline transportation.

With regard to fatal occupational injuries, according to the census of fatal occupational injuries data for 2004, the construction industry sector recorded 1,224 fatal work injuries, the most of any industry sector.

CPWR published a study in 2001 titled "Trends in Work-Related Death and Injury Rates Among U.S. Construction Workers, 1992 to 1998". According to the study, the fatality rate among truck drivers was consistently higher than the fatality rate for all of construction.

The Teamsters Union urges NIOSH to continue research into diesel and combustion particulate exposure; general wellness issues such as hypertension, weight-induced diabetes and heart disease, and the use of tobacco products and caffeine. The adverse health effects of extended work cycles and chronic fatigue should be examined, as well.

Teamsters Union is particularly concerned with injuries and fatalities resulting from highway accidents and struck-bys in the heavy and highway construction and excavation subsectors, musculoskeletal injuries and disorders among construction drivers, noise-induced hearing loss among construction drivers, and crystalline silica exposure among ready-mix concrete drivers. It is the Teamsters Union position that these issues should be included in the agenda.

Drivers should receive better and more thorough driver education which is specifically tailored to the driving tasks that they perform. This driver education could also include components which specifically address the importance of seat belt use, proper lifting and lowering practices, hearing conservation training, or other hazards present at the work site. NIOSH should perform research on the most effective training techniques for educating this particular group of workers.

Of course funding for research and education is the backbone of any initiative which seeks to implement change in an industry as dangerous and diverse as construction.

Employers and unions alike cannot and should not bear the entire cost of making sweeping changes to make our industry safer. New technologies in vehicle safety -- for example, sonar, radar and video technologies -- need to be investigated. New truck and heavy equipment design should be investigated in order to make trucks and heavy equipment more driver-friendly and ergonomically safe. NIOSH and other government agencies, including NIEHS, need to continue to fund this research and education if we're truly to get to the very core of these issues.

Thank you.

Verbal Comment 2005/12/19: Thank you. And I thank you for the opportunity to speak on behalf of the construction equipment manufacturers. My name is Russ Hutchison. I'm the director of technical and safety services for the Association of Equipment Manufacturers. We are a non-profit trade association based in Milwaukee, Wisconsin. We have offices in Washington, D.C.; Ottawa, Canada; and Beijing. We have over 700 members, and we serve the construction, agricultural, forestry, mining and utility industries.

I'd like to highlight construction occupational safety areas that our members are telling us are of concern to them. Many of these NIOSH is already active in and aware of, and we are going to encourage them to stay in those -- stay working in those areas and do more -- do more, maybe expand.

The first I think one of the high priority items is silica -- silica dust control. On the top of the list are the cutting, grinding, drilling. Methods of dust control and mitigation that have practical application in the industry should be looked at. You've looked at some of them. You've begun that process. I urge you to stay active in that area.

In addition, I think it's important that you look at methods of effective communication to the construction worker. And I think this goes -- this is sort of the training area, and I'll highlight that a little bit more, as others -- and Mr. Shanahan started right off the bat with it. But we need to impact the

worker with regard to the hazard and the means of controlling the hazard. It's got to make sense to them. They shouldn't be out there in the middle of that cloud of dust not worried about anything.

Silica dust is generated by a variety of the equipment that our manufacturers produce. Not only is it the concrete cutting, grinding and drilling, but it's also the milling of concrete -- the cold planers*, as they call them -- and work is going on in that area right now. NIOSH is doing some work with the contractors and with the manufacturers. But again, this is an area that needs to be continued to address. In addition, there -- we have manufacturers of equipment used in quarries, used in mines. Their issues with regard to how you control silica dust are different, but they are another area where silica exposure is an issue and needs to be attended to.

And finally in that regard, I would urge NIOSH to put more effort or dedicate more resources to the control banding concept. I think that was alluded to briefly before, but the idea that you identify a process and then you identify the controls or the PPE that's appropriate for that process. And it allows the contractor to probably conservatively protect the employee without having to go through and do air sampling, but it will require air sampling and that's where NIOSH comes in, and I think we need extensive testing, air sampling, and it needs to be very comprehensive so we've got good numbers.

Secondly, training. We started it off and on -- I would again, and our members would, urge that training be a focus. We need insights into the most effective methods of training, how to best accomplish the communication process, and are there different methods that are more effective in different industries or different crafts, that kind of thing. Let`s look at classroom training. Let`s compare it with internet-based training or web-based training. Let`s look at the interactive CD, DVDs -- and these are just ideas. There are many more methods of training. But let`s compare them and see which are the most effective and share those results with the people that need to do that.

Let's move on to crane power line contacts. We have crane manufacturers and they're looking at upcoming new regulations or highly revised regulations in the crane industry. During the course of writing those -- their draft regulations, proximity warning devices and insulated links became an item of discussion. We would strongly urge that NIOSH dedicate resources to evaluating those devices. There -- there's questions and there are human factors issues related to them, and we really think it's important that those be addressed prior to the regulations -- finally adopting them.

Verbal Comment 2005/12/19: Thank you, and thank you for the opportunity to come here. My name is Scott Schneider. I'm the director of occupational safety and health for the Laborers' Health and Safety Fund of North America. We are part of the laborers' union. We're a joint labor/management group. And laborers' union represents primarily construction workers, about 800,000 members in the U.S. and Canada.

I've been honored to be a member of two different NORA teams over the past ten years, the noise team and the intervention effectiveness team, and it was a great experience. I thought it was very useful and important work, and we did accomplish quite a bit. And now NORA is being reorganized by sector and there's a lot more work to be done, but it's a different kind of work.

Since its inception, NIOSH has focused primarily on identification of hazards and solutions. And the philosophy was pretty much -- until recently, I think -- if we identify the hazards and show people the solutions, they'll sort of naturally adopt them.

In some cases this worked. In other cases, though, NIOSH testimony helped spur the development of new OSHA standards. And while there's still some new hazards to identify, new solutions to develop, there's already a lot that's known that's not being put into practice. So the issue now I think is more how do we get people to adopt the solutions that we do know work.

So I would like NIOSH to focus in this next decade on dissemination research and intervention effectiveness research, and to fuse the NORA process with the R2P initiative. They need to do more research on the barriers to adoption than how to address and overcome those barriers.

When I visit job sites I see many obvious hazards that are going uncorrected. The 50 or so construction workers that die in trench collapses each year don't die because they don't know how to -- we don't know how to protect them. They die primarily because trench boxes were not used, even though in many cases they were sitting next to the trench at the time of the accident. So I can't -- here's a couple of things --

I mean obviously I endorse a lot of the stuff people have said before -- do more research on training effectiveness and on noise and on ergonomics and many of these other issues, which I think still need -- research should be done on them. But I'd like to see NIOSH focus -- and the NORA process focus on six areas.

One of them is how do we communicate more effectively about risk with both workers and employers so they understand the true dangers and the consequences.

Two, how can we encourage more intervention effectiveness research to show what really works.

Three, how can we better convince employers of the cost-effectiveness of interventions, calculating both the direct and indirect costs on an employer level, and making those costs tangible to employers in a simple way.

Four, how do we widely disseminate throughout the industry existing interventions and encourage their use..

Categorized comment or partial comment:

Five, where is more research needed to fill the gaps to develop interventions where existing ones are too cumbersome or costly and there are significant barriers to adoption.

And six, to accomplish all this NIOSH I think needs to do intervention surveillance in each industry to see how widely interventions are being used, and for future reference as a measure of success. In the past NIOSH looked at hazard surveillance but didn't do intervention surveillance.

As a footnote, I also would like to see -- I'd like to see NIOSH fund -- we have education and research centers around the country, but I would like to see basically translational research centers where -- R2P centers where people would take what exists and figure out how to get it into practice in their areas.

So the second decade of NIOSH (sic) needs to focus on intervention evaluation, increasing adoption of interventions and overcoming the barriers to their adoption, development of new interventions as a secondary goal, but there already exists many interventions that are being under-utilized. So thank you very much.

Categorized comment or partial comment:

But I kind of sidestepped my beginning comments, so let me give a little background industry (sic) on the roadway construction industry and why I think it's so important that NORA look at this industry in particular.

Just several months ago President Bush signed a law, (unintelligible), that will provide \$236 billion through 2009 for roadway construction. The federal budget makes up about 45 percent of the total amount of money spent on roadways, so between 2004 and 2009 we're looking at about a \$500 billion expenditure on transportation, and roadway construction in particular. This type of spending makes this industry one of the most stable and also one of the most robust in the country.

It's also one of the most challenging environments, because like construction, it's ever-changing. It's never the same place when you go back twice. But it's also an environment that's moving constantly. You're not going to a construction site the same place month after month. You're going to a new location.

It's also challenging because we have vehicles coming in and out of the job site constantly, delivering asphalt, taking away dirt. And when you have the workers on foot adjacent to this big equipment, it creates a very dangerous environment.

Now we add a new segment that's unlike the rest of construction, and that's the motoring public are part of our construction sites. Most of our work is done in rehabilitation and maintenance. We're not building new roads in areas that are cordoned off. So you mix all these elements together and you find that we are in very hazardous conditions, in very small work areas because we want to keep those lanes open and keep motorists moving, and it's a very dangerous environment.

We began to address some of these issues that are coming up as a result of these environments. NIOSH has done some great work. A lot more needs to be done in that area.

The next thing we want to talk about a little bit is the worker demographics, 'cause they're also challenging. Right now about 30 percent of our workers are Hispanic, and most of those are immigrant workers. And as we've heard, and I think we'll continue to hear, while these are very important workers to our industry and very valued workers, unlike many who come to the Americas and enter into the melting pot, this segment of Hispanic workers tends to cling very tightly to many native customs and even native languages. And there's this large percentage of this immigrant population that does not even learn English like they do for many other parts of the world, so we have to deal with all those challenges. And again, with 30 percent of our workforce, some statisticians are saying that as much as 50 percent of the roadway construction workforce could be Hispanic within the next 20 to 30 years, so another huge challenge for us.

As a result of these conditions, we're looking at, in roadway construction, a fatality rate of about 30 people per 100,000, as compared to 12 per 100,000 for the remainder of construction, and four per 100,000 for general industry. Also there's a great public health concern that's combined with this, as about 1,000 motorists are killed each year in accidents that take place in work zones, while another 40,000 are injured. So there's a lot of work, both from the public health point of view and from the occupational health point of view.

In addition, the one injury cause that stands out above all are injuries dealing with manual materials handling -- that word, ergonomics. And while perhaps many of my members would not like to see OSHA come up with an ergonomic standard, I'm sure they would more than welcome information coming from NIOSH on how we can deal with this injury. It's a huge cause of insurance claims. It's a huge cause for the industry, and we need help in this area in particular on how to do that better and to do that more quickly.

We are -- as we're looking to enter this new phase with NORA we're certainly hoping to work closely with NIOSH to address many of these injuries. We really want to look and work closely with you on how we can take information that we now have, information that we will have, and put that into best practices so that every employer, as he's sitting down and trying to balance his sheet and put together a bid for a job, he understands that safety is part of that whole equation and it becomes a normal course of business and not an add-on, which it is now. And that's where we're hoping to go.

Thank you very much.

Verbal Comment 2005/12/19: Yes, I'm not Mike Connors. The B team got sent in in the afternoon, so -- I work for Mike. I'm Charlie Shields and I'm the assistant regional administrator, enforcement programs, in the Chicago OSHA office. And it's great to see a lot of you guys out there today 'cause I've known many of you for a long time, so -- and perhaps may-- that's the first thing NIOSH should consider, and I hadn't -- I wasn't here this morning, but a lot of expertise here. Use them. Use them, you know, after you decide your agenda. Get them involved. That's the first thing.

I'm going to talk of a couple of topics today and then we'll be able to split up even in that. And I tried to organize it, so I thought okay, research need, why do we need it, maybe some examples or evidence, and what is our desired state. And the two things I wanted to talk about, first one is tower construction and tower reinforcement, and the second one -- and that's kind of a newer one, and the second one is an old -- well, not a favorite, but construction fall fatalities.

Okay, so first of all, the tower construction and tower reinforcement, and the need is safety technology for tower erection and tower reinforcement. Why? There's a couple of things going on here now. One is wind farms coming up, and the second one is adding equipment onto existing communication towers, such as high definition television. So you know, we're putting things on top of towers that were never intended to have these additional loads. And the safety and health programs are -- you know, have had some development, but not fully developed within these areas. And in fact, you know, some of these groups are asking for our help. OSHA has partnered with the -- with NATE, the National Association of Tower Erectors, and also recently our tower coordinator got called by a guy who's -- I think there's an association for wind farm people, also. So you know, we're working on that.

And the deal on the wind farms is you've got a 5,000 to 7,000-pound load on top of a monopole and it's got a 25-foot blade, and the blade's spinning and, you know, it goes around, too, and you've got a lot of forces there. And you know, I don't think there's a lot engineered yet as far as fall protection, and the

OSHA standards cover part of it but not all of it so, you know, that's not the greatest, either, formula for success, as far as us being able to push them. And secondly, there's lockout issues there. And in fact, there's been at least one lockout fatality in this country already during -- on a wind farm. So -- so that's one issue.

The second one was putting more stuff on top of existing towers -- you know, antenna platforms, you know, and the example was HDTV. You know, you're putting a lot of weight where it wasn't engineered to be put. The towers are not always being re-engineered, and they're not considering the sequence -- the construction sequence; i.e., you put in a new brace before you take the old one out. I think there's been a collapse where they took the old one out first before putting the new one in. It couldn't support it and down it came. So you know, we have to have properly designed towers, properly reinforced towers so they don't fall down and injure employees and so, you know, what's the desired state? To integrate safety and health into the wind and communication tower design and construction, and we need to develop equipment and methods to safely re-engineer existing communication towers, so that's the first one.

Categorized comment or partial comment:

So let's go into the second issue was fall fatalities in construction. So the need is new methods and equipment to promote construction fall protection safety. And I'm going to say some things some other people have already said. Why -- just in general, construction falls increased last year.

One minute, is that it? Okay.

We thought we were doing okay. We had a couple of years of decline, and all of a sudden we're right back up where we were several years ago. You know, we need to do more. And as a subset of that, the workplace fall fatalities among immigrant construction workers are increasing more rapidly even than for the overall population.

And I'll just reiterate briefly. You know, we'll go with immigrant, and particularly Latino in this area. We're not meeting it -- we're not -- we're not able to reach them through our conventional methods. We've tried some in this area. We've worked with church groups and with community action groups locally, and there is still a problem. You know, we need to do more there. And last year the Illinois fall fatality for Hispanics doubled, went from four to eight. So you know, we're trying and we don't seem to have, you know, mastered it yet, so there's a need.

So development of new construction methods and equipment, meaningful training materials, particularly for immigrant workers, and methods to reach these workers.

Thank you.

Categorized comment or partial comment:

Verbal Comment 2005/12/19: Hi, good afternoon. Thank you for giving me the opportunity to comment. My name is Janie Gittleman. I'm associate director of research from the Center to Protect Workers Rights in Silver Spring, Maryland. Today I'd like to address my comments to two areas, or two and a half areas, surveillance, training and education.

CPWR resources are used in collaboration with a wide array of agencies and organizations, including NIOSH, to conduct research on safety and health in the construction trades; NIEHS, National Institute of Environmental Health Studies, to do hazardous waste and disaster response training; DOE to do former worker medical screening; DOL for energy compensation programs claims assistance; and DoD with the Helmets to Hard Hats program to transition folks from the military into the construction trades. And at this time I'd like to make a plug or suggest the need for NIOSH to move efforts forward in NORA II towards these cross-cutting efforts to coordinate safety and health surveillance across agencies for the next decade.

Well, the goals of safety and health research are to prevent injuries and illnesses. Surveillance data are used to characterize the construction industry workforce, examine how changes affect construction safety and health, and also to use the data to lead to efforts to development and implementation of risk reduction interventions, and evaluation of the impact of interventions to reduce injury and illness on the job. Ultimately this leads to efforts to promote strategies to diffuse information throughout the industry to employers/employees that can influence policy and economics, impacting changes in safety and health.

NIOSH historically has done a great deal of injury and ill-- has a great deal -- developed a great deal of injury and illness data which can be used to understand health and safety issues in the construction sector, including environmental and radiation remediation workers at DOE sites. Surveillance data are used to identify patterns and trends, and they're critical to monitoring safety and health in this critic-- in this sector. So for example, there are many data sources that we now use to conduct surveillance.

There's the fatal assessment and control evaluation data, the national traumatic occupational fatality surveillance system data, the national electronic injuries surveillance system data in emergency rooms, the national occupational exposure survey data. There's BLS data on the census of fatal occupational injuries, CFOI; the survey of occupational injuries and illnesses, and OSHA data; the integrated information management system, IIMS. There's also additional CDC data. You'll get the point after I go through all these surveillance systems what I'm getting at -- the national interview survey data, the national ambulatory care survey data. There's also household surveys, the current population survey, the national longitudinal survey, the panel study of income dynamics, the current employment statistic surveys, national health interview surveys. Then the Census Bureau has surveys of the economic census, construction statistics series, the survey of business owners, and the IRS, who also reports in their Statistics of Income Bulletin. Then there's also private data such as the Dodge Reports and Dun & Bradstreet reports.

Well, all of this surveillance data that are collected from a wide array of governmental agencies are used to tell us about patterns and trends in the construction sector. And on a positive note, all these surveillance data are now released on a much more timely basis than had previously been done. One could conveniently query databases on the internet for information on CFOI, SOI*, FACE*, NICE*, and many of the surveillance data are standardized.

However, there are many limitations in the current surveillance data that impact our ability to identify high-risk occupation and activities in construction. Let me start with incomplete data. SOI excludes self-employed and government workers. Day laborers, new immigrants, and undocumented workers may be under-reported in government data collections, and efforts to understand and improve this reporting problem should be expanded.

Many of the surveillance systems lack denominators. There's no linkage between injury and illness data and workforce data. They lack information on industry and occupation in the NICE data and in ambulatory care surveys. There's missing data, lots of missing data, in FACE. There's non-standardized data in FACE. There's out-dated data in the occupational health supplement of the national occupational exposure survey, which was last done in 1988. And there's no information on effects of safety training for the sector in national surveys. There's also no productivity measures and cost measures, and it's difficult to get access to state-specific data.

In addition, these issues with surveillance data -- in addition to these issues with surveillance data, we'd very much like to see NIOSH address the inclusion of race as an identifier in national surveys during NORA II.

NIOSH has worked closely with state health departments over the past several years to develop occupational indicators for injuries and illnesses, and we would like to see sector-specific information collected to help target necessary interventions in construction. NIOSH is already supporting some of the construction sector surveillance and extramural programs, and to consider the overlap when considering new intramural surveillance programs.

I'd like to shift focus for a minute now onto the area of immigrant worker health and safety, which other people have also mentioned today. Recent study published in The American Journal of Industrial Medicine shows that immigrant workers in construction, primarily Hispanic workers of Mexican origin, are much more likely to die or to become seriously injured in construction in the U.S. than non-Hispanics. We are deeply concerned about the national trends that detail what is happening to our members and to all construction workers. It's troubling that construction deaths are not decreasing as they should, and particularly worrisome that Hispanic immigrants construction -- in construction are much more -- for them it is much more deadly than for construction workers at large.

What we do know about Hispanic immigrants entering -- or what do we know about Hispanic immigrants entering our unions and our industry? Do we know what assumption expectations they have for the industry? What do they think about unions, or about unions in general? What do they expect regarding safety and health on the job? What's the best way to improve health and safety training for this population of construction workers? To date there's little research addressing this -- these pressing questions and NORA II ought to focus on that.

Verbal Comment 2005/12/19: Good afternoon. My name is Chuck Stribling. I am the safety standards specialist for the Kentucky Department of Labor's occupational safety and health program. We operate an OSHA-approved state-planned program, exercising jurisdiction over private and public sector employment. On behalf of the Department I'd like to express my appreciation to NIOSH for providing this opportunity to speak to you about and participate in the development of the second NORA.

Having been bred, born and raised in Kentucky, I cannot talk that fast, so my comments -- it's genetically impossible, so my comments will be much shorter.

The Kentucky Department of Labor believes, and statistics confirm, that within the construction sector group fall protection unfortunately remains a very significant issue. We believe this is especially so in the residential construction subsector.

For the second NORA, we request your consideration of research specifically into residential construction fall protection issues. Fall protection in residential construction affects nearly all trades, if not every single trade on a residential site. With today's construction techniques and commonplace multi-level residential structures, many individuals may be exposed to significant fall hazards during residential construction. Comprehensive research and findings from NIOSH could benefit a tremendous amount of people, both within the industry and public sector.

There are many, many, many issues that could be researched, many more than my time here today will allow for discussion. However, our experience indicates that many employers and employees are opposed or reluctant to utilize fall protection during residential construction based upon one or more of four general misconceptions.

They are, number one, fall protection is too expensive; number two, fall protection is inconvenient and time-consuming; number three, fall protection is counterproductive to production; and number four, fall protection is infeasible. These four misconceptions, either taken as a group or taken independent of each other, present a wealth of research possibilities.

Additionally there are three specific fall protection issues in residential construction that we would like to submit for your consideration. Issue number one, research into the use of slide guard systems as a form of, quote, fall protection, unquote, during residential construction. Our experience reveals that data is woefully lacking related to slide guard systems when used for fall protection. Do slide guard systems indeed provide adequate fall protection? Why or why not? If so, in what applications? For what type of roofs? For what pitches or slopes? What are the minimum dimensions and installation techniques for a slide guard system to be effective?

Issue number two, research into alternative construction techniques that eliminate exposure to fall hazards during residential construction. Obviously building a residence in a manner that eliminates the hazard is the best solution.

And finally, issue number three, research into alternative construction techniques that reduce to the greatest extent possible exposure to fall hazards when elimination of the hazard is not feasible. Is there a different way to build the residence that may be safer?

Again, on behalf of the Kentucky Department of Labor, I thank you for your time today.

Verbal Comment 2005/12/19: Good afternoon. My name is Tonya Smith-Jackson. I'm the associate director of the Center for Innovation in Construction Safety and Health. I'm also associate professor in industrial and systems engineering at Virginia Polytechnic Institute and State University. Our director is Brian Kleiner*, and currently in our Center for Innovation in Construction Safety and Health, which is NIOSH-funded, we are implementing a total of seven research projects to address a variety of issues, using an integrated sociotechnical systems perspective.

But based on our existing knowledge, the existing knowledge in the domain of construction safety and health, and also from our own experiences and background, we've identified four important strategic areas that should be included in the next NORA, as it relates to construction safety and health, and these are as follows.

The first is new emphasis on mixed-methods approaches in construction safety and health research. We suggest that more emphasis be placed on the use of mixed-methods approaches that include the elicitation, collection, analysis and translation of both quantitative and qualitative data. Research that uses a more comprehensive mixed-methods approach will yield results that are more descriptive, predictive or explanatory. Construction environments are complex systems, as we know, that consist of a number of complex interdependencies. Translation, intervention, surveillance and even exploratory research are not valid unless the methods used to extract the data are appropriate for the specific environments under study.

Unfortunately past initiatives have placed higher value on traditional controlled experimentation, including field experiments that support reductionist and positivist research philosophies, and these have been used to study construction environments. These approaches have not been successful in clinical health research, as we know from several well-known examples -- and tragedies, even -- in the

clinical research literature. Yet we continue to place very high value on these approaches in construction safety and health.

To enhance external validity we would like to see more value placed on methods that are beyond the traditional, and perhaps more conducive to the study of the populations we target in construction. In addition, approaches that are multi-method and that examine the convergence of data from different research approaches should be included as a required consideration in research involving construction safety and health.

The second -- we want -- we suggest a more of a focus on valid research methods and approaches using socially-valid tools and yielding socially-valid outcomes for special populations at risk, such as ethnic and class minorities, older workers, female workers, workers with disabilities, workers with low literacy, day laborers, et cetera.

The NORA agenda has for a decade placed emphasis on special populations at risk in occupational research. Construction is an environment that attracts populations that have been traditionally marginalized (sic) by workforce formalisms and policy constraints, and by scientific research that was designed and predicated on Western centric perspectives. Some of the existing research seems to have relied on simply including representatives from these groups, without consideration of how to design studies that will support equitable benefits. Simply including these groups in research samples did not -- does not necessarily yield outcomes that are beneficial to the groups.

To ensure equitable benefits in safety and health research outcomes, the research that is conducted must use methods and data collection instruments that are meaningful to these groups. For example, the use of certain quantitative metrics to assess problems or predictors or factors among marginalized workers may not be a valid method across the board. Face-to-face interviews held in local communities that allow workers to tell their stories may in fact be a more valid method compared to a controlled administration.

For some construction problems, socially valid methods for marginalized groups may not be produced by collecting quantitative data, but may be more validly studied by eliciting purely qualitative data, such as verbal reports, and by methods that do not place value on aggregated numbers or on frequencies of occurrence, but may place more value on one person's report. Yet the existing agenda does not seem

to give voice to the use of non-traditional research methods, nor has the review process and subsequent scoring of applications.

There is a need to place more value on the use of socially-centered research methods such as participatory or action research, as well. A more inclusive approach is needed in research projects involving marginalized groups, and the research domain needs to scrutinize the social validity of both the methods used, the empowerment and involvement of and the outcomes of research related to special populations at risk to ensure that the safety and health benefits resulting from research for these groups are on par with the benefits experienced by majority group workers in construction context.

The third one, emphasis on research related to group process and constraints on group process. A number of events in the past decade have led to a predominance of construction environments that are informal work systems consisting of workers who are transient and unfamiliar with any given work site or setting. Research is needed that will address how to study group process, the implications of group process for construction safety and health, and the design and evaluation of interventions to improve group process, safety and efficiency.

Finally, we need inclusive review panels with multi-disciplinary backgrounds. As the diversity of construction environments increases, and given the demographic shifts expected to be obvious in the year 2030 where minorities and women will outnumber majority group members in the workplace, we need to ensure that our methods and research philosophies are multi-disciplinary and valid in the context of the increasing complexity of problems in construction safety and health.

In addition to methods and research philosophies, our research teams need to be consistent with the sociotechnical system principle of compatibility. The research teams that are funded should exhibit a comparable level of diversity as their target populations. We need to be ensured that review panels for such research proposals are themselves diverse, multi-disciplinary and knowledgeable of how to conduct inclusive, multi-layered, systems-centered research. Inclusiveness in the NIOSH implementation and administration of NORA will have a critical impact on our success moving from research to practice in the next decade.

On behalf of the Center for Innovation in Construction Safety and Health, I'd like to thank you for the opportunity.

Verbal Comment 2005/12/19: Good afternoon. There`s disadvantages and advantages of going at the end of the day. The disadvantages are that most people`s already spoke on topics that I`m about to bring up. I guess the advantages is I don`t have to speak as much and I can emphasize the points that I want to make.

My name is George Middleton. I`m the senior manager for labor safety and health services for the National Association of Homebuilders. We are a trade-based association based out of Washington, D.C. with well over 220,000 members. And within that, there`s well over 800 local associations throughout the United States. In 2005, of the 1.7 to 1.9 million homes being built, we -- our members will represent about 80 percent of that. So some of the issues that I bring to you today will impact a lot of workers in construction.

One of the first things that I`d like to emphasize and bring up again is -- obviously falls still are the leading cau-- is the leading cause of fatalities in construction. Is that the same for residential? Well, we commissioned a study -- it`s old data now, but `93 to 1995, and that follows in suit with commercial construction. So falls is still the number one fatality and it`s a big issue for us.

Within the last five years there`s been a lot of fall protection products put out on the marketplace. Unfortunately there`s a lot of lack of or no engineering data to support some of the claims that some of the manufacturers are making. Their claims are correct, in essence, that their system basically will hold 5,000 pounds per however many workers that they claim that they -- that you can attach to it. One of

the things we found, though, is what system do you attach it to? They will not stand by or they don't have -- actually I shouldn't say they won't stand by. They don't have the engineering data available to actually hook that structure onto the types of structures that our membership is currently building.

I personally have spoken to a few -- some of our larger member corporate safety directors, and they are very interested in the product, but they will not use it because of the fact of just plain liability issues. Did -- you know, they ask for the engineering data and it's not available. So I think there's an essential need here for NIOSH to look into some of the systems, and especially with this -- you know, the agenda looking into the future of ten years, on systems that can be used in residential construction specifically.

Another subpart of this is looking at the whole roofing structure in its entirety. I have seen on some websites photographs of systems where they're showing it being attached on roofing -- roof -- roof structures that is only partially sheathed. Now if you asked the Truss Manufacturers Association will you and can you give us data and will you put your blessings on the fact that you -- we can tie a system to an un- or partially-sheathed roof system, the answer is going to be no. So obviously there's some critical data that needs to be collected looking at partially-sheathed roof systems out there. So in other words, there's just a lot of inconsistencies out there when -- when people who want to utilize these systems, you know, are going to purchase them and then actually use them asking for the data and it's not available.

Somebody earlier, I believe Tom Kavicky, mentioned the fact about data and talked about that. We would like to see a better breakdown of data for falls in general. If you look at the BLS data, and I've looked at that many hours, sitting there trying to go through it and decide what useful information can I use out of this. If you look at it close enough, it doesn't really give you enough detail to be able to attack the problems of risk reduction.

For example, did the worker fall from a top plate? Did he fall to the outside? Did he fall to the inside? That data is not available and that's crucial. One pie chart in particularly (sic) that I looked at on the data stats showed, in residential construction, falls that resulted in fatalities -- I believe it was HVAC. If you looked at HVAC and the mason contractors, they had a higher percentage of fatalities than roofers. Now that's -- they're -- to me, that's very shocking. Is that data absolutely correct? I don't know. I mean there needs to be a source of somewhere to where somebody can further define that and look in detail. Unfortunately the only people I know that has that is the insurance companies, and they're not at liberty I believe to give that data out. And I believe NIOSH would have that capability, to be able to look further into the causes, and systematically maybe we can come up with some interventions. And also, lastly, be able to train toward that.

I believe some-- you know, a few people have mentioned silica already. I just wanted to say that NHB's conducted a pretty in-depth literature search, and we have found very little to no data with silica exposures in residential construction. We feel that, you know, that the exposures are somewhat different than commercial construction, and we want to know where we need to protect our workers because obviously the exposures do exist out there, and at this time we don't know where to get -- gather that data.

And lastly, I just wanted to speak about training, and particularly -- it was mentioned earlier the mom and pop shops out there, you know, I've asked the question to many of them, well, what about silica exposure? And they're like well, isn't that the stuff that's in computer chips? They really don't have a grasp on what any -- you know, a lot of these hazards are, especially with silica. And that is -- you know, I'm giving you some actual answers here of what people come back to me. They don't really know what it is. I don't know if it's a mass mailing or what have you, but there's got to be a route and a mechanism in which to put information out there so they can at least become aware of the hazard before they can follow a regulation.

And lastly, looking at Hispanic training, some of the hurdles. On-site training I believe is critical. If -- you know, if you go out onto a site and look and you try to put all of this stuff on the internet, most of these workers do not have internet access. We can talk about internet, internet, internet, but the actuality of it is is you -- on-site training to date is the most effective way to reach the immigrant worker population. Number one, they're doing piece work. They want to be working. They won't take time out to do training. I've worked with OSHA and NIOSH trying to get institute -- free training under the Harwood grant and we could not get participation in a classroom. It's the culture, they're -- and a communication barrier.

Thank you.

Verbal Comment 2005/12/19: So what it comes down to is I stand between Miller time and the rest of the day here. Well, one of the neat things about being at the caboose of the program is I get to listen to all of my colleagues addressing a plethora of issues.

And I guess I should start off by saying a couple of weeks ago I was briefed at an ACOSH meeting about the strategic research council and the draft of the strategic goals for NIOSH in construction. And I took notes on each and every speaker today, and I'll quickly run down through the strategic goals for NIOSH in construction, if that's all right with you, Matt.

And parenthetically, I feel that the program is well thought out and it reflects the most ubiquitous hazards in our industry.

It includes falls. Falls have been discussed today by a number of speakers. A number of speakers have focused on falls in the housing sector. But as we all know, the fall fatality is kind of an equal opportunity killer in that gravity doesn't really discriminate as to whether the person is on a structural steel member, on a roof of a house, on the roof of a building or at the edge of an excavation.

And again parenthetically, I'm going to come back to talking about the Gulf, but I think that one of the things that we all in the safety and health profession need to keep our eye on is the progression of the cleanup, the demolition and the repair in the Gulf states, because that ultimately could be one of the largest catastrophes, beyond that which has already happened, in terms of worker safety and health. For instance, one day within the last month there were three fatal falls from roofs just in Kenner, Louisiana. And that kind of a cluster is very disturbing.

But falls, on the happy side, is one of the strategic goals for the construction research council.

Electrocution, there are plenty of opportunities for research regarding electrocution at construction sites, everything from -- as our friend from the equipment manufacturers group spoke -- the new subpart, the OSHA subpart on cranes and derricks, which we should be seeing out sometime in the next, oh, four or five years, I would say. So I wouldn't panic at this point or sell all your stock in crane companies.

Struck-by -- as a matter of fact, in Chicago last week we had two people who perished when they were struck by a large piece of concrete.

And caught-in and caught-between, including trenching accidents, we're still burying people in trenches. Now it's interesting to talk about research gaps and all of the various and sundry things that we kanoodle about what we could look into. And yet the people who are getting killed on our construction sites are getting killed the old traditional ways. People are still getting buried in trenches. We had one this summer that was very tragic where we had -- and I guess they all are -- where we had a 72-year-old man who was buried in a trench and his son was buried next to him and was recovered alive. The father was not so fortunate. So I'm very encouraged that we will be looking more into effective interventions in the caught-in and the struck-by area, especially with regard to trenching.

Categorized comment or partial comment:

Musculoskeletal disorders, I was pleasantly surprised today to hear people from both the worker perspective and from the employer perspective verbalize what we have known for a long time, that financially these sorts of injuries are putting some employers out of business. Back injuries, shoulder injuries, a number of different types of repetitive trauma and musculoskeletal injuries really plague the construction site. When we look to other countries, especially those countries where there's cradle-to-grave insurance and where the government is responsible for workers and their families, and we take a look at how they manage musculoskeletal disorders, we find a great deal of creativity. And I think that one of the things we're up against here in our country -- and I'm not sure that NIOSH is necessarily the forum to try to overcome it; I don't know where it exists -- but is to change the culture in the construction industry to accept that sometimes it takes two people to lift an object where common practice has been using one. That's as simple as it gets.

But things like the dimensions of materials, the weights of bags of materials, the dimensions of pieces of plywood, the dimensions of drywall, other countries have been successful in changing these and making them more worker-friendly, and have reduced the incidence of work-related musculoskeletal disease and trauma.

So, moving on, noise; we heard a lot about noise today. I actually was a driller in my former life. I worked in tunneling. I worked as a laborer. And I lost a fair amount of my ability to hear. Occasionally I wear hearing aids. The other day I was in the grocery store and I had my hearing aids in, and the lady in front of me kept looking at me and I finally said could I help you? And she said are you going to answer your cell phone? So apparently I need to go back to my audiologist and get that corrected.

But noise is a huge problem, and it's something that we have just grown to expect as a part of the construction culture. If you're in the building trades for X number of years, you're going to have lost some of your hearing. As I look out in the audience, I have a few friends here that are in the same predicament that I am. And that's another cultural issue that I think we need to tackle.

Occupational illnesses from lead, welding fume and silica. We spoke about silica. It's something that I know that we have people in here that feel strongly on both sides of the issue, of reducing the PEL, of increasing the PEL. But it's just interesting to me that the -- next to September 11th, 2001, the largest calamity in terms of worker safety and health, happened in West Virginia many years ago when a company was working on a tunnel and the tunnel was a part of a hydro project and they were under some constraints to quickly get the tunnel built. And so they chose a path for the tunnel that yielded two results -- well, more than that, actually. One was to get the tunnel built. The second one was to use the veins of silica that were in the route that was selected. And it was later discovered that the route that was selected was selected because of the high silica content, and it was later found out that the company was actually using the silica as a product to sell as an enterprise. But in that single project, if we -- there are a number of books that have been written about it. It's been discussed today. But The Hawk's Nest Incident by Cherniak I find to be a very interesting book -- over 1,000 workers died as a result of silica exposure. In some cases it was acute, where the workers died at their drills. And in some cases it was shortly thereafter.

I agree with the people who spoke today that said we need better data to protect our people. But I think, as a safety and health professional, I believe that if we assume that the tasks that have already been identified by OSHA and NIOSH are creating this dust -- dust which, by the way, is invisible; the dust that really does the harm -- that we overprotect our people until we get to the point where we have the data that allow us to back off on the personal protective equipment.

Categorized comment or partial comment:

Improving surveillance, I believe that this was brought up by a number of people. One of the things that I would like to see improved or expanded upon is the FACE program. As a training organization, we have used the FACE studies a number of times to create case studies for worker training. These are real people that were killed in real accidents. I would like to see that program expanded. I know the State of Illinois Department of Public Health has tried to become a state-based FACE program, without success. I think that's intolerable, because we have a large worker population and plenty of opportunity for study. And of course, I would like to see a focus on construction.

In conclusion, I would like to thank NIOSH for coming here to Chicago. It's the heartland. We have people that have come here from a lot of different places. My ability to be here was made possible by a couple of opportunities from the National Institute for Occupational Safety and Health. The first one happened back in the early '80s when I was a much younger safety person. I was able to go back and get a graduate degree at the University of Minnesota with a full scholarship from NIOSH. For that I am deeply appreciative.

And then secondly, the Construction Safety Council was created in the early '90s by a cooperative agreement that was to create a model statewide safety and health program. The person that spearheaded that, the principal investigator, Ron Stanovich*, was a civil engineer who felt very strongly that each state should have, could have, an organization like the Construction Safety Council to reach out to the construction population to have local trainers work and local intervenors working with local contractors, local worker groups. And so that organization, once the funding ran out, was able to survive and is with us today. And under that aegis I am able to be here with you.

So again I thank you for being here. And as Bono said as he accepted the Person of the Year award the other night -- I guess it was last night -- this is the fun stuff. But what we really need to do is get the job done. Thank you.

Hispanic American Construction Industry Association

Categorized comment or partial comment:

Verbal Comment 2005/12/19: Good afternoon. Good afternoon to everyone. As I was so introduced, my name is Caesar Santoy. I`m the executive director of HACIA, the Hispanic American Construction Industry Association. We`re a not-for-profit trade organization whose mission is to promote the growth, professionalism and equitable participation of its members in the construction industry.

Our membership includes over 240 companies, including architects, engineers, contractors, suppliers and related industry firms representing thousands of employees including construction workers, both Hispanic and non-Hispanic. Our membership represents, as I mentioned before, Hispanic and non-Hispanic owners, union and non-union companies, and firms with business interests in both the public sector and private sector projects.

HACIA has recently formed an alliance with OSHA to develop outreach, training and communication to promote a safe working environment for Hispanic workers. HACIA also serves on the State of Illinois Governor`s Panel for Worker Safety, as well as the board of the Construction Safety Council. How are you, Tom?

MR. BRODERICK: Good.

MR. SANTOY: In short, the safety and welfare of all construction workers is of paramount importance to us. Through our work we have found research in the area of construction industry accidents, illnesses and deaths, and their impact upon the Hispanic worker and the Hispanic community. This information is

a valuable tool which not only brings awareness of the issues to the industry, but also provides a system by which to judge the effectiveness of our collective efforts.

HACIA supports the accuracy and soundness of these statistics as provided by various experts and agencies. But their research efforts might be improved by additional tracking of injuries, deaths and illnesses; another layer of investigation, if you will. For example, just to cite some of the more readily-known statistics, in 2002 Latinos accounted for 13 percent of the construction industry population, yet they accounted for 50* percent of occupational fatalities. And again, this is a statistic that is fairly well known among the construction community.

Which leads to the following questions. What was the immigration status of these workers? What was the literacy level of these workers? What was the language proficiency level of these workers, either in English or Spanish? Awareness of these questions and issues is increasing, but these items, when combined with other factors, can lend itself to new areas of research. And again, I just want to repeat that of the three questions that I posed, there has been some work that has been started. There are some studies that we have seen. And again, referencing back to the statistics which allows organizations like HACIA and other organizations to set policies, strategies, programs and services.

And then awareness of these questions can lend itself to new areas of research. How do unreported accidents impact the overall statistics? Is there a difference -- is there a difference in incident rates between labor union members versus non-labor union members? Are incidents under-reported or not reported in cases where the employer or employee is working on small-scale projects or for small companies? These are questions -- these questions are presented to address cases which might be, quote/unquote, off the radar, or that exist independent of traditional reporting regulation and compliance requirements. How different would our statistics be if we accounted for these factors? Is this even possible?

We believe that statistics can influence policy and strategy, and provide a benchmark by which to measure progress. Because of our belief in this regard, HACIA applauds the efforts of NIOSH and NORA for their significant work, and we offer our outreach capacity and advocacy voice to NORA and NIOSH for the purpose of addressing workplace-related injuries, fatalities and illnesses.

I'd like to thank everybody for the opportunity to speak today. I'd be more than happy to answer any questions, and have a great day.

Verbal Comment 2005/12/19: Good afternoon. My name is Rashad Johnson. I'm with the Mason Contractors Association of America. I'd first like to start off by thanking both NORA and NIOSH for the opportunity to speak. I apologize, I do not have anything written and ready, as some of my counterparts. However, I felt passionate enough to sit up here and talk to you all, so bear with me.

Again, as I stated before, I'm with the Mason Contractors Association of America, and we are a non-profit trade association representing masonry company owners, so we are the management portion. We're concerned with all of the aforementioned topics that were mentioned earlier, such as training, fall protection, hearing loss and protection, silica, musculoskeletal work disorders, and I've actually -- we've actually worked with NIOSH on a lot of these different areas.

The two areas that stick out the most and are of most importance to our organization at this point in time would be silica and musculoskeletal work disorders.

As it pertains to silica, as already and previously noted, there's been quite a bit of research done that represents and talks about the actual exposure limits and what they should be. What I'd like to see is practical research done. What I mean by practical research is giving someone a limit to reach, but actually telling them how to get there. And we've -- some of the other people have talked about the control banding ideas, some of the ideas of a best practices, something that says what works in order to make these exposure limits feasible.

For example, when I say feasible and practical, those are the big words there. It's one thing to say hey, you should wet cut. It's another thing to understand that you can't wet cut today in Chicago on a scaffold. It's not going to happen. You need to be able to give some practical -- practical research when it comes to some of these things.

Some of the controls, there's tons of research that says that these particular action items are higher than the permissible exposure limit, but very little on the controls. We'd like to know, from a management point of view, what works. Which of these controls are going to give us the maximum amount of protection for our workers such that when we are out doing things and trying to protect our workers we know to stay away from certain things or -- or certain controls are much better than others as it pertains to safety.

A lot of the research that I've seen, and I've been working with some of the NIOSH people on the silica issue, and there are a lot of research done on -- on five or six major topics. But as I found out the hard way, and I'm sure all you all might know, too, the world is beyond masonry and concrete. There's a whole lot of silica in construction that's not necessarily related to masonry and concrete materials. And what we're finding is that a lot of those areas don't have research and don't have the same exposure, so to speak, as the high -- the high profile ones, the concrete and masonry. So I'd like to see some research done on some of those other -- some of those other things than masonry -- in construction in general. What I mean by that are different alternate materials that might have silica content, some -- some of the actual things that they do on construction sites, such as mixing mortars that might have something to do with silica and respirable silica that really don't have very much research done.

And then, again, we talked about the control banding idea, the idea of actually putting something in writing, giving guidance to the person reading it, letting them know that if I do this, I do this, I do this, then I will be below the exposure limits. And make it real plain, real easy to read. I don't have to do any monitoring. I don't have to do any testing. We know from monitoring and testing that these are the controls, whether it's respiratory protection or engineered controls, et cetera. These are the controls that if you do with these particular tasks will make sure that we're providing the level of safety that you need for your workers. That idea is not -- nothing -- is not anything foreign, and it should be something that should be investigated a lot more by NORA and NIOSH.

Categorized comment or partial comment:

The second big topic that I'd like to discuss from the mason industry is musculoskeletal work disorders. When everyone talks about musculoskeletal work disorders or ergonomics -- that's the fancy word for ergonomics is what I call it -- and construction, realistically they're talking about masonry industry. Why do I say that? We are the industry that has the heavy materials that are manually lifted. We are the industry that has a lot of the back problems, the musculoskeletal orders (sic), et cetera. So when I hear about things such as all of these musculoskeletal disorders as it pertains to construction, we take it very personally because they're talking about the masonry industry. I would imagine that the majority of these injuries happen in our industry, and we're looking for ways to help our workers, as earlier stated, because we don't want to have to incur the cost of people hurt. And everyone knows those are not inexpensive things. But -- but again, I'd like to see some practical research.

And what I mean by practical research is the effects of smaller cement bags. If it's not a 90-pound bag, what is 45-pound bag going to do? From a productivity point of view, it might not change. But if it'll help us in terms of keeping our workers safe, then I'd like to see some research on that, focused on ways to work smarter. I don't know that there's going to be very many mechanical solutions to musculoskeletal disorders. And if there are, chances are a lot of people in the construction industry will fight it. I've seen some of the things in Europe that talk about machines laying brick and machines laying block. That's not a practical solution as far as I'm concerned, so I'd like to see money spent on practical solutions to help us protect our workers.

Thank you for all of your time. Thank you all for listening, and again, appreciate the opportunity to speak.

Verbal Comment 2005/12/19: I wouldn't consider myself a panelist. I'm Jim O'Connor with the mason contractors here locally. I have no formal training and no letters after my name, but on a labor -- I used to be a laborer, and for a laborer's standpoint, I'll kind of address this on some common sense issues I sat and listened to. And I hear a lot of folks that know a lot more about this than me talking about training, training, training. And one of the training might be to teach people how to speak English. I know a lot of labor's -- labor's union has already gone and done that. That might be a quick way to address some of the problems is let's have an English class for some folks. Then we won't have to go through the problem of translation and all those other things. And that's -- again, it's a -- laymen's terms looking at what you guys have talked about and ladies have spoke of.

Another issue that's drawing my heart is personal responsibility. And some of the responsibility, I believe, needs to go to the actual worker who has been able and paid to go to training, gone and taken the training, and then refused to wear the glasses or refused to wear the safety helmet. And if it is proven that this person has gone through X amount of classes and goes ahead and does not follow the rules, that maybe that person could receive a 20th of the fine that the contractor does. And if we're truly trying to affect a safe workplace, why not make the person who's causing the problem address it in his head that hey, this is going to cost me? And I don't see anything wrong with it. Again, I'm a layman and I'm asking. I'm not telling you what to do, but I certainly think that if it was a \$25 fine and the laborer or the brick layer or the steel worker said, you know, last time I got hit for this; I'm not going to do it again, that essentially affects a safer workplace. And it doesn't have to be a terribly huge monetary cost to the worker 'cause obviously he's not making as much as the contractor. But if it does what we're trying to get done, why don't we do it?

For silica, I know it's a problem, I know it's been proven to be a problem. And Tom has talked about it in a confined space where people are drilling and there's no air. Most of our contracts, and there are a lot that they're in, but a lot of them are out on walls where there is wind blowing and there's less likelihood of getting -- getting the PEL as high as you would in a tunnel. What I would like to see, and I'm sure the unions have the information, I would like to see a polling of all the unions to see -- if someone breaks a leg, I assume when they write the check to the insurance company or they write the check to the hospital, it'll say why that check is being written, broken limb, broken back, back injury, silica -- how many people have truly been affected by silica or are we really on a witch hunt? And I don't know, and I'd like to know and I think our people would like to know. And again, I'm a layman and I see a lot of people shaking their heads, so you can beat me up outside.

But another thing that I was interested in was substance abuse is something that nobody talked about and sometimes we have difficulty getting that in our contracts. And I would like to know any of these accidents -- how many of them have been involved with substance abuse, 'cause there's post-accident testing on a whole lot of folks, and I don't think that data -- I don't know if it can be released, but I don't think that data's ever been released. So if we've got 25 falls, was one of them, was two of them, were three of them where someone had traces of substances that he shouldn't have had on the job? And are we blaming the wrong person all the time? And that -- I don't know. Again, I apologize, 'cause you guys are all professionals and I'm -- but this just seems like common sense stuff to me, so...

) Glove safety should be further evaluated: gloves have been evaluated for barriers to bacteria, but what about being barriers to viruses and prions?

2) Alcohol hand-sanitizing gel: what is the absorption amount of alcohol thru the skin or inhaled, when the gel is used repeatedly--such as in a Neonatal ICU during a 12 hour shift? (alcohol is a neurotoxic substance.) Does alcohol gel use result in skin colonization with resistant bacteria or fungi?

3) how much body fluids and resistant bacteria/viruses do healthcare workers take home with them when they wash their workclothes at home?

How much contamination occurs to their cars, coats, washers/dyers, etc.?

I am uncomfortable with the "industrial sector" approach to identifying research needs in occupational health. In order to control the large issues that cut across industrial sectors we need a better understanding of how work influences musculoskeletal disorders (a major issue for industry). I can not understand how efforts led by a sector can improve our understanding of causality and intervention effectiveness.

I am urging you to conduct a study on the risk of cancer faced by firefighters.

In 2004, the Bloomberg School of Public Health at Johns Hopkins University conducted a study called, An Occupational Health Investigation of Cancer Among Firefighters in Anne Arundel County, Maryland. Researchers completed a 10 month investigation to determine if cancers diagnosed among a group of Anne Arundel County firefighters could have been caused by smoke inhaled during training. The investigation was conducted at the request of the Maryland Department of Health and Mental Hygiene. The study concluded that compared to the general public, firefighters with greater exposure to fires have higher risks of cancer. However, they were unable to identify the specific risk firefighters have for cancer and other diseases. Additional research, including a formal epidemiological study, was recommended.

There are over a million firefighters across America. Cancer rates among firefighters is an issue of national significance. Senator Barbara Mikulski of Maryland, State and local officials believe further research is essential on this issue for our community public safety servants.

Occupational Health Disaster Expert Network

Categorized comment or partial comment:

"I am writing to express support for OHDEN, the Occupational Health Disaster Expert Network. Established under a Presidential Directive for Homeland Security for critical infrastructure protection OHDEN has a prototype webportal to assist IHs, docs, nurses and other EHS professionals plan and respond to natural and man made terror disasters.

NORA is seeking information on important occupational safety and health issues, such as: diseases, injuries, exposures, populations at risk, and needs of the occupational safety and health system. Input is also requested on the types of research and partners needed to make a difference. The following types of information may help identify the areas where new research will make the greatest contributions to preventing work-related injuries, illnesses, and deaths:

Numbers of workers at risk

Seriousness of the issue

Probability that new information and approaches will make a difference.

The entire US workforce is at risk. The seriousness is that most businesses close and do not reopen after disasters and the US needs to improve on this record in the future with likely climate change related disasters and terror. Recent events with Katrina and current activities within OHDEN to assist for a pandemic influenza outbreak are examples of where information and resources need to be coordinated for effective foresight and governance for such issues. OHDEN is a very good answer but financial and

technical resources are needed to support OHDEN. This is too important for volunteerism alone and something NORA should consider a priority. "

MSDs remain the number one reason why people miss work and occur across industry sectors. Given the one "catch-all" category for MSDs and every other OH&S issue that affects more than one industry sector, there is a chance for MSDs to become a marginalized or altogether overlooked research area. With the rapidly rising cost of health care, MSDs will continue to occur in all industry sectors and contribute to lost time, productivity, reduced work quality, reduced work quality of life and increased costs. With such a far-reaching impact, we need to maintain a specific focus on MSDs in NORA2.

I strongly encourage NIOSH to examine the workplace exposure of a wide variety of workers to radon and radon decay products. Residential exposure is responsible for about 21,000 lung cancer deaths per year in the U.S. Other than underground miners, we have either no or insufficient exposure data for other workers such as those in water plants, fish hatcheries, phosphate plants, utility and subway tunnels, oil refineries, and those who work in spaces in ground contact (plumbers, heating service personnel, radon mitigators). I encourage NIOSH to work with the American Association of Radon Scientists and Technologists (I am President-Elect) and EPA on this issue. Thank you.

Categorized comment or partial comment:

The meat and poultry processing industry has taken many great strides in an attempt to reduce the number of injuries related to repetitive tasks that workers are forced to perform. More ergonomic equipment has been designed for worker comfort and safety. Increased training efforts have been put into place by companies to avoid injuries and give workers the opportunity to become more knowledgeable about their working environments. Better personal protective equipment has also been utilized to protect workers from various injuries related to slips and falls, mechanized equipment, cutting tools, loud noise areas, etc. The industry is working together to share innovations and ideas in the area of worker safety so improvements benefit all at-risk employees. The number of injuries/illnesses continues to decline yearly.

Since members of the American Association of Meat Processors (AAMP) are mainly small and very small processors, it would be beneficial to have continued research in products and implementation strategies for small operations that are not costly or cumbersome to put into place. These plants may not have the financial resources to provide the "top-of-the-line" equipment and facilities, but they are very conscious of the dangers surrounding the industry and importance of a safe working environment. Many times in small plants, the same employee is responsible for several of the slaughter/processing steps, so it is not

an option to simply rotate the work tasks. There is a need to continue designing affordable processing/slaughter equipment as well as personal protective equipment for the small and very small processors. Additionally, training materials or guidelines designed for these types would be helpful when communicating safety messages and improving the safety of a facility.

Employers need healthy and safe workers in their plants to ensure their businesses are meeting the desired goals and production levels. It is to their benefit to provide plant employees with appropriate training, equipment, and working environments. Routine re-evaluations and educational sessions on safety in the workplace give plants an opportunity to determine if their safety program is satisfactory. Safety is a priority, and employers take pride in having safe establishments for themselves and their employees, especially small operators who only have a few people working in their plant.

AAMP is an international organization whose members include meat and poultry processors, slaughterers, caterers, food service companies, wholesalers, retailers, suppliers, and consultants to the meat and poultry industry. There are 33 state, regional, and provincial associations of meat processors that are also affiliated with the Association.

Sincerely,

Andrea H. Brown

Director of Legislative and Regulatory Affairs

Categorized comment or partial comment:

Remarks from John P. Sestito

NIOSH Hamilton Laboratory, Cincinnati, Ohio

February 23, 2006

I offer the following thoughts for the ongoing support of occupational surveillance generally, and occupational disease surveillance specifically. Occupational surveillance lacks the prominence of a

Sector or Cross-sector program within the National Institute for Occupational Safety and Health (NIOSH) Program Portfolio structure. So, as NIOSH moves forward under the Program Portfolio framework, NIOSH leadership should be mindful of the importance of injury, illness, hazard, and exposure surveillance data for establishing research agendas, making judgments about research priorities, and developing program performance metrics. Many of my remarks speak to disease surveillance, but are generally applicable to occupational surveillance.

Surveillance defined. Surveillance is the collection, analysis, interpretation, and dissemination of data describing a health related event, exposure, or hazard. Surveillance is critical to effective occupational safety and health programs. It enables decision-makers to identify the problem and the affected group of workers. Surveillance also describes the magnitude and severity of an issue, and assesses progress made in reducing the burden of occupational injuries and illnesses. As a result, surveillance programs create added value by establishing baseline and trend data, assisting in priority-setting and providing information to guide research, interventions, control, or prevention.

Congressional oversight in the 1980s. In passing the Occupational Safety and Health Act of 1970 (OSH Act) [29 USC § 651 et seq.], Congress mandated extensive authority to the Secretaries of Labor and Health and Human Services to develop regulations requiring employers to record and report occupational illness, to conduct medical examinations, and to notify employees of clinically significant results [29 USC §§ 655(d)(7), 657(c) and (g), and § 669(a)(5)]. In addition, the OSH Act requires the Secretary of Labor to "compile accurate statistics on work injuries and illnesses which shall include all disabling, serious, or significant injuries, and illnesses, whether or not involving loss of time from work." [20 USC § 673(a).] This authority has been delegated to the Bureau of Labor Statistics (BLS). Unfortunately, much of this broad authority remains unused.

Accurate and reliable data on occupational disease is essential for informed public policy decisions, employer and employee awareness of health problems, and employers' ability to correct harmful working conditions. Congress recognized the importance of good information systems when it passed the Occupational Safety and Health Act of 1970 (OSH Act) [29 USC § 651 et seq.] Today, 35 years after its passage, the state of present national disease surveillance systems is - as described by Dr. J. Donald Millar, the former Director of the National Institute of Occupational Safety and Health (NIOSH) - "90 years behind...[surveillance] of communicable disease." No reliable national estimates exist today, with the exception of a limited number of substance specific studies (such as on asbestos), on the level of occupational disease, cancer, disability, or deaths. It cannot be meaningfully determined if diseases from chronic exposures to hazardous substances represent a greater problem today than when the OSH Act was passed in 1970. The lack of complete, reliable, and accurate injury and illness data greatly hampers any broad-based evaluation of the occupational safety and health programs, and threatens the statistical foundations for the current NIOSH Program Portfolio of Sector and Cross-sector research. Furthermore, the existing data from employer logs, used in BLS's Annual Survey, are generally viewed as unreliable and under-report occupational disease.

Accurate and reliable data on occupational disease is essential. For public policy, these data assist the Occupational Safety and Health Administration (OSHA) and NIOSH in setting and revising health standards under § 6 of the OSH Act, as well as setting enforcement and research priorities. The early reporting of disease causing exposures to vinyl chloride and kepone heightened the public awareness of previously undisclosed dangers of occupational exposures. Occupational disease information is also essential to employees and employers in alerting them to disease patterns as early as they become

clinically significant. This is particularly important to the health of the worker, and is also significant to the employer who can take corrective action and understand the full economic cost of doing business.

BLS's ability to implement an occupational disease statistics program is hampered by the nature of occupational disease study, where expertise in epidemiology and occupational medicine is required. If the purposes of the OSH Act are to be achieved - if effective measures of prevention of occupational disease through elimination of hazards in the workplace are to be developed, and the effectiveness of these programs is to be evaluated - NIOSH must find solutions to the problems of obtaining adequate data on occupational diseases.

Future Directions and Challenges for NIOSH

Many of the following comments reflect the ongoing national dialogue on developing and improving the nation's occupational surveillance. The major "bullets" are distilled from the work of the NIOSH NORA Surveillance Research Methods Team.

- NIOSH must maintain a strong national surveillance program to establish priorities. Future surveillance should (1) maintain ongoing surveillance and disseminate of surveillance data as guided by the NIOSH Surveillance Strategic Plan, and (2) respond to emerging occupational health and hazard issues.

Problem: Federal surveillance of occupational disease is fragmented among many agencies; i.e., NIOSH, NCHS, NCI, SSA, and CDC. The current activities of these federal agencies do not assure the nation's workers access to comprehensive occupational surveillance data in the United States.

Comment: Comprehensive information for occupational disease, disability, and mortality is needed to (1) develop effective measures of prevention of occupational disease through elimination of hazards in the workplace, and (2) evaluate the effectiveness of these programs. The one agency which focuses on the surveillance of occupational disease is NIOSH. NIOSH has long-standing expertise both in the study of occupational disease and in focusing research toward better a understanding of the etiological association between disease and workplace hazards and exposures. NIOSH is well-equipped to take on the central role and responsibility for the ongoing collection, analysis, interpretation, dissemination and use occupational disease statistics.

Problem: No reliable national estimates exist today on the magnitude and trend of occupational cancer, disability, and mortality.

Comment: It cannot be meaningfully determined if diseases from chronic exposures to hazardous substances represent a greater problem today than when the OSH Act was passed in 1970. State and local mortality, cancer incidence, and disability data have significant potential as data elements within a comprehensive surveillance system for occupational disease. Such data have yet to realize their potential because of incomplete or inconsistent data collection through local and State-level data sources, insufficient resources to support State and local agencies to collect or compile these data, as well as limited and inconsistent coding and classification of employer\employment (i.e. SIC or NAICS codes) and occupation (Census occupational titles and codes) information.

Problem: Employers are unable to record, and thus report, many chronic and latent occupational diseases.

Comment: Employee and household surveys are excellent alternative sources of data on the prevalence of disease in working populations. The National Health Interview Survey (NHIS) was adapted in 1988 for occupational surveillance purposes, gathering a wide range of occupational health and safety data. Medical examinations provide more accurate methods for determining occupational disease, disease precursors, and biomarkers. The National Health and Nutrition Examination Survey (NHANES) is used by CDC to gather a wide range of population demographic and health data. The NHANES could be adapted to monitor the population for selected occupational conditions and exposure measures.

Problem: BLS surveys of nonfatal occupational illnesses are unable to identify or report diseases with a long latent period. There is no adequate evaluation of the extent of under-recognition, under-reporting, or over-reporting of nonfatal occupational injuries and illnesses.

Comment: NIOSH should establish a dialogue with our federal partners, OSHA and BLS, on the feasibility of undertaking a comprehensive Quality Assurance Program on the OSHA logs. This dialogue should explore options to assess the accuracy and reliability of employer logs and the differences, if any, in levels of occupational disease as found in medical records, the OSHA logs, the Annual Survey forms, and employee surveys. NIOSH should provide epidemiologic, industrial hygiene, medical consultation and other assistance as needed. Such efforts could be expanded to general recordkeeping and reporting for nonfatal injuries. As possible collaborators in such a program, NIOSH's state-based surveillance partners have significant experience in state-level data sources. These data sources should be explored to better understand disease under-reporting.

- NIOSH should support new program initiatives and projects to develop and adapt methods for state and non-governmental partners. New surveillance programs and research methods are advocated in the NIOSH surveillance strategic plan, as well as the reports of NORA research priorities for cancer, emerging technologies, exposure assessment methods, musculoskeletal disorders, traumatic injury, reproductive outcomes, and workplace organization factors.

- NIOSH should link the results from state-level surveillance to intervention and prevention activities. This could produce significant improvements in occupational safety and health. Recent evaluation and planning activities reinforce the importance of expanding and enhancing state-based occupational surveillance.

- NIOSH should advocate an expanded surveillance research program that focuses upon smaller employment establishments in a private sector surveillance research initiative. An estimated 7 million private sector establishments employed 115 million workers in 2001. Establishments with 19 or fewer employees accounted for 85.7% of all workplaces, but only 24.1% of all employees. Establishments with 100 or more employees accounted for only 0.7% of all workplaces, but over 46.8% of all employees.

- NIOSH should establish Collaborating Surveillance Research Centers of Excellence to guide the development of surveillance to prevention practices including new R & D teams that harness the strengths of occupational health researchers, non-government organizations, insurance carriers, and public health agencies. Specific activities within the Centers should include (1) providing technical assistance and consultation with respect to developing and evaluating occupational surveillance methods; (2) establishing outreach programs to identify specific methodological and research needs, evaluate occupational surveillance follow-up methodologies, and develop and evaluate innovative strategies for improving the quality and utility of surveillance data; and (3) expanding surveillance and surveillance research that focuses on smaller scale employment establishments.

Docket NIOSH-047

Robert A. Taft Laboratories (C-34)

4676 Columbia Parkway

Cincinnati, OH 45226

Tuesday, February 21, 2006

Dear NIOSH and NORA,

Health and safety risks in fresh fruit and vegetable packaging and processing industries across the United States include ergonomic, musculoskeletal injuries, accidents, chemical exposures, noise and stress. Agricultural workers, most of whom are Hispanic and/or female, need a safe and fair workplace. Research is needed to reduce hazards and improve conditions in the warehouses.

Thank you for the opportunity to submit comments on the National Occupational Research Agenda (NORA). I am a public health biocultural anthropologist at the University of Washington. I have been working on occupational health and safety issues in the fresh fruit warehouses in Washington State since 1997. This research was supported by the National Institute for Occupational Safety and Health (NIOSH), Pacific Northwest Agricultural Safety and Health Center Grant #U07/CCU 012926-02, the University of Washington Field Research and Consultation Group, and the Department of Anthropology.

This comment will describe the number of people affected, the current (limited) research on health and safety hazards, and specific information on occupational risks in the apple warehouses of the Pacific Northwest. It concludes that additional research on the workplace will help identify the scope of the problem and assist packing houses to reduce the risks for workers.

Packing houses, warehouses, packing sheds, canneries, and other fruit and vegetable packaging and processing plants employ thousands of workers throughout the year, all over the country. This work is often classified as 115114 Postharvest Crop Activities - this U.S. industry comprises establishments primarily engaged in performing services on crops, subsequent to their harvest, with the intent of preparing them for market or further processing (U.S. Bureau of the Census). These establishments provide postharvest activities, such as crop cleaning, sun drying, shelling, fumigating, curing, sorting, grading, packing, and cooling. The U.S. Bureau of Labor Statistics lists over 45,000 employed in the 45-2041 Graders and Sorters, Agricultural Products category (Bureau of Labor Statistics 2004). However, many if not most fresh food packing and sorting workers are part-time and temporary, interspersing warehouse work with field work or other agricultural work throughout the year. Thus, the actual number of people working in fresh fruit or vegetable packing houses, processing warehouses or canneries is much higher.

Furthermore, statistics from one industry in Washington State show that these numbers are huge underestimates of the number of people working in warehouses. Washington State is the leading producer of apples in the nation (Washington Agricultural Statistics Service 1999). More than half of the apples grown for fresh eating in the United States come from Washington State (Washington Agricultural Statistics Service 1999; Washington Apple Commission 2000). This billion-dollar industry

produces over three million tons of fresh apples for the domestic and export markets each year (Washington Agricultural Statistics Service 1993; Washington Agricultural Statistics Service 1997; Washington Agricultural Statistics Service 1999). There are about 4,000 growers and an estimated 41,000 people working in the apple industry including packing houses (U.S. Bureau of the Census 1994). This is about the same number of people as the Bureau of Labor Statistics estimates for the whole United States.

NIOSH has noted that women make up a significant part of the U.S. workforce but that health and safety issues specific to women have not been researched and addressed as they should. Women make up the majority of packing house workers. Jobs in fresh fruit and vegetable warehouses are generally segregated by gender. Women tend to be packers and sorters. Almost all forklift operators are men. Inspectors and supervisors may be male or female, though women generally hold supervisory positions on the warehouse floor, while men control the overall operations of the warehouse. Female majority jobs, such as packer, sorter and housekeeper average considerably less than comparable non-skilled labor for males, such as forklift operator (\$6.72/hour vs. \$8.77/hour in Yakima County, Washington in 1995).

There has been limited reported research on health and safety conditions in the packing houses. The literature contains some information on conditions in meat and poultry packing houses, fish processing plants, the sugar processing industry, and for pear and apple orchard workers (Cherniuk et al. 1989; Chiang et al. 1993; Jacobs and Smith 1988; Kurppa et al. 1991; Manuaba 1995; Sakakibara et al. 1993; Sinks et al. 1987). Sakakibara et. al. (1995) identified musculoskeletal disorders in the neck and shoulders from bagging pears and apples. Cherniuk et. al. (1989) found neuromuscular strain in female sugar beet sorters. Carbon monoxide in warehouses is a concern (Ely, Moorehead, and Haponik 1995; Fawcett et al. 1992; McCammon, McKenzie, and Heinzman 1996), due to the use of propane-fueled forklifts in enclosed spaces. There have also been a few studies on ergonomic strains to the back and hands from warehouse work (Gagnon and Smyth 1991; Keyserling et al. 1993; Kuorinka, Lortie, and Gautreau 1994; Studman 1998). Messing has investigated disparities in occupational injuries related to the division of labor by gender, but has not looked specifically at agricultural labor (Messing 1998). There is a dearth of information on occupational hazards and injuries to Hispanic workers.

Fruit and vegetable packing was among the top 5 industries for gradual onset upper extremity disorders in Washington State workers compensation claims between 1989 and 1996 (Silverstein and Kalat 1998). A study of work-related disorders of the back and upper extremities ranked the fruit and vegetable packing industry as 10th in Washington State for frequency of all upper extremity disorders, and 6th for those injuries with gradual onset (Silverstein and Kalat 1998). The fruit and vegetable packing industry had 2.3 times the overall industry rate for all upper extremity disorders and 3.0 times the rate for gradual onset upper extremity disorders. The Department of Labor and Industries developed a Prevention Index (PI) to combine information about the frequency of cases within an industry and the relative risk for workers in that industry compared to all other industries combined. For all gradual onset upper extremity disorders, fruit and vegetable packing ranked 6th on the basis of frequency and 40th on the basis of relative risk. It ranked 5th on the prevention index (PI = 23.0). Similarly, fruit and vegetable packing ranked 12th overall for gradual onset shoulder disorders, 10th for gradual onset elbow disorders, 3rd for gradual onset hand / wrist disorders, 19th for rotator cuff syndrome (shoulder), and 16th for epicondylitis (elbow). Clearly, this industry, which includes apple warehouses, requires further investigation and intervention to reduce work-related injuries.

In the period from July 1994 to July 1995, three occupational groupings accounted for 57 percent of the unemployment insurance claims filed in Yakima County. They were agriculture (32 percent), processing jobs (12 percent) and packing and material handling (14 percent), all of which are based in the agricultural economy (Labor Market and Economic Analysis Branch 1997).

Between 1997 and 1999, I conducted a study of the perceptions of workplace health and safety risks among female Hispanic apple packing house workers in eastern Washington State. Sixty-nine workers were interviewed using a combination of quantitative and qualitative research methods. In addition, I worked with the University of Washington Field Research and Consultation Group on a study of musculoskeletal hazards in several apple packing houses. The following data come from these studies. The quotations are taken from the interviews with warehouse workers. More details regarding data collection can be found in Snyder 2001.

Most of the problems of apple warehouse work relate to the physical labor involved in sorting and packing fresh apples. Repetitive motions, heavy lifting and awkward positions are examples of the problems identified by the Field Group (Simcox et al. 2001). In addition, many workers complain about exposure to the chemicals used to clean the apples, pesticides applied to the apples in the orchard, and waxes applied to preserve shelf-life of fresh apples (Teamsters / United for Change 1997b).

There is very little published research on chemical induced illnesses in warehouses. Many workers whom I interviewed mentioned skin rashes, watery or itchy eyes, congested nasal passages, and "allergies" resulting from exposure to these irritants. One participant told me,

"The dust makes me sneeze all day. It plugs my sinuses. It is allergies from working there a long time. It is the same in [all the areas of the warehouse]... There are many working there and they say all that stink goes into the lungs. Right now we sneeze with the allergies." DOC 331

In addition, some warehouses are very noisy, due to the large amount of machinery in use. Noise levels are of concern to management as well as workers. Some workers wear ear plugs, but personal protection devices have their own problems, since workers cannot hear if they are spoken to.

Warehouses are often too hot or too cold, as well. In general, warehouses are large buildings on cement floors with little heating. The apples need to be at cool temperatures, so localized heaters are often used to keep workers warm in winter. In the summer, the metal buildings heat up, and ventilation is a concern of some workers. Temperature control is also a place for management-employee conflicts. In some warehouses, temperature control is principally a matter of opening or closing exterior doors. Some workers mentioned difficulties with supervisors in maintaining temperatures at which they could work in comfort.

Ventilation is also a major issue for carbon monoxide poisoning. Many warehouses use propane-fueled forklifts to move pallets and crates of apples through the warehouse. In unventilated buildings, carbon monoxide can build up and sicken workers (Associated Press 1997). Some warehouses now use electric forklifts, and others have installed monitors that sound an alarm if carbon monoxide reaches hazardous levels

"They have that carbon monoxide and I think that it is really bad for your health. And the chlorine. It is so strong that your eyes get irritated. We had a meeting about that, because [several] years ago we got really sick. Almost half of the warehouse had to go home because they were so sick. And I was one of them. I thought I was going to have to go to the hospital. We had a meeting about that. We even

talked to the owner and everything. The thing is that, the only thing he said was that, 'You don't like the job, there are jobs everywhere. Go find another job.' I don't think that is right.

Sometimes they open the doors, but sometimes it gets so strong. They have a monitor there. I don't know what the name of the monitor is, but that tells you if it is really high, the carbon monoxide. They open the doors, but still you can smell that really strong. Sometimes we get headaches with that and feel nauseated." DOC 302

Some participants view accidents as an inevitable cause of apple warehouse injuries. And in fact, 45 pound boxes do fall, packing carts tip over, and fingers get caught in machinery. More insidious are the acute injuries that result when well-meaning workers try to prevent boxes of apples from falling and wrench their backs by reaching or grabbing heavy objects with sudden movements. In these cases, workers feel particularly wronged when the employers try to downplay the injury or refuse to pay for treatment. These workers feel that their injury was caused when they were specifically doing something to help the employer, and the consequences should be compensated.

"For me, it is a very fast and hard job. I am not used to it. I don't know how dangerous it is, but when you see people getting hurt, you just wish it does not happen to you." DOC 353

"But still, people are very pressured, and have a lot of work. They get way too many injuries because of what happens. They try to do 10 days of work in one week. They force the people to do a lot of work. It is difficult." DOC 105

"I don't think there is much they can do [to prevent risks] because the risks are there. All they can do about it is let you know, and talk to you about it. And let you know where are the most risks. Other than that, preventing someone from getting hurt, no, anyone can get hurt." DOC 307

In my study, 54 percent of the participants reported a workplace injury or illness (37 out of 69). This is a very high proportion of workers, and cannot be assumed to be the prevalence of injuries and illness for all warehouse workers in Washington State. However, the Field Group survey of musculo-skeletal injuries among male and female workers in three Yakima area warehouses found a prevalence of 70 percent for any problem that occurred in the current job (Simcox et al 2001). The Field Group defined a work-related musculoskeletal injury as one that occurred at least once a week, or lasted one week or more, was not an accident, occurred on the current job, and had affected the worker within the previous year. Based on these criteria, 52 percent of the Field Group sample had experienced an injury. Sixty-two percent of all women surveyed in the Field Group study met these criteria, including 55 percent of all Hispanic women.

There are many avenues for further research urgently needed for the safety and well being of agricultural warehouse workers. Public health and occupational health researchers need to increase research into the unique occupational health issues experienced by female workers, especially packing and sorting fresh fruit and vegetables. In particular, research is needed to understand the scope of illnesses and injuries associated with agricultural warehouse work, including musculoskeletal hazards and the effects of high speed low-paid tasks and the associated stress to workers. In addition, NIOSH funded researchers should work more closely with health care workers in local communities to understand and identify work-related problems. Finally, interventions such as slowing the speed of the conveyer belts, providing mats for standing and to prevent slipping, and ergonomic adjustments of the packing and sorting equipment are urgently needed.

Given the size and importance of the industry, it is critical that health and safety hazards be reduced as much as possible.

Thank you for your consideration,

Karen Snyder, PhD MPH

Fire, EMS and Law Enforcement personnel are being struck at roadway incidents in greater numbers than ever before. There is no data base except for fatalities. Strategies must be pursued to protect these workers. The motoring public must be educated about the danger these responders face while they work in these hazardous conditions.

A concerted effort is needed to develop an occupational exposure database across all industry sectors. The NIOSH NOES database contains information on potential exposures that existed 25 years ago. While resources to update this database would probably be prohibited without special congressional funding, its a high enough priority for NIOSH to be proactive in seeking existing exposure data from industry. I`m aware of NIOSH`s effort to work with the AIHA to seek such information; however, additional sources of exposure information need to be investigated. For example, within DOD a number of the armed forces and others have developed exposure databases. The NAVY has a large database that contains exposure and job information collected on workers involved in ship building and repair. Likewise, the Insurance Company`s have exposure information, although not well organized, that might be of value in identifying populations at risk. Also, many of the States that have their own OSHA programs have developed exposure databases similar to OSHA`s IMIS database. Exposure data is critical for establishing research priorities and making recommendations.

Psychosocial/emotional characteristics (including vulnerability to stress, anxiety, and depression) strongly impact pain, injury, and chronic conditions. I hear clients asking for "real world studies using real world interventions in real world workplaces", especially those including stay-at-work/return-to-work interventions that address these issues. Thank you.

Future Research / Service Sector: Hotel Room Attendants

Pam Tau Lee, Labor Occupational Health Program, UCB

<ptlee@berkeley.edu>

My name is Pam Tau Lee. I am from the Labor Occupational Health Program at the Center for Occupational and Environmental Health at UC Berkeley. I am here to speak on future research needs to support a public health approach to workplace health and safety for service sector workers.

I have over 20 years of work experience with hotel room attendants, and assisted in directing two recent room attendant health studies in Las Vegas and San Francisco.

In the U.S. there are over 1.5 million workers employed in this industry and the numbers are expected to increase as business continues to improve. Over the past two decades, guest services have increased; twin beds have been replaced by queen and king luxury mattresses; simple bedding by triple sheeting, more pillows, duvets or heavy bed spreads. Bathroom and sleeping quarters have more supplies, amenities and equipment. In a nutshell, the workload for room attendants has increased. But what is the implication for room attendant health?

In two landmark health studies with room attendants conducted by UCSF researcher Dr. Niklas Krause, it was found that:

- workloads have increased, and because of that,
 - 66% of room attendants report that they are unable to take needed rest and recovery breaks.
- health status for room attendants ranged from "fair to poor."
- 40% of room attendants had high blood pressure as compared to the national average of 25%.
- 78% experienced work-related pain or discomfort but only 21% of these room attendants filed formal reports.
 - 46% of the room attendants who took off work for injury or illness got well before returning to work.
- 83% took pain medication in the last 4 weeks.
- vitality and energy was rated low at 36 points for Las Vegas room attendants out of a score of 100, compared to a national average of 61.
- psycho-social indicators such as effort-reward, job strain and job control may be significant indicators for injury.

Dr. Lester Breslow recently published an article "Health Measurement in the Third Era of Health." In this article, he makes the case that health be considered as "a resource for everyday life." Given that 90% of Americans believe that their health is "excellent or good," as opposed to "fair or poor," it is reasonable that future worker health research efforts focus on sectors such as room attendants who currently do not enjoy good health, are working in pain, and lack energy to perform everyday chores. Our experience with room attendants is similar to many other low wage service sectors such as janitors and health care workers. Future research focusing on identifying workplace hazards and effective interventions, can contribute greatly toward improving health for workers in the U.S., especially the most vulnerable such as immigrant workers.

High rates of injury and illness for this sector of workers have implications that go beyond lost days and productivity. Workplace injury, illness and stress interfere with normal, healthy family activities and community engagement. In a developed country such as ours, we should have the resources to prevent these conditions from occurring.

Recommendations for future research include:

1. Comprehensive ergonomic studies that utilize the best and latest technology to measure ergonomic strain.
2. Long term studies that look at health indicators such as blood pressure, diabetes, musculoskeletal strain and other conditions among service workers and room attendants in particular.
3. Studies that measure psycho-social conditions especially job strain, job control, and effort-reward.
4. Workers' compensation and return to work. Vulnerable workers such as low wage immigrant workers are less likely to file for worker compensation. This is further complicated by the fact that there is often no light duty task available for these injured workers, and lack of access to health care.
5. Intervention studies that measure the effectiveness of interventions not only for traditional health and safety injuries and illness but also workload, work organization and psycho-social health.
6. Community based participatory research methods to incorporate those who are directly impacted in the research activities and focus on findings that can contribute toward identification of effective interventions.

Thank you

Hearing loss is a common work-related condition in agriculture. In this sector, exposure to pesticides might also be a factor in hearing loss. In fishing, there is indication that hearing loss is also common. Initiatives to better understand the risk and prevent it should be sought.

Thank you for the opportunity to present comments regarding concerns for work-related injuries in the healthcare sector. I would like to direct your attention to the field of diagnostic medical sonography. The professionals of this valuable diagnostic imaging modality include those individuals who practice within the ultrasound division of diagnostic imaging labs, echocardiography departments, vascular labs, perinatal practices and breast imaging centers. They are employed primarily in hospitals or outpatient clinics but also staff mobile services in order to provide services to rural areas or non-ambulatory patients. The profession is not very large, especially when compared to nursing. It is estimated that there are approximately 100,000 sonographers in the United States. However, the incidence of work-related musculoskeletal disorders (WRMSDs) among sonographers is 80%, with 20% suffering career-ending injuries. 1

The use of medical sonography as a diagnostic tool has increased significantly since it became readily available to the medical field in the late 1970's. A Sonographer Benchmark Study performed by the Society of Diagnostic Medical Sonography in 2000 showed a 55.5% increase in the numbers of studies performed per year per sonographers between 1992 and 2000. Furthermore, data provided by a national radiology management and acquisition firm, U.S. Radiology Partners (USRP) that same year indicated that 42% of hospital imaging departments were understaffed in sonography. This same study reported a 71% increase in imaging volume over the prior year. Staffing shortages were perceived to have a direct effect on the quality of care, with 56% of respondents indicating that staffing shortages have diminished the quality of care their departments are able to provide.³ The impact of occupational injury on manpower and access to healthcare by patients requiring ultrasound procedures has been felt and continues to be of growing concern.

The risk factors inherent in the practice of diagnostic medical sonography have been clearly demonstrated to correlate with OSHA-defined risks for WRMSD. Solutions outlined in the Industry Standards for the Prevention of Work-Related Musculoskeletal Disorders in Sonography address feasible control measures related to administrative and engineering controls and best practices. OSHA and the Society of Diagnostic Medical Sonographers (SDMS) signed a formal alliance in Washington, D.C. in October 2004 to reduce and prevent work-related musculoskeletal disorders (WRMSD). Using the Industry Standards as a guide, the alliance goal is to provide SDMS members and others in the medical community with the tools and resources they need to reduce and prevent exposure to work-related musculoskeletal disorders.

Occupational injury in sonography is causing a significant impact to the industry and the workforce in the medical sonography profession. Patient care is being affected because this modality cannot be fully utilized due to lack of staff. This is unnecessary and could easily be avoided with education and the implementation of administrative and engineering controls. NORA has the unique opportunity to facilitate the implementation of functional programs for addressing WRMSD in diagnostic medical sonography. It is my hope that this profession will be considered as a subject of practiced-based research within the NORA program.

I wanted to put in a good word for continued funding of NIOSH's research into the health effects of RF/EM fields of both low and high frequency. I feel this is a research field that has important implications for business and innovation. At the same time, this is exactly the kind of research that only government can perform with validity as it requires very long term tracking and statistical data gathering and analysis. Please consider continued support for this critical aspect of occupational health and safety. Many thanks.

Research is needed to demonstrate whether or not employer accommodation of work-restrictions (alternate duty) results in faster recovery times, reduced work-comp costs, and less disability. My experience as an Occupational Physician has been that injured workers who are not able to return to work due to non-accommodation of restrictions have longer and more complicated recovery courses.

The following are the full comments regarding the presentation at the NORA Town Hall Meeting in Tampa, FL, on February 13, 2006 on excavation safety. These comments are submitted personally and do not necessarily reflect the views of my employer.

As it is generally known, there are about 60 deaths each year and over 1,000 injuries from excavations. These figures are not estimates but actual reports. As such, it is widely accepted that these figures fail to account for all types of excavation incidents.

Employers who engage in trenching and excavation are expected to comply with OSHA standards at a minimum as well as consensus standards of the industry as a reasonable measure of diligence and be able to document an adequate standard of care to protect against litigation.

The OSHA standards at 29 CFR 1926.650-652 as well as the consensus standard ANSI/ASSE 10.12 are inadequate in many respects in addressing serious issues of compliance with everyday provisions and considerations.

Unfortunately, the ANSI standards failed to address all the concerns of interested parties (not represented in the committee) and instead for all practical purposes, settled in copying the text of the OSHA standard itself. To its credit the 10.12 Committee addressed a few areas of vagueness which helped clarify some issues (Compare for example the Definitions and the requirements for ramps, stairs or runways at 29 CFR 1926.651 (c). where it becomes clearer what a runway is and the slope of adequate ramps is given as guidance to the employer.

After reviewing the OSHA interpretations on the subject, one concludes that these are too general in many cases. Particularly, often OSHA answers that the "competent person" is responsible for and expected to accurately judge the conditions or assessing the risk.

The main issue of concern is the experience, skills, judgment, education and training (the competence) of the "competent person" (CP), who is expected to and entrusted to be the judge, jury and executioner of most options, systems, issues, and problems arising out of the trenching and excavation activities on a busy construction jobsite.

A competent person needs to have only authority and the ability to recognize hazardous conditions. No technical qualifications, prior experience or knowledge of trenching are required for the competent person. The following parts of the standard will illustrate the serious issues raised by this omission:

a. At 1926.651(a), the standard requires the CP to judge accurately whether surface encumbrances and nearby foundations and other buried elements may pose a risk.

b. When are surface encumbrances so located that they pose a hazard to employees? What combination of depth and proximity makes such an encumbrance a hazard? At what degree of probability is such a risk going to be addressed?

c. 1926.651(i)(1) addresses adjoining structures. What guidance does the CP have for judging that adjoining structures are too close and would be adversely affected by the excavation? At what distance is a structure 'adjoining'?

d. 651(i)(2) If excavating below the level of the base or footing of a foundation or retaining wall (while not supported or dug in stable rock) is NOT IN EVERY CASE expected to pose a hazard to employees in the trench, then what guidance is there for deciding when it COULD BE REASONABLY EXPECTED to pose a hazard to employees. Note that when not supported or dug in stable rock, the standard requires a registered professional engineer to make the determination that the REASONABLY EXPECTED hazard does not after all pose a hazard to employees?

e. At 1926.651 (c) (1)(i) competent person is permitted and required to direct or install stairs, ramps, and runways, but no guidance is provided through optional designs, and no requirement that the "competent" person has experience in the construction or installation of these systems is provided for in the standards. When does the CP decide to use a structural ramp (made of steel or wood) rather than an earthen ramp? What factor of safety, compressive strength, maximum slope, and other specifications are there to guide such a design?

Another issue beyond the capability or training of the average "competent person" is the requirement from App B that the CP judge how less steep a slope should be in response to surcharge loads from equipment or materials near the edge in App B (c) (3) (ii).

The competent person is expected to accurately classify soils. There are several problems with this concept.

a. OSHA provides a reference to the USDA textural classification system and ASTM D-2488, but no text from these sources is provided in the OSHA standards or in most "competent" person "train-the-trainer" courses. The information provided in the text of the standard itself is woefully inadequate to understand what is required for soil analysis. The sedimentation test, which is not a "strength" test, is needed to differentiate between some Type B and type C soils. It is commonly covered in excavation CP

classes but not described in the OSHA standard. Is a small excavation employer with expected to purchase the ASTM D-2488 or search for the USDA textural classification system and study it after or instead of taking one of the commonly available excavation competent person classes?

b. Another example of the standard's vague or misleading instructions is the mention of a dry and drying test. In the available literature, it is abundantly clear that to be considered thoroughly dry (by natural exposure), a sample may need up to twenty-four hours, yet the reader of the OSHA standard is led to believe that this "soil classification" is a "field" method. The other option is that of "forced" drying, but this is not readily a field method, and neither method is discussed in the standard.

c. In the 'Definitions', the standard is lacking definitions of textural classes (clay, silty clay, clayey silt, etc.) that are used to define the OSHA soil classes. The definition for stable rock (and OSHA interpretations on the subject) in the text of the OSHA standard is a circular definition in that in order to conclude that a rock is "stable rock" one must observe it indefinitely to confirm that it will stand forever when excavated with vertical sides.

A common method of "compliance" with the provisions for a competent person is to send supervisory personnel to a four hour class. This CP "qualification" through a four-hour class is plainly too short. A minimal soil overview, covering the preparation of a sample and tests for cohesiveness, water content and composition of a soil, would take longer than 4-hours if the participants are to do any hands-on. An introduction to help assess whether surface encumbrances, utilities or adjacent activities may pose a hazard and what appropriate actions on the trench would be adequate responses, as well as practice, exercises or field demonstration of excavation protective options, would require in all likelihood not less than two whole additional days.

Is the safety of employees entering trenches and excavations really served when their lives depend on the "competency" acquired by a junior foreman without prior knowledge or experience in trenching in a mere four hours? I submit NOT.

A serious omission in the standard is the lack of a requirement for logging of the daily inspections by the CP, along with the observations and soil test results supporting a soil classification, and that these records be available on the jobsite. Whether or not this may have been addressed in the preamble and discussion to the OSHA standard, it remains one of the main weaknesses and may be substantially responsible for the continuance of trench accidents.

Wherefore, as a safety professional and a person who is responsible for the safety of employees entering trenches and excavations, I respectfully request for NIOSH in its advisory role to research and publish Criteria for a Recommended Standard on Excavation and Trenching. At the very least, NIOSH should issue specific recommendations to OSHA that address these problems in the excavation standard. Clearly, after fifteen years of application of the excavation standard, OSHA is not likely to make any substantial improvements in the safety deficiencies discussed here.

The health effects of exposure to electromagnetic fields (EMF) in the work environment must be defined.

Epidemiology studies may be questioned, but recent laboratory research has shown that the stress response, the universal response of cells to potentially harmful environmental stimuli, is induced by both power frequency (ELF) and radio frequency (RF) fields. In addition, new evidence from proteomics indicates that even weak ELF fields ‘...damage ...macromolecules.’ (Kültz, *Physiol Rev*, 2005). Since the same biological mechanism is evoked by non-thermal (ELF) and thermal (RF) stimuli, it is clear that safety standards based on temperature rise (SAR) are fundamentally flawed. A research agenda aimed at protecting workers must develop new safety standards that take into account (1) non-thermal responses and (2) cumulative exposures across the EM spectrum.

There should be a consideration on young workers. Statistics indicate that up to 80% of high school students worked in various jobs during high school. There are about 4 million students that work during Summer and 2.9 million during the school year. Students/young workers face the same hazards as adult workers. Most of the vocational school students work after school hours practicing their skills. Students are more vulnerable than adults because they are lacking physical, emotional, and cognitive maturity needed for certain tasks, and lack job experience. They are experiencing rapid growth of organ system that can be harmed by exposure to hazardous substances. Their non-fatal injury rate twice that of mature workers. They may not know their legal rights, nor which work tasks are prohibited by child labor laws. Work-related injury costs (direct and indirect) mounted to \$5 billion (Miller and Waehrer, 1998). More than half of the injured adolescents workers reported that they had not received any training in how to prevent the injury they sustained.

NIOSH must put emphasis in the NORA2 because young workers are found in every one of the Sectors.

Thank you very much.

An estimated 1,594,980 U.S. workers were employed as heavy and tractor-trailer truck drivers in 2004; 929,530 others worked as light or delivery services drivers.

Previous studies have shown truck drivers to be at increased risk for low-back pain; heart attack; hypertension; ulcers; cancers of the bladder, lung, prostate, and stomach; and premature mortality. Truck drivers are also more likely to smoke cigarettes, not exercise regularly, and be overweight compared with the general population. While individual risk factors play a role in the high disease risk of drivers, the extent to which occupational exposures contribute to disease and individual risk factors / health behaviors is largely unknown. Truck drivers experience a unique constellation of exposures - diesel exhaust, shift work, irregular schedules, sleep disturbances, isolation from their family, sitting for long hours in the truck cab, and stress from a prolonged state of vigilance. Yet, little research has been done directly on this population. Knowing the prevalence of health conditions such as diabetes, cardiovascular disease, and hypertension among U.S. truck drivers is important for determining the potential impact of interventions and rulemaking. In evaluating the potential health effects of the revised hours-of-service rules for trucking (effective October 1, 2005), the Federal Motor Carrier Safety Administration stated, "Because relatively little of the available evidence was derived from motor carrier

operations, the Agency had to evaluate and weigh information from different fields and adapt it to a trucking environment."

Research is needed to provide prevalence estimates for important health conditions, and to explore the associations among health status, individual risk factors, and occupational exposures related to work organization and hours of service.

MAJOR POINTS PERTINENT TO CHILDREN AND YOUTH

The 1996 National Action Plan for Children and Agriculture (adopted by the U.S. Congress and funded through a special appropriation) should be maintained as the primary strategic plan for federal agency and private sector funding and action.

By 2011, a review of progress in achieving objectives of the 1996 Action Plan (and its review at the 2001 Summit on Childhood Agricultural Injury Prevention) should be conducted to ensure priorities and funding for childhood agricultural injury prevention are appropriately aligned.

NIOSH surveillance has revealed that more than 50% of children injured and killed on farms are not working when the incident occurs. It is important that NIOSH retain a commitment to non-working children on farms because no other federal agency addresses this concern. Research is needed to understand what incentives (e.g. financial, regulatory) will motivate farm owners to remove children

from hazardous conditions on the farm. Additionally, pilot projects should be funded to determine if/how available and affordable rural childcare programs can be provided for children of farm parents and farm laborers.

Methods to increase awareness of, and adherence to, state and federal child labor laws in agriculture should be undertaken via education translation projects. In particular, the Department of Labor's "Youth Rules" website should be revitalized and used as the primary source of timely, accurate information for agricultural employers, work supervisors and youth employees.

The USDA funded a major initiative to address Hazardous Occupations Safety and Training in Agriculture (HOSTA) for young workers while NIOSH funded youth educational program evaluations, as well evaluation of the North American Guidelines for Children's Agricultural Tasks (NAGCAT). A process should be undertaken to synthesize and analyze lessons learned from these related interventions and their respective study results. Findings from these efforts should be widely disseminated to provide valuable guidance to safety professionals and agricultural employers.

We commend NIOSH for its leadership of the national initiative addressing injury prevention for children on farms. We believe benefits of this initiative are already evident and expect to achieve further success in the coming decade.

Occupational acquisition of MRSA and other emerging drug resistant pathogens with secondary spread to family members and nosocomial transmission to patients. MRSA rates of illness are alarming. Lifting and patient handling and hospital design also of interest. Also use of "green chemicals" and hospital disinfectants and deodorants that contribute to occupational airway diseases. These problems potentially affect all health care workers at the bedside, in home health and some of the ancillary. MRSA infections are recurrent and disfiguring and have caused serious conditions requiring hospitalization.

Our eyes are the most important part of the body when it comes to working at a computer display. They are the sole means by which most computer users obtain information to perform their work. In order to streamline the computer work process, the design of the visual task environment and the vision of the person need to be optimized. If there is a problem with the person's vision, then they will not be able to perform their job as well as they should.

If we think of computer work like any other production process and do what is needed to improve the process efficiency, then we discover that it is cost efficient to insure that the computer worker has good vision.

The visual symptoms that computer workers experience are the most obvious expression of the shortcomings in the ergonomics and visual characteristics of the worker. Because of the high visual demands of the computer task and the visual shortcomings of many operators, vision problems and symptoms are very frequent among computer workers. Most studies indicate that visual symptoms occur in 75-90% of computer workers, by comparison a recent study released by NIOSH showed that 22% of computer workers have musculoskeletal disorders. A large survey of optometrists indicated that 10 million primary care eye examinations are annually given in this country primarily because of visual problems at computers- not a small public health issue!

Adequate research should attempt to quantify computer use and visual stress, including affect on productivity and performance. Recent initial studies have shown a 2.3 cost benefit ratio of improving

visual performance of computer users. There need to be more studies that support this preliminary finding.

Categorized comment or partial comment:

This is a statement of support for funding for the Non-Ionizing Radiation program. Protecting workers from the known and emerging health risks of non-ionizing radiation is a vital service. The public has counted on and received excellent information and guidance from NIOSH on non-ionizing radiation in the past, and it is imperative that this function continue. Possible health risks from EMF exposures (power-frequency 60-Hz electric and magnetic fields continue to be a topic of great public concern. Radiofrequency radiation sources, possible health risks and choices the public may have to reduce exposures during this time of uncertainty - while the research continues - must be handled in terms of good, independent public information. NIOSH is uniquely suited, and funding should be provided for it.

NIOSH's process for dispersing intramural and extramural research funds (the National Occupational Research Agenda or NORA process) needs to give a high priority for funding for continued involvement in non-ionizing radiation issues.

31-33.

Heavy manufacturing exposes populations to biomechanical hazards. Many of these job tasks are especially risky for populations below the 50th percentile for women; however, laws prohibit discrimination practices. Therefore some people may be placed in harms way. We need to identify a common ground for worker protection when risk assessment pulls us in one direction and legal rights in another.

Workplace exposure conditions to electromagnetic fields have increased over the past decade. In addition to electrical power sources (ELF), which NIH and WHO have since 2002, recognized as a Class 2 carcinogen, the workplace now includes wireless sources from mobile communications devices and transmitting antennas where public safety personnel, telecommunications and electrical workers, as well as newly exposed occupational groups, such as teachers in the classrooms with wireless laptop computers may be at risk. More safety training to limit or reduce EMF exposure among workers is needed, including for contract employees. Epidemiology studies and exposure assessments of high risk groups would evaluate associations between exposure and any adverse health effects. This information could be useful to public health agencies and worker safety programs whose mission it is to make workplaces safer.

I understand you are seeking comments on avenues for investigation and on concerns that need to be addressed in order to keep workers safe.

An area that must be addressed at this point in time is exposure to electromagnetic fields and radiofrequency radiation.

The number of devices and base stations emitting such radiation and fields has exploded within the last ten years. Workers on buildings and roofs are constantly being exposed at close range to cell phone base station antennas. Many workers are now required to use RF equipment or use cell phones or cordless phones on the job or spend many hours in front of video display terminals. What the public and workers don't know is that a high proportion of the research on this kind of radiation and EMF is showing biological effects from it---in other words, the body's cells are responding to this low level signalling.

To what degree this may cause negative health effects is uncertain at this point, but there are credible studies suggesting that it is already having an effect on health, at least for a portion of the population, even when emissions are within federal guideline levels. Let us not wait for the possibility of noticeable harm to some of our workers before we take precautions.

I would like to strongly support Dr. Bowman`s request for more research into the potential health effects of non-ionizing radiation from technologies such as cell phones. The rapid deployment of these technologies -- coupled with increasing evidence of potential health effects -- makes it imperative that we research this area more thoroughly and develop protective policies, particularly with regard children. For example, if health effects impacts even a minority of our children, then the negative impact on human health and productivity may be very large, given the widespread and growing use of wireless technology. I helped organize a group called Protect Schools (www.protectschoools.org) that worked to improve public awareness of the health effects of wireless technology, particularly as they impact children attending schools.

state-based surveillance systems

Categorized comment or partial comment:

The agriculture sector is an arena that has limited baseline data available due to lack of data collection by BLS of farms with less than 10 workers. State-based surveillance systems and agricultural centers are useful to identify the current prevalence of many hazards facing farmers(baseline data), and to measure whether any projects geared toward reducing these hazards are actually effective. Specifically, surveillance systems focused upon asthma, repetitive stress disorders, pesticides, and noise induced hearing loss are necessary. Surveillance systems that are aimed at special populations such as youths, foreign-born, and migrants, are also important for this sector.

state-based surveillance systems

Categorized comment or partial comment:

In order to measure any improvement in efforts gained through any of the sectors, baseline surveillance data is necessary. There are currently many state-based systems for occupational health that can assist with this. NORA-2 sectors need to be aware of and include this data, and should include individuals on their committees who understand the limitations and benefits of these data for interpretation.

While injury risks, such as falls, are well recognized as hazards with construction, there are many disease-related hazards also. State-based surveillance systems are useful to identify the current prevalence of these hazards (baseline data), and to measure whether any projects geared toward reducing these hazards are actually effective. Specifically, surveillance systems focused upon lead, silica, asthma, repetitive stress disorders, and noise induced hearing loss are necessary.

Categorized comment or partial comment:

The public service sector is an arena that is under-studied and has limited baseline data available due to lack of collection by BLS. State-based surveillance systems are useful to identify the current prevalence of many hazards facing these workers(baseline data), and to measure whether any projects geared toward reducing these hazards are actually effective. Specifically, surveillance systems focused upon lead, silica, asthma, repetitive stress disorders, pesticides, needle-stick injuries and noise induced hearing loss are necessary. Surveillance systems that are aimed at special populations such as youths, foreign-born, and migrants, are also important for this sector.

Categorized comment or partial comment:

NIOSH needs to step back and take a hard look at what it has been doing relative to what the real problems are in agriculture, and set NORA and NIOSH funding policies accordingly. Most hazards and corresponding solutions are well known. What is lacking are the financial and/or policy means to implement them. If farmers cannot afford to buy new equipment with the latest safety technology, or cannot afford to retrofit older equipment with newer safety technology, then NORA needs to address that. NORA needs to focus on how to implement known solutions.

An example: Hearing loss to farmers and farm family members has been very well documented, for years. We do not need more data on hearing loss; we need research on how to implement the well-known solutions: How do you get farmers to buy (or afford to buy) the newer tractors with low-decibel cabs, how do you desing hog buildings to minimize sound, how do you get farmers to buy (or afford to buy) hearing protection, how do you get farmers to wear hearing protection, how do you make hearing protection more comfortable or more socially acceptable, etc.

For those farmers who can afford to purchase the necessary technology, we need research to find out why they are not doing so, and to find out what policies have been successful in getting them to make the necessary investments.

Another example: Animal-related injuries are a very important issue in some states. Ergonomic concerns relative to raising animals are a big issue. Often the problem stems from the fact that the farmers must use very old facilities, say from the 1920's or 30's. Rather than looking at these problems on the "micro" scale, NORA needs to look at the "macro" scale, and focus research on why farmers are not able to upgrade or replace new facilities. If our factories were all built in the 1920's or 30's, wouldn't the highest, or near highest, priority be to upgrade or replace ancient factories with facilities built with health and safety in mind?

There are systemic causes to the agricultural health and safety problem that must be addressed. Finances are definitely one of them; finances limit what farmers can or want to spend relative to safety and health. (This ties into the facility issue.) Just look at how many farms are going out of business or cannot sustain themselves without off-farm income. Ask any agricultural economist about farm income. NORA needs to include research into these root causes, into why the known agricultural safety and health solutions are not being adopted with any rapidity, and how to solve or overcome these root causes. At the same time, many in the public are calling for smaller farms, for saving the family farms, for stopping so-called "factory farms". How can that be done while at the same time allowing small farms to afford to implement health and safety solutions? NORA cannot ignore this.

NORA should also do research on the differences between agriculture and other industries, so as to learn why solutions used in non-agricultural industries often do not work, or are not adopted, by agriculture.

NORA should also prioritize based on injury and illness data. NIOSH has funded some projects in the past that are well-designed scientifically, but really address lesser issues relative to the magnitude of the problem. Projects may be well-designed but have limited applicability to other more pressing problems.

In developing NORA for agriculture, NIOSH needs to not just rely on submitted comments, but on seeking out input and holding meetings with people who are really knowledgeable about farmers' issues and problems, such as the USDA NCR-197 Agricultural Safety and Health committee, or the Extension agricultural safety specialists, or state Farm Bureaus' safety staff. Everyone is busy with their own work, and attending a NORA workshop might not have been a possibility or priority. People not familiar with NIOSH may not know about NORA or the need to submit comments to this site, or they may have felt their comments would not be taken seriously compared to those from well-funded injury prevention professionals.

Thank you for the opportunity to comment.

- Nanotechnology
- Pam Tau Lee, Labor Occupational Health Program, UCB
<ptlee@berkeley.edu>

My name is Pam Tau Lee, Labor and Environmental Justice Coordinator at the Labor Occupational Health Program, Center for Occupational and Environmental Health, UC Berkeley. I am submitting testimony to request that NORA strongly consider conducting research on the health effects and effective occupational health controls focusing on the application of nanotechnology. My testimony below is based on information provided by the Center for Environmental Health and the International Center for Technology Assessment.

What is Nanotechnology

Nanotechnology refers to the manipulation of individual atoms and molecules, by engineering matter at the atomic level. At the nanoscale, familiar materials can have dramatically different properties: changes can affect color, elasticity, strength, conductivity, and other properties.

Already nanotech materials are used in hundreds of consumer products from tennis rackets to sunscreens. Nanotech applications are currently being developed for use in computer technology, energy, food and agriculture, biomedical, the military and other fields.

Risks of Nanotechnology

Health threats can occur from the production, use and disposal of nanoparticles. Workers in nanotech industries are especially at risk, as they can be exposed to high concentrations of nanoparticles that may enter the body through ingestion, inhalation, or skin exposure. Nanoparticles used in consumer products may threaten public health, yet there are no labeling requirements for products using nanomaterials.

Particles in air pollution can be up to 50 times more damaging to lung tissue than fine particles of the same chemicals. Scientists believe that ultra fine particles are more toxic due to both their small size and their ability to carry large loads of toxic metals and hydrocarbons into the lungs, exacerbating breathing problems and asthma. Nanoparticles can also damage the body's natural defenses or, conversely, cause increased responses to common allergens.

There has been little study of the health affects of manufactured nanoparticles, but there are already reasons to be concerned. Animal studies suggest that nanoparticles can trigger unpredictable inflammatory and immune responses. Studies have found nanoparticles in the livers of lab animals and show that they can seep into living cells. In a summer 2002 study, fifteen percent of rats exposed to nanotubes in the lung unexpectedly died immediately, and a 2004 study showed damage to the brain in fish exposed to nanoparticles.

Current regulations

In 1995, Wired magazine asked leading scientists for their predictions about nanotech. The majority believed that federal regulations in the U.S. would be in place by 2000. But today, there are still no federal regulations. Since nanoparticles can change properties dramatically and unexpectedly, knowledge of the properties of a substance in bulk is useless in evaluating the risks of nanotechnologies. Yet regulators currently rely on existing chemical statues, allowing industry to market nanomaterials even though these materials have never been assessed in their nano-form. In Europe a new chemical policy called REACH requires companies to present safety data on new chemicals but analysts have noted that even this new policy fails to address the special risks posed by the unique, unpredictable and untested properties of nanoparticles.

The Need for Precaution

The insurance industry's concerns are useful guideposts: Allianz Insurance and Swiss RE have each developed briefings that point to the hazards and lack of regulations. They call for minimizing exposures and note that some nanotechnologies may be excluded from coverage.

I believe that the occupational health community can draw on the lessons from the electronics industry. When Hi-Tech was first introduced, it was promoted as a clean industry with little risk to the health of workers and the environment. Today, the damage to worker health by the use of multiple toxic chemicals is well documented. Many of these processes were subcontracted to small businesses, facilities that did not have the resources to effectively control the hazards, nor were they effectively monitored by the manufacturer or government agencies. This practice especially put the health of low-wage and immigrant workers at risk. It is sound public health to get in front of this emerging technological advancement that works to identify health concerns and sound occupational controls; be proactive rather than reactive.

Recommendations for future research include:

1. Occupational health effects from exposure, use, handling and transportation of nanoparticles.
2. Identification of hazards from occupational and take-home exposures of nanotechnology in manufacturing and transportation.
3. Identification of effective controls/interventions to protect workers from exposure to nanoparticles.
4. Application of worker-based participatory research methods to identify health effects, occupational take-home exposures, and effective interventions for this emerging technology.

I think there should be an emphasis on the validation of safety program evaluation questionnaires and ergonomic risk assessment tools.

NIOSH should take the lead in testing these types of tools and making them available online for general use.

For example, there has been a great thrust for the development of safety program standards (ANSI Z-10, AIHA etc). However, quick questionnaires as criteria for rating program effectiveness are largely not available. The AIHA tool is quite intensive and costs \$100- a price most companies will not pay. OSHA has the old PEP tool, but few people know about it and it was never validated for use. NIOSH could perfect this tool to help companies achieve OSHA VPP status or Z10 certification.

In general we also need to develop gold standard ergo risk checklists (such as the former Washington State and OSHA checklists). There are too many tools out there currently- some are likely valid, but others are junk that water down the perceived value of ergonomics.

If a few methods can be deemed as valid by an authority such as NIOSH, companies will use them. Companies do not necessarily want to be forced to have ergo programs, but they do want standardization and voluntary guidelines so progress can be tracked.

General NIOSH research and NORA comments from the ICWUC/UFCW. An edited version was presented at the Piqua, Ohio Nora meeting on March 6.

My name is John Morawetz and I am speaking today on behalf of the International Chemical Workers Union Council of the United Food and Commercial Workers Union. I have been active in this field for almost 30 years; I worked for NIOSH in the early 1980's, then for the Molders Union, and I currently work for the chemical workers both as the Director of a national HAZMAT training program for a Consortium of seven unions and as the ICWU's Director of Health and Safety. These comments are on behalf of the chemical workers union.

First, NIOSH has a proud history of service to America's workforce. From Health Hazard Evaluations, Industrywide Studies, Control Technology to Hazard Alerts, library services, respirator approvals and the NIOSH Pocket Guide, to name a few areas we are familiar with, NIOSH is the primary national research organization in improving our nations workplaces. For the chemical industry and many others, for people at companies both large and small, NIOSH is viewed as an important source of assistance in what is all too often a difficult situation and your help is welcomed. For the ICWU Health and Safety activists, there is no other place for them to turn for all these services and followup.

In these efforts, NIOSH provides essential services and although not all activity results in a scientific article, they are invaluable services. We have often called NIOSH and you have rapidly responded, walked us through a range of technical subjects and met our needs. We will continue to assist in securing adequate funding for your institution and in the future restore full staffing levels.

NIOSH conducts research in a tripartite format which involves both management and labor at each stage. Workers all too often perceive themselves as at best, subjects, and at worse, "guinea pigs" for research. Worker and union involvement helps to minimize this, produce better and more useful research and is a practice to be consistently implemented in all research efforts.

Second, the overall aim of research should always be kept in mind. Occupational Health and Safety research is not done for its own sake; it is done to identify areas to intervene, to improve the workplace, to lower exposures, to lower illness and injury rates, to give workers and their employers information to ask the right questions and to get answers that will improve people's working lives. All NORA projects, therefore, should include implementation and evaluation on how the research is utilized.

Third, NIOSH should continue their efforts to investigate hazards such as nano technology and special populations. Industries, hazards and demographics change and NIOSH must have the necessary resources on hand to launch investigations. Some may be industry specific while others will cut across various sectors, similar to the original NORA priority research areas, and will therefore be an issue, I presume, for the Cross Sector Research Council. Although not a new area, most workplaces rarely have a single exposure. I am well aware that multiple exposures presents significant difficulties for the researcher, but it's an area of great concern for workers and need of continuing investigation.

Fourth, we all need to review the overall NORA process and accomplishments to date. NIOSH has committed significant resources and we need to clearly understand what are realistic short and long term goals. NIOSH should continue to openly discuss what the accomplishments were of the first decade, what was learned and what questions remain in each of these priority areas. I've tried to find current information on the NORA web site however it does not look like some web pages have been updated for some time.

Fifth, for all research, documents need to be issued timely for our members and any recipient to make full use of them. All publications should be examined for their usefulness to the workers they are intended to serve. Clear recommendations and brief synopsis, as well as the full document, need to be available for NIOSH's hard work to be useful to the communities it serves.

Comment ID: 387.01 (partial comment categorized separately)

Categorized with the following terms:

Categorized comment or partial comment:

Sixth, the use of significant NIOSH resources in recent natural disasters clearly will delay or reduce most other research efforts. Although we firmly support all efforts to secure additional funding, the political reality is that NIOSH will have to use existing resources. Rather than trying to accomplish everything with finite resources, NIOSH must have a plan to adjust its normal research agenda when responding to another anthrax incident or hurricane. These will occur and we are pleased that NIOSH can contribute its expertise to these public health disasters but they will have a significant negative impact on other work.

Seventh, we have serious concerns on the future possibility of contracting out of NIOSH's workforce.

We do not believe this is in the best interests of either quality research, NIOSH's workforce (many who are members of the AFGE), NIOSH as an institution, the companies and workers who are NIOSH's stakeholders or our national interests. Chasing the elusive rhetorical goal of cheaper work all too usually only serves the lucky contractor but few else.

Eighth, a related point is the need to preserve and strengthen your highly qualified and dedicated workforce. Although there are many excellent professionals outside NIOSH some of whom are here today, a strategic view should balance the contracting out of research projects with the need to preserve your internal professional resources. Specific priorities will change but ensuring your strong professional staff and institution is crucial. We are concerned that some figures indicate a decrease in research funds.

From a national perspective, NIOSH adds a valuable approach and skills to public health. NIOSH needs to remain institutionally separate within the nation's public health structure to insure continuing and appropriate emphasis on protecting our workforce. A recent example of NIOSH's contribution was their collection of anthrax exposure data after a musician was infected. The rapid use of antibiotics to his friends and fellow musicians, one might say fellow workers, is a protective measure that we learned

after the failure to take these steps for Washington DC postal workers in 2001. Tragically, occupational health research all too often reaches conclusions at the expense of the health of workers, as in the death of postal workers in 2001. NIOSH, and its NORA agenda, is a vital institution in investigating and disseminating information to decrease this national burden.

Thank you for your time.

My interest is in Health and Safety in the general environment with two aspects of environment in mind. I carry out surveys in homes and workplaces for Radiation - Technical (Man-made) Electromagnetic influences and natural (but distorted) radiation from the earth which cause areas of disturbed energies commonly known as "geopathic zones". Both of these influences contribute to the overall radiation load in the working and living environment with very serious consequences for human health.

and well-being. One of the worst cases I encountered was a young woman who, after giving birth to her eldest child (son) gave birth to two babies with severe deformities and parts of the body missing. Both died within 8 weeks of birth. The environmental source of her problem was her workplace. Having located the source, my advice was to move her workplace to another part of the office. She did so and subsequently gave birth to a healthy daughter. When her first child was born she had worked in a different office in another part of the building. Among the illnesses that I have come across are the following; cancer, leukaemia, CFS(ME), depression, general malaise /fatigue, digestive upsets, allergies, ibs, asthma, immune suppression. Two of the childhood leukaemia cases I came across are living normal healthy lives after 3 & 8 years respectively. Where there is doubt or uncertainty about the aetiology of an illness, the living and working environments must be examined for the aforementioned influences. The solution can, in most cases be as simple as moving a work-station or a bed.

Yours, Con Colbert, Dublin, Ireland.

Categorized comment or partial comment:

I plea for NIOSH and other federal agencies to provide more support to hazard and disease surveillance activities. Currently there is no comprehensive national surveillance system for occupational illnesses not for nonfatal occupational injuries. Adopting the following recommendations can help fill this gap. These include:

1. Expand the National Exposure at Work Survey (NEWS). NIOSH supported extensive exposure surveys in the 1970s and 1980s. These provided estimates of the numbers of workers exposed to almost any occupational toxin. Unfortunately, no exposure surveys have been conducted recently. The most recent national exposure data available is from the 1980s. Given the substantial changes in the US economy over the past 20 years, these 1980 exposure estimates provide interesting historical data but are of little relevance for estimating the numbers of workers exposed to a given toxin in 2006. NIOSH is currently working on a pilot exposure survey. But this pilot is limited to the health care sector and involves only a few hospitals in Washington State and Oregon. There is a glaring need for updated exposure surveillance data. Without this information, it is difficult to identify public health priorities, since information on the number of exposed workers is one compelling statistic needed for this prioritization.

2. Support an occupational health supplement to the National Health Interview Survey (NHIS). The NHIS is considered the principal source of information on the health of the civilian non-institutionalized population in the US. Unfortunately, the NHIS collects little information on work-related health and safety problems. To rectify this, in 1988, NIOSH supported an occupational health supplement to the NHIS. This supplement was a rich source of data to assess the magnitude and severity of several work-related outcomes including occupational injuries, dermatitis, carpal tunnel syndrome, back pain and lung diseases. The NHIS occupational health supplement needs to be repeated to provide up-to-date statistics on magnitude and trends that cannot be obtained anywhere else.

3. Support development of a computer program that will automatically code industry and occupation information. Information is captured by many public health records systems. These include death certificates, cancer registries, and birth defect registries. However, this information is rarely utilized to its full potential. This is often because the industry and occupation information is not available in a useable form. Often it is not available in an electronic database and is not coded. Coding industry and occupation information by hand is very time intensive. NIOSH developed an automated coding system to provide 1990 Census codes to industry and occupation. However, these codes are now outdated and have been replaced by the 2000 Census codes. A new automated coding program needs to be developed that will permit industry and occupation information to be coded into 2000 Census codes. Such a program would vastly increase the usefulness of industry and occupation information that is currently collected, and could lead to improved and expanded collection of useful industry and occupation information.

4. Provide support to the National Occupational Mortality Survey (NOMS). NOMS is a mortality statistics database. Since the early 1980s, NIOSH along with NCHS and NCI supported State vital statistics programs collection and coding of decedents usual industry and occupation. Approximately 27 states participated in this program. This program generated a large number of peer-reviewed publications and allowed NIOSH to assess mortality patterns and risks in various industries and occupations. Unfortunately, this database has not been updated since 1998. As this data becomes more dated, the usefulness of NOMS to detect and access mortality patterns becomes weaker and less relevant.

5. Increase support to state-based surveillance programs. State health agencies can provide essential information for nationwide occupational illness and injury surveillance. Although a vast majority of states conduct surveillance of adult lead poisoning through the Adult Blood Lead Epidemiology and Surveillance program, relatively few states conduct surveillance of other occupational disease and injuries (e.g. pesticide poisoning, asthma, pneumoconiosis, and fatal injuries). In addition, no states receive targeted funding for surveillance of some of the most important occupational disease and injuries, including dermatitis, musculoskeletal disorders, and noise-induced hearing loss. It is amazing that these are among the most common disorders arising in US workplaces, and NIOSH has not targeted resources to place them under surveillance. This information is important to identify the magnitude and trends of occupational disease and injury, to identify emerging occupational health and safety problems, and to target scarce public health interventional resources. NIOSH needs to identify, facilitate and encourage the development of model state-based surveillance programs.

6. Re-initiate the writing of "criteria for a recommended standard" documents. These are important documents. Since NIOSH was created in 1970, it has written many criteria documents. These are used to develop and support recommended criteria for safety and health standards under development by OSHA and MSHA. However, to my knowledge, NIOSH has not released a criteria document is approximately 8 years. (In 1998 two criteria documents were released: one for metalworking fluids and another for occupational noise exposures.) Although these documents require a large amount of effort to produce, their creation is important for protecting the health and safety of American workers.

Support development of a computer program that will automatically code industry and occupation information. Industry and occupation information is captured by many public health records systems. These include death certificates, cancer registries, and birth defect registries. However, this information is rarely utilized to its full potential. Coded data is the most electronic-friendly form of industry and occupation information. NIOSH developed an automated coding system to assign 1990 Census codes to industry and occupation. However, the program was prone to coding errors and the codes it assigned are now outdated. A new automated coding program needs to be developed to improve and expand collection of useful industry and occupation information. Surveillance data that may be grouped by industry or occupation is critical for the growing number of hard-to-study occupations or industries that do not keep centralized personnel records. It is needed to improve the quality and quantity of injury, illness, and exposure data for prioritizing safety and health research for these industries. These data may be used to track progress and evaluate prevention efforts. Development of an automated computer program that will automatically code industry and occupation information is the next step in closing the gap between work and health.

John Howard, MD

Director, National Institute for Occupational Safety and Health

Docket NIOSH-047

Robert A. Taft Laboratories (C-34)

4676 Columbia Parkway

Cincinnati, OH 45226

March 6, 2006

Dear Dr. Howard,

Thank you for the opportunity to submit comments as part of the National Institute for Occupational Safety and Health (NIOSH) preparation for the second phase of the National Occupational Research Agenda (NORA-II). As a physician with the Occupational Health Branch (OHB) of the California Department of Health Services (CDHS), I am writing to urge you to continue funding surveillance for occupational pesticide illness. Funding from the NIOSH Sentinel Event Notification System for Occupational Risk (SENSOR) project has allowed OHB to conduct surveillance of occupational illness from 1987 to 1992 and from 1997 until the present time.

Over the past eight years, I have been the project lead for the pesticide portion of our occupational illness surveillance program. This work remains important for several reasons. A third of the nation's agricultural workforce is employed in California. An estimated 1.1 million farmworkers worked on California farms in 2001. Widespread pesticide use in agriculture creates significant risk for these workers. In addition, our surveillance program reveals that structural pesticide application (in buildings) also poses risks to a variety of building occupants, including workers and vulnerable populations. Moreover, our surveillance program captures changing trends in pesticide use and resulting illnesses. For example, pyrethroid pesticides, once thought to be completely safe, are increasing in use and are associated with a growing proportion of illnesses. Finally, our target population is underserved workers with limited health and safety resources. A large proportion of pesticide illnesses occurs among agricultural workers with limited or no English language skills and with inadequate awareness of their workplace rights.

The California SENSOR pesticide program contributes a significant proportion of cases to the NIOSH national pesticide illness surveillance database. In 1998 and 1999, 58% (588/1007) of work-related non-disinfectant pesticide illnesses cases reported to NIOSH were from the California program. Moreover, the incidence rates for acute occupational pesticide-related illness were highest in California, possibly reflecting a combination of high illness risks and better case reporting. Because of relatively unique data sources available in California, we are able to collect and analyze occupational pesticide illness cases through multiple modalities that are not possible in most other states.

In spite of the high numbers of pesticide illnesses reported in our state, we believe that these and other occupational illnesses are underreported because of multiple barriers to recognition and reporting of these and other occupational illnesses. These barriers include physicians' lack of knowledge about the subject area and reporting requirements, and lack of knowledge and fear of reprisals among workers. In order to prevent occupational pesticide illness, we need to continue to identify and address both illnesses and barriers to reporting.

We place great emphasis on case follow-up and workplace investigation. We believe that this approach allows us to identify recommendations for the primary prevention of pesticide exposure and additional illnesses. As a result of our investigations, we have identified methods to reduce occupational illnesses due to pesticide use aboard aircraft, agricultural use of fumigants, and pesticide drift. With supplemental NIOSH funding, we have been able to expand our work on preventing occupational pesticide illness. Among other activities, we have assessed the efficacy of pesticide training for farmworkers and suggested methods for improvement; prepared a curriculum for training physicians on pesticide illness; and evaluated the efficacy of laboratory reporting of cholinesterase test results for surveillance of occupational pesticide illness.

An important reason to continue pesticide illness surveillance is that our current methods detect only acute pesticide illnesses. We are fairly confident that a large number of chronic illnesses associated with pesticide exposures remain undetected. Continued funding for surveillance of occupational pesticide illness can lead to improved primary prevention of pesticide exposure, resulting in decreases in both acute and chronic illnesses associated with pesticides.

In summary, given the large, underserved population at risk for occupational pesticide-related illness, the magnitude and scope of this preventable occupational disease, and the potential for primary

prevention methods to reduce the burden of disease, we believe that surveillance for this condition should continue in California as well as in other states.

Sincerely,

Rupali Das, MD, MPH

Public Health Medical Officer

We have experienced trans-border (state and international) issues with migrant workers in our state. Workers may be exposed here, seek treatment in another state and live in a third location. NORA should address facilitating reporting across borders. This applies for agricultural and other transient workers, such as those in the transportation industry.

Occupational exposure to 50/60 Hz EMF cuts across multiple occupations, and is especially important where there are high currents, large motors, and work in very close proximity to energized high current electrical equipment. There are exposure issues with other frequency ranges that cut across occupations as well.

There are US and international guidelines for limiting occupational exposure to EMF, though the models and input data used by guideline setting organizations to relate 50/60 Hz magnetic field exposures to induced current densities differ significantly. A number of scientific and compliance issues are ambiguous or unresolved. The purpose of these guidelines is to protect workers from acute effects such as cardiac and neural stimulation. Work is needed to: better document supporting data and differences in various guidelines, develop operational definitions, evaluate dosimetry models and assumptions, delineate "safety" factors, define understandable, achievable compliance measures and measurement, and work with guideline setting organizations to fill important data gaps.

Workers with implanted devices such as pacemakers need better information to understand risks associated with exposure.

To: Dwyer, Jami Girard

Subject: RE: Happy New Year!!!

Jami,

I started the following text on 1/5. I got taken away for some operational tasks and you had already sent me some other data by then. So, a bit of this is dated. However, I wanted to get the improvement ideas off to you for your long-range planning work.

The hydrohoist was actually called a Coal Airlift Hydrohoist. I believe Phil presented a paper at an SME show about it. The principle is pretty straightforward. Imagine a u-shaped tube, one leg of the tube is higher than the other. Water is pumped into the high side and flows out the low. At the bottom of the U, ore is injected into the pipe and the flowing water carries it to the surface.

It sounds a bit like a perpetual motion affair, but Phil constructed a working prototype in Colorado. I consider it interesting because we mine a soluble mineral and the ore could be dissolving on its path up to surface. Once there, the water could be processed in one of our plants and the remaining product could be processed in another plant.

There are lots of benefits for us if this thing works. Before I stuck myself out by proposing the project, I wanted to see where the research was at. I did find that Lindahl has his name on a patent for a piece of the technology--he proposed introducing compressed air with the product to enhance the flow up the pipe.

The technology may be something the Gov would be interested in helping develop. Any mine that wants to improve total capacity output could install this pipe in their existing shaft and add a few tons per hour with out tearing out the existing hoist works.

As far as other ideas for improvement: (Keep in mind that many of these might already exist in a form and others are just the strange mental concoctions of a mine engineer!)

Remote sensing of strata boundaries. A device that can measure the distance from the cutting head to the upper or lower boundary of the seam. There is some technology available, but its not "there" yet. Stolar, a company in Raton, NM, has done some work in our mine on this. The benefits are improved direction/horizon control, better roof conditions, enhanced ability to operate the continuous miner from a remote location. The technology is a fair distance from being reliable.

Employee monitoring devices. Some kind of marker device that can locate the wearer in the mine works. Of course, after Sago, this will be a big issue. There is technology out there that does this too, but its not that good.

All-in-one bolting. This is a roof control device that can drill a hole, release a resin and anchor itself all in one trip into the hole.

Mine-wide communication through utilities. Are there ways to better utilize the pipe and conductors in the mine infrastructure for communication by inducing the radio signal on the pipes and creating a huge antenna. This saves a big, old mine from installing all the new leaky feeder and such that comes with the current, working systems. I know a company called RIMTech was marketing some of this, but it was not that good.

Ground penetrating radar to see caving over a longwall. Can GPR "see" the extent of gob caves in deep longwalls?

Those are just a few, I hope I am not to "Buck Rogers" on it.

Sorry for the delay, have a super Thursday!

Rich [Kramer]

Comments offered to NIOSH, as NORA is revised

Carol Rice, Ph.D., CIH

Professor

University of Cincinnati

Under Section 21 of the Occupational Safety and Health Act, NIOSH shall

provide for the establishment and supervision of programs for the education and training of employers and employees in the recognition, avoidance and prevention of unsafe and unhealthful working conditions in employments covered by this Act.

These are very specific phrases in the Act--phrases that characterize the outcomes of training and education: recognition, avoidance and prevention. This comprehensive description given to NIOSH extends the responsibility well beyond the creation and dissemination of information. Information understood and retained is essential to any increase in knowledge--the foundation for activities that lead to recognition, avoidance and prevention. However, knowledge alone cannot provide the vital skills, abilities and attitudes to fully recognize hazards, or to design and successfully implement actions

or programs to avoid and prevent unsafe and unhealthful conditions. Identifying meaningful outcomes and the success of the outcomes in the work setting requires research.

In the current climate of smaller regulation and even smaller enforcement, it is increasingly incumbent on employees to take improving their safety and health into their own hands. Increasingly, a union or active joint labor-management committee that might provide effective health and safety training resources are absent, especially at small companies. NIOSH can, and is in fact mandated, to address this need. Certainly the crafters of Section 21 intended that the change to a more healthful and safer work environment would be successful—a result that can only emerge from continued research, and then research to practice.

Currently, the need is enormous.

In dimension it exceeds that of improving science literacy—which has been identified by President Bush as a national priority.

And the easy approach of providing information is a fundamentally flawed and failed system, as illustrated by a situation we have each been subjected to or witnessed:

The struggle with written directions to operate any one of the wide array of electronic devices now on the market.

(This has been reviewed recently in a strictly academic mode by Burke et al, AJP 96:315-324.)

While the task is large, it must also be recognized that the benefits are also large. Workers participating in training designed through research in one sector to increase knowledge, skills and abilities and to develop attitudes that support continued diligence and improvement are able to make changes that improve working conditions. Four anecdotal reports follow:

We now use cameras in confined spaces—camera goes in, people remain out.

We had not had an ammonia release in our facility for many years... Because of the skills my team members had, we were able to isolate and abate the ammonia leak efficiently and were able to keep anyone from getting hurt.

Training was helpful in siting and setting up a decon line for a spill of chlorosilanes caused by equipment failure. A portion of the hazardous material formed hydrochloric acid fumes when it mixed with moisture in the air. Even though it was a very hazardous situation, only one person received minor injuries and was treated and released.

Training changed our work behavior and made us think about working safe.

(See final report, Midwest Consortium for Hazardous Waste Worker Training to NIEHS, October 2005).

The economists can put dollar figures on these examples; they are essential to documenting value to employers and insurance companies. To the workers and families of the workers who benefit from the training, the dollar value is not relevant. They are guided by the expectation that each day their family member will return from work with no diminution in health.

Most importantly, the benefits of avoided exposures are meaningful on an individual level—and the individual is our foremost constituent in occupational health and safety.

The following are some steps to consider in addressing this mandate of quality training to achieve recognition, avoidance and prevention:

--. Update and supplement the NIOSH review by Cohen and Colligan, 1998 to identify models of worker training and education that have proven to accomplish the NIOSH mandate. This will be very useful in identifying gaps and sector differences.

--. Identify targets for improvement and design research to identify why current approaches have not met the need, such as:

a. training programs needed: industry sectors or cross-sector operations where increasing workforce skills, abilities and attitudes in "recognition, avoidance and prevention" would have substantial impact on health.

b. better use of existing media: For those who will be workers, NIOSH might conduct research to identify effective methods of implementing the NIOSH school checklists as part of the science literacy initiative in teaching programs.

--. Define knowledge, skill, ability and attitude goals resulting from the research

--. Conduct intervention research to evaluate the impact of training

Evaluation of the impact of each element will necessarily include feedback from participants after the return to work.

These ideas are not new to NIOSH leadership. They are articulated here because I believe Section 21 must be at the forefront of a comprehensive approach focused on research that will benefit workers during the next decade. In both large and small workplaces, the workers are central to the reduction of unsafe and unhealthful working conditions. They need this research, and it is the legal mandate of NIOSH to identify through research the determinants and elements of both educationally effective and cost effective programs to increase health and safety at work.

I believe that more research needs to be conducted on the hazards of weld fumes. So far, all of my research has shown me that there is no definitive study on the effects of weld fumes. I believe that this should be a long-term study to in order to accurately see the over all picture. I am troubled that a judge in Ohio has cleared the way for employees to sue welding wire manufacturers if they develop Parkinson's disease. What evidence has this judge seen? OSHA has plenty of TWA's and other measures for components of weld fume, but I think it is time we take a look at the weld fume as a whole.

Town Hall Meeting

January 17, 2006

Seattle, WA

Migrant Clinicians Network

Comments and Recommendations

On the National Occupational Research Agenda, Agricultural Sector

Good Afternoon, my name is Deliana Garcia and I represent the Migrant Clinicians Network based in Austin, TX. The Migrant Clinicians Network is the nation's oldest and largest clinical network dedicated to improving the health of the mobile underserved. For 22 years we have worked to prepare clinicians to meet the health care needs of migrant farmworkers, those "persons who cross a prescribed geographic boundary and stay away from their normal residences overnight to perform farm work for wages," and other mobile, underserved workers. Occupationally-related illness and injuries continue to be some of the most complex and frustrating health care events handled in the primary care practice setting.

I am grateful for the opportunity to address you today with our recommendations for the Agricultural Sector of the National Occupational Research Agenda under development. Your work will have enormous impact for many years to come.

We have seen this in the critical pesticide-related research that has been conducted over the last 10 years based on the previous National Occupational Research Agenda. The body of knowledge has greatly improved. Yet those crucial advances must be taken to the next level. Understanding of the impact and effects of pesticide exposure must be translated into clinical evaluation strategies, and treatment and management protocols for the clinician in the field. Related to the research to practice initiative, Our first recommendation would be that NIOSH funded research include an applied component to swiftly translate findings into clinical practices. We ask that future requests for proposals include requirements to link research findings to programs or organizations that can apply the results. In this way as studies are designed and executed, they will have as a specific aim the rapid deployment of major findings into the setting where they will have the greatest benefit. Currently, MCN is involved in a five-year partnership with the U.S. Environmental Protection Agency to integrate pesticide practice guidelines into the primary care setting. We would like to see additional partnerships with NIOSH that take the cutting edge research sponsored by your agency to the front-line provider.

Categorized comment or partial comment:

Our second recommendation is that the Agricultural Sector of the National Occupational Research Agenda redouble its efforts to study injuries and illnesses resulting from occupational insults to workers. When caring for migrant workers, it is critical that the clinician look beyond just pesticide exposure at incapacitating injuries resulting from rapid and repeated motions, awkward body mechanics, and the strain of supporting excessive weight. I would suggest that pregnant women workers are of particular concern. These work requirements results in a whole host of traumatic injuries and musculoskeletal disorders that greatly impact the longevity of workers in many segments of the agricultural industry. The longer-term effects on the human body are not fully understood. Yet, due to these injuries, we see a growing number of workers no longer able to maintain employment either in agriculture or in another work setting. For many of these individuals, their very survival and that of their family depends on the ability to work at whatever job is available to them. The field of workers compensation and rehabilitation has far to go. I would again urge that future research incorporate the identification of strategies for the prevention, as well as, the treatment and clinical management of these injuries. The NIOSH-Northeast Center for Agricultural and Occupational Health (NYCAMH) provides an outstanding example of research in this area that has been translated into clinical recommendations and more efforts like this are needed.

Categorized comment or partial comment:

While there is enormous concern about the impact of injuries and exposures on adult workers and the young children in the families, little attention has been paid to adolescents, older children ages 14-17, functioning as emancipated minors. Reports of studies looking at the changing face of migration repeatedly indicate that the migrant population is increasingly non-English and non-Spanish speaking and getting younger. These young workers are not yet fully developed either physically or psychologically but life circumstances have required that they function in the adult world of work. They are, however, children unfamiliar with worker protections and often incapable of requesting assistance and additional research is needed to understand the impact of occupational injuries and illness on the adolescent worker. We do not believe that this population can be adequately addressed in adult research. Our third recommendation is that research funding targeted at children remain in place with a special focus on the older child. We have benefited enormously from our partnership with the NIOSH-National Children's Center (Marshfield, WI) and our active involvement in the Childhood Agricultural Safety Network. Such partnerships led to the development of highly sought after resources to help educate farmworker families. Continuation of this kind of intervention is critical. Again, it is important that the research work to assist the health care provider in understanding the effects on the developing body and identify strategies for prevention and clinical management.

There are a number of additional occupational issues facing the migrant agricultural worker that merit attention and research. For instances, there is a dearth of information regarding water and sanitation. In a recent pesticide study in the state Washington, researchers asked farmworkers what issues were most pressing to them. Many expressed concern regarding field sanitation and access to water. Research examining the conditions of sanitation and access, as well as the health implications would have an important impact on health care and policy in this area.

Another topic includes exposure to hazardous chemicals from large animal confinement. These are just a few examples.

In the brief time available to me, I would like to reiterate our appreciation for the work of the National Institute for Occupational Safety and Health and the importance of the agenda under development. We ask that in the coming ten years funding be dedicated to: So our recommendations:

- Linking studies to organizations able to translate finding into clinical strategies.
- Broadening the research agenda beyond pesticide-related illnesses to strengthen the emphasis on musculoskeletal disorders.

- Expanding child-focused initiatives to include the emancipated minors functioning as adult workers.

Thank you again.

Note: Similar verbal testimony was provided during the NORA Town Hall meeting in Seattle, WA, 2006/01/17, and was given Comment ID w507.

Night shift work causes sleepiness, falling-asleep incidents, performance decrements and accidents at work, as well as insomnia when workers try to sleep during the day after work. Night work is a risk factor for cardiovascular disease, gastrointestinal disorders and breast, colon and rectal cancers. Up to about 10 million full-time US workers work permanent night shifts or rotating or other shift schedules that often include night shifts. Stimulants (such as caffeine and modafinil) during the night shift and sleeping aids (such as hypnotics and melatonin) for daytime sleep provide minimal help. However, it is possible to eliminate or greatly reduce the physiological problems associated with night work by resetting (phase-shifting) the circadian body clock to a night work, day sleep schedule. This adjustment rarely happens in night workers. However, intermittent bright light at work, sunglasses during the commute home and dark bedrooms have been shown to produce circadian adaptation and improve performance during the night shift in combination laboratory/field studies. More research is needed to perfect these techniques and devise the most practical and feasible methods to phase shift circadian rhythms in night workers. Then the shift workers have to be educated about how to use and modify

these techniques, and the employers and families of shift workers have to be educated about what they should do and what they should not do to help night workers avail themselves of these techniques. Public education about the health and safety consequences of night work will be vital for producing the cultural changes necessary to permit full-scale adoption of these techniques.

Urgent research funds needed for non-ionising radiation. Please read enclosed, this is a matter of emergency.

March 2006

Mobile Phone/Mast Radiation

I attended the first meeting for the EMF Discussion Group at the Health Protection Agency for Radiation Protection (HPA - RPD) on 2nd March 2006; the meeting was chaired by Sir William Stewart and included key people from the HPA, Department of Health, Mobile Operators Association (MOA) and representatives from campaign groups. It was a positive meeting and hopefully the first of many. Sir William has invited the EMF Discussion Group to provide a forum to consider health concerns related to exposure to EMFs and provide an input to EMF advice from the HPA.

Discussion needs to be followed up with action and I along with fellow members of the group are committed on behalf of EHS people, cancer patients and the many other people suffering with problems related to emfs to see this through to the end. I would like to take this opportunity to thank Sir William Stewart for opening up an important and urgent debate. Details about the meeting will be posted on the Health Protection website.

Reporter Nic Flemings article in the Telegraph 4/11/2005 reported Dr Jill Meara of the Health Protection Agency as saying people who think they suffer from electro-sensitivity should consider keeping their distance from electrical appliances. This was the advice from the Health Protection Agency following the Irvine report:

http://www.hpa.org.uk/radiation/publications/hpa_rpd_reports/index.htm

It is not good enough telling the estimated 2 million EHS people suffering to keep their distance from electric devices. What do you do if you have a phone mast next to your home? How do you keep away from that?

What sort of society are we living in when only certain people are allowed to earn a living, consigning the rest to live out their lives in pain, enforced poverty and isolation? By encouraging the proliferation of wireless devices, society has created an invisible under-class who are denied the opportunities available to everyone else. ES victims are often unable to use their talents and capabilities to earn a living through denial of access to transport and places most people take for granted. With other forms of disability, society has taken the view that such a situation is unacceptable and as legislated to ensure equal access and equal opportunity.

It is offensive, dismissive and wholly unacceptable to say "keep your distance from electrical appliances" or "Get over it, take a pain killer" then you could travel to work and be employed in our WiFi office surrounded by cordless and mobile phones". They have no idea or any understanding of the nature of EHS, why should we be any different to the recognised EHS people in Sweden?

We want prevention and protection, we need to be treated with respect and honestly represented by the people in power we deserve nothing less.

The UK has allowed the highest output of radiation in the world. The UK recently adopted lower levels of radiation by accepting guidelines set by the International Commission on Non-Ionising Radiation Protection 'ICNIRP'. However, the ICNIRP standard does not offer any form of protection other than from the heating effects of microwave radiation. In other words ICNIRP only protects your body from properties of high levels of elevated temperatures. A very substantial body of peer reviewed science clearly shows many biological changes have already happened.

The Government and Health Protection Agency Radiation Protection (HPA RPD) -formerly known as the NRPB now admit that magnetic fields at the power levels of 0.4 microtesla doubles the risk of contracting leukaemia, whilst other European Countries have brought down their power levels to 1 or 2 microtesla, the UK remain 100 times higher. They also admit that they have known about this for over three years. www.electric-fields.bris.ac.uk/PressRelease.htm

The Government has taken over £22 billion in the selling of the licences to the mobile phone industry. They put £3.5 million back into research along with £3.5 million from the Mobile Phone Industry. Further support was announced on November, 04 for research on three additional studies for the MTHR programme. While we welcome further research, we are concerned that it lacks true independence and would prefer the funding to go to an independent group of scientists.

Other countries medical professions recognise that some people are sensitive to non-ionising radiation. Sweden now has a medical register of 285,000 and California 700,000. We believe these figures are underestimated, since many people are not aware that their symptoms are connected to a condition known as electro-sensitivity or hypersensitivity (EHS) people. However, if the same figures apply to the UK this could indicate over 2.1 million people are knowingly or unknowingly affected to environmental fields (EMF).

Sir William Stewart, head of the UK's Health Protection Agency (HPA), has called for the precautionary principle to be invoked, especially where children are concerned, as they will absorb a higher dose of radiation and for a longer period of time.

We are now seeing evidence of cancer clusters appearing in radiation from phone masts after long-term exposure, throughout the UK. There appears to be a cancer epidemic across Europe with younger people developing this deadly disease.

The Naila Study, Germany (November 2004) - This study, conducted over 10 years was released by The Federal Agency for Radiation Protection, Germany. Medical doctors compiled case histories since 1994 - 2004, looking at heightened risk of taking ill with malignant tumours. They discovered a threefold increase after five years exposure to microwave radiation from a mobile phone mast transmitter for up to 400 metres distance, compared to those patients living further away.

A study carried out by Ronni Wolf MD and Danny Wolf MD, Kaplan Medical Centre, Israel (April 2004) discovered a fourfold increase in cancer within 350 metres after long-term exposure to microwave radiation from a mobile phone mast and a tenfold increase specifically among women, compared to patients living away from the mas

Five other short-term mobile phone mast studies have also found significant health effects such as headaches, dizziness, depression, fatigue, sleep disorder, difficulty in concentration and cardiovascular problems:

The Microwave Syndrome - Further Aspect of a Spanish Study - Oberfeld Gerd. Press International Conference in Kos (Greece), 2004

<http://www.mindfully.org/Technology/2004/Microwave-Syndrome-Oberfeld1may04.htm>

Austrian scientists Dr Gerd Oberfeld send out a press release 1 May 2005 with this report:

'A study in Austria examined radiation from a mobile phone mast at a distance of 80 metres; EEG tests of 12 electro-sensitive people proved significant changes in the electrical currents of the brains. Volunteers for the test reported symptoms like buzzing in the head, palpitations of the heart, unwellness, light headedness, anxiety, breathlessness, respiratory problems, nervousness, agitation, headache, tinnitus, heat sensation and depression.

Bamberg, Germany 26-April, 2005

Dr C Waldmann-Selsam, Dr U. Säeger,

Bamberg, Oberfranken evaluated the medical complaints of 356 people who have had long-term [radiation] exposure in their homes from pulsed high frequency magnetic fields (from mobile phone base stations, from cord-less DECT telephones, amongst others).

People suffer from one, several or many of the following symptoms:

Sleep disturbances, tiredness, disturbance in concentration, forgetfulness, problem with finding words, depressive mood, ear noises, sudden loss of hearing, hearing loss, giddiness, nose bleeds, visual disturbances, frequent infections, sinusitis, joint and limb pains, nerve and soft tissue pains, feeling of numbness, heart rhythm disturbances, increased blood pressure episodes, hormonal disturbances, night-time sweats, nausea: Open letter to German Prime Minister following from the Bamberger study <http://www.tetrawatch.net/links/links.php?id=stoiberlet>

If you compare the results of the "Bamberger Appell" study to "The Microwave Syndrome - Further Aspects of a Spanish Study Oberfeld & Navarro 2004". Both studies seem to show the same symptoms being reported at the same level of powerflux density.

Campaign groups have also been working with retired physicist Dr John Walker. Six studies now show an increase in serious illness appearing in radiation from masts after long-term exposure. I would suggest that the threefold increase found in the Naila study up to 400m and the fourfold increase found in the Israel study will be much higher. These figures will be diluted; they will have taken in the whole area within the 350/400m range. Dr John Walker's research clearly shows the clusters of illness appear in radiation at exposures of around 1.5v/m, which is below the guidelines significantly permitting around 40 to 50 v/m (varying according to microwave frequency). We believe the increase will be approx 10 to 12 per cent within concentrated areas see examples at:- <http://www.starweave.com/gallery/> This situation demands proper and full investigation

The hamlet of Wishaw is a prime example:-

<http://www.telegraph.co.uk/news/main.jhtml?xml=/news/2003/04/25/nmast25.xml>

Five ladies developed breast cancer

One case of prostate cancer

One bladder cancer

One lung cancer

Three cases of pre-cancer cervical cells

One motor neurone disease age 51, who also had massive tumour removed from the top of his spine.

People have developed benign lumps

Electro-sensitivity

Three cases of severe skin rashes

Many villagers suffering with sleep problems, headaches, dizziness and low immune system problems.

Horse with blood problems, continuous treatment needed by the vet.

Out of the eighteen houses surrounding the mast at up to a range of 500 metres, 77% of the tiny hamlet had health related illness believed to be as a result of radiation from the mast. The out break of illness occurred in 2001 after seven years of exposure to the radiation emitted by the T-Mobile mast. We are now in contact/communication with many people who are suffering from this form of radiation throughout the UK and Europe.

One other important fact is that since the Wishaw Mast vanished on November 2003, many of the residents are reporting a restored feeling of well-being. The residents are reporting improvement in their sleep patterns and increased energy levels. The headaches and dizzy symptoms have disappeared. We have recently seen a baby boom with three babies born in the village, one of the ladies had previously had treatment for pre-cancer cervical cells, another had previously suffered a miscarriage. We have also seen a return of wildlife in the area and the horse has since recovered and is now strong and healthy and no longer needs treatment. Finally a tree has blossomed for the first time in 10 years in line with the mast.

<http://www.telegraph.co.uk/news/main.jhtml?xml=/news/2003/11/30/nmast30.xml&sSheet=/news/2003/11/30/ixhome.html>

Many animal studies have shown biological effects. The most recent study White Stork *Ciconia ciconia* by Alfonso Balmori Vallodolid, Spain is published in *Electromagnetic Biology and Medicine*, 24: 109-119, 2005.]

Behavioural observations of white stork nesting sites up to 300 metres were carried out. Productivity and behavioural observations were made. The results have shown microwaves are interfering with reproduction which is comparable with other lab studies.

Animal studies are of great importance as biological effects cannot be put down to psychological effects.

Microwaves seem to also be interfering with human reproduction according to a recent paper by Dr Imre Fejes of the obstetrics and gynaecology department at the University of Szeged in Hungary who concludes: "The prolonged use of cell phones may have a negative effect on sperm production and male fertility that deteriorates both concentration and motility." See news report-:

<http://www.timesonline.co.uk/article/0,,2087-1159951,00.html>

The effects of EMR are being felt by wildlife and the environment as a whole, Birds, bees, worms, trees are all being affected. We need to fight for not only the future of mankind but for the future of the whole environment.

Medical Doctors are also campaigning for precaution.

Finland: Helsinki Appeal 2005

http://www.emrpolicy.org/news/headlines/helsinki_appeal_05.pdf

The Helsinki Appeal 2005 from EMF Team Finland calls on the European Parliament to act promptly for the adoption of the new safety standard in the European Union. Physicians and researchers, feel great concern about the Precautionary Principle not being sufficiently applied to electromagnetic fields. They want the standards recommended by ICNIRP to be rejected, because recent scientific studies report various disturbances caused by mobile phone and other RF radiation. They also appeal to the European Community to take prompt measures for solving the refunding of the REFLEX project, which showed evidence of genotoxic effects of mobile phone radiation and should be continued:

<http://www.emrpolicy.org/>

The Irish Doctors` Environmental Association believes that a sub-group of the population are particularly sensitive to exposure to different types of electro-magnetic radiation. The safe levels currently advised for exposure to this non-ionising radiation are based solely on its thermal effects. However, it is clear that this radiation also has non-thermal effects, which need to be taken into consideration when setting these safe levels. The electro-sensitivity experienced by some people results in a variety of distressing symptoms which must also be taken into account when setting safe levels for exposure to non-ionising radiation and when planning the siting of masts and transmitters.

Catania Resolution September 13-14, 2002, 16 world leading scientists at the International Conference State of the Research on Electromagnetic Fields, Scientific and Legal Issues, by ISPEL*, the University of Vienna, and the City of Catania, held in Catania (Italy) on September, 2002,

Thirty GPs in Liverpool

http://icliverpool.icnetwork.co.uk/0100news/0100regionalnews/tm_objectid=13656858&method=full&siteid=50061-name_page.html

It was reported in the Liverpool Echo on November 2003 "bad medicine". A group of thirty, hospital doctors and consultants have signed a petition over the installation of a mast which they believe is a risk to health.

Freiburger Appeal

http://www.laleva.cc/environment/freiburger_appeal.html

In October 2002 a team of German medical doctors started the Freiburger Appeal. After seeing a dramatic rise in severe and chronic diseases, they have noted a clear temporal and spatial correlation between disease and exposure to microwave radiation. The appeal has since been signed by thousands of doctors.

My oncologist and breast cancer surgeon supplied me with a letter on 9th December 2003 stating that "we agree that there is some scientific evidence that suggests microwaves can damage cells but as yet there is no direct evidence that this is a problem in humans. We would agree that this issue needs to be raised at the highest level and funding released to support the debate and independent research to get a definitive answer."

Furthermore, the Russians, Chinese and many other parts of Europe are rejecting ICNIRP standards and are concerned about the biological effects. The Ministry of Chinese Health revealed that in the last ten years studies on radiation similar to that emitted by the mobile phone industry have shown a majority of results are showing biological effects. Out of 154 studies, 88 or 57% have shown biological effects such as cancer, genetic molecular and cellular changes, electro physiology effects, behaviour changes etc. in a

survey by Dr Henry Lai, Washington University, Seattle 2003. It said that the amount of evidence for biological effects and the characteristics of these are so alarming, that all efforts should be dedicated to find a way to minimize these effects.

China held an International Conference September 2005 in order to discuss and establish Asian Commission on Non-Ionizing Radiation Protection (ACNIRP). Research scientists have found that relatively low-level of RF (radio-frequency) radiation can lead to DNA breaks.

The REFLEX report also highlights RF-induced DNA breaks. The REFLEX project was set up to investigate the effects of low-levels of RF radiation on cellular systems; cost of approximately \$3 million. The work was carried out by 12 research groups in seven European countries. Yet again it was shown RF radiation could increase the number of DNA breaks in exposed cells and could also activate a stress response - the production of heat shock proteins. It was clear chromosome damage could be seen in the cell exposed to mobile phone radiation over 24 hour's exposure. You can view an image of the cell damage on Dr Gerd Oberfeld's Westminster Presentation on www.radiationresearch.org for the full report visit

http://www.verum-foundation.de/www2004/html/pdf/euprojekte01/REFLEX_Final%20Report_Part%201.pdf

The Daily Mail reported a 25% increase in young people being hit by mouth cancer on 25/9/05. The British Dental Health Foundation (BDHF) said risk factors are normally caused by smoking and drinking, however none of these are common risks in younger people. The figure is forecast to rise sharply in the next ten years, with people in their twenties and thirties increasingly vulnerable. (Daily Mail Report 10/11/03).

I am concerned that radiation from phones will intensify around the mouth if children or adults are wearing braces or have fillings, metal intensifies radiation. See statement http://www.chemistryquestion.com/English/Questions/ChemistryInDailyLife/23c_microwave_metal.html. This is an area that needs urgent attention!!!

Also enclosed recent BBC report on 50% increase in cancer in teenagers as reported by Tim Eden - from Manchester's Christie hospital

<http://news.bbc.co.uk/1/hi/health/4366606.stm>

I have taken this fight to Westminster, visited Director Generals in Brussels along with fellow trustee Mike Bell and scientists Dr Oberfeld and Professor Olle Johansson. I have given evidence to Birmingham and Liverpool City Council, met with Merseyside Fire Authority along side Dr Gerard Hyland and given presentations to 100's of packed meetings throughout the UK.

I and also met with Health Secretary Patricia Hewitt on 6th January 2006 with fellow trustee Brian Stein. I met with Minister, Solicitor General QC MP Mike O'Brien on 1st October. David Davis Shadow Home Secretary met with Mike Bell, Dr Oberfeld and I earlier this year and has encouraged us to keep him up to date with any further developments

Overall background radiation is excessive not least because we have eleven national infrastructures, four GSM operators, five 3G, one TETRA and shortly the Network Rail GSM. No other utilities duplicate their infrastructures, yet maintain competition. Further, the mobile phone operators have gone far beyond being a utility, into hi-tech mass marketing of entertainment and business services.

For the sake of us all especially our children, non-ionising radiation is a high priority for public health. Mobile phone networks should use the lowest possible exposure values, exclusion zones for masts from schools and homes should be brought in based on current empirical evidence. A huge education programme should be launched providing public information, encouraging the use of mobile phones for emergency use only.

Control Banding, an innovative risk assessment and risk management model, has received international attention. The model assigns intervention approaches ("control bands") to work tasks after the completion of a semi quantitative risk assessment. Control banding tools are attractive because they offer employees and workers across industry sectors simple, accessible risk assessment strategies that can be used to target the tasks that require exposure controls or professional risk assessment advice. NIOSH should 1) continue to communicate the Control Banding concept to both workers and managers (especially in light of the increased interest in the Globally Harmonized System for the classification and labeling of chemicals) and 2) fund research that seeks to validate the model.

With motor vehicle-related crashes the number one cause of occupational fatalities, there is little information available on the much larger group of crashes that result in injuries to the workforce. Having access to the events associated with the crash, as well as the classification by industry, occupation, season and geographic locations of those involved would provide the Network of Employers for Traffic Safety and other mission-similar organizations with the opportunity to better understand the risk factors and develop more effective and meaningful strategies to prevent these motor-vehicle related incidents.

An Urgent call to Fund Research into the Health Effects of Non-Ionizing Radiation

I am concerned about the risk of the growing problem of electro-smog and its impact on people in the workplace where technologies that emit various types of electromagnetic radiation are growing in number. There has been significant research that suggests that there may be significant health risks from ongoing exposure to such radiation. Because of this potential risk and the speed with which these technologies are propagating, it is crucial that funding for research into the health effects of non-ionizing radiation, including Radio Frequency Radiation (RF) and Extremely Low Frequency Radiation (ELF), be made available immediately. The failure to provide such funds over the past ten years has allowed this hazard to grow, putting many people at risk in ways that we have not taken the necessary steps to understand or mitigate. The longer funding for such research is delayed, the greater the number of people whose are at risk of having their health compromised by excess exposure there will be and the more difficult it will be to mitigate the risk that is being created. Please see that substantial funding for research into the health effects of non-ionizing radiation, RF, and ELF are made available as soon as possible.

There is emerging evidence that coordinating and integrating worksite health promotion and occupational health and safety enhances the effectiveness of efforts to promote and protect worker health. Integrating worksite health promotion and occupational health and safety is a core principle of numerous international efforts and declarations in support of worker health, and has been the subject of growing interest internationally.

Occupational health and safety and worksite health promotion clearly share the common goal of promoting worker health, with complementary functions in protecting and enhancing the health of workers, and thereby provide an important opportunity for coordinated and integrated efforts.

As part of the next phase of NIOSH research, it is important that research include an agenda for integrating OSH and worksite health promotion. Research to develop and test effective intervention strategies integrating OSH and WHP requires an interdisciplinary approach. Advancing knowledge in this area requires that we attend to barriers for scientists, including the real work of assembling multi-disciplinary teams and identifying funding sources to support integrated studies. Overcoming the segmentation of these fields ultimately will require an inclusive, comprehensive model of work and health, providing for resolution – or at least understanding – of our differences assumptions, vocabulary, research methods, and intervention approaches. Multi-disciplinary research teams can help to address this gap in our current research base.

National Occupational Research Agenda Town Hall

February 21, 2006, Los Angeles

Comments from

Barbara Materna, Ph.D., CIH, Chief, Occupational Health Branch,

California Department of Health Services

850 Marina Bay Parkway, Building P, Richmond, CA 94804

(510) 620-5730; bmaterna@dhs.ca.gov

I want to thank the National Institute for Occupational Safety and Health (NIOSH) for convening these meetings around the country to hear input from many people and organizations about the workplace health and safety needs that should be addressed in the next 10 years of the National Occupational Research Agenda (NORA).

I represent the Occupational Health Branch in the California Department of Health Services, a non-regulatory public health program that conducts research and provides services to prevent injury and illness among California's workers. Our program was created in 1978, after exposure to dichlorobromopropane was found to cause sterility in a group of manufacturing workers despite the existence of studies showing the chemical had this effect in animals.

One of the important responsibilities of our program is to translate scientific data into practical information for employers and workers to use in creating safe and healthy workplaces. Another is to

collect and summarize statistics describing worker illness and injury. As a public health agency, we are charged with investigating the causes of illness and injury and making recommendations for their prevention and control. To carry out these functions, we have the legal right to enter California workplaces, review health and safety records, and interview both employer representatives and workers.

Meeting the occupational health and safety needs of California workplaces and workers is a daunting challenge. We have over 16 million workers and over 1 million worksites that fall under OSHA jurisdiction. Some are located in large urban areas such as Los Angeles, the nine-county San Francisco Bay area, and the rapidly-growing Central Valley. Our state's large geography includes vast rural regions where many other workers are employed.

California borders both Mexico and the Pacific Rim and, as a result, large numbers of recent immigrants enter our workforce from Mexico, Central and South America, and many different Asian countries. The language, literacy, and cultural challenges of providing effective health and safety training to our workforce are enormous.

Twenty-five percent of California's workforce is employed in the private services sector, where many jobs provide low wages, long hours, significant health and safety risks, and no benefits such as health coverage. Another 15% of our workforce is in government services where the working conditions and benefits are likely to be somewhat better, but musculoskeletal disorders related to computer use are widespread, and stress due to inadequate staffing and looming layoffs takes its toll. Other important industry sectors in California include agriculture, with over half a million workers, and construction with almost 900,000 workers.

California workers are exposed to long-recognized hazards like silica in sand and gravel mining and falls on construction sites. But our state is also a center for new high-tech industries like nanotechnology and biotechnology, with a host of potential hazards that may not yet be identified or well understood.

It is extraordinarily difficult to reach the large numbers of small businesses in our state with the latest health and safety information; over 87% of California firms employ fewer than 20 workers. Like other states across the country, we are seeing changes in the nature of work that include fewer regular, full-time permanent jobs with benefits and, instead, more use of contract and temporary jobs, where health and safety is often not a priority.

Given these challenges, the Occupational Health Branch has to make difficult decisions about where to focus our limited resources. One of our priorities is to identify and address the unique concerns of low-wage, immigrant, and underserved workers. Under this focus, we have, for example:

- Collaborated with others to develop safer workstations to reduce musculoskeletal disorders in Asian and Latino garment workers;
- Provided educational seminars and materials statewide to improve the quality of safety training in construction ("BuildSafe California");
- Investigated deaths among Latino and other workers in Los Angeles County; and
- Promoted the creation of the Working Immigrant Safety and Health (WISH) Coalition, a unique network of community-based organizations and others who are concerned about these workers and their communities.

Our program has a long history of collaborating with NIOSH, public health departments in other states, and many other organizations on these projects. We are one of 13 states currently funded by NIOSH for occupational health surveillance and prevention activities, with a particular emphasis on work-related asthma and pesticide illness. NIOSH funding has played a crucial role in enabling our program to track many types of injuries and illness, to investigate worksites and formulate recommendations for prevention, and to carry out special projects to address health and safety problems in high-risk industries and occupations.

We recommend that NIOSH consider the following priorities for the next decade of NORA:

1. Place special attention on supporting research and other activities that will improve working conditions for low-wage, immigrant, and underserved workers.

These workers are found in large numbers in the services sector, as well as in other sectors that are high-hazard and significant in California, including agriculture and construction. NIOSH should support and promote efforts that:

- Determine the most effective ways to provide health and safety information and training that is appropriate to the languages, cultures, and literacy levels in the workforce;

2. Enhance and expand partnerships between NIOSH and state public health departments for conducting occupational injury and illness surveillance and intervention activities, and to assist in translating research findings into safer workplace practices (NIOSH's Research to Practice initiative, or R2P).

We work closely with many NIOSH staff who understand that state-based programs are uniquely positioned to carry out these efforts; for example, we:

- Have legal right of access to workplaces to carry out public health investigations;
- Have statutory access to data sources (e.g., California's Doctor's First Reports of Occupational Injury or Illness and electronic Workers' Compensation Information System) for conducting epidemiologic analysis and "sentinel event" case follow-up investigations;
- Are part of the state's public health infrastructure, with useful ties to colleagues in communicable and chronic disease control, environmental health, family health, and health services delivery;
- Have existing relationships with local partners including trade associations, unions, community-based organizations, health professional organizations, and local health departments;
- Have a long history of collaborating with other states, NIOSH, and the Council of State and Territorial Epidemiologists (CSTE) to share information and experience, and to promote a growing network of state-based programs to prevent occupational injury and illness.

NIOSH support, collaboration, and technical assistance have been critical to many of these state-based activities. We have been successful in encouraging more states to expand their efforts in this important area of public health. More states are gaining expertise in doing this work and are able to identify important state priorities that need to be addressed, propose well-conceived research efforts, and write competitive grant applications. Therefore, we recommend that NIOSH:

- Increase the total amount of funding for activities conducted by state public health departments;
- Provide enhanced funding for projects that involve developing and implementing intervention projects;
- Support proposed partnerships that allow states to work with stakeholder groups to address health and safety issues identified in a participatory group process (such as the BuildSafe California construction industry training effort funded under the NIOSH Core Surveillance cooperative agreement); and
- Partner with states on efforts that involve widespread dissemination of research findings and adoption of the best health and safety practices in our states' workplaces.

We look forward to working with NIOSH and others in creating new opportunities and approaches for promoting workplace health and safety in California over the second decade of NORA. Thank you again for the opportunity to offer these comments.

In 2005, the ACGIH recommended a TLV of 1 mg/m³ inhalable particulate for most wood dusts. The ACGIH does not recommend appropriate exposure monitoring methods to enable comparison with their TLV's. NIOSH has only one method in its manual for inhalable particulate. Many industrial hygienists and researchers believe the equipment listed in that method to be inappropriate for wood dust, and, if it is so used, there are probably few, if any, industries where wood products are sawn or sanded that would meet the ACGIH TLV. Urgent research is required to provide hygienists in the forest products industries with guidance as to the appropriate technique for assessing exposure to wood dusts.

The effectiveness of the Material Safety Data Sheet (MSDS) has been hindered by workers' inability to understand the information presented because it is often vague or generic and the sheets also contain additional information beyond the basic hazards information for chemicals. It has been estimated that the average literate worker understands only 60% of the safety information on an MSDS. The MSDS does not have a uniform format and this reduces the worker's comprehensibility to understand the standardized terms. The HCS requires that the MSDS be written in English and this makes it difficult for American workers who do not speak English as a first language and worse for illiterate workers to be able to understand the safety information on the MSDS. The accuracy and completeness of the chemical safety information on most MSDS are severely lacking. It has been determined that only 11% of all MSDS are completely correct. The European Classification and Labeling Inspection of Preparations (ECLIP) found only 25% of all SDS are correct.

The current lack of effectiveness of both the MSDS and SDS can ultimately create safety and health and transport problems domestically and in the international trade system. To combat these problems, international manufacturers, transporters, industrial producers, warehouses and emergency responders need to have a global means of communicating chemical hazards and a classification system.

I am troubled by the lack of a coherent approach to deal with our most vulnerable workers, the immigrant workforce, who, though they are covered by OSHA, do not complain to OSHA, talk to OSHA, or exercise any of their rights under OSHA. They are far less likely than the English speaking workforce to have adequate training in the hazards that they face. These are the workers now doing the industrial work, facing the most hazardous exposures, with the least protection. They only rarely find their way to a tertiary care clinic such as ours and when they do, they are afraid to let us call their employers. I have read that some between 12 and 17 % of our workforce, depending on sector, is from Mexico alone. I have no seen hard numbers which I understand are difficult to obtain. But this is a lot of people at risk! I recognize they are covered by OSHA but they will not

I would like to see NIOSH taking the lead in trying to establish a framework for absorbing these workers safely into our workplaces. I know NIOSH is concerned about minority/vulnerable workers and has held conferences and funded projects in many setting. It's not enough.

I am not sure what NIOSH could do short of advocating an amnesty for workers and establishing an aggressive program to inform immigrant workers of their rights. Perhaps, in accordance with NORA's new sector based approach, a strategy could first be developed for a particular sector. But I feel we need a coherent strategy to keep up with our rapidly changing workforce in addition to the small and wonderful efforts that are already taking place in some places. I would like NIOSH to:

1. Seek to develop and present data on this segment of our workforce in a more systematic way. We don't even know how serious the issue is, but with more and more of our hazardous jobs falling to this workforce, we should know. How can we do this without injuring the people we are trying to protect?
2. Develop and publish guidelines on how to do outreach to these workers, perhaps based on the projects they are already supported. What groups should we be approaching to partner with? What has been successful elsewhere?
3. Make available sufficient money for this work, so we can catch up with our rapidly changing workforce.

Lacking data, it is hard to demonstrate that something could make a difference, but we cannot afford to overlook the extreme vulnerability of this workforce and allow our traditional protections to be eroded.

One priority for this sector is the need for guidance documents for workers who handle or work with unbound nanoparticles. There are a number of good partners in industry (ORC, DuPont, PPG, etc) that should be willing to participate. A major immediate need is research on the effectiveness of engineering controls and personal protective equipment (PPE). A longer term need is to develop exposure limits for nanoparticles.

One of the leading causes of death among firefighters is heart attacks. It has been speculated that heat stress caused by their equipment may be one of the underlying causes. Research on new materials and technologies that reduce heat stress among firefighters and first responders is needed. An example research project would be cooling garments that would be worn underneath turnout gear, hazmat suits, bomb suits, etc. Potential project partners include the IAFF, IAFC, NFPA, DHS, and equipment manufacturers.

21,000 people die each year in the United States from radon-induced lung cancer. The occupations that have the potential for elevated radon exposure is quite broad - http://www.cheec.uiowa.edu/misc/radon_occ.pdf

Mine workers, including uranium, hard rock, and vanadium

Workers remediating radioactive contaminated sites, including uranium mill sites and mill tailings

Workers at underground nuclear waste repositories

Radon mitigation contractors and testers

Employees of natural caves

Phosphate fertilizer plant workers

Oil refinery workers

Utility tunnel workers

Subway tunnel workers

Construction excavators

Power plant workers, including geothermal power and coal

Employees of radon health mines

Employees of radon balneotherapy spas (waterborne ^{222}Rn source)

Water plant operators (waterborne ^{222}Rn source)

Fish hatchery attendants (waterborne ^{222}Rn source)

Employees who come in contact with technologically enhanced sources of naturally occurring radioactive materials

Incidental exposure in almost any occupation from local geologic ^{222}Rn sources

Farming (plowing), grading, etc.

Employees of radon chambers

Hospitals (radium implants, etc.)

Academia and research facilities that use ^{222}Rn or ^{226}Ra .

Antique stores and collectors (radium items)

Research is needed on the distribution of radon exposure nationwide in the workplaces. In addition, little is known about the fate of radon progeny nanoparticles in regard to their redistribution in the body.

Hello,

NORA funding for research about the adverse health effects of non-ionizing radiation exposure and a public education program is urgently needed!

A local newspaper in Wisconsin recently covered an extraordinary case of health improvement at a local school. Angela Olstad, a teacher diagnosed with benign multiple sclerosis, suddenly recovered completely from her condition after the installation of electrical filters which significantly reduce high frequency transients from the power net:

<http://www.jacksoncountychronicle.com/articles/2004/02/12/news/00lead.txt>

An article that recently ran in the Vancouver Sun:

<http://getpurepower.ca/resources/vancouver.sun.pdf>

Highlight:

>One of her subjects was Brad Blumbergs, 28, who was diagnosed with progressive >MS when he was 25. When Havas met him, he could not walk without a cane or >railings. Since his diagnosis, he had lost 30 pounds and looked, said Havas, like a >drug addict. Havas installed 14 filters in his home and within three days he reported >walking unaided. Two weeks later, Havas returned to videotape Blumbergs and was >shocked at his improvements. When she arrived, he was shovelling snow from the >driveway. He could walk forwards and backwards and did a little dance for the >camera. "You can't even tell he has MS," she says, adding she has seen similar

>results from others with M.S.

More information about the filters can be found below:

<http://www.electricalpollution.com/>

Read Angela Olstad`s touching letter to the public five years after the installation of the filters!

More information about case studies done with the filters(and related EMF/health research) can be found at:

<http://www.stetzerelectric.com/filters/research/>

The results include a reduction of the number of people using asthma inhalators a public school from 37 to three(and those are only used prior to phy. ed. classes).

20% of the staff expressed reduction of symptoms(headaches, migraines, allergies etc. etc.) during a single blind study!

Havas & Stetzer, who conducted the studies described below, were recently interviewed on Wisconsin public radio:

http://wpr.org/webcasting/ideas_audioarchives.cfm?Code=bme

Monday

12/12/2005

5:00 PM

Ben Merens - 12/12M

Have you experienced unexplained dizziness, memory loss, or physical weakness?

After five, Ben Merens` guests say electronic pollution may be the cause of these and other ailments.

Guests:

- Magda Havas, Associate Professor of Environmental and Resource Studies.

- David Stetzer, Owner of Stetzer Electric. www.stetzerelectric.com

Highlight:

* The blood sugar of diabetics and electrosensitive people sky-rocket after only 20-60 in front of an electrical device. Stetzer`s comment: "I doubt that people can affect their blood sugar value psychosomatically!"

I hope you will take your responsibility and avoid futher damage and a safe world for future generations!

Best regards,

Jimmy Granstrom

Lobstering Industry:

As the island physician on Vinalhaven Maine for 10 years from 1994 to 2004 I observed lobstermen`s work related injuries on the boat and previously unstudied frequent respiratory symptoms from their winter workshops. Through a NIOSH Pilot Project/NIOSH Training GrantT42/CCT 110421 in 2002 and with mentorship at the Harvard School of Public Health we quantitated lobstermen`s exposures to indoor paint fumes, for the first time.

This remains an understudied industry with over 7,000 lobsterman representing a 262 Million dollar a year industry in Maine alone. (2002 figures)

In contrast, more centralized industries with fewer total employees such as Bath Iron Works (BIW) in Bath Maine receive significantly more attention to work related risks.

I therefore recommend that NIOSH fund further measurement of lobstermen`s occupational exposures, document exposure related illnesses, and facilitate outreach to lobstermen to reduce these exposures. Lobstering is a thriving industry, one of New Englands quintessential industries, and deserves nothing less.

Thank you,

Rick Donahue, M.D.

A Town Hall Meeting for the
National Occupational Research Agenda (NORA)
Tuesday, March 21, 2006

Comments by Robert E. Koedam, M.S.

Chief, Fatality Investigations Team

Surveillance and Field Investigations Branch

Division of Safety Research, CDC/NIOSH

Hello, my name is Robert Koedam. I serve as the Chief of the Fatality Investigations Team within the Surveillance and Field Investigations Branch, Division of Safety Research, NIOSH. Within the Fatality Investigations Team lies the Fatality Assessment and Control Evaluation (FACE) program. I would like to speak today to impress upon the NORA Research Program industry sector managers, coordinators, and research sector councils the significant impact that the FACE program can have on NIOSH's research

agenda - across those sectors with high numbers and rates of fatalities. As a matter of fact, between 1983 and 2005, the FACE program completed 2,096 fatality investigative reports - including investigations in all eight NORA Sector Programs.

The Bureau of Labor Statistics (BLS) Census of Fatal Occupational Injuries collects occupational fatality data that are useful in setting safety research and prevention priorities. We know that the BLS data collected is highly effective in identifying common causes of death and worker groups that have experienced large numbers and/or rates of occupational injury.

What we also know is that unfortunately, there are "gaps" in the data in that it does not completely include the needed detail that would enable researchers to clearly identify a specific hazard, identify the specific factors that allow workers to be exposed to a hazard, and/or identify a specific means to control an emerging or existing hazard. In order to develop effective, sector-specific prevention measures, more in-depth information is needed to understand all of the circumstances and events that lead up to and contribute to fatal injuries.

The NIOSH FACE program fills this niche' nicely through the execution of it's primary objectives - which include identifying work situations at high risk for fatal injury, performing in depth on-site investigations, collecting specific, comprehensive information, and performing analysis of collected data. This data analysis includes all information related to the agent, host, and environment in the pre-event, event, and post event phases of the incident. NIOSH FACE has both an intramural and an extramural component (currently active in 15 States.) The State FACE programs, because of their close relationships with other intra-state agencies and safety organizations, as well as with employers and workers, have also been particularly effective at administering FACE programs while reaching out quickly to employers within their respective state when hazards are identified and prevention strategies are developed. This type of collaboration would work well within the NORA sectors as well.

Perhaps the most unique characteristic of the FACE program is that it contains the surveillance component as well as the field investigation component. The field investigation component allows for the gathering of the needed detail pertaining to an incident. This enhances the existing BLS data and fills many of the existing information gaps. Perhaps more importantly, the additional detail collected during field investigations allows for the development of a summary fatality report that includes prevention recommendations that can be immediately used in future or existing training programs, and feeds into the implementation of safety controls and research - including product substitution, developing engineering controls and administrative controls, and addressing the development and/or use of adequate personal protective equipment.

Each of the FACE-generated reports and documents also incorporate a dissemination component. The dissemination component allows the summary reports and their timely, effective, and realistic prevention strategies to reach those who can intervene in the workplace - thereby preventing future similar incidents. The dissemination has included forming partnerships with other government agencies, civilian agencies, trade associations, trade journals, and private and corporate industry. The NIOSH FACE program has been able to direct this information to targeted audiences in a variety of FACE products and interventions - including working with partners such as the OSHA training institute and its satellite training centers to incorporate FACE reports into safety and health training as case studies.

In closing, with very limited resources, FACE has contributed to changes in regulations and equipment and current research. FACE materials are also used in training for employees, and by employers by creating a safer work environment through the implementation of the aforementioned safety controls. These direct impacts and R2P examples include, but are not limited to; the State of New Jersey enacting safety laws regarding lights in swimming pools, OSHA implementing CPL 2-1.36 - which covers the Interim inspection procedures during Communication Tower Construction Activities, a North Carolina OSHA telecommunication tower standard, and engineering and administrative controls implemented by the international community following two investigations by Nebraska FACE of accidental injections from Micotil 300®, a deadly cattle antibiotic. Other impacts include the implementation of FACE findings into training programs in the telecommunication tower, roadway construction, and logging industries - just to name a few.

I urge you to consider including surveillance, as well as the FACE program in your NORA recommendations.

Thank you for this opportunity to speak before you today.

I would like to highlight the need for research in allergy and immunology. It is one of the identified cross-sectors that doesn't fit nicely into any one of the defined sectors. There is, however, often a very close linkage between work place exposures and the immunological health of the workers. This can range from skin exposures to various chemicals that cause a simple contact dermatitis, to more systemic or inhalational exposures that can cause allergic reactions, sometimes being acute or severe like anaphylaxis, to much more chronic problems such as occupational asthma.

There are work place exposures that are not necessarily related to any particular occupational setting but can occur in relatively clean environments such as office buildings and schools to more hazardous places such as manufacturing plants or farms. In modern society, the increased use of personal protective equipment in the form of latex gloves resulted in a million workers with latex allergy, a difficult and sometime life-threatening condition. Water damaged or damp indoor places, for example, can grow molds that after relatively long but low dose exposures, result in allergic reactions such as rhinoconjunctivitis or more serious problems such as asthma or hypersensitivity pneumonitis.

Sometime these are high dose exposures, but they often low dose, chronic exposures that are difficult to detect and to characterize. There is much work that needs to be done to understand these problems, to develop biomarkers for these kinds of exposures, and to be able to assign workplace risk. Monoclonal antibodies can be developed and used for exposure assessment. We need to establish standards of measurement that relate to the risk. There are relatively new technologies such as proteomics that could be very powerful in identifying and characterizing biomarkers and workplace hazards.

The other side of the coin are exposures which do not stimulate the immune system but suppress it. In these situations, such as exposure to welding fumes or certain manufacturing chemicals, an immunosuppression occurs. Here, instead of a hyper-reactivity or an allergic response there is a reduced immune activity and this can leave workers more susceptible to infections or the development of cancer and other diseases. Laboratory hazard identification methods can help identify potentially immuno-reactive materials in order to prevent worker exposures. Better methods of assessing the immunological status of a worker should be developed where either hyper-reactivity or immunosuppression can be detected early so intervention can occur before the development of disease.

While allergy and immunology are not readily placed into a sector, they are extremely important for workers health and should not be overlooked.

Categorized comment or partial comment:

Exposure assessment to coarse aerosols requires appropriate monitoring methods. The ACGIH now recommends sampling a wide variety of coarse aerosols in accordance with an internationally harmonized "inhalable" sampling convention. This recommendation extends to many pesticides, metals (nickel, molybdenum, beryllium), organic dusts (flour, wood, asphalt), and inorganic dusts (glass fiber, diatomaceous earth), as well as to the large class of Particles Not Otherwise Specified. NIOSH has developed only one method for inhalable sampling (for the specific case of formaldehyde on wood dust) and needs to develop more. Recommended limit values for the thoracic fraction (NIOSH metalworking fluids REL, ACGIH sulfuric acid mist NIC) are also being developed. The only currently available thoracic cyclone has too low a flow-rate to meet the requirements of sensitivity for these methods. NIOSH needs to research the issue of coarse particle measurement to provide appropriate exposure assessment technologies to practitioners.

Categorized comment or partial comment:

North Carolina is a prominent agricultural state. It ranks nationally in the amount of pesticides used and numbers of farmworkers employed in agriculture. Pesticides have been found to cause both short and long term health effects. Our agricultural status places workers at high risk for overexposure. There is no system in place in NC to track, respond to, and help prevent, incidents of pesticide-related illness. We would like to establish a pesticide surveillance system and this would require federal dollars put towards occupational surveillance.

state departments of public health

Categorized comment or partial comment:

Specific occupational-related hazards continue to cause unacceptable injury and fatality rates and require monitoring. Occupational surveillance programs are fundamental to assessing and responding to issues affecting worker health and safety across sectors. These activities are usually conducted by state departments of public health and they rely on federal dollars to support them. Funding for surveillance appears to be dwindling. Further, the new NORA priorities may diminish its importance. We are asking that that surveillance be valued as an approach to help reduce injuries and fatalities and be funded in an equitable fashion.

My name is Mike Attfield.

I am Surveillance Branch Chief in the Division of Respiratory Disease Studies. I second what Dawn Castillo has said.

Surveillance data form the underpinning of the work of NIOSH. Without knowing the where, what, and when of disease occurrence we cannot make informed and logical decisions on where to place our research and prevention efforts. We cannot measure where we are, and we cannot assess the worth of what we have done. In other words, Surveillance is a critical tool for measuring our needs and our success.

This applies to all of outcomes, whether mortality, injury, or morbidity. It applies to all of our sectors, from Agriculture to Wholesale and Retail Trade.

I feel that a lot of lip service has been given to surveillance. Yet, over the recent years surveillance activities have been contracting rather than expanding. In connection with this I'd like to mention two of our surveillance applications that supply us with critical information.

The first of these is our state-based surveillance program. This program is one of the few to supply morbidity data. It also leverages federal funds with state and local effort, and provides a very practical mechanism for disease detection and prevention. Yet state-based surveillance is marginal in that only a slight minority of states can participate in the program because of limited funding. In respiratory disease we have been lucky to retain our asthma and silicosis states, but the whims of the funding mechanism could see these critical components disappear at any time. In addition, since the state-based program is cross-cutting and extramurally funded, its significance and utility may not be apparent to the industry sectors, resulting in the potential for it to be overlooked or neglected.

The second surveillance I will mention concerns death certificate coding for occupation and industry. For almost 15 years NIOSH and NCI paid for the records from a subset of states to be coded for occupation and industry. This enabled us to publish extensive data on the relationship between mortality and work in various occupations and industries. It showed us where disease was occurring, and it enabled us to track those trends over time.

For over 10 years we published that information in the WoRLD Surveillance Report, a periodic compendium of occupational respiratory disease mortality and morbidity information. The information has been used widely both internally and by our stakeholders.

In 1999, funding for coding ceased, and unless funds are found, it will not resume. With this cessation, we have lost a major source of surveillance data, not only for respiratory disease but for many other outcomes too.

Since we will need to monitor the success of our efforts, as well as detect new problems in the occupational health arena, it behooves us to improve our surveillance efforts, not permit them to languish. For this reason I argue for the maintenance and expansion of our state-based program and the resumption of funding for I & O coding for death certificates, in part or whole. The results will benefit all sectors and provide objective data for furthering the work of NIOSH.

Thank you.

Statement to the NORA Town Hall Meeting

3/20/06 Lowell MA

Funding and Promoting Multi-Level Work Organization Research Initiatives
and Researcher/Practitioner Collaboration

Introduction:

I was trained as an ergonomist here at UMass Lowell. In a number of different sectors, the trajectory of my research has led me through an expanding examination of risk factors for MSDs, starting with job-level biomechanical exposures, to include the contribution of psychosocial risk factors, and finally to examine the underlying multi-level work organization characteristics, including organizational structure and culture.

One of the 8 sectors identified for the NORA sector-based approach is HealthCare and Social Assistance. Working within the Veterans Health Administration, our research team has been studying the relationships between organizational characteristics of healthcare facilities, the working conditions experienced by employees, and product quality: i.e., the safety and quality of care delivered to patients. Of the 8 NORA sectors, Healthcare is arguably the one in which a systems-based, multilevel approach to improving employee health has been adopted and accepted for the longest time, with the largest body of useful data to study and evaluate relationships between organizational characteristics, several levels of work organization, working conditions of employees, and quality/safety of care delivered to patients.

Interestingly, the primary driver for the explosion of information about the healthcare sector is not concern for employee health, but the recent 'discovery' of a fact that most practitioners already knew, at least qualitatively: that there are between 48,000 and 98,000 preventable deaths per year due to medical errors, as estimated by the Institute of Medicine. However, the focus on patient care has translated into increased attention to employee working conditions and resultant health status (both mental and physical) as a primary path through which organizational characteristics, culture, and systems exert their effect, negative or positive, on quality and safety of care.

The problem for occupational health research:

Workers are still exposed to a wide range of risk factors: for traumatic accidents, for occupational disease, and for job stress. In hospitals and many other sectors, these include:

- Biomechanical (physical) risk factors for MSDs - force, posture, repetition, vibration, etc.
- Psychosocial risk factors that contribute to MSDs as well as job stress
- Chemical and biological exposures
- Physical agents such as radiation, noise, temperature, etc.

Primarily as a result of research sponsored by NIOSH, as well as other federal, union, and private sources, many of the most egregious risk factors have been greatly reduced or eliminated. But in parallel with these exposure reductions, workers and their employers experienced increased exposure to the global marketplace and neoliberal economic policies. Competitive pressures, local, regional, national and global, have a profound influence on how work is organized within healthcare institutions and within other companies. The intransigence of remaining occupational health problems, the difficulty with even identifying the full spectrum of exposures as well as controlling them, is partly due to their multiple roots in this hierarchically nested structure of work organization exposures.

Indeed, it becomes more difficult (and it was always difficult) to draw the boundary at the door between the workplace and the "rest of life". For example: our Ergonomic Technology Center developed an ergonomic program with an aerospace manufacturer that was experiencing a very high incidence of MSDs and was unable to address them with traditional, very well designed workstation changes. We finally realized that the group of young engineers who were experiencing very high rates of MSDs was the first crop of students who had used computers regularly, from kindergarten on. They entered employment as an already compromised, predisposed or even preinjured workforce. This demonstrates the need for casting a wide net when trying to identify exposures for occupational illness.

The basic message is this: as the low hanging fruit of obvious, job-level exposures are controlled, the occupational health problems in healthcare (and in the other sectors as well) are increasingly the result of multi-level "exposures", a complicated and recursive network of characteristics of the job, the work teams, the departments, facilities, and even extra-organizational factors: the economic, political, technical, educational and cultural environment in which the facility operates.

The good news: what already exists to address these factors?

1. A broad and vital area of research and practice under the umbrella of Organizational Development, Industrial/Organizational studies and associated, practice-oriented fields.
2. A growing tradition of Action Research and Participatory Action Research, to develop theory and practice based in the ownership of both data and research approaches by the populations studied.
3. In Occupational Health intervention practice, there is now wide experience with large and small participatory interventions (that is, development of sustainable, continuous improvement programs, based in labor/management teams that own, guide, evaluate, and correct the interventions) and widespread acceptance of the practical usefulness of this approach
4. Recent NIOSH and NIH emphases on cross-disciplinary, inter-disciplinary and trans-disciplinary research.
5. The recent emergence of Occupational Health Psychology as a vibrant discipline in its own right, not just a poor stepchild of psychology. Supported by NIOSH and the American Psychological Association, this field brings together researchers and practitioners from the diverse set of traditions and practices noted above. The interdisciplinary approach generates theory and interventions targeting the work environment as well as the individual, to create healthier workers, workplaces and organizations.

The need: Recommendations for NORA

Fund and promote research that addresses the full spectrum of multilevel work organization analysis already detailed by NIOSH in the 2002 booklet, "The Changing Organization of Work and the Safety and Health of Working People". This builds on the work organization focus of NORA 1.

Fund and promote multi-institution, cross-disciplinary, consortium-based research efforts that bridge and combine the expertise and practice disciplines of the wide range of participants outlined above. Our group had very good experience with the power of this approach working with the MSD consortium funded by NIOSH

Request that these multi-disciplinary grant applications explicitly lay out a roadmap for forging learning partnerships between academic researchers and field practitioners. The sad truth is that these disciplines do not often talk to each other, although the forum provided by the Occupational Health Psychology approach is beginning to make inroads into the communication barriers, and NIOSH Research to Practice initiatives can encourage this communication. As a researcher I have developed a wealth of information about the complex relationships between healthcare organizational characteristics, employee working conditions, and quality/safety of patient care. But my training and experience do not fully prepare me for developing interventions designed, for instance, to change the organizational culture.

In sum, we recommend that NORA take a two pronged approach to controlling the multilevel causes of occupational disease:

- Fund and promote research that identifies, with quantitative and qualitative approaches, the multi-level web of factors underlying job-level exposures and disease.
- Fund and promote active collaboration among the research and practitioner disciplines outlined above.

The benefits of funding and promoting these approaches are simply stated:

This approach allows us to identify underlying risk factors and interactions of risk factors that are not immediately identifiable on the shop floor but that have a profound effect on job-level risk factors and disease.

This multi-level, multi-disciplinary approach to the identification and control of workplace risk factors is a more efficient way to improve employee and organizational health, compared to our traditional approach focused on job-level exposures. An intervention aimed at changing organizational culture or practice can simultaneously reduce seemingly disparate job-level exposures (e.g., biomechanical, psychosocial, and chemical risk factors) rooted in work organization.

This multilevel, multidisciplinary approach is also efficient in reducing the chances that solely job-level interventions often encounter - sub-optimal performance, limited or no change, and even unanticipated negative effects.

Categorized comment or partial comment:

NIOSH has made many important contributions in exposure assessment and methods development by supporting basic research in analytical chemistry, aerosol science, clinical laboratory science and toxicology. This focus and these areas should remain a center of attention in NIOSH's future research agenda.

The conduct of occupational epidemiologic and exposure control studies, depends on the development of robust scientific methods for measuring exposures and health effects. In turn, the development of field ready methods depends on a firm foundation in the basic sciences.

It has been estimated that there are about 80,000 chemicals listed in the TSCA inventory of chemicals in commerce. Of the approximately 2,800 high production volume chemicals that the US imports or produces, EPA has reported that 43% have no basic toxicity information and only 7% have OSHA standards. Although there is now underway an EPA voluntary program for companies to supply missing toxicologic data, there is a glaring gap in human data for these widely used chemicals. This is a gap that NIOSH could fill by focusing epidemiologic studies of these chemicals, many of which are used in commercial products that could also cause non-occupational exposures.

Over the past several years, there has been a push to move away from exposure surveillance and quantitative exposure assessment and towards a control banding approach to exposure control.

Although on the face of it this has the potential to be a useful tool in the public health arsenal of prevention, there has been very little work done to validate this approach across a range of industries, jobs and tasks. This type of validation through measurement of exposures would assure that this public health intervention model is actually protecting workers adequately. I strongly encourage NIOSH to engage in a rigorous and extensive validation of the control banding approach before encouraging its wholesale adoption.

However, in order to do research on new chemicals in commerce or to validate the control banding approach, it is likely that new methods of exposure assessment will have to be developed. NIOSH has always been in the forefront of exposure assessment methods development, yet in the past few years this pre-eminence has been declining as resources have dried up. This is an important area for NIOSH to focus its resources. Areas of exposure assessment that need particular focus include:

1. Development of analytical methods. Currently there are several hundred NIOSH analytical methods for use in exposure assessment with several dozen added over the past few years. However, as I mentioned above there are almost 3000 high production volume chemicals and over 80,000 other chemicals in commerce. We need exposure assessment methods that can identify and characterize exposures as they appear in new products and processes such as nanotechnology, as well as to help us identify the hazardous components of older technologies such as metalworking fluids

2. NIOSH should expand its work in the development of methods for assessing mixed exposures.

- Increasingly we see dermal exposure as an important route of exposure and even a target organ for the development of systemic health effects. Yet, methods for dermal exposure assessment are in their infancy.

- There is a desperate need to work on methods for assessing multiple exposures within occupations or industries. It is time to develop the tools to address multiple chemical exposures in a workplace, as well as the physical and psycho-social milieu of a worker when assessing occupational hazards.

- One set of tools that NIOSH could put more of a focus on would be the use of biomonitoring methods to assess the relationship between external exposures and internal dose. These methods should not substitute for measurement of external exposures, which is where control interventions must be targeted, but, they can help us understand the relationship between various routes of exposure and potential health hazards.

- Other tools that should be developed include pharmacokinetic models that could be used with animal tox data to back extrapolate equivalent human exposures as part of a basic risk assessment for the many unregulated and unstudied chemicals in commerce.

3. Another important area for NIOSH research is to encourage toxicologists and analytical chemists to collaborate in identifying classes of chemicals with similar biologic activity. Then analytical methods that measure these classes of materials, rather than each compound individually could be developed. For example isocyanates as a class rather than each type of isocyanate separately. This type of approach could simplify exposure surveillance and exposure assessment for epidemiology. In addition, it would facilitate the validation of control banding which uses the concept of "risk groups" for chemicals to assign them to control bands.

4. In addition, there are many situations where measuring with direct reading or portable and expedient field methods, even those with less accuracy or those measuring only classes of chemicals, would be

extremely useful in targeting control efforts in the field. For example, the constantly changing work environment of construction would greatly benefit from a portable method to measure airborne silica exposures in the field. Development of new robust, convenient and quick measurement methods that can assist field personnel in determining what level of control to implement should also be a priority for NIOSH research.

Although developing practical public health interventions in the field of occupational safety and health is vitally important, so too is the basic research needed to improve our understanding of the nature of workplace exposures and their health effects. I strongly believe that a major focus of NIOSH research should be in the basic science of developing exposure assessment methodologies. For if not NIOSH, then who will support the fundamental science of our field?

Categorized comment or partial comment:

The surveillance of occupational illness and injury fatalities within each of the eight sector groups can not be fully addressed, unless within a cross-sector program there is research focused on developing a system of coding industries and occupations from death certificates using the new classification of employer/employment (NAICS codes) and occupation (Census occupation titles and codes - COC codes). Since the Year 2000, the availability of mortality statistics of illnesses and injuries from death certificates by industry and occupation does not exist. Two reasons for the lack of this information are 1) The insufficient funds at the state level to code the literal text from the death certificates; and 2) The lack of an industry and occupation coding system capable of coding with the current NAICS and COC codes, and one that is capable of being intergraded into current vital statistic programs (e.g., Electronic Death Registration (EDR) system) at the state level. If we want to continue to monitor the mortality trends for occupational diseases in this country then plans need to be developed within a cross-sector program for decade two of NORA.

Topic and title of comments: Occupational osteoarthritis in the older worker

I appreciate this opportunity to bring the concern of: Repetitive lifting, walking for hours (8, 10, 16 hour shifts) on cement floors, non-ergonomic work situations creating undue stress on weight bearing joints.

As the average age of nurses at the bedside is advancing and is now noted at 46 years, and the healthcare industry continues to grow at the fastest rate of all industrial sectors, this concern of injury is important.

It has been my experience that: Many nurses report bone and joint disease requiring extensive surgical repair and replacement. This is particularly true as the nursing workforce is aging. Workers who would

normally require this type of orthopedic surgery in their late 60's and 70's, are now requiring this surgery in their 50's and 60's. Nurses and other workers in the healthcare industry are also developing osteoarthritis of the feet from cement floors in hospitals and osteoarthritis of the back from repetitive lifting.

These conditions are not recognized as work related injuries and therefore workers are on their own when in payment is due for medical treatment and lost time wages.

I would like NIOSH to: conduct research related to the issue of osteoarthritis in nurses and others in the healthcare industry, in relation to the work environment, mainly long hours and inappropriate conditions, specifically large work areas and cement floors, and address this issue as a work related injury.

Thank you for this opportunity to share my interest and concern before the NIOSH, National Occupational Research Agenda.

Topic and title of comments: Continuing problem of latex allergy among health care workers.

I appreciate this opportunity to bring the concern of: Nurses and others experiencing continuing symptoms of latex allergy, inability to work in hospital settings, a lack of access to safe medical care, and an inability of latex allergic nurses to accompany children to medical appointments/hospitalizations.

My experience has been: As a member of the Massachusetts Nurses Association Congress on Occupational Health and Safety, long time editor of a national nursing specialty journal, and advocate for victims of latex allergy since 1997, I am familiar with nurses and physicians who continue to struggle to earn a living and obtain safe health care due to latex allergy that was developed from exposure to latex at work.

The problem is: "Low protein", "low powder" latex gloves are being aggressively promoted by industry and even some researchers with ties to industry, as being completely safe when they are not. Common sense dictates that less allergen (low protein) and less ability to enter lungs (low powder) would likely decrease the number of users becoming sensitized, but we shouldn't be lowering the rate of sensitization, we should be eliminating sensitization and eliminating life threatening reactions in those already sensitized. It only takes a few molecules of latex to cause an anaphylactic reaction. Please consider that it does not matter what amount of peanut butter a person with peanut allergy eats. The results of exposure are rapid, dramatic and can be deadly. It is not different with latex.

The vigilance and response to latex allergy seems to be relaxing. Strides made to make hospitals safer are being reversed. In settings where latex gloves have been eliminated, they are coming back in.

Allergenic latex gloves with high protein and high powder continue to be used in prepared medical procedure kits such as those used to insert a urinary drainage catheter and to suture a wound.

The myth that latex is required for barrier protection from is being promoted when we know that many synthetic gloves provide equal and often superior barrier protection from bloodborne pathogens exposure. The fact that synthetic non-latex gloves, are even safer than low protein, low powder latex gloves is being ignored.

The Massachusetts Nurses Association Congress on Occupational Health and Safety is aware of nurses and doctors, who are already allergic to latex who have still not been able to return to hospital settings. Many will never be able to return if latex gloves are used, no matter how attenuated. Worse, these same nurses and doctors and other health care workers are also patients whose access to medical care is seriously compromised.

Widespread ignorance about latex continues. An OR team with a latex allergic child on the table called me last week to ask whether it was OK to use a silicone catheter on the patient. [Silicone and other synthetics are a completely different material than allergenic (rubber) latex and pose no hazard to someone allergic to latex.] This occurred in a hospital in which one OR nurse educator had made changes that made the hospital safe for staff and latex allergic patients, but when that nurse left two years ago, latex gloves began to be ordered once more, and the hospital's gains in safety have been lost.

I am aware of new nurses coming into health care facilities with virtually no knowledge of latex allergy as it relates to them or their patients. This is directly opposed to the recommendation in the 1997 NIOSH Alert: Preventing Allergic Reactions to Natural Rubber Latex in the Workplace, clearly states that employers should "provide workers with education programs and training materials about latex allergy".

I would like NIOSH to:

-- ensure that articles and preliminary quotes from NIOSH funded researchers do not reinforce the myth that low protein, low powder latex gloves are safe. They are safer, but they are not safe.

-- continue to raise consciousness and educate health care professionals about latex allergy and strategies to keep staff safe, including the fact that latex, no matter how attenuated, is still dangerous to those who have begun their sensitization.

-- conduct research related to the effect of using synthetic, non-latex gloves, not just low protein, low powder latex gloves.

Thank you for this opportunity share my interest and concern to the NIOSH, National Occupational Research Agenda.

I wish to offer support to the request from Dr. Bowman for more intensive NIOSH funding and support in the area of non-ionizing radiation (NIR). There are still important biological questions to be resolved for cell phone use, power frequencies (ELF), pulsed electric and magnetic fields and NIOSH is uniquely suited to perform that work.

Due to possible limited funding for the ELF/MW/RF area I would propose that this request for continued NIR work in this area be folded into a larger area denoted as Physical Agents. When this is done then topics such as pressure vessel safety, heat and cold stress, electrical safety, noise, laser non-beam issues, vibration-whole body and impact, optical radiation (ultraviolet and infrared), illumination, infrasound and ultrasound can be addressed which would help with obtaining research funds across the spectrum of topics. It is vitally important that the entire spectrum of physical agents not be dropped by NIOSH since the field has a large impact on almost all workers. I recommend NIOSH provide funding for physical agents effects studies for all the above topics as well as the very important work that Dr. Bowman is doing in low frequency and RF/MW areas.

It is critically important that NIOSH maintain a vigorous program in bioelectromagnetics research. Exposure to electromagnetic energy at both radiofrequency (RF) and extremely low frequency (ELF) is nearly ubiquitous in the workplace. In particular, opportunities for RF exposures continue to increase because of many devices that are part of the information technology activities in the workplace, including wireless devices for communications, security, and process control. RF energy also remains in widespread use for a wide variety of industrial purposes. It is apparent that applications of RF energy in all areas will continue and grow with no foreseeable limit. Similarly, electric and magnetic fields at low frequencies, particularly in the extremely low frequency (ELF) range, also are ubiquitous in the workplace and are inherent in a large number of industrial processes.

NIOSH must continue to be a center of excellence and a knowledge resource in bioelectromagnetic research concerning the above areas of workplace concern. This can only be done effectively and at the necessary level of professional standing by continuation of a high-quality research program. I recognize that this program will be of modest size in numbers of scientists and budget commitment, but the program is no less important for those reasons. In fact, the modest program size represents an opportunity to advance knowledge and maintain a necessary resource for the health of the nation's workers at relatively low cost.

In considering the importance for occupational health of NIOSH programs in the ELF and RF areas of bioelectromagnetics, I am struck by the leverage the current program has had. This is particularly exhibited by its impact on development of science-based worker health and safety guidelines and in the formulation of health standards in the USA and worldwide. Moreover, NIOSH scientists have played a leading role in research conducted under guidance from the World Health Organization and, in a worldwide study of exposure to wireless handsets that is being conducted by IARC (a WHO agency).

RF and ELF exposures of great diversity occur in all sectors of the workforce. For this reason, and others, I am pleased to have this opportunity to address the importance to the Institute agenda of a strong research activity in RF and ELF bioelectromagnetics in the forthcoming decade.

Categorized comment or partial comment:

Agriculture has historically been ranked as being one of the top 3 most dangerous industries in which to work, based on fatality rates. In addition, this industry is always in the top 3 industries for having the most fatalities. This tells us that besides being at high risk for death (rate), there are also a large number of deaths associated with the industry of agriculture.

The single most prevalent event associated with agricultural production deaths are tractors. A known intervention has been around since the 1960's (ROPS) and has been a voluntary ASAE standard since 1976 for all new tractors manufactured in the US. However, tractor fatalities due to roll-overs still remains the #1 problem for agriculture production. We need to fund research in the following 2 areas in order to address this issue:

1. Fund intervention research (or demonstration projects) to identify the reasons why farmers do not install ROPS on their tractors and what barriers need to be addressed in order to rectify the current situation (including financial incentives and/or policy initiatives);
2. Fund research into whether pre-ROPS manufactured tractors can be effectively retrofitted with a low cost, easy to mount ROPS, since this group of tractors currently make up the majority of tractors which are on American farms.

Agriculture production has high rates of fatalities for older workers, older than 65 years of age. This is a unique aspect of agriculture production, since this class of workers is generally retired from all other industries. Having this older class of workers brings special issues into occupational safety, such as medication issues, general health status, mental acuity, vision/hearing impairment, physical dexterity limitations and recuperative/regenerative issues associated with injury. These are all issues which should be researched in order to better protect and serve this population.

Additionally, young agriculture production workers are at increased risk of death compared to their counterparts in all other industries. The reasons for youth work, hazard issues, supervision and risk abatement should all be foci of research into the youth mortality problem.

Non-fatal injuries to youth are important. Injury prevention to youth working in agriculture should be funded. Also, youth being injured due to living or being present on a farm should not be ignored, since USDA/NIOSH research indicates this is the majority of non-fatal injuries which occur to youth on farms. Funding to prevent or mitigate these effects should be a priority.

- physical therapists

Categorized comment or partial comment:

Verbal Comment 2006/01/17: Good morning. Thank you for the opportunity to provide comments to NORA. My name is Janet Peterson, and I'm a physical therapist and an ergonomic consultant in the Seattle area. I also am current board member of the American Physical Therapy Association, or APTA, and a past president of the Physical Therapy Association of Washington.

In looking at future research directions, I'd like to encourage NORA -- and it's really just acknowledging what you are already doing -- to consider an interdisciplinary model when creating research teams. Various disciplines, including engineering, epidemiology, medicine, psychology, physical therapy, and

basic scientists working together with the end user of businesses and industry, can produce a more comprehensive outcome than a single discipline working alone.

One example of this is the upcoming collaboration between APTA, the Association of Rehab Nurses, and the American Occupational Therapy Association on a project entitled "Therapeutic Use of Patient Handling Equipment". This is the continuation of a very successful corroboration with the ARN last year when we developed and published a white paper on safe patient handling.

The purpose of the upcoming program is to develop clinical tools that will assist the clinician in the selection, implementation, and assessment of safe patient handling technologies to reduce the risk of injury for both care givers and patients. Physical therapists are well suited to assisting the research of work-related musculoskeletal disorders. They're educated at the doctoral level now for about 70 percent of the programs across the United States and master's degree level for the remaining, and work in a variety of settings including research -- clinical research, basic research and industry.

There's other presenters already on the docket today that can -- that can show that there's evidence already that repetitive motion, stressful postures, and forceful exertions are associated with a variety of musculoskeletal disorders. The rub with that is that I think there's still a great deal of lack of acceptance of that information out there, especially in the business community.

Where I think that physical therapists may have a special role in NORA or NIOSH-related research is in looking at things like older workers, those with chronic diseases, obese workers, children, things where you're really looking at specific musculoskeletal issues and chronic disease issues that may have an impact on the kinds of interventions that you're looking at to reduce musculoskeletal disorders.

You know, one small thing -- and you mentioned nanotechnology -- that really gets to me as a physical therapist and alarms me is looking at all of the -- how all of our PDA devices and things are getting smaller and smaller and smaller, and our older and older eyes are -- and repetitive issues with thumbs and fingers are problematic, and on the other -- on the other end of the scale, you know, we have -- right here in our area Microsoft is doing basic research on -- and just came out with a new computer keyboard design, and I just saw a presentation from the primary research on that and asked questions like well, did you think about the younger computer user and how the large keyboard is a mismatch with their anthropology -- or anthropometrics? And the response was, well yeah, but the money is driving us elsewhere. And the money is driving us so that we are not detaching, for example, the numeric pad on the keyboard -- on the new keyboard. If you could detach that you could save a lot of musculoskeletal issues with shoulder, elbow, hand problems on the right side. And computers obviously are -- cross all of the sectors were -- that were listed today because everybody's using computer technology to some extent or another in their work.

So I -- APTA -- on behalf of APTA, and we applaud NORA's efforts to seek further evidence to assess the most effective interventions for decreasing the risk for work-related injuries, and we invite you to include physical therapists in those efforts. Thank you.

Verbal Comment 2006/01/17: Thanks. Good morning. I'm Patricia Butterfield. I applaud the inclusion of a cross-sector research council to address issues across the eight proposed sector areas. Many workers living in America's small towns work across sectors holding down two or more part-time jobs. It's essential that the research agenda by NORA address the health and safety needs and the system needs of such workers.

Critical issues faced by rural workers and their employers include rural workers that are employed 40 or more hours a week, but still lack having health insurance. What barriers exist in rural communities? What are the infrastructure needs? What types of incentives do we need for small employers to offer their workers benefit packages? How does the lack of private or public insurance impact worker injuries and illnesses associated with workers compensation claims? Our pilot work in rural Whatcom County, Washington outside of Bellingham and in Bozeman, Montana and Gallatin County, Montana -- which is not in this region, but is nearby -- our pilot data, 45 percent of our workers did not have private healthcare insurance.

Some of them had two or three different jobs, and they worked not in the service industry, but they might be thinning sugar beets in the spring, working in Burger King in the winter, and then working in construction in the fall, and that's a very common scenario.

Another work -- another issue is what are the needs of rural workers caught up in economic downturns? Economic trends in the inter-mountain and Pacific northwest are changing, with fewer families involved in agriculture and mining and more families employed in service industries. Low income families are frequently caught up in local economic downturns, which may result in the loss of health benefits, extended periods of un- or underemployment and the loss -- and the economic necessity of multiple part-time jobs. In addition non-urban areas have relatively few employers, and there's very few options in terms of other types of -- of ways to go.

Rural areas experience wide seasonal variations in employment, a phenomenon that Bashier* refers to as a feast or famine economic cycle, which we see in many areas that are gentrified. Whether you're looking at, you know, ski areas or rural areas in central Washington, you see this kind of urban flow. What resources and what types of research do we need to do to really understand this phenomenon in terms of both housing and the experiences of workers? One of the things we saw in rural Gallatin County was a donut effect where poor workers needed to move out of these areas as they became gentrified and move out into areas where they had no resources, and move out into unincorporated areas of the county.

The last area I want to address in terms of the theme of rural workers are the lack of occupational health professionals in rural communities, leaving many employers without the requisite information they need to look at risk reduction opportunities. They tend to see illnesses and injuries in workers as a specific event related to a specific worker rather than a pattern of risks that can be assessed and minimized.

What types of things can we do to reach out in meaningful ways through occupational health professionals? I direct the nursing program here. We're well suited to providing nurses in those areas, but a lot of times employers are not able to -- small employers are not able to hire a nurse. Actually I see Karen Bowman in the area. She's one of our graduates that has done consulting work with small companies all over the northwest, including out on the Olympic Peninsula. What research do we need to really look at the feasibility of such types of opportunities to meet the needs of rural employers and workers?

These and many other issues impact the lives of a considerable proportion of the U.S. workforce. The sustainability of a rural community depends on the vitality of its local employers. A NORA-supported research agenda needs to address the reality of rural workers and employers across sectors. Thank you for the opportunity to comment this morning. Thank you, Max. Thank you.

Categorized comment or partial comment:

Verbal Comment 2006/01/17: I'm an Associate Professor in the Environmental and Occupational Health Sciences at the University of Washington and a practicing occupational medicine physician. I direct a training grant that provides opportunities for health and safety professionals and scientists from Asia and Latin America to study at the University of Washington that's jointly funded -- leveraged, as you might say; as Sid would say -- between NIOSH and NIHS. My goals to encourage NIOSH to include support for international occupational health and safety training and research in its next -- in its next National Occupational Research Agenda or the continuation of the former one. It will protect B- in the end protect American workers.

You might ask why should NIOSH fund occupational health and safety and research outside the United States? I'll give you two good reasons, though there are more. The first reason, based on an ethical mandate, is just that we in the United States, as we give economic support to populations struck by natural disasters and epidemic disease, it's also appropriate that we help protect workers and their families from developing countries from the consequences of occupational illness and injury which, where social nets are inadequate or nonexistent, can be as devastating as natural disasters.

A second reason, potentially more in keeping with the mandate of the Occupational Safety and Health Act which brought NIOSH into being, is that approving the occupational health and safety standards for the workers in developing countries through training of health and safety academics and professionals will in fact protect workers in the United States.

And how does this work, you might ask. The lightning fast movement of capital across borders as a result of the neoliberalization of the world economy has made the flight of jobs a painful daily reality for

workers in developed -- in developed countries. This mobility of capital in jobs has led to a bidder's war among developing countries where, in order to attract investment, salaries and benefits must be low, and the workplace environmental regulations must be enticingly unintrusive. The bidder's war cannot be totally ignored by developed countries. In order to compete with developing countries in the new global marketplace and maintain industrial activities in the developed countries, industries there must cut the cost of production at home or decrease the relative cost advantage presently enjoyed by competing countries.

In industries such as agriculture, where land capital is not transferable, survival unquestionably will involve correcting this discrepancy in some way. Several options exist for reducing this cost of production. One of the most obvious is by reducing the costs related to the workforce. Mechanization of labor is one option that's been particularly the aim of the Washington tree fruit industry as displayed by the technology road map. This is a long-term strategy, as new tools must be developed and tested and deployed.

Another more immediate option is cutting the expenses of employing workers. This includes reducing the cost of salaries and benefits and health and safety standards. The news is full of large companies who have chosen this approach. The arguments for the repeal of the ergonomics initiative, both nationally and in Washington state, were based on this premise. It's evident that the low cost of workers including -- the -- the low cost of the workers, including health and safety, in developing countries is driving the move to limit these costs in the U.S. O'Rourke* and Brown made the point by amending the question posed by the economist Freeman, who had asked whether American wages were set in Beijing, by saying -- asking whether the world's B- world's health and safety standards and conditions are set in coastal China. Morgensen* made the same point in his chapter on workers' safety under siege, stating that the globalization of the free market economy is eviscerating the sociopolitical framework that assures that workers -- that assures workers the rights to free association and safety and health protection in the United States and around the world.

Industry in the U.S. will no doubt work to level the playing field in one way or another. I would argue that the best way is to increase the standards for worker health and safety in competing developing countries, rather than lowering our own. Lowering our own standards will increase the number of injured and ill workers and their families, requiring support from the existing social -- social safety net. It is a false solution that results in an inefficient covert cross-subsidy of industry by the greater society. I believe the training of occupational and environmental health professionals and researchers in developing countries will lead to a data driven pressure on governments to improve their occupational and environmental safety standards.

My experience as an educator at a world class university with a high quality occupational and environmental training capacity, and my experience internationally, tells me that there are ample developing country professionals and scientists looking for these skills and knowledge who are committed to improving the health and safety of the workforce in their own countries. We need only give them the tools, and they'll do the rest.

In summary, I believe that NIOSH -- that by NIOSH supporting and training occupational and environmental health scientific and professional workforce in developing countries, an important portion of the relative cost of production -- the relative cost of production advantage enjoyed by competing countries will be diminished. This will contribute to a leveling of the playing field and a

reduction in the downward pressure on American health and safety regulations. It will in the end help protect the health of American workers. This is clearly not the only solution, but it is an important investment for NIOSH and for America to make. Thank you very much.

Verbal Comment 2006/01/17: Thank you, Noah, and thank you to NIOSH for the opportunity to comment on the research agenda, and also thanks to our friends at the University of Washington for hosting this event.

My name is Claude Golden. I'm here representing the Boeing Company. As most of you know, Boeing is the largest aerospace manufacturing company in the world. We're the number one U.S. exporter. Our products are commercial airplanes, defense projects, and space exploration vehicles. We have over 150,000 employees in 67 countries. Our largest site of operations is here in the greater Seattle area, and the vast majority of our manufacturing occurs in the United States.

Most would agree that the main purpose of occupational safety and health research is to reduce the risk of injury and illness to our workers. The best way to accomplish this goal is to help employers build the most effective safety programs, and to help government adopt the most productive regulations. Effective research is practical research, and research should be targeted to high risk exposures and high risk industries.

There is a finite pool of resources available to any employer, no matter how small or large. It's very discouraging to be forced to spend those resources on compliance with standards where there is very little risk at your workplace and have fewer resources left over to spend on higher risk areas in your workplace. Research dollars should not be used on esoteric subjects where injury and illness rates do

not show high risk. Aerospace and all of the sectors should be targeted for research in those areas where statistics indicate a problem. And manufacturing sectors should also be contrasted and not necessarily pulled together with construction and agriculture in terms of risk analysis where the types of risk can often be very different.

We need much more research on effective mitigation methods of compliance through pilot projects and fit for use and usability testing. We need field testing of different approaches to reduce risk. Oftentimes small pilot programs are inadequate to address very broad questions of productivity issues. Research the best methods for industry to more easily comply with standards, and you'll really see an improvement in safety.

And as we've heard about nanotechnology, that emerging field needs to be researched for methods of monitoring and detection, and for protection methods of workers.

Thank you.

Verbal Comment 2006/01/17: I`m an Assistant Scientist at Oregon Health and Science University in the Center for Research on Occupational and Environmental Toxicology. I`m also an adjunct faculty member with the Portland State University Occupational Health Psychology Program, which is one of the original eleven NIOSH/APA co-sponsored occupational health psychology programs, which is a very excellent interdisciplinary training effort. I am an industrial organization psychologist and an applied behavior analyst. My research areas are diagnosing the causes of deficiencies or excesses in critical behaviors relevant to health and safety, self-management and motivation.

I`m here to highlight basically the plight of occupational drivers, their health and safety needs, but I also have experience with other transportation populations. The transportation and warehousing sector in 2003 represented seven percent of employment, but 19 percent of illnesses and injuries in the workplace. In 2004 it was the second highest fatality -- number of total fatalities, transportation. The plight of occupational drivers is highlighted by urban transit operators, where literature reviews have

shown that this population has higher rates of hypertension, heart disease, respiratory disease, alcohol consumption, smoking, and musculoskeletal disorders.

In the state of Oregon, in the trucking industry, our highest number of workers compensation claims are in that industry. In 1999 there were twenty -- nearly 2,500 claims totaling \$25.5 million in costs. Our occupational fatality investigation program, Oregon FACE -- we're one of 14 states with a FACE program -- showed that in 2003/2004 nearly half of our fatalities had a transportation component.

A particular trend of interest is that mobile machinery operation fatalities often involve the worker being outside of the vehicle, so behaviors in and around machinery while it's not in transit.

And in general I just would like to emphasize that the trucking industry is the backbone of the economy in many ways. And their health and safety and well-being is a significant public safety concern, especially when hazardous materials are being transported or when large semi trucks are involved in collisions on the highway.

This -- occupational driving is faced with significant constraints. Performance is generally a function of ability plus motivation minus constraints. Constraints for truck drivers include hours of service regulations that give them approximately three hours of discretionary time during the work day. Truck drivers work 1.5 times the hours of a regular 40 hours per week worker annually, and often work 60-70 hours over seven to eight-day periods. They're exposed to vibration and postural constraints for up to 11 hours a day, and are paid by the mile, which encourages driving those 11 hours.

They face serious diet, activity and sleep constraints. They're basically rotating shift workers. Their dietary choices are limited to what's available at truck stops, and we are all aware of the sugar, fat, and salt available at those locations.

They're also constrained by where they can go to be active, and during cold and rainy and wet conditions it's very difficult for drivers to get in activity.

Psychosocial factors relevant to truck drivers include the isolated nature of the work. Isolated workers like drivers have less exposure to modeling, feedback, social reinforcement, and have less opportunities for assistance from workers in dangerous situations.

Stress is also a psychosocial factor with great concern to this population. Work/life balance, significant time away from family, traffic, and the stresses of sustained vigilance over 11 hours of driving a day; delays with loading and unloading material, which means you're not getting paid for rubber on the road.

Another psychosocial factor relevant to this population are public perceptions of the occupation. The public often views drivers as being at fault for collisions by default. There are stereotypes about drivers and what they are like, and the occupational prestige of the profession sometimes is discriminatory.

We also need to learn more about the characteristics of drivers, their individual differences. The Getting in Gear health promotion program, which is one of the first comprehensive health promotion programs among drivers, appeared to have significant challenges keeping drivers in the program. They had a nearly 50 percent attrition rate, and drivers failed to use phone consultations, health consultations, or free fitness memberships.

A few final notes about particular interventions that I think are important to study for this population. The first include self-management, feedback from technological monitoring systems, and training interventions. The second area is encouraging involvement, which I've already mentioned, recruiting

drivers into health promotion programs and retaining them. The third point is the crossover between safety issues and health issues and driving. I have not yet seen data that a healthy driver is a safe driver, but there`s a popular perception that that is the case. And last of all, these critical organization of work issues -- vibration and posture constraints, limits drivers face related to activity and diet, and exposures to such things as diesel exhaust when sleeping in a trailer and in the winter time when engines are idling.

And that concludes my remarks. Thank you.

Verbal Comment 2006/01/17: Hi, I'm Catherine Thomsen, and I'm with the Oregon Health Services Environmental and Occupational Epidemiology Program. I am the epidemiologist with our occupational health programs, as well as some environmental, because as a small state we kind of try to do as much as we can. I want to thank NIOSH for coming around to as many parts of the country as possible to hear all the different input that there is on the National Occupational Research Agenda, because I think there are a lot of issues that are really critical to all of us.

I am also really excited about the idea of this being a reinvigorated process. I thought that the first ten years of NORA was really interesting and helpful for helping to set the tone nationally for the kind of focus that there would be on occupational safety and health issues.

Oregon has had a very active state-based occupational safety and health program for about 15 to 20 years now. Although we get almost no state funding, we're reliant almost entirely upon funding from NIOSH, we have been conducting surveillance of different conditions in the state for quite a number of years. And I'd like to make the distinction between surveillance and research because I think that that's a really important point.

We do ongoing data collection in our state, as does the State of Washington, to try to supplement some of the data that we're able to get at the national level. And this is really critical for us to be able to identify the trends, new emerging issues that are occurring, as well as the patterns that are currently existing, so that we are able to better address what the needs are, what the real issues are in worker safety and health in our states. I think that looking forward to the cross -- this new round of NORA, to

what used to be called NORA II but is now the continuation of NORA, is -- one our biggest concerns is how these cross-cutting issues will be addressed.

In the first round of NORA there was the more condition-specific focus, and so a lot of the funding that came to states like mine was for a very particular issue. For example, we had a burn surveillance program. We had a pesticide surveillance program, and we also had a dermatitis program. We've worked in asthma, in the fatality assessments that Ryan was referring to, and we were able to do a fair amount in there. It's very exciting the idea now of being able to look at an individual sector and look at the multiple different factors that are affecting the health of the workers in those areas. But there is still I think the potential problem of any time that you are siloing or looking with one particular structure at the health and safety issues, and so I just want to highlight some of the things that we have done in Oregon and how some of those issues might be needing to be considered by the cross-sector research council or by even some of the individual research councils.

In Oregon we had a project through our dermatitis program looking at latex, and Max had mentioned this morning that that was one of the issues that came up, and they worked very hard at NIOSH to get the word out to healthcare facilities across our nation to limit exposures to latex, if not to completely remove those from a number of healthcare facilities. What we found in Oregon, looking at our data with our ability to partner with a number of different -- number of different healthcare facilities, sentinel data sources, as well as looking at some ongoing data sources, was that the latex gloves were then being diverted into other sectors. It went from healthcare then into a lot of the service sectors, including to child care and to food service. And what we found was that the number of latex-related problems that we were seeing in food service industry rose dramatically in a very short period of time. And we were lucky enough in our state to have very good relations with a number of different agencies, and we actually won a NORA Partner Award -- so another reason why we like NORA so much in our state -- for our work with the local health departments to do inspections of the restaurants, with the restaurant industry in our state, and also with the labor union that represented, while a minority, still some workers in food service. And we were able to do an education campaign and eventually to have a policy change in our state to remove latex from the restaurants, so it is no longer okay to be a food service establishment and in food preparation to use latex gloves.

But they are still used in a number of other areas, and so to latex, even though it is not an issue now in that sector, could still be moving into another industry sector.

Another one of the areas that we've worked on in Oregon is pesticide poisoning prevention. And we've had mostly national, but also some state funding in that area. We've worked with our state Department of Agriculture. And while agriculture is a very important area for pesticide use and poisoning prevention, we have also in our data in Oregon seen that a number of years we've actually had more occupational pesticide poisoning events reported outside of agriculture than within agriculture, in office settings and in warehouses in particular. And so again this is not necessarily something that is limited to an individual sector, and something that needs to be addressed across different sectors. So that information -- the outreach and education efforts, the toxicology information -- can be shared across those different industry sectors.

DR. SEIXAS: Can you sum up, Catherine?

MS. THOMSEN: Yes, I will try to do that very quickly.

Now the other topic that is of great importance to us is special populations. I am a public member on the National Advisory Committee for Occupational Safety and Health and on the committee that is looking special populations. And we're very concerned that both federal -- OSHA as well as NIOSH are working together to really try to address some of these issues. Aging and youth workers are other areas where we feel like it's very important, and so it's important again to share that information, the outreach and education.

So to sum up, in Oregon we think that state-based surveillance is a really important issue. It's good to have these ongoing data surveillance efforts, and they can't always be pigeonholed into a specific industry or by a specific condition. And so we very much look forward to participating and collaborating on the cross-cutting issues with the research council, nationally as well as regionally. Thank you.

Comments from Margaret S. Filios, SM, RN, State-based Lung Disease Surveillance Project Officer, Surveillance Branch, DRDS

My comments pertain to the function, location, and support for occupational injury, hazard, and illness surveillance.

Concern #1: Surveillance appears to lack importance because it is not specific to any one Sector or Cross-sector program, although it is critical to informing research priorities.

Concern #2: The activity of identifying and using surveillance data to inform research priorities by the respective Sector Research Councils will become static.

By its very definition surveillance is on-going. While each of the Sector Research Councils may identify and use surveillance data to develop their respective agenda's, once this activity is complete, I'm concerned that the ability of surveillance data to inform each Sector Research Council will stop.

The current NORA2 structure doesn't appear to allow for surveillance data (which is on-going) to continually inform the Sector and Cross-sector Councils. Occupational surveillance activities are 'outside' the current NORA2 structure.

Concern #3: The ability to identifying where surveillance is 'located' within each Program Portfolio is too prescriptive and may limit its impact.

While this does allow identification and action on data needs and gaps, it doesn't allow surveillance to inform the Programs of emerging problems identified by surveillance data that may be out of context of the specific Sector/Program/ or Cross-Sector.

Recommendations:

-- Include at least 1 representative with expertise in occupational surveillance on each Research Sector Council and at least 1 on the Cross-Sector Council

-- Make sure current data systems are maintained, enhanced and supported

-- Include or develop a transparent mechanism for occupational surveillance data, and surveillance activities at the state level, to inform the Research Councils of emerging or re-emerging issues and problems.

Verbal Comment 2006/01/17: Thanks, Noah. My name is Jim Denovan, and I'm President of EIC Environmental Health and Safety, but today I'm here representing HELP, Health safety and Environment Laboratory Professionals. It's a group of health and safety professionals within the biotechnology and biomedical industry, and we meet on a once-every- two-month basis to help the member companies in our organization to solve their joint problems.

I'll tell you a little bit about the biotechnology industry. In the Seattle area, the greater Seattle area -- well, actually in Washington State we have about 190 biotechnology companies. Forty percent of those are R&D therapeutic drug-based companies. About 30 percent are diagnostic products and around five percent are plant, agriculture, and animal research companies. Generally these companies start out in research and development in clinical trials, so mostly laboratory kinds of operations, eventually go to process development -- if they make it. And then if they really make it they get into manufacturing, and they will start manufacturing drugs or what-- or the diagnostic product they are making.

Within Washington State they employ close to 20,000 people. Most of companies employ less than 50, but of course there are several large biotech companies within the Washington State area. We also have many other centers within the U.S. that have large numbers of biotech companies: San Francisco Bay area, San Diego, New Jersey, North Carolina, Boston, Iowa, just to name a few, and Portland has a few, also. These companies generally are biologically-based or chemically-based or a combination, and so they may be working primarily with human tissues, human blood and fluids, or they may be working with specific organisms -- viruses, bacteria, that sort of thing; we're doing research on those, developing vaccines -- or as chemically-based. They can be working with thousands of different chemicals. One

chemical -- one company, excuse me, that I work with has approximately 13,000 different chemicals in their inventory -- a lot of different chemicals.

Now all these companies have very good control, fume hoods, all the latest in laboratory equipment, but they do have a lot of issues that I believe need to be addressed from a research standpoint.

One of them is multi-chemical exposures. A chemist might work with a hundred different chemicals in a day, in a given day. They might be working with multiple carcinogens, mutagens, reproductive toxins, that sort of thing, and of course with mixtures of different chemicals. And more research is needed on the effects of these small exposures and the effects of the mixture --exposures to mixtures.

Data on glove penetration, especially for these obscure chemicals, is extremely difficult to find out what gloves work for what chemicals, especially when you've got all of these rare chemicals that you're working with.

Compiling Information on infectious agents -- great book put out by NIH/CDC, "Bio-safety in Microbiological and Biomedical Laboratories," but we need more -- we need more information on occupational exposure from infectious agents, laboratory exposures. Health Canada has some great microbiological MSDSs. It would be nice if we had something applicable in the U.S. that gave us more information in one place. Eventually you can find the information, but getting it in one place.

And then developing safer standard analytical processes. There's a lot of different processes that are used by every company to do analysis -- perhaps for proteins, RNA, DNA, that kind of thing. Many of them -- they use radioactive material to do those analyses. These companies try to figure out other means of doing this with safer types of materials, but so far they haven't been able to do it because they're small. But a larger body that could do the research -- one example is a Western blot which is used for protein analysis, you use sulfur 35 -- there must be a different way to do that to -- that would be a safer process.

And that's basically it.

Verbal Comment 2006/01/17: Barbara Silverstein, SHARP Program. There are two things that were addressed by earlier speakers that I really would like to support. One is that as NIOSH moves more into the sector-based research, I think it's important to recognize that sectors are pretty critical for intervention research and for dissemination of information in figuring out ways to do that the most effectively. However it should not be done at the expense of basic kinds of research that need to underpin all of our more applied research methods. So I would definitely support NIOSH continuing and even, if possible, expanding some of the basic research that's necessary for the rest of us to be able to move forward.

The second thing is I would like to second what Matt Keifer had to say with respect to the role of NIOSH and NIOSH's occupational health and safety partners in both research and training in the international arena. I think it's particularly important, as the rest of the world is involved in harmonization in terms of both standards and practices, that we be an integral part of it and help in the research, expertise development, so that we also can learn from others and have a healthier and safer work environment.

Thank you.

Verbal Comment 2006/01/17: Thanks, Noah. There`s just a few other topics I would like to elaborate on, some that have been discussed, some that have not. I think one of the interesting topical areas are our kids as kind of a workforce at risk. Kids are exposed to computers at younger and younger ages now. At age five, 80 percent of kids are using computers either at school or at home.

Another problem is obesity in the United States. Combined with being a kid, and obese kids may be older -- they`re 18 when they enter the workforce, but physiologically they may be older due to the greater exposure to repetitive low-force work and their sedentary nature of what it is to be a kid today.

So I think kids are a very important population, and they may be predisposed or more predisposed than prior populations as far as their physical state entering the workforce.

The other thing I'd like to elaborate on is what Matt Keifer presented, is the need for NIOSH to take on more of an international role. Basically we're outsourcing a lot of our problems to developing countries, and I think we have the knowledge and infrastructure to help these developing countries. And it would be great if NIOSH could leverage with some of the work of the Fogarty Foundation and other international countries to assist in occupational health-related issues.

And the last thing I wanted to talk about is just the focus and the strengths of Region 10, our area. Washington is a self-insured state. There`s just a great wealth and depth of resources collected here. And a lot of this is evidenced by the work done by SHARP, Barbara Silverstein and others, as well as Gary Franklin, just looking at the cost of occupation-related entries.

And the final comment I wanted to make was maybe a model. There`s an interesting model in Ohio State, the safety grants program, where they`re tying funds to understanding occupational injuries and the costs and benefits. And I think that`s been a very interesting and successful model for delineating the cost and benefit of occupational health.

Thank you.

Training

Partners

Categorized comment or partial comment:

Verbal Comment 2006/01/17: Thank you, Noah, and to NIOSH for holding this meeting. I'd like to talk a little bit about training. In 1998 an excellent publication came out from NIOSH by Alex Cohen* and Mike Colligan* in which they reviewed the training literature. They concluded that of the several thousand -- I think it was 2,000 to 3,000 locations they reviewed from the peer-reviewed literature -- that 80 -- 80 -- met the basic requirements for a scientific publication that could be evaluated based on basic scientific principles. Recent training research, meta-analyses have been published in the academic literature, almost ignore totally the research on the shop floor -- I mean training research on the shop floor. And I think it's because they've concluded that it isn't high quality research.

Increasingly I think training research -- the thing that probably disturbs me the most is aimed at -- is internet-based and really aimed at what used to be called the MTV generation. It is rapidly moving and aimed at people that are easily distracted. This is not good training for a lar-- a significant section of our population, and the one that worries me the most is the one that's coming from outside the country where we're outsourcing our work and our production to. Some of those people are coming into this country. And in the research we've done with Hispanic workers, which is one of the largest groups that I'm speaking of, they're averagers of education and most in Oregon come from Mexico, are -- is 5.4 to 5.6 years of education.

Now what that means is that half of that group has got less than 5.5 years of education, and many of them have not been to school at all. Those people are not going to learn from internet-based training. And I think primarily one of the biggest problems is the speed of presentation, but another is the keyboard, which is -- has appeared scary to the people that we've worked with, though we've been working on this issue ourselves.

I think most people abandon the hope of making change happen in the workplace, particularly in the agricultural workplace, if they are not able to change the equipment and sell it to the company. If it

involves training, forget it. It just isn't going to happen. I have to make a new piece of equipment that will protect people. And I think they're ignoring training, which is I think a critical and will remain a critical issue for that workforce.

The second issue I'd like to turn to just very briefly is the issue of durability. Most OSHA training requirements are annual or one time only. And yet there's very little training research on durability. How long does the training information that you get -- the information you get in training -- how long does it last? A principle often reminds -- my wife often reminds me of happily is use it or lose it. And I think the fact is we -- if we don't use the information we get in training fairly quickly, we lose it fairly quickly. In research we've done with kitchen workers on using -- making the correct selection on fire extinguishers to put out fires, you have three or four options from which to choose. We taught them what is the correct option to use for electrical fires, for hot oil fires, and so forth. And when we went back and tested them six months later, they'd completely forgotten that. Now happily they'd not had to put out a fire in that period of time. But if they had, they would not be reaching for the right fire extinguisher. In lab-based research we've done where we've looked -- and that's just cause we only looked at it at six months when they had lost that information. Had we looked at it earlier, we don't know when -- how long they retained it really, but in lab-based research, within weeks, and certainly within a month, people have lost significant amounts of the training -- the information they've learned in training if they don't use it in their occupation.

So, two things I wanted to say, and did I mention my name is Kent Anger* and I'm from Oregon Health and Science University. Thank you.

Verbal Comment 2006/01/17: Looks like some people will still be filtering in here as I talk. Thank you very much, Noah. I'm a research scientist at the University of Washington, Department of Environmental and Occupational Health Sciences. I actually want to commend NIOSH for continuing this NORA process and for gathering all this public input. I think that's a very valuable service they're providing. And I for one am enjoying getting everyone's take on where we need to go for the next ten years.

I also want to say I think the sector-specific focus is a very interesting idea, and I'm glad to see there's some infrastructure in place to deal with the cross-sector issues, but I also want to emphasize that I

hope cross-sector issues are not in any way downgraded because obviously they impact many, many of these sectors -- essentially all of the eight that I've seen identified so far.

In fact, one specific issue I'd like to speak on that covers just about every sector, every industry out there, is occupational noise and noise-induced hearing loss. Obviously this is not a new issue by any means. It's no nanotechnology. In fact, we've known for hundreds and hundreds of years that if you're exposed to high enough noise, you will lose your hearing. Nevertheless, this remains a tremendous issue that we face in the area of occupational health and safety, not only in the U.S. but throughout the world. There are literally millions and millions of workers in the U.S. alone who are exposed to potentially hazardous levels of noise, further millions who have already suffered permanent and irreversible noise-induced hearing loss. That's a pretty heavy disease burden just in the U.S., and if you look globally the numbers are tremendous. In fact, there's an article that just came out in the American Journal of Industrial Medicine that tried to describe the burden of noise-induced hearing loss globally, and the numbers are just staggering. So I do again want to applaud NIOSH for including hearing loss in the first round of NORA, and I want to emphasize that it really needs to stay there. It's not as if we've fixed this issue by simply having it in the first NORA.

Again, despite all the information that we have on noise and noise-induced hearing loss, this remains a tremendous essentially obstacle that we need to face. There's been very little regulatory enforcement on this particular exposure. A lot of industries in the U.S. have acknowledged that they have high noise exposures, but the solution has simply been to hand out hearing protectors. And as I talked to some construction workers last week who described to me having to stick an ear plug in their ear with a pencil as far as they could and then stick a second ear plug on top of that in their ear to just get enough noise, it occurred to me that perhaps hearing protectors alone is not a viable solution in America.

In fact, it's a flawed and ineffective approach to depend only on hearing protectors, and I what I'd like to encourage NIOSH to do is emphasize and promote the development and implementation of effective noise controls in the industry. There also needs to be much more of an emphasis on the behavioral and organizational aspects of preventing noise-induced hearing loss in the workplace because there are myriad issues that present to workers who try to wear hearing protectors. Without this research on noise controls and on organizational and behavioral aspects of hearing conservation, workers will continue to lose their hearing.

I'd also like to put in a plug for basic research as a way to develop and disseminate information that's very practical for the industry. For example, we've just finished up a prospective study of noise-induced hearing loss among construction apprentices. And from this basic research came seven peer-reviewed manuscripts, eight master's theses, a joint effort to develop a hearing conservation program with the local associated general contractors; a collection of educational materials, some of which are available out at the booth; a web site that offers information for the public, and a variety of other very practical results that have come out of this supported basic research. So I think that basic research definitely needs to have a large and perhaps larger space on NIOSH's funding.

And finally I'd also like to put in a plug for NIOSH support of partnerships like the one that NIOSH and the National Hearing Conservation Association have. NIOSH and NHCA have sponsored several workshops that have looked at ototoxics and solvent exposures, and also exposures to impacts and impulses for noise in the workplace. Those workshops have produced very practical, very usable

materials that have benefited hearing conservationists, regulators, academics, and ultimately and most importantly, workers out in the workplace.

So thank you very much for giving me the opportunity to put in my two cents` worth, and let`s hear from the next speaker. Thanks.

Verbal Comment 2006/01/17: Thank you. I'm really pleased to be here this morning. My name, as Noah said, is Mary Salazar, and I'm a professor in the Department of Psychosocial and Community Health at the University of Washington. And I want to say that these comments reflect not only mine, but also my colleague, Dr. Randall Beaton*, who's a research professor in the School of Nursing as well.

I want to begin by thanking NIOSH for the work that they've done these past years -- really since the first NIOSH priorities were identified in the early 1980s -- in the area of occupational stress. And I'm here to address that issue, an issue that I think has a profound effect on all of American workers and is in -- present in every workplace in one form or another.

The adverse effects of stress has been well documented in the literature. These effects include an array of psychological conditions such as depression, anxiety, sometime sleep disturbances, as well as physiological conditions, including cardiovascular diseases, gastrointestinal, immunological disorders and so forth. For example, one study found that an exposure to even a month of high levels of stress dramatically increased an individual's susceptibility to upper respiratory infections, and another study

identified a direct -- a very direct relationship between workers who had low control on the job and poor health.

Inordinate workplace stress may lead to work performance decrements, decreased attention in concentration, increased distractibility, increased muscle tension, and poor judgment. And of course the results of these things might be things such as low productivity, burnout, and even an increased rate of accidents. In more extreme cases exposure to workplace stressors may be a work -- or excuse me, a risk factor for violent acts such as suicide, homicide, and other forms of assault on self or others.

Occupational stress is ubiquitous. It's everywhere. Studies suggest that close to half of workers view their jobs as somewhat or extremely stressful, and that the majority feels that their jobs have become more stressful in recent years. In one study about half of the respondents indicated that job stress adversely affected their health, their personal relationships and their job performance.

The causes of stress are multifactorial and they're really difficult to quantify. There are numerous factors that contribute to occupational stress, and these include things like increased workload, declining job satisfaction, unsafe working conditions, and oftentimes management and leadership styles. Workers' stress levels are related to the structure of work, the organizational culture and climate, and interpersonal relationships at work.

And lastly, occupational stress is costly. Claims for stress-related conditions are the most expensive claims in the workers compensation system on a per claim basis. Other costs related to stressful working conditions include increased absenteeism rates, on-the-job injuries, increased health insurance costs, workplace malfeasance and higher turnover.

So what needs to be done? To summarize, it's increasingly clear that although psychosocial hazards may be more nebulous and less tangible than other categories of workplace hazards, they nevertheless exert a pervasive influence on the health and safety of American workers. There are no quick fixes for the multitude of stressors experienced in the workplace. Indeed, recent strategic advances in our understanding of occupational stress, largely supported by NIOSH, must continue and must be accelerated. Despite the number of studies that have effectively documented the cause and adverse effect of occupational stress, there's still a great deal of uncertainty and confusion about the nature and definition of stress, the evidence linking working conditions to health and safety, and the breadth of problems attributed to stress.

While much has been accomplished since NIOSH first identified occupational stress as one of its top ten priorities, there's still much work to be done. The conditions that lead to adverse health and safety outcomes are deeply embedded in the climate and culture of organizations. And unfortunately, competition and nearsighted economic priorities often lead to unhealthy and unsafe compromises. Organizations are constantly dealing with competing priorities, and sometimes the choice must be made between short-term profit and worker safety.

We need to continue in our efforts to understand how work-related stress affects workers, and we also need to determine what factors cause the greatest burden. And more importantly, we need to develop and test interventions to ameliorate conditions that lead to adverse stress responses that affect workers, their families, and our communities.

Thank you for the opportunity to share these comments.

Verbal Comment 2006/01/17: I'd like to first thank NORA for hosting these town hall meetings. My name is Karen Bowman. I'm the Chief Consultant with Karen Bowman & Associates, an international occupational environmental health firm based in Seattle. I'm also the vice president of the Washington State Association for Occupational Health Nurses, and I am the environmental health consultant for Washington State Nursing Association.

Inappropriate staffing is the number one concern of nurses today, not only because of the effects it has on patient care outcomes, but also because of the detrimental effect it has on health and safety of nurses. Presently research is available that demonstrates the causal relationship between poor staffing policies and patient care outcomes and safety. Now research is needed using current data that explores the relationship between staffing patterns and on-the-job injuries of nurses.

Healthcare is the largest growing industry in the United States, employing over 12 million workers, with nurses constituting the majority. One out of every 100 U.S. citizens is a nurse. There's three million of us. It's a large -- it's the largest group of healthcare providers in the United States. The healthcare industry is expected to grow exceedingly over other industries over the next ten years. It's estimated that, between 1996 and 2008, 14 percent of all new jobs will be in healthcare, adding another 2.8 million new jobs to the United States. With this growth and given that nurses make up that largest

portion of those new jobs, it's imperative to identify and eliminate occupational hazards that cause injury and illness to this work group.

A recent Institute of Medicine report, "Keeping Patients Safe, Transforming the Work Environment of Nurses", not only shows the relationship between nurse staffing practices and increased errors, it also emphasizes that poor working conditions, including poor staffing practices, is not only related to the patients' risk of nosocomial infections, but also to occupational injuries and infections among staff.

In a cross-cut -- excuse me, in a cross-sectional study of more than 1,500 nurses employed on 40 units in 20 hospitals, poor organizational climate and high workloads were associated with 50 to 200 percent increase in the likelihood of needle stick injuries and near misses among hospital personnel and primarily nurses. And needle stick injuries are the principal exposure route for hepatitis B, hepatitis C and HIV.

Emerging new infections such as SARS and avian flu highlight the need for improved health and safety systems for hospital personnel. For example, the SARS outbreak was mostly hospital-based, and in many of the countries where the outbreaks occurs -- occurred, nurses were the largest group that was affected. Nurse staffing issues and organizational problems, along with the lack of appropriate fit-testing for respirators, are thought to have compromised the containment of SARS in Toronto. And nurse staffing shortages have been identified as major factors in how hospitals will manage future potential biological threats.

Therefore, future research in the global healthcare community is needed addressing staff levels and the risks for healthcare associate infections, occupational injuries, and illnesses. In addition, research findings will assist occupational health professionals determine what's needed for surveillance, work practice changes, and health and safety training of workers.

Poor staffing, increased frequency of schedule changes, and increased shift work for those nurses who are not normally acclimated to those shifts cause circadian rhythm disruptions, leading to a variety of physical and mental health issues, some of which Mary Salazar mentioned -- GI disturbances, depression, exhaustion, increased accidents on the job, and lateral abuse.

Stress manifests differently according to specialty, nursing specialty and facility. Intensive care unit nurses and hospice nurses perceive an increase in stress directly related to death and dying. Whereas med/surg nurses directly relate it to overwork, and poor staffing and mandatory floating to other units.

When you add up all the healthcare industry sick codes, hospitals, nursing homes, home health and residential care, healthcare is the leading industry in the State of Washington for back injuries. Without appropriate staffing, one policy to reduce these injuries is totally eliminated. We do not fully understand the impact staffing has on the magnitude of occupational injury and illnesses in healthcare -- in the healthcare setting, excuse me.

Occupational health professionals have an obligation to protect and advocate for nurses, along with other allied healthcare professionals. Further research identifying occupational health hazards related to poor staffing patterns will not only help develop systems to decrease patient errors, but will also improve the health and safety of an endangered profession, as evidenced by the global nursing shortage. Thank you very much.

Verbal Comment 2006/01/17: Thank you. Good morning. My name is Chris Barton, and I'm a registered nurse and the Secretary/Treasurer of District 1199 Northwest, representing 20,000 healthcare workers across Washington State. We're a local union of the Service Employees International Union, representing 1.8 million healthcare workers, building service workers, and public sector workers.

I'm glad to participate today and speak on behalf of my local union and our international union and thank NIOSH for planning this series of town hall meetings. In the limited time before me today, I'd like to briefly touch upon a few more of the significant workplace health and safety issues facing our members, and the important role that we believe NIOSH can play in addressing them.

However, first we'd like to recognize and support NIOSH's decision in this second round of NORA to move towards an industry-based approach. NIOSH historically has done some of its best work when this industry-based approach has been taken, as been demonstrated in such sectors as agriculture, construction and firefighting. The service sector is clearly worthy as a separate priority area, as the vast majority of injuries and illnesses now occur in this rapidly growing sector.

Furthermore, healthcare and social assistance also deserve their own category, as this growing sector reports a disproportionate (sic) share of reported injuries and illnesses, with hospital workers now suffering

rates higher than workers in mining, manufacturing, and construction. Nursing home worker rates are substantially higher. In fact, taken as a group, healthcare workers now suffer a higher absolute number of injuries and illnesses than any other industry sector.

We also want to reaffirm our support of NIOSH focusing their very limited resources on applied or intervention-based research. While some basic research is also necessary, our experience tells us for many of the hazards our members face, the solutions have been known for years, if not decades.

The main problem that workers face is getting these known solutions adopted in the workplace, where the rubber meets the road, so to speak. NIOSH needs to do more to identify the obstacles that prevent known solutions to workplace hazards from being implemented and develop more practical guides, such as NIOSH alerts, to spur the adoption of these controls at the work site level.

Publishing and publicizing studies that highlight pilot intervention programs by progressive and responsible employers is another important avenue to motivate others to adopt similarly protective measures.

NIOSH is to be commended (sic) for its past work for recognizing and addressing hazards facing healthcare workers by issuing alerts on latex allergies, needle-stick injuries, and most recently on hazardous drugs. There`s clearly a need for more NIOSH alerts on the ranges of hazards facing healthcare workers. Such hazards worthy for more NIOSH alerts include an alert on how healthcare worker staffing levels impact the quality of patient and rates of worker injuries and illness rates, as we just heard; an alert on how to best control glucardihide* exposure and the use of substitutes; an alert on controlling technologies for reducing anesthetic gas exposures on both the operating and especially in recovery rooms; and an alert on implementing workplace violence controls in healthcare and mental health settings.

The issue of workplace violence prevention in particular has never gotten the attention by NIOSH that it deserves, based on the very high number of injuries caused by these acts. It was buried within the traumatic injuries NORA category, and we believe has suffered from a lack of leadership commitment and a lack of resources as a result. Last year Marty Smith, a community mental health worker and a member of my local, was violently killed in his client`s home. A survey we just completed of over 300 Washington State community mental health professionals found more that (sic) three out of four workers recorded being assaulted, including one in five being physically assaulted in the past two years. Nearly two out of five workers reported that they felt they did not get sufficient training in workplace violence protection. NIOSH needs to provide more tools for front line mental healthcare workers to avert such attacks in the future.

And finally, perhaps the biggest unaddressed hazard facing healthcare workers that deserves additional attention by NIOSH is the epidemic of neck, back, and shoulder injuries among healthcare workers being caused by inherently dangerous practice of manual patient lifting and transferring. Nurses on average are getting older, while patients on average are getting heavier. This is a recipe for disaster, as such conditions promote a shortage of nurses willing to work in healthcare. In fact, 12 percent of nurses who have already left the profession report the main reason being that they have already suffered one or more of these preventable, disabling injuries.

While at least one NIOSH-funded study has appeared in a peer-review journal showing how the use of mechanical lifting and transfer devices, with or without the use of lift teams, can save backs and bucks, it

is clear that what now is needed is a healthcare worker-friendly NIOSH alert -- a tool book, if you will -- on implementing a safe patient handling program.

Thank you for your attention and the opportunity to provide these comments.

Verbal Comment 2006/01/17: This is quite a role. My name is Barbara Silverstein, and I'm the Research Director for the Safety and Health Assessment and Research for Prevention Program at the Washington State Department of Labor and Industries. At the request of the Washington State House of Representatives' Commerce and Labor Committee, we recently committed -- completed a patient handling task force report with stakeholders from both labor and business in hospitals, nursing homes, home care, home healthcare, hospice care, and pre-hospital medical services, such as emergency medical services. I'm including in -- what I'm going to hand over to you are the -- a list of suggested approaches for addressing patient handling concerns that were identified by task force members. We also have a final report of the task force that's available upon request if NIOSH would like a copy.

As the last two speakers said, there's an integral relationship between patient and staff safety with respect to increasingly older, heavier, and often sicker patients being cared for by skilled healthcare workers who are getting older, thereby -- therefore, making recruitment and retention of qualified, experienced staff a critical issue in and of itself. The legislative committee requested that the Department of Labor and Industries convene this task force to examine current lifting programs, policies, and associated challenges in Washington state; to examine how the programs work and how they're funded; to review the current literature in the workers compensation data; and to identify the culture necessary to sustain a successful program. I think these issues have also been touched on by the previous speakers.

Let me briefly say that we did as requested, and I would like to first present some conclusions from the task force and then talk a little bit about some of the issues.

First, all of the hospitals and nursing homes that we visited were working to implement a no-lift program in some form, with the intent of reducing staff and patient injuries. This was less evident in the other sub-sectors of healthcare. The literature review of facilities with no-lift programs clearly shows reduced injuries to patients and staff, reduced time loss, reduced costs, and reduced staff turnover, and there's very little question about that.

A clear barrier to implementing no-lift programs is lack of funding to purchase the mechanical lifting equipment, despite the relatively high return on investment that has already been demonstrated. Home and pre-hospital medical service sectors may present some unique, but not insurmountable, challenges to minimize manual lifting. Developing and testing these solutions in this sector should be a research focus.

So with the workers compensation analysis that we did in Washington state, musculoskeletal injuries, particularly of the back, continue to be a problem in this industry. In 2003, in the state fund workers compensation program, healthcare employers had 3.9 times the compensable or lost time back injury claims rate as other sectors combined. For the self-insured in 2003, which represent most of the hospitals, the healthcare sector had 1.5 times the compensable back injury claims rate of other sectors combined.

In our literature review and the review of the workers compensation data, we were able to estimate that in Washington state approximately \$32.8 million are spent annually in workers compensation claims in hospitals and nursing homes combined. A 53 percent reduction in the claims rates, which is the median reduction that we see from the literature -- all the studies in the literature -- would save basically in Washington state \$17.4 million a year in direct claims costs. So when thinking about the equipment and the difficulty in purchasing it, there's some disconnect.

With the site visits, I think it's important to say with the hospitals and nursing homes that they're similar in that their services are provided in facilities that are under their control. However, they are dissimilar in patient acuity, staffing type and level, and financing mechanisms. I think this is important when you're looking at sector-based research to look at sub-sectors as well. Hospitals and nursing homes were different in the stages of moving toward no-lift environments. All of them had some type of mechanical lifting equipment, with most hospitals having at least one ceiling lift. Both management and employees interviewed recognized that while mechanical patient handling equipment was essential, it was not sufficient without an integrated program or process in place. And all recognized the increased challenge presented more obese patients.

The biggest barrier to full implementation of a no-lift program in hospitals and nursing homes was the up-front cost of equipment. For the home sector -- and again this involves home health, home care, and hospice care -- the goals there are to keep the client at home for as long as possible. And this, in and of itself, presents a unique challenge that requires I think more investigation.

Homes are often not structured for ease of client-assisted transfers. The home sector workers often work alone. The client handling equipment is not generally portable, and insurance rarely covers any kind of mechanical lifting devices.

With respect to emergency medical services, they have amongst the most difficult tasks in transferring and handling patients. One of them was -- that we identified was as a result of having no-lift programs in nursing homes -- that there is a transfer of risks from the nursing home to the EMS worker who picks up the injured nursing home patient who is on the floor in the nursing home.

The next part of that has to do with government involvement, and let me just say what I think NIOSH should be doing in terms of government involvement. Not only should there be funding for testing and evaluating no-lift approaches in home and pre-medical service sectors, NIOSH should work with federal healthcare agencies, such as Medicare, to determine the costs and benefits of including portable patient handling devices into federally-funded home care. Additional evaluation of ways to reduce physical load in pre-hospital medical services is urgently needed. Thank you.

Verbal Comment 2006/01/17: First I want to thank NIOSH for this opportunity to give input to its research agenda. And I want to thank Noah and the Northwest Occupational Health Center for coordinating this event. My name is Ron Tubby. I am with Intel Corporation. I am the program manager for chemical management with our corporate operations. I'm an alumni of the University of Washington program so it's an honor to be back here again talking with folks in this setting. I've been with Intel for over 15 years.

Intel as a company has over 16,000 employees in its Portland, Oregon operations, and Portland is by far and away Intel's largest location. We have our significant research and development operations there in Oregon that research the next generation of logic processing devices and memory devices that we introduce into the market. Intel employs about 100,000 employees worldwide. About half of those employees, little bit over half of those employees, reside in the United States. We introduce about \$40 billion into the U. S. economy annually. You didn't hear that from me because we're announcing revenues this afternoon, so don't run and call your stockbroker.

The semi-conductor industry sector in the United States represents about 230,000 workers and that's about \$100 billion of revenue annually. That's made up of about 90 companies in the United States, and you can generally multiply those numbers again by two if you want to look at global numbers for the semi-conductor operations worldwide. The semi-conductor industry spends about \$14 billion annually on research and development, and our company is a significant contributor to that by over half.

In terms of the people that engage in manufacturing devices that you use in the consumer market. and work in our factories and work with chemicals and work with equipment to manage and process those chemicals, that represents about 50,000 workers for us globally. In the last ten years we have seen a shift of our revenue sources from the North American market, which used to comprise about 60 to 70 percent of our sales, to the Asian market, which now comprises about 60 percent of our sales. Commensurate with that shift in market, we are shifting our manufacturing operations to reflect those markets and manufacture products in those emerging economies. That poses new challenges for us, as it does for many other industries, as I'm sure you're familiar.

For us specifically, we have engineering staff and technician staff that work inside of our clean rooms inside of our factories that work with chemicals on a daily basis, and process materials through those machines that make the devices that you use. Our top research needs and concerns as an industry and as a company -- first on top of the list is nanomaterials, and we've talked about that several times, several speakers have mentioned that today. In our industry specifically, we will see growth in the next five years in the use of those materials, quantified in terms of the dollars we spend purchasing those materials, from a \$50 million market to well over a billion dollar market in the use of those materials to manufacture the devices that we sell. That presents a significant increase in the use and propagation of those materials in our workplaces, and significant challenges to occupational health professionals and industrial hygienists to come up with effective and consistent and matching control strategies to ensure that our workers are safe when they are using those materials.

Likewise, the equipment market that will process those chemicals will go from what is today a \$500 million market to well over a \$3 billion market five years from now. That's projections from the Semiconductor Industry Association. If you think on what that might look like ten years from now, you can see probably a logarithmic growth in both the use of the materials and the use of the equipment processing those materials. So we need help in research in toxicology, pharmacokinetics, permeation and transport of PPE*. There's some real fundamental industrial hygiene and occupational health questions that we need help getting answers to, and research to back that up.

NNI, ISO, and ANSI* are fully engaged. We need NIOSH to be a player in those conversations in helping us create a safe workplace.

Second on our list of research needs is wireless technology. Many of you today use computers that have wireless LAN devices, and I mean that's transformed the workplace. You can now sit in Starbucks and be as effective in Starbucks as you can in your office setting. What we will see over the next five to ten years is a evolution of that from a personal 30 to 50 to 300-foot network to a community network, which will pose interesting challenges and interesting benefits to us. But you'll see cell towers -- like cell towers -- projecting broadband wireless signals to the consumer market. You'll be able to access content, instead of through a wired device in your house, through radio signal.

That presents unique risk communication and hazard communication challenges as we have seen with cell phones, as we have seen with WiFi and wireless LAN. What people cannot see, what they cannot feel, what they cannot smell comes with, I think, additional and significant risk communication challenges. And we've seen that frequently in the wireless LAN space in terms of our markets.

Another issue we need help with, and we've seen this over the last -- emerging over the last three years, is help with pandemic and fomite control strategies for businesses. SARS introduced those terms, that language to us. Avian flu is challenging us right now. We're, as a business, trying to develop strategies to deal with what may happen should we face that kind of outbreak.

Commensurate with the use of nanomaterials, we need help with control strategies when we lack environmental health and safety data. Increasingly, we are using new and novel materials that don't come with a breadth of toxicological research. That leaves us in the space of having to apply (unintelligible) principles in many cases, and we need help in looking at the use of complex materials in synergistic combinations.

DR. SEIXAS: Can you sum up there, Ron?

MR. TUBBY: We introduce over 5,000 new chemistries into operations every year. And increasingly a significant percentage of those new materials coming in fit that makeup where we lack basic tox research to support the kinds of control strategies that we have to implement internally to our company.

And I'd like to thank NIOSH and the Northwest Center for the opportunity to provide these comments. Thank you.

Verbal Comment 2006/01/17: Well, thank you, Noah. My name is Dave Eaton. I`m a professor of Department of Environmental and Occupational Health Sciences at the University of Washington and Associate Vice Provost for Research at the University of Washington. I`d like to thank NIOSH for the leadership in providing this opportunity for me and other NIOSH stakeholders to provide input into the National Occupational Research Agenda.

NIOSH provides a critical component of the national strategy to reduce occupational injury, illness, and disease by supporting both basic and applied research that then provides a scientific foundation for the regulatory polices that protect worker health and safety. I`d like to address to [sic] critical areas of research, and this is focused heavily on basic research, that I hope will become a central element of NORA, both of which are technology-driven and represent the applications of new cutting edge science to major occupational health issues.

The first of these is exposure assessment. The importance of good quantitative measures of actual exposures to occupational hazards, particularly for chemical and physical agents that represent chronic health risks, really cannot be overstated. This is particularly important for occupational epidemiology studies, oftentimes of which serve as the foundation for new insights into disease relationships with exposures, that often relied in the past on crude estimates of exposure to assess occupational risk to chemical and physical hazards, oftentimes crude in the sense of exposure assessment being based on job title, or even more crude measures of actual exposure.

Poor exposure assessment can lead to erroneous conclusions about the hazard or the presumed safety of a chemical or a physical agent in the workplace. I encourage NIOSH to stimulate new innovative approaches to occupational exposure assessment to take advantage of the new tools of genomics, proteomics, and metabolomics that have been developed as an offshoot of the Human Genome Project. Applications of these tools may identify new molecular bio-markers of exposure that will help to

accurately and quantitatively quantify biologically relevant exposures to chemical or physical agents in the workplace on an individual basis.

Although much work remains to be done in the development and application of these tools to occupational exposure assessment, the time is now for NIOSH to recognize the promise of these approaches and to invest in basic research that will ultimately lead to accurate quantitative bio-markers of exposure, some of which may even allow retrospective assessment of past exposures. Better exposure assessment will reduce exposure misclassification in occupational epidemiology studies, thereby increasing both the power and the accuracy of such studies to identify real associations between exposure and illness or disease.

Categorized comment or partial comment:

The second area I'd like to address is for the application of new technologies to occupational illnesses and diseases is in the area of genetic susceptibility, also an offshoot of the Human Genome Project. OSHA as you know is mandated by law to protect even the most sensitive individuals from workplace hazards. It's now becoming evident that the same exposure to a chemical or physical agent may affect one individual but not another, based largely on subtle genetic differences. For example, it's now well established that chronic lung disease from occupational exposure to beryllium is largely confined to a relatively small portion of the workplace population that carries a genetic disposition to the disease. Although the recognition of this poses huge ethical challenges in how such personal information is used, it is critical to understand the magnitude of variability and sensitivity to workplace hazards if one is to establish workplace standards that are both cost effective and adequately protect sensitive individuals.

Such information is also useful in understanding the etiology of disease. Another example of where genetic sensitivity has been shown to be important in occupation diseases is perhaps worth illustrating. A colleague of mine, Dr. Martin Smith at the University of California Berkley, recently published an article in Science Magazine about a year ago that demonstrated that a subset of workers with specific genetic variance demonstrated a measurable decline in white blood cell counts and other markers of blood or hematotoxicity following occupational exposure to benzene at workplace concentrations at or below the current standard of one part per million. And this is a study done in an international circumstance in a workplace population in China. Although the long-term biological significance of the effects that he measured is not certain, it clearly demonstrates that the current tools of genomics can help to identify susceptible populations to occupational hazards and help to quantify the range of human variability. And I would add that in addition to using interesting genetic bio-markers of susceptibility, Dr. Smith utilized some really cutting edge exposure assessment tools. So he combined the best of new technologies in exposure assessment with genetic susceptibility.

As I stated previously, there are many ethical, legal, and social implications of using genetic susceptibility information in workplace hazard assessment and policy. NIOSH should support both the basic research necessary to increase our understanding of individual susceptibility, and policy research to ensure that such information is used in a socially responsible manner.

So as NIOSH goes forward with their next ten-year research agenda, it's important that the advances in basic science and technology be built into the research agenda and future funding priorities.

Thank you again for the opportunity to comment on the NIOSH NORA. Thank you.

Concurrent to this submission I am submitting the published manuscript:

Lawson, C.C., T.M. Schnorr, G.P. Daston, B. Grawjeski, M. Marcus, M. McDiarmind, E. Muro. S.D. Perreault, S.M. Schrader, and M. Shelby. 2003. An Occupational Reproductive Research Agenda for the Third Millennium. *Environmental Health Perspectives* 111:584-591. Editor's note: Accessed March, 2007: <http://www.ehponline.org/members/2003/5548/5548.pdf> .

This is the research agenda recently set by the NORA 1 team.

Historically there have been working conditions in each of the sectors which have had a negative effect on reproductive health. In the agriculture sector, pesticides like ethylene dibromide and dibromochloropropane have had adverse effects on sperm production and function. In the health care sector ethylene oxide and anesthetic gases have had negative reproductive health effects in both men and women. Several chemical exposures (e.g. 2-ethoxyethanol, dibromochloropropane) in the manufacturing sector have been associated with fertility problems in men and women. Boron, lead, and nickel are examples of known reproductive toxicants in the mining sector. Sexual dysfunction of bicycling police officers is a recent example of reproductive health issues in the service sector. An example of reproductive health issue in the transportation sector is lower sperm counts in long distance truckers who are seated for long hours. (More extensive list is in the Lawson paper page 584). It is

paramount that each sector research council considers reproductive health as a legitimate and important health issue. They should each be given a copy of the Lawson paper indicating that occupational reproductive health research is needed in each sector.

The NORA 1 goal was to set a research agenda to address serious occupational health issues. The reproductive health research agenda was published in 2003 and should be key element in setting each sector's research agenda.

Verbal Comment 2006/01/17: Yes. Thank you, and thank you for having me. I've always wanted to say this in front of a group. I'm from the fishing industry; I'm here to help you -- since I never get to say I'm from the government, I'm here to help you -- so I did it. I don't need to say that anymore. It's gone.

I want to focus on fishing vessel safety, and just before I even begin, say this is -- I understand this is a really hard industry to study because it's so dynamic. I mean it's -- basically you're studying an environment in which the place people are sitting and standing on works in all cardinal directions, and the environment is exposed to weather and it's just -- it's not a controlled laboratory. It's very difficult.

So I have five points I want to make that I think are worthy of NORA to look at in terms of research.

One is traumatic injuries. I was doing a drill once on a boat in Petersburg. It was the -- 90 percent of the ownership of Icicle Seafoods, these old Norwegians in their 70's. I had six of them all in one class together, and all their hands were on the table. And I was debriefing the drill with them, I realized there wasn't a complete set of fingers on that boat. You know, there should have been 60 fingers there; there was only about 48. And it's just endemic in the industry, and we don't have good statistics on that due to a number of things.

Everybody is collecting the data differently so it's even hard to get a handle on it when you don't know what injuries are happening with what frequency. So if nothing else, just that collection of data would be good and that's going to -- but that will be a challenge. A lot of it's hard to collect due to liability and privacy issues and the Jones Act and many other things, but it's very worthy to try to do something about.

The second issue -- it's closely related -- is ergonomics. How many people here have bad backs? If this was a group of fisherman it would have been 90 percent would have raised their hand. It's totally endemic to the industry. You can tell experienced crew members and fishermen because they have scars on their wrists that go this way. Not this way, that might be due to something else. But they go this way because of -- they've been getting the operations to open up their carpal tendon sheathes so that nerves don't -- when they get inflamed, can -- won't bother them so much. And many, many other things. The work that Don Bloswick* has done out at the University of Utah is a great beginning on that, looking at ergonomics and developing procedures and practices for fishermen to use. The challenge of course on that one is getting people to change their work habits.

The third issue, which is related to the first two -- again, all of these are related -- is fatigue, fatigue on vessels. There's been some work done on that in fisheries in Australia and at IFISH II. At the IFISH II Conference, the Australian women working on that were interested in working with the UK and Alaska fleet to begin to study that a bit. And the challenge and problem there is the management and work regimes may not be compatible with any of the guidelines they could develop for this. Developing a work schedule on a fishing boat -- when you're on literally 24/7, weeks on end, when in the middle of the night, when it's not your watch, you've got to get up to haul gear, to tie up to the dock, to do other necessary work is going to be a really hard one to do.

Fourth issue, which is again very endemic, and not much work has been done with it that I know about, is hearing loss. Any fisherman that's been around boats for 10, 20, 30, 50 years especially has -- many of them have hearing aids, and it's very difficult for them to hear, which means that they can't hear alarms on boats. They can't hear things on the radio with other machinery noises going on, so -- and they just can't hear communications between -- between crews, so it would be good to develop some data on the long-term effects of hearing loss on fishing vessels, if nothing else except just to develop some awareness that this is a problem.

Categorized comment or partial comment:

And the fifth issue -- I'm glad Ken brought this one up. Thank you, Ken. I thanked him during the break - - was we are involved with training fishermen in how to survive major casualties at sea. And as a result of this training, we train them to be drill instructors and do skills once a month so that in a casualty at sea they'll be able to put on their immersion suits in 60 seconds, fight a fire efficiently, et cetera, et cetera. But what's the -- I think the term Ken used was the training durability of this -- what type of refresher training needs to happen and how often should these skills be reinforced. Ostensibly (sic), they're supposed to be reinforced once a month during the drills, but the only data we know about says that about only 18 percent of the boats at best, overall, are doing drills once a month. The training they may get just might happen when they get their once-in-a-lifetime drill training. So it's important I think to study the digression of the -- of those skills over time.

And this is important not just to look at that to see what that retention skill rate is, but as a lot of your work goes into -- it's not just facts and figures you're dealing with, but it's going to be used to set policy also, and I think it's really important when you're looking at some of these things to remember that. People are going to be using this information to set policy and regulations and other things, so that's it.

I'll just conclude with saying that the research that's going to be taking place in this -- hopefully in fishing vessel safety is not going to take place in a sterile lab. It's a very dynamic environment and lots of challenges in that, but it's very, very worthwhile. It's the -- always been the number one and two loss rate in industry so it'll be great to have your attention. Thank you.

Verbal Comment 2006/01/17: Good morning. My name is Ken Lawrence, and I don't know where Chris is. I didn't even know Chris was supposed to be here. I came up from Portland. I'm with the Coast Guard -- what used to be the Marine Safety Office down there. Now we're something called the sector, to more properly recognize a more multi-mission organization. I'm the commercial fishing vessel safety coordinator down in Portland, and my representation along the coast is the Oregon and coastal Washington small fishing communities. Basically, we have about 2,000 vessels with crew size varying between one and five, so we're talking about small organizations. We're talking about family businesses, that sort of a smaller organization.

Jerry has eloquently addressed a lot of the issues that I have. I'm going to go and repeat, for -- just so that I can stay with my notes, a little bit of that. But basically what we've seen with small fishing vessel casualties and fatalities at those rates, although the numbers are small, the rates are unacceptably high, somewhere between 70 and 300 fatalities per 100,000 workers, depending on what specific fisheries. And almost all of those are directly attributable to human factor causes and lack of safety and survival training.

The exposures that commercial fishermen have to deal with -- it's a very dynamic environment. You've got the physical marine environment, and especially during the winter off the Pacific northwest that seems to concentrate the fatalities and the vessel losses that we're used to seeing. There's a very highly competitive and complex, market-driven economic forces that influence all of this behavior. There's very complex and often risk-promoting fishery management that drive a lot of those economic forces, as well as a long tradition of risk tolerance and avoidance of regulation within the industry, either the government or self-industry.

There's a lot of lip service lately that's been paid to safety, but when we get down to it there's not always a lot of action. The population that we're dealing with -- this is one of the great unknowns as far as the Coast Guard is concerned. We've got a very diverse, mobile, disaffected and seasonal employee base. We've got people that will one season fish in Oregon, and then they're down to California, then they're out to the south Pacific. These folks are moving all over the place.

There's a lot of data out there, but there's very little rational denominator information out there that I've been able to cull that allows us to go ahead and get a more quantitative idea of some of those risks, especially by specific fisheries. A lot of the conclusions that we end up coming to when we start playing with numbers -- there's lots of swag, wild-ass guesses, and it's very rarely more than a broad brush across the entire industry, which makes a specific fishery intervention very difficult to develop or justify.

Some of the failures in the systems that we've seen is the commercial fishing industry, for the most part, lacks OSHA jurisdiction and the regulations from the Coast Guard have had, in my opinion, a poor prevention-based result history. And there's very poor injury tracking, although there are some specific areas -- Alaska, for example -- where they are very good at tracking the injury rates and some of those data. But the communication and the applicability to other fishery sectors can be ambiguous, complicated at the least.

As far as our key partnerships, I've enjoyed a long working relationship with the NIOSH Alaska Field Station, and I want to thank them for their research and support over the years in the fields of crab vessel safety, deck safety, training studies, PFD usage studies, those sorts of things. It's very specific research and development that's allowed the Coast Guard to partner with industry and to make some very specific, effective interventions to try to minimize some of those fatality rates.

The other NIOSH sponsorship that's I think benefited the Coast Guard quite a bit is the sponsorship of the IFISH Conferences, the International Fish Industry Safety and Health Conference. The first two, in Woods Hole and in -- I'm sorry was it Woods Hole or Newfoundland? Woods Hole, and the second one in Sitka. The third one is coming up here in Chennai, India in another couple of weeks -- has provided us a really valuable forum to get the -- some of these key players together to start concentrating and figure out where some of the vacuums and the holes in the data and the information are so that we can go ahead and start to fill in some of that collective knowledge that we have.

Some of the future research that I'm looking forward to working with my NIOSH colleagues, as well as Jerry Dzugan, for example, the Alaska Marine Safety Education Association, the areas of crew training and crew competence, which are going to help us get a handle on some of those human factor accident causation, as well as a better idea of injury prevention. Generally, the Coast Guard is very attuned to an accident when somebody dies because those numbers are hard to hide. But injuries become almost transparent given the population group. We really don't have any handle on injury prevention.

government and industry interventions and policy and regulations. So I want to thank NIOSH for a chance to make this input.

Verbal Comment 2006/01/17: My name is John Garland. I'm a professor and timber harvesting extension specialist in the Forest Engineering Department at Oregon State. I should point out the remarks are my own and not those of the university.

For the past 32 years I have been providing problem-solving education, research implementation, and technology transference in building of human capacity for the forestry sector in Oregon and the region nationally and to some degree internationally. I'm the ergonomics research leader for the International Union of Forestry Research Organizations which deals with international cooperation on forestry research.

The emphasis in my career has been on selection training, motivation, and safety and health for the forestry workforce. Over the years I've participated in three revisions of Oregon's safety code over ten year cycles, and have seen the efforts to improve safety in that sector advance through those revisions.

I don't need to tell you that forestry work is dangerous. The news media does it for us regularly, in that it's among the top industries and has been for the past 30 years. I think what I would tell you, though, is that there have been improvements, and Oregon has seen a reduction in fatalities in the logging workforce that are significant over the years, going from fatalities in the 40 person per year range down to less than ten and some years just one or two. So there have been changes that do work.

However, logging workers are aging faster than the general male population. I mean that for the entire group. More than 45 percent of the workers are over 45 years of age, and that isn't the way it was in the past, so that workforce is aging substantially. Firms themselves are becoming smaller, so their ability to do management and oversight to improve safety is becoming less and less. In addition, recruitment among the forestry sector is reduced because of comparative losses in relative wages compared to other industries. So forestry workers are losing ground compared to other opportunities.

There have been increases in the Hispanic population of all western states that I'm aware of, but in Oregon we've grown from four percent in 1990 to about -- over ten percent right now. And that means that that Hispanic workforce is also finding its way into the sectors. Some firms have Hispanic crews entirely, with separate gringo crews, and others are mixing the cultures, with some interesting complications in language problems. We'll see Hispanic populations make up more and more of the forestry services sector.

Mechanization continues in the forestry sector and improves safety, but it changes the kinds of hazards related mostly to maintenance kinds of injuries and sometimes injuries from thrown objects, let's say from the machines themselves. Operators suffer cumulative trauma from the work that they do in long hours and restricted positions, and that's been noted in other countries.

In recent years I've worked with synthetic rope to replace wire rope in logging as a tool to reduce workloads, but it really needs to be done on a system-wide basis rather than a rather isolated research projects.

New technologies able to monitor workers status by the clothing they wear would give us some good insights as to what the workloads are and what the fatigue factors might be for workers, and this relates to the nanotechnologies listed earlier.

Training is crucial to forestry workers, but effective approaches and evaluation of materials hasn't been done along the same lines. We don't have materials that can be used within the individual firms themselves. Sometimes the training schools do quite well, but are not sustainable once the grants run out.

Oregon's landmark revision of the Forest Activities Code changed it from a prescriptive code of do this/don't do that sort of an approach to more of a safety and health management where workers are asked to be competent for the work that they do. And the training and supervision and oversight needed to produce that is what's called for in the codes. So we have different approach for the logging sector now, and we'd like to see some evaluation of that to see what would happen.

Let me just list quickly the ideas that relate to that for OSHA or NIOSH research that would be helpful. Demographics of the forestry workforce -- there are about four different regions for the forestry

workforce. We lost ground when we changed some of our industrial classifications, so there now no is -- there is no series relating to this sector. So we need to look at the demographics.

The aging workforce is critical. We ought to treat the workforce more like we do trees. Consider regeneration, a little fertilization in terms of education, and consider the old growth that is our aging workforce.

We need to have the technological developments necessary, and the prior sources for that in the federal government with USDA and the equipment manufacturers is no longer there. Those have been cut back. So if safety is going to be the prescription for research, it may need to come from something like NIOSH.

We need evaluation of training strategies and documentation of those systems that work within firms, and we need to find ways to integrate the Hispanics into the logging and the forestry services workforce, keeping in context the cultural and language differences, indeed including some of the risk-taking behaviors that may be different for the Hispanic culture.

I think we need to look at the new approaches to safety and health regulations that I mentioned and study whether or not those have merit for small firms that we're working with.

One special project that I've called for for years has been understanding the risk-taking behaviors of seriously disabled workers. Once all the dust has settled, it would be helpful to find out what was really going through the minds of the workers when they actually encountered the incident. You can't do it right after the accident for a variety of reasons, but I've had anecdotal evidence that workers provide important risk-taking characteristics interviewed some time after the accident has occurred, and that hasn't been done for forestry workers. It would be very helpful.

Operator overload and cumulative trauma from machine operators is an area that will continue to be of importance as more and more of these operations are mechanized.

I'd like to see us study smart clothing and worker feedback in real time so we could tell when the stress is high, when the worker fatigue is at high levels, and I think there are some technologies now in military uniforms that provide a starting basis for this, as well as monitoring heart rates and other measures that we have traditionally used.

One of the areas that's been critical in recent years has been fighting wild land fires. And much of the applications have been done by individual workers with shovels and by airplanes. But there's a whole category of work that needs to be done with mechanized equipment that can make this wild land firefighting more effective, and that hasn't been studied from its safety and health aspects and certainly needs to be looked into. I've not had good success encouraging that among the firefighting community.

Two other points, we need to evaluate research proposals within the CDC research system because I think the process now doesn't give good attention to the kinds of proposals that may help the forestry sector. It tends to focus medical research rather than operational research.

And finally, I thank the opportunity to speak to you today.

Verbal Comment 2006/01/17: Still good morning. My name is Bill Krycia. I'm a Regional Manager with Cal. OSHA Enforcement out of Sacramento. I'm also the Chair for the External Advisory Panel for the Western Center for Agricultural Health and Safety at the University of California at Davis where my daughter now goes. I'd like to thank you for this opportunity, and talk about western ag. And I've been reading these comments and trying to -- you know, the great speakers this morning -- and trying to follow with that. And what I'm going to say, to me, sounds so simple that I'm almost embarrassed to say it, but I feel that I have to say it here. And that's that western agriculture, California agriculture, is very labor intensive -- very labor intensive. And that that labor workforce has a significant population of non-English-speaking immigrant, low-income laborers. And that brings special needs I think to the west coast.

Leaping into things that I want to address from an enforcement standpoint, it's clear that this group does not file complaints with us, so they're almost invisible. That doesn't mean that they don't have needs. And I may be speaking from my very limited perspective as an OSHA enforcement person, not a

consultant. I'm an enforcement person. My folks are -- you know, write citations. We sign off on citations. We take employers to court, and we do all those things that a lot of folks don't really like. But from that perspective, there's -- there are groups out there, the Penaros*, I was just thinking about the Penaros when we were talking just now about logging, and I know that next week we have to reach out to that group. And so there's a lot of things that we're trying to develop right now that I think bear some research, even though I haven't included them in my notes here. But I think that that's a group we need to outreach to in research and find out what hazards address those folks and what needs they have.

To get back to my notes, I'd like to suggest that we continue with ergonomics in agriculture. California has a hand-weeding standard, and it addresses one facet of ergonomics in agriculture, and there are a lot of other issues in ergonomics and agriculture that need to be addressed, not the least is hand harvesting. I think that we need to continue on and take a look at issues for that.

I'd like to see additional research on the practice itself of hand weeding and the impacts of the engineering, horticultural and administrative interventions that employers are currently involved in. I think we need to follow up on that. Just because we have a standard now, I wouldn't want to see that dropped.

Work involved in high heat environments has been in the focus this past season for us. And California currently has a temporary emergency standard in effect. There's clearly a wealth of literature and research on the subject of heat-related illness, but I see significantly less information available on the components of agricultural workloads. One of the things I said I wouldn't do but I think I'm going to do it is say that -- you know, my initial review -- and I'm not an epidemiologist, I'm an industrial hygienist -- is that it's almost all exertional heat stress. And so that's one of the things that I think that we need to bring to -- information in, maybe do a little bit more research on, so that the -- it's important for employers to have this so that they can understand what exertional heat stress is and have information to train -- I wasn't going to talk about training but I heard other people do that -- so that they can train their employees, to protect their employees. I think that's just critical for prevention, so research on that.

I also think that information about the early recognition of heat-related illness is absolutely critical, and so these employees -- these agricultural employees -- work in remote locations, some exceptionally remote locations. And they're at some distance and time from advanced life support, and so the failure to recognize heat-related illness very early means that they only recognize it when the employee's in the final stages of heat stroke. And when it takes 45 minutes to get an ambulance out some place that doesn't have advanced life support, or it may take, in some cases, 90 minutes to get a helicopter if they even call a helicopter, that's unfortunately in about a dozen cases been too long. So I think we clearly need to address early recognition.

One of the other things, too, that I've noticed this past year is night work in agriculture. I don't think anybody else is talking about that, and what I mean by that is they harvest at night. They harvest tomatoes, they harvest grapes. And there's other night work going on, and some it's due to they're -- they're trying to avoid the heat, and some of it's due to the special crop requirements. You know, they want a nice crisp white wine for the consumer and so they'll harvest at night. So that's okay. But when they run over and kill their employees, that's not. And our standards, I noticed, are -- they really haven't

addressed that. I think that's a change in an agricultural practice, and I would suggest that additional research be done on night -- night work in agriculture.

I'd also like to acknowledge the western ag centers, both of them, for their input. One of the things I've talked about my myopic focus on enforcement, and I really use the ag centers to kind of broaden that because again, like I've said, the workforce that we're dealing with in agriculture doesn't call in and file complaints about it's too dusty. They don't generally file complaints, even in California, about ladders. I don't see that, and there's some work to be done on ladders, too.

Okay, and I'd like to thank NIOSH for their cool publications that we use a lot, and that's it.

Note: Verbal testimony provided to NORA Town Hall meeting in Seattle, WA, 2006/01/17.

Verbal Comment 2006/01/17: Good morning, members of NIOSH and OSHA. Thank you for the opportunity to provide input on the future research on reducing work-related injury and illness in employees in agriculture, forestry, and fisheries. My name is Jim Sedore. I've been the Safety and Health Manager for the Washington State Department of Natural Resources for the last 20 years.

The state manages about five million acres of state-owned land, and protects 12.7 million acres of -- of private and state-owned forest lands for wildfire management. We have approximately 1,200 employees, 400 summer firefighters, and 400 inmates who work for us every day.

Employees file approximately 180 work-related claims per year that require medical attention beyond first aid. Despite the exposures to wildfires, SCUBA-diving, mine inspection, and timber harvesting, the DNR has one of the lowest rates of claims per hour of any state agency. At your request, I can provide statistics on accidents, severity, and frequency for the last six years.

However, I'd like to talk about three related claims that need further research. I appreciate John's comment related to timber, and we can talk about old growth, mid growth, and reprod. In old growth, age-related injuries -- as retired parameters result in older employees in the field, what can employees and employers do to reduce the number and severity of age-related injuries? I'd like to give two examples.

Injuries to load-bearing joints -- the number and seriousness of knee injuries are increasingly significant in field employees over 45. DNR employees, most them now cannot retire until they're 65. It's one thing for a person to carry a chain saw up and down the mountains when they're 25, 30 years old, but when you're 60 do you want to do that? What can be done to improve conditioning, footwear, medical treatment for knee injuries? In the past five years DNR employees have suffered 127 knee injuries costing \$320,000, including about \$50,000 dollars in time loss, an average of \$2,500 per knee injury.

Hearing loss -- the cumulative effect of years of working around equipment, even with hearing protection and engineering controls, is resulting in significant hearing loss in aging employees. Much hearing protection is cumbersome and unclean in a logging and firefighting environment. We also see of course hearing loss occurring -- hearing injuries occurring in young ages, but manifesting itself in degrees of hearing loss as they become older.

Among the mid-aged workforce, creating and maintaining a physical fitness in wild land firefighters and natural resources workers is more and more an issue for us. While vehicles and equipment are great, there are many places where fire engines and bulldozers can't go.

In government, managers don't know if they can justify fitness programs and gym memberships to the taxpayer. However, many tasks in natural resources environment require a high level of physical fitness. Objective research is needed to show if there is a value of on-the-job fitness programs on injury prevention, productivity, and sick leave reduction.

Ideally this research would identify the most effective fitness and conditioning programs for those people who must do arduous work. This research would follow up on current NORA research projects on aging effects and intermittent work capacity, effects on physical conditioning on lifting biometrics, and evaluating the effectiveness of the logger safety training program.

The last -- the new workforce, the upcoming workforce I call weak, fat, and electronic. In years past, natural resources employers often hired children of loggers, farmers and fishermen. The young population -- this young population is shrinking and being replaced by young adults who are great with the joy stick, but have never used a chain saw. They can operate an iPod, but they don't know what a manual transmission is. And more and more of them are overweight with asthma or diabetes. What medical exams or fitness tests are best at identifying the fitness of applicants?

As much as our young culture becomes more high tech, how do we teach arduous, hand-labor skills like digging a fire trail or operating a chain saw to remove downed trees?

Lastly I'd like NORA to do a better job of marketing the results of your research. We need to implement the findings of many NORA research projects by sharing the results with employers. On the web I found many NORA research projects that apply to my workplace, but I could not find many results or implementation strategies to apply in the woods.

Thank you very much.

Verbal Comment 2006/01/17: Thank you very much for inviting me here and for putting me at the end. We've been waiting for my colleague, Guillermo Torres, who had car trouble, but he never showed up, so I'm just going to have to speak on both of our behalf. I am the Executive Director of CASA Latina, and we're a community-based organization that educates and organizes low-wage workers -- mainly low-wage immigrant workers. We've had a day labor center for immigrant day laborers that we've been operating for seven years. We're also a member of the National Network of Day Labor Organizers, which is a national organization that includes 30 different organizations around the country located in 12 different states.

Our experience is typical of all of these organizations. We were formed in response to the growing number of day laborers gathering on the streets to be picked up by contractors that need them for home renovations and residential construction, and homeowners that need help with their gardening or any other type of home improvement projects.

We have -- we started to organize this underground economy to provide more protection to the workers, as well as to address public safety issues related to unorganized laborers using the public sidewalks as a hiring hall. We see over 1,000 day laborers who register at our center per year in Seattle. In addition, there are at least 500 who never register at our center and prefer to work on their own on the outside -- on the sidewalks surrounding the center, or in different Home Depots in the area.

It's very hard for us to measure the number of day laborers who are working outside of our center, but we know that it's growing because more and more places have sprung up as pickup sites. A few years

ago, there was -- all of the pickup was done in the Belltown* area, and now there are pickup sites in several Home Depots around the area. And in one Home Depot in the Soto* area, there's 50 to 75 workers that gather there daily.

And these day laborers form a growing and significant sector in the labor force; however, they operate in an underground economy where few records are kept.

Workplace injuries are very common. We see people with bad backs, cut fingers, cuts on their legs, et cetera, and we know anecdotally that most day laborers receive very little safety training on the job. When they're hired for one day or two days, the -- their employers -- doesn't waste any of that time giving them any safety training. And many times they're left alone unsupervised.

Often they're expected to complete work for which they've had little or no training, and they're not able to do it. Part of this is because they say that they know how to do something just to get the job, when they actually have never had any experience doing it. And if safety equipment is available, they often don't use it since there's very little supervision. And culturally they don't have the experience of using that safety equipment in their own countries even if they have had experience doing that type of work before.

This is a huge unregulated field where little data is available, so it's very difficult to determine the proper remedies. Because the problems are undocumented and therefore it's so invisible, it's very hard for us to get resources to address these problems.

We need research on the extent of safety training and workplace injuries of day laborers, and particularly on immigrant day laborers. Thank you very much.

Verbal Comment 2006/01/17: Well, I'll try not to get this started off wrong and be tackled up here the first -- first subject. Good afternoon. My name is Shari Kuther, and I am here to represent the Progressive Agriculture Safety Day Program and its governing body, the nonprofit Progressive Agriculture Foundation.

The Progress Agriculture Safety Day Program trains local volunteers and provides the resources needed to conduct one-day, hands-on, age-appropriate community-based safety days for children. This program relies completely on corporate sponsors, such as Farm Plan, Bear*, Case, IH, and it reaches children throughout the United States, its territories, and into Canada.

I have actually been involved in the program since 1998 when I first applied to begin coordinating a safety day for my community in Nezperce, Idaho. We're proud that since its inception in 1995, more than half a million children and adults have participated in this program.

Representing the Progressive Agriculture Safety Day Program as a volunteer coordinator, I'd like to tell you how my community and others involved in this international program have benefited from several NIOSH-funded initiatives.

First of all, in 2002 NIOSH funding was awarded to the University of Alabama's Institute for Social Science Research to evaluate the program, which was at that time called the Progressive Farmer Farm Safety Day Program. My community was one of 28 involved in this study. At the same time, funding was awarded to the University of Kentucky College of Nursing to evaluate similar programs. These

studies have -- results have demonstrated that our programs have a positive impact on children's knowledge, attitudes, and behaviors.

Also, the Progressive Agriculture Safety Days have benefited from NIOSH-funded materials and program developed by the National Children's Center in Wisconsin. First of those that we use is the North American Guidelines for Children's Agricultural Tasks, also known as the NAGCAT Guidelines; Safe play areas on the farms, a review of child safety -- a review of the child safety section of the National Agriculture Safety Database or NASD; and also the multi-organization Childhood Agricultural Safety Network. Many grants awarded to various recipients through the National Children's Center have also allowed our staff to develop and/or evaluate new lessons and guidelines, such as reaching migrant farm worker children, evaluating the age appropriateness of the program curriculum, reaching old order in a Baptist populations, and developing a variety of teaching resources. All of the evaluations and projects that I've just listed would not have been available to our programs or to my community without the funding provided by NIOSH.

At the same time NIOSH has probably funded many other research studies having implications for our program, and we need further guidance in using these results. We do greatly appreciate NIOSH support.

Thanks to NIOSH we have made progress in teaching children to safe on farms located across North America. However there's still much to be done. We urge that NIOSH funding be targeted toward continued evaluation of programs such as ours that rely on corporate donations. There should be greater collaboration and advanced planning between NIOSH and other federal agencies, such as USDA, the Department of Education, and the Maternal and Child Health Bureau. For example, both NIOSH and USDA funded separate evaluations of tractor certification programs.

Lastly we request that funding be available directly to nonprofit organizations, such as the Progressive Agricultural Safety Day and Farm Safety for Just Kids. These organizations have the capability and track record of incorporating NIOSH-funded research results into grass roots level programs that fulfill NIOSH's research to practice goal. Thank you.

Verbal Comment 2006/01/17: You actually pronounced it like they do in Montreal, which is refreshing. It's great. Here we say Dansereau. I am Carol Dansereau.

I'm with the Farm Worker Pesticide Project, which is a nonprofit directed by farm workers and their allies. And I want to urge that high priority be given to increasing research on farm worker pesticide issues. Certainly the huge number of workers affected, the high toxicity of the chemicals involved, both in terms of acute and chronic effects, and the documentation of (unintelligible) exposures warrants this priority. That documentation includes extensive urine and dust sampling, air monitoring in California, pesticide instant reporting; focus groups with farm workers here in our state that found that three out of four experience health effects from pesticides at work, but most of that is not reported; and our cutting-edge cholinesterase monitoring program, which you're probably familiar with. But in its first year, two years ago, one of five of the workers who were monitored had the significant depressions of cholinesterase after handling the pesticides. This last year, with a wider pool of workers, it's one in ten, though the majority of workers have depressions after they start handling.

I want to highlight two specific research needs. One is related to exposure monitoring. We have lots of general information about exposures happening. We have the cholinesterase monitoring evidence of actual physiological changes from exposures. But what we don't have is exposure monitoring itself that shows the concentrations of chemicals to which workers are being exposed.

It's very important to pay attention to the California air monitoring and the results down there. The California researchers have found that very high percentages of the general population are inhaling agricultural pesticides in concentrations that exceed health guidelines, and they warn that farm workers are almost certainly inhaling at much greater rates.

So we want to see research that focuses on collecting this kind of data, which is sorely missed in the policy discussions that we're having. We also want the research to target identifying what sorts of exposure methods there are so that governments can establish the kind of monitoring that we should be having as a matter of course in these workplaces.

And it is ironic to me that we have in other workplaces, industrial workplaces, air monitoring, exposure monitoring, as a given where we're talking about relatively small concentrations of chemicals and unintentional byproducts of manufacturing in general. Whereas in this workplace we have intentional massive direct releases right next to workers, and yet we have no monitoring.

Categorized comment or partial comment:

The second research area that I want to highlight is the need for research related to pregnant farm workers. The terrible events in southern Florida with the severe birth defects of farm worker children have spotlighted this issue over the last year. I want to mention that I work with farm workers in Mattawa, a small town here, who are deeply concerned about the very high levels of cancer in their children. Now we have no idea whether the birth defects in Florida, the cancers in the children in Mattawa are caused by pesticide exposures, but there is every reason to believe that pesticide exposures are causing health effects, birth defects, cancers, other health effects in some farm worker children.

Because of the toxicity data that exists for the chemicals that we are dealing with here and because we know exposures are happening, we need to focus on this very vulnerable population and be gathering information such as how many pregnant farm workers are there, what kinds of concentrations are they being exposed to, and what does that mean for their fetuses and embryos. And as we do that, we need to use things like focus groups and forums in which farm workers can speak freely.

I'm sure I'm almost done with my time so I will end by asking that the research institutions here, NIOSH and others, and the researchers also take seriously the need to go beyond the research and to leverage action. And in particular, I would urge you to advocate government-mandated exposure monitoring and collection of data that is sorely missing in this area. Please speak out for air monitoring and other exposure monitoring in this workplace, which is lacking in this workplace and that's really a travesty. Speak out for national cholinesterase monitoring, pesticide use reporting, and other data collection.

And also I would urge you to speak for the precautionary principle. If ever there is a time to break the silence and speak about the need for precaution and advancing sustainable agricultural alternatives to end these exposures, this is the scenario because we are talking about highly toxic chemicals. We are talking about documented exposures. And we are talking about exposures not only for farm workers but for their extremely vulnerable children.

Thank you.

Verbal Comment 2006/01/17: Good afternoon. Thank you very much for this opportunity to speak here today. Most people who know me know that I can't say anything in five minutes, so I want to thank Sharon Morris for slicing and dicing some of this, so -- sorry if I go over a little bit. I'm speaking this afternoon on protecting young workers. Those are the folks under 18, who are our future adult workforce. I'll begin with some general comments about young workers in all industries, and then continue regarding youth working in agriculture.

While focusing on issues of a specific industry, it's important not to lose track of the cross-cutting issues unique to this special and vulnerable population, regardless of industry sector, and the subgroups within them such as immigrant workers. When I began working at the Washington State Department of Labor and Industries in 1991, I was assigned to work on an advisory group to update our non-agricultural child labor regulations; the agricultural regulations had already been updated in the previous couple of years. My first question to ask was where is the data to tell us where these kids are getting injured or killed? Where are they working?

That set me on the path I continue today to look at data trends beginning in 1988 to the present in our workers compensation program, as well as searching the literature for others doing this work. The field at that time was quite limited. In addition, at that time health and safety professionals did not really consider the issues facing young workers typically, nor did those in pediatric or adolescent injury

prevention acknowledge that work was an important contributor to morbidity and mortality. We spent years trying to blend these disciplines.

I want to acknowledge the remarkable work that NIOSH has done to bring us to where we are today regarding the body of knowledge about teen workers. As a result we can proceed with new directions in addressing causes of injuries and prevention strategies. We've identified a great deal about the patterns of injuries and where they are happening, but not necessarily the why or the how to fully prevent them from happening in the first place.

My initial thought when I first began working in this arena is what could be more mom or dad and apple pie than keeping kids in school and keeping them from getting injured or killed at work. After all, isn't their primary job supposed to be getting a basic education to be able to have more job and career options available to them.

My next realization when I started to look at the data and the literature was dismay at how many were getting injured, and often severely and even killed. I work in a regulatory arena, and jurisdiction is an issue that determines where youth can and cannot work and when. And so protecting them becomes a political issue no different than for adults. However, I believe youth are different and deserve special protections by those who claim to be responsible for their well-being. That would be all of us.

Risk to youth should be addressed regardless of industry and irrespective of regulations. Youth face the same hazards as adults, but are at a disadvantage to protecting themselves. We know that there are different protections for teens, depending on which industries they are working in. In agricultural settings teens can do far more dangerous activities and at a younger age than they can do in non-agriculture. On a family farm there are no protections in the form of work restrictions, unlike non-agricultural family businesses. Teens under the age of 18 have been found to be injured at a rate two times higher than adults.

A majority of the injuries may be minor, so to speak -- lacerations, strains and sprains, and contusions and burns. However, many that I have found in this state have been amputations, concussions, dislocations, fractures, head injuries, and multiple injuries, injuries with potential to have severe long-term consequences. Like adults most of the claims cover medical costs only -- approximately 85 percent for medical costs, 15 percent for lost work time. But to qualify for work -- lost work time or time loss payments, the injured worker must have a specific number of days lost. Here in Washington that's three days; elsewhere it may be more.

However, we cannot compare the severity of these injuries between youth and adults. Youth do not work in the same pattern as adults. They do not work consecutive days. So if you think about it and they lose three days of work, that may mean a more severe injury because they're not working full-time. And then they are missing more, just as important, age-appropriate activities such as school, sports, extracurricular activities and the like.

There is little or no data on the consequences of these early work experiences -- experience injuries, either in terms of their psychological impact including their general attitudes about work and risk, the effect on their future career options and potential loss of earning power, and long-term disability and associated costs. We need more research in this area.

We in Washington State have an amazing database on our workers comp claims with the majority of Washington employers insured through the state fund and managed by labor and industries. It's an important database that can point us in the right direction, but it has limited -- it has limitations.

There is under-reporting. Teens may not -- may be working informally and therefore not come to the attention of the system. This is a particular concern when young workers -- by my anecdotal evidence and talking to hundreds of teens over the years -- is that they -- they are unaware of their right to file workers compensation claims. Given that a large proportion of youth are uninsured, teens need workers compensation to be able to access appropriate care for occupational injury as soon as possible to mitigate the severity and complication.

David L. Hard, Ph.D.

Agricultural Safety and Health Scientist

NIOSH/DSR/AFEB

Morgantown, WV 26505

Comments provided at an internal NIOSH NORA 2 forum March 21, 2006, Morgantown, WV.

I am speaking today regarding the Agriculture industry, North American Industry Classification System (NAICS) code 11. In order to assure that the NORA 2 priorities are data driven, I will attempt to provide some data for this industry. What I provide is not comprehensive, but it is compelling.

For 2004, the latest year that data is available from the Bureau of Labor Statistics (BLS), their released "National Census of Fatal Occupational Injuries in 2004" (CFOI) reports that the Agriculture, forestry, fishing & hunting industry had the highest fatality rate among all the industrial sectors with 30.1 deaths/100,000 workers. Mining came in second (28.3 deaths) followed by the Transportation and warehousing sector (17.8). This compares to an all industry average rate of 4.1/100,000 workers.¹ The Agriculture industry's rate is over seven times (7.3) the industry average.

The Agriculture, forestry, fishing and hunting industry was ranked 3rd in the total number of deaths (659). Construction was ranked first (1,224) followed by the Transportation and warehousing sector (829). Mining had 152 deaths and was ranked 12/15 industry sectors.²

Speaking of mining (and since we're in WV), the Sago mine tragedy is still fresh in our minds, even though it is beginning to fade from the headlines. This calamity took the lives of 12 men in a close knit mining community not far from here. There was an outcry by news commentators and editorial writers about the "human cost" of coal as an energy source. However, can you imagine the outcry if farmers were to die in groups of 12? The Agriculture sector could sustain that number every week (12 deaths a week) for a year and still be under the 2004 total number of fatalities (624 vs 659). But these deaths do not generally happen in groups and thus escape the national media, even though they appear all too often as single incidents in our nations local newspapers. The point I wish to make is that there also is a "human cost" to the most basic of our human necessities, food. We must not forget this point.

Within the industry of Agriculture, crop and livestock production (which most closely parallels the occupation of farming) accounts for 70% (458/659) of the deaths in the agriculture, forestry, fishing and hunting sector. Surveillance studies have shown there are high fatality rates for older agricultural production workers (those older than 64 years of age) along with higher numbers of deaths for these older workers. A 2001 study of 7 years of CFOI data found these older agricultural production workers had a fatality rate of 65.9/100,000 which was 2-3 times the rate of other agricultural production age groups and 13 times higher than the national average (5.0/100,000). Also, these older agricultural production workers incurred 2-4 times the number of deaths of their younger agricultural production age groups.³

Additionally, young agricultural workers are at increased risk, too. The youth who work on farms face unique risks which are not present for many other young workers. These include machinery, large animals, electrical hazards, chemical hazards and excessive noise. From 1992-2002, the agriculture production workforce 15-19 years of age comprised 7.1% of the total youth workforce (full time equivalent - FTE adjusted) but incurred 15.8% of all the fatalities. For workers under 16 years of age, the agriculture production sector accounted for 60% of the deaths, and for workers 10 years of age and younger, the agriculture production sector accounted for 79% of all the deaths. The highest fatality rate for this time period among young agriculture production workers was for 15 year olds (18.5/100,000). The rates for young agriculture production workers was 3.6 times higher than their counterparts in all other industries.⁴

For young agriculture production workers, fatality rates for the time periods 1992 – 1996 and 1997 – 2002 were calculated. In comparison to young workers in all industries, the rates were lower for all age categories (15 – 19). However, for agriculture production 3 of the 5 age categories increased during 1997 – 2002. The 15 year old rate was 24.1/100,000, an 81% increase over the 1992-1996 time period. The crop production sector had the highest occupational fatality rate among youth @52.2/100,000 (for 15 year olds) during 1997-2002. The overall rate for 15-19 year old workers in all industries decreased between the study periods while it increased for agriculture production.⁵

The previous statistics have all been fatalities. However, there have been a number of surveys conducted for non-fatal injuries which NIOSH has sponsored that indicates there is a greater percentage of injuries occurring to youth who live on farms from non-work activities.⁵ There is no other industrial sector where the workplace is also the home and leisure activity area for the worker and his family. This provides for some unique and complex situations which have to be understood and addressed in order to reduce the unacceptably high numbers and rates of agricultural injuries and deaths.

Let me conclude by noting that the Agriculture industry consistently ranks high in both the rate and number of occupational fatalities. It is an industry sector which warrants priority funding and our attention and efforts in order to alleviate this situation. Within the agriculture production sectors, there are high rates and numbers of death for older farmers. Also, there are high fatality rates for young agricultural production workers as compared to their counterparts in all other industries. Additionally, nonfatal injuries, both work and non-work related, occur to youth who live on farms. The unique situation of working and living on farms creates many opportunities for research and intervention activities that are not found in any other industry. There is a human cost associated with the production of food in the US that I believe is at an unacceptable rate and frequency for those who work in these sectors. I would encourage you to keep this in mind as priorities are selected and put forth for the NORA 2 initiative.

Verbal Comment 2006/01/17: Mary, you`re a hard act to follow. I will try and stay under five minutes. So my name is Barbara Morrissey. I`m a toxicologist at the Washington State Department of Health, and I work in our state pesticide program which conducts surveillance for pesticide-related illnesses and injuries -- and that includes occupational and un-occupational events. I just want to thank NIOSH for funding pesticide illness surveillance in general through the former Pesticide Sensor Program and encourage your future support for this activity and also research that helps these surveillance programs evolve and continue to be relevant and collect relevant information.

Our state program is actually funded by state general fund dollars. We have not been -- we have not been a NIOSH sensor program, but we have received two grants over the years to enhance our surveillance program. One of these grants helped us identify some of the gaps in -- especially in under-reporting, and helped us settle some of the issues that we`ve had in coming up with good denominator data. And a grant that we were just awarded is going to help us dig a lot more deeper in our interview strategy and how to dig up root cause for the incidents that are occurring, and hopefully help us get a better list of risk factors and preventable causes of these illnesses.

I just want to make a few comments for why pesticide illness surveillance should stay on the NIOSH radar screen. One of course we`ve already heard about, that farm workers are a high-risk population, both in terms of their pesticide exposure and in terms of their ability to manage health effects. And if we want to prevent pesticide-related illness in this high-risk population, we really do need to understand how their exposures are occurring and what are -- what are the safety messages and who needs to hear them.

And one of the reasons that our public health program is really important in this area is that we get the stories that the other regulatory agencies often miss. That's because our regulatory agencies, at least in Washington, are largely complaint-driven. If a farm worker calls and reports a safety problem, then these agencies will go out and investigate. But many farm workers are unwilling to make a complaint. They are afraid they will lose their jobs. Others just may not know the workplace laws, or they may just fear speaking to anyone in the government because of their legal status.

And our program is different. If a farm worker sees a healthcare provider for a pesticide-related illness, then we're notified of that and we call them. Then we hear their story and we ask what could have prevented the exposure. We offer to report the incident to regulatory agencies, but for the most part they ask us not to, and that -- at least in this case -- in these cases, their experience is not lost because we can then take the data that we collect from them and we strip off the personal identifiers, and then we can provide that to the regulatory agencies in an aggregated way so that they still get an idea of what's happening in the field without the farm workers being put at risk for loss of their job. And then of course we also publish our data so that all of our partners can use it as well.

Just to underscore this difference in our ability to get stories, in a recent two-year period our state OSHA program at LNI investigated 30 complaints involving agricultural workers. The other regulatory agency that works in this area, the Department of Agriculture, issued violations for 23 incidents of human exposure to agricultural pesticides. And during this same time we investigated 248 cases and sufficiently documented 148 cases of illness or injury from agricultural pesticides. So the numbers aren't totally apples -- or they're a little bit apples and oranges, but I think you get the general idea.

Just a recent story -- this is a case that happened in 2005 -- to just illustrate the importance of being -- trying to be proactive and get these stories. There was a group of women told by their foreman to change the sprinkler heads on an irrigation pipe in an apple orchard. The orchard had been sprayed the day with a potent organophosphate insecticide. The re-entry level was -- the re-entry interval was 14 days so the workers should have donned their full PPE before entering the field, but they did not. There was a strong odor noted by the crew. Only one woman in the group reported symptoms, and she did seek healthcare so we found out about her. Her symptoms were not severe, but they lasted for about five days and she was pregnant. She did not want to report the incident to authorities because she lived in the orchard and the foreman was her husband.

Now in this case we had the opportunity to talk with the foreman and also the employer to make sure that the -- what was broken there would be fixed and that mistake would not happen again. Then we were also able to, again without personal identifiers, share that story with the regulatory agencies.

Am I getting close?

DR. CONWAY: You're over.

MS. MORRISSEY: I'm over.

DR. CONWAY: That was a good story. Compelling.

MS. MORRISSEY: So can I just tell you two more things? So in terms of research for --

DR. CONWAY: Two more short things.

MS. MORRISSEY: -- for NIOSH, we would really support some field research into engineering controls that will prevent exposure to farm workers, and I'll hand you the rest.

Verbal Comment 2006/01/17: Hi. Thank you for the opportunity to speak. My name is Anne Powell. I work for Northwest Regional Primary Care Association. We are a nonprofit member association of community and migrant health centers in Region 10, and that includes Alaska, Idaho, Oregon, and Washington. Just to let you know, community and migrant health centers are public and non-profit organizations that receive federal funding under the Public Health Service Act. They provide comprehensive health services that are high quality, cost-effective, and culturally appropriate to underserved communities, without regard to financial or immigration status.

My position at the Association is the migrant health coordinator so I provide resources, trainings, and do some conference planning for healthcare providers that work in those health centers. And just -- I wanted to thank NIOSH for their support with our Western Migrant Stream Forum, which is actually happening next week in Portland, Oregon starting next Friday. They fund our research and evaluation track at that conference.

So anyway, I'm here today to speak briefly about the issue of immigrant agricultural workers who migrate to Alaska, or elsewhere even, to work seasonally in the fishing and canning industries.

First I will give a brief background on farm workers, which -- I missed out on some of the talks this morning so you may already have heard some of this information, but there are an estimated three million farm workers in the United States. Within our region we have probably over 583,000 migrant seasonal farm workers. As you've heard before, they are largely Hispanic, and according to the National Agricultural Workers Survey, 81 percent of farm workers reported Spanish as their native language; 44 percent self-reported that they could not speak English at all.

So due to a combination of factors including poverty, language, and cultural barriers, low literacy, frequent mobility, and fear of the system, migrant farm workers have minimal access to healthcare and social services. So last spring, May 2005, in Anchorage, Alaska my organization, Northwest Regional Primary Care, held a organized discussion with some Alaskan healthcare providers on the issue of migrant fishery workers and cannery that also work in the lower 48 as agricultural workers, and this is basically what we found.

There`s not a lot of data on this population that is duly employed. Administrators and clinicians from migrant health centers in Washington, Oregon, and Idaho have seen these patients that -- you know, they may mention that they work -- they pick apples in Wenatchee. And then during the off season they head up to Alaska to the fisheries and maybe canning salmon in Alaska -- in Kodiak, Alaska, for example.

So they also reported that the fishery and cannery workers came from many different backgrounds and nationalities. They migrate from cities all over the United States -- cities and states all over the United States including North Carolina, Florida, California, Salt Lake City, and Seattle of course, as an example. And so I wanted to point out that a lot of these same areas have high levels of agricultural workers and agriculture industry.

So my recommendation is that there is a need for data on the number of migrant workers that work in both in agriculture and the fishery/cannery industries because both of these jobs are obviously extremely hazardous, physically demanding, and require long strenuous working hours. And they also have the potential for exploitation and can result in significant environment and occupational related injuries, such as musculoskeletal disorders.

I think this data would be useful for many reasons, but for the purpose of today`s discussion, the workers who are employed in a combination of agriculture and fishery and cannery work may have multiple or more complex occupational health problems. And these problems are likely compounded by the barriers to care that many migrating immigrant workers suffer, which I mentioned earlier.

So anyway, thank you so much for the opportunity to speak today.

Verbal Comment 2006/01/17: My name is Mike Gempler, and I'm Executive Director of the Washington Growers League in Yakima, Washington. I also serve as Vice President of the National Council of Agricultural Employers, and I also serve as the Chair of the EPA/OSHA Committee of the National Council of Agricultural Employers. And I would like to thank NIOSH and the researchers here for doing the work that they do and for working with our industry, and for the generally cooperative and collaborative attitude that we have seen put forth, especially here in Washington State. I very much appreciate that.

I would like to speak generally about a few perceptions and recommendations. First of all, our industry supports measurable results in research. We would like to see measurement of how many agricultural employees are benefiting from various types of research. We're frequently asked to support or endorse research projects or to cooperate to give access to employers in our industry. And I think a lot of the research projects kind of blend together in the minds of the employers and start to lose relevance, and I think it's a challenge before all of you to measure the impact of this research.

We will support safety research that brings results. A few of the approaches related to that. First of all, pesticides may not present a hazard that impact as large a population of employees as other hazards. It needs to be recognized. The industry feels that research on pesticides sometimes is disproportionately -

- or the research is sometimes disproportionately focused on pesticides, to the detriment of research on other hazards that may in fact affect more agricultural employees.

We think that there should be a fresh look at education and training, changing the culture of the workplace, promoting and developing a culture of safety within the agricultural workplace. It's difficult with high turnover, short duration of employment, a lot of factors. We think there's a lot to gain there.

Also research should grow with the changes in the technology of the industry. Some of that is occurring now as we're looking at picking platforms, harvest aide equipment. The new technology that's coming on line, let's make sure it's safe, let's make sure it's ergonomically appropriate, et cetera.

Research implementation approach, in addition to relevant basic research, our industry supports research that brings -- that results in practical solutions, that brings the research to the field, if you will, and implements it. In this way we can really maximize the impact on the safety of the agricultural workforce.

And lastly, communication -- communication, the way researchers communicate, it affects trust, affects cooperation, affects public policy, and affects public attitudes about all this, and especially the subjects of that research. Media releases impact our industry but not always positively. They don't, in and of themselves, necessarily change behavior or result in more safety. Sometimes they just make people mad. And I think there needs to be an examination of why media releases are issued, what purpose they serve, how it coordinates with the overall dynamic of a collaborative approach to safety, and how it relates to appropriate risk communication to the public. And I think it's a very important area that we need to explore together as we move forward. Thank you.

Verbal Comment 2006/01/17: Yeah, and I`d just like to correct that -- and thank you, you got my name right. I`m only going to be speaking on heat-related illness in the -- in looking how much time there was I didn`t feel it was appropriate to prepare for cramming those two topics together.

I work for Columbia Legal Services. Again, my name is Evi Licon. I`m a staff attorney, and I focus on issues of health and safety affecting the farm worker population in the state of Washington. I have spent some time on working on pesticide issues and Carol very adequately covered those. And I`d like to second what she had said, and really offer my support on that issue and the fact that it is a huge risk to so many workers in our state, and we really need to continue focusing on those efforts to protect workers.

What my office works on again is we do what's called impact litigation and legislation. We work on issues that affect a broad range of workers in the state of Washington. And within our own client consultations and seeing what's kind of coming in through our intake procedures, we can get a gauge of what is needed in this state, and heat-related illness has come up as a really major topic in the state.

There was a death in the summer of 2005 in the state of Washington and this issue kind of came to a head. It spurred (sic) a state agency, Labor and Industries, to do an in-depth study of accepted labor and industry workers compensation claims over the past ten years, and they've come up with a number of close to 450 claims that have been accepted. This doesn't include claims that were just filed, claims that were decided for whatever reason weren't going to be investigated. This is a widespread issue across the street -- across the state, excuse me. Labor and Industries has done a wonderful job with that study, and it indicates the need for more focus and more effort on these issues. Deaths for any reason should be unacceptable in any occupation in our state.

In light of the death that occurred in Washington, there were also six deaths that similarly occurred in the State of California. California has passed an emergency rule-making due to these heat-related deaths. And it's starting to become an issue of greater importance and an issue that's really come out into the light, so to speak, because of recent deaths unfortunately.

There are several factors that need to be looked at when you think about heat-related illness, and one of those is a provision of water by employers. Although this is already provided in the Washington Administrative Code, it is certainly not abided by by all employers. Also in the summer months, more

water needs to be -- to be going into the body to keep hydration levels appropriate. There are also needs to be access to cooled areas and shade for our workers. They also need to experience a few research -- research shows five to seven days is appropriate for an acclimatization of the workers to a hot environment. The same would go for a cold environment.

And in this case workers that are working during summer months become -- their body heat, their core temperature rises significantly, especially as in the case with Manuel Camacho* who died this past summer. He'd worked in the field for 40 years. He was wearing leather chaps and swinging a machete, cutting down weeds in the hot fields. And if there had just been a little more knowledge on the part of the worker and the supervisor to know that when you're wearing leather in a really hot temperature in a place where the air doesn't escape very easily, the heat stays in this area, they would have known that because of the fact that he wasn't sweating and he was experiencing other grave symptoms that death was upon him very shortly and -- you know, so we need education and training on the areas that need to be focused on, which is water, provisions of shade and cooled areas, training and education specifically in those areas.

And also how do you access emergency information. Do they have phone numbers where they can call?

Do they also know how to treat on a first -- I'm thinking in Spanish right now -- on a first response where you have your CPR and other issues where if they start to notice that they are experiencing these symptoms, they know how -- okay, we need to get this person to the shade, we need to take their clothes off.

They also need to be educated on what they're wearing in these fields if they're not working with pesticides, which is a separate issue. You don't want the cotton and things that really absorb the chemicals but when you're dealing with just heat and not the application of pesticides, you want to be wearing cool clothing. And some workers are more aware of these issues than others, but a lot of these workers that don't even know the English language and they're depended on to be bringing in these products for us, we need to be providing them with them with a safe environment.

Verbal Comment 2006/01/17: Thank you for giving me the opportunity to comment today. I'm a professor of pulmonary and critical care medicine in the department of internal medicine at the University of Nebraska Medical Center, and I have a long-standing interest in rural health and safety.

I would like to propose that the food processing aspect of agriculture be actually included in the agriculture sector. And I say that because the plants where meat packing occurs or other food processing are usually located in rural areas. They take the materials that are brought in from farms and turn them into what we know from the grocery store. And many of the workers are rural people. Often they also work in production agriculture.

I'd also like to point out that meat packing in particular has a very high rate of injury, both repetitive motion injury and injuries such as lacerations.

And finally many of the meat packing plant workers, and I'm sure this is true for the other aspects of food processing, have many unmet health needs. In Nebraska a large number of them are Hispanic. They do not have ready access to healthcare because many do not have health insurance. Many of the providers do not speak Spanish. And their health needs include such things as chronic illness like diabetes, also infectious diseases such as tuberculosis are on the rise again in the communities where there are a lot of immigrant people working in meat packing.

So those are my comments. Thank you.

Verbal Comment 2006/01/17: Good afternoon. I'm Paul Gunderson, a farmer on the high plains and advisory board member for the Inter-Mountain Center for Agricultural Safety and Health located in the great state of Colorado.

If you and I were to read the book entitled, *Through the Looking Glass and What Alice Found There*, by Lewis Carroll we discover that the red queen runs frantically just to stay abreast of circumstances. This futile race is suggestive I believe of the evolutionary forces that keep both pathogens and their targets on the move. Such I believe is the case with infectious zoonotic disease, largely because in our life span changes in climatic conditions and agronomic and husbandry practice have permanently altered human exposures within North American agricultural work sites. Additionally, demographic changes in the agricultural workforce in many regions of our nation has permanently altered the perception of risk by individual workers due to life experiences from abroad that are different from those here in the U.S.

Just this past summer the emergence of the B. anthracis as an infectious bacterium in cattle, cattle handlers, pen riders, and veterinarians on the northern high plains, extreme northeastern South Dakota, extreme southeastern North Dakota is a reminder of a work site risk that is perpetuated by both a profound change from cool, dry weather to warm, moist conditions on the northern high plains, and changes in agricultural technologies which I submit (unintelligible) by a geographic diaspora. These are also due to workforce interactions that are changing with livestock and the emerging concentration of livestock enterprises.

And if anthrax weren't enough, we have other examples -- Q fever, several of the hantaviruses, swine brucellosis, and tsutsukans disease or T fever. Because these infectious diseases occur in populations exposed to agricultural risk they're quite likely to go unrecognized, at least initially, and under-reported in this nation's disease reporting networks. That's true because these networks are notoriously unable to capture these kinds of phenomena, and in the written comments I'll detail that in more -- more adequately.

As a nation it's my postulate that we can do better, and NIOSH is in a unique and favored position to promote resurgence of our nation's capability to detect and interdict these kinds of infectious zoonotic outbreaks. NIOSH could encourage its funded agricultural centers to focus some resources, first of all on target local surveillance tests within selected high-risk agricultural settings. Secondly, NIOSH could develop additional laboratory capability which would be in a position to make critical detection. And thirdly, NIOSH could develop field-tested educational materials for (unintelligible) centers to do that, materials and strategies for use by working agricultural populations and perhaps even clinicians who are responsible for their healthcare.

Additionally, NIOSH itself needs to hold onto its current laboratory capability as well as its occupational hygiene capacity so that it stands ready to assist state public health departments, local public health agencies, and perhaps local medical facilities and veterinarians in interdicting zoonotic disease. It's important to prevent spread and identify opportunities for its prevention at the agricultural work site and surrounding environs, in part because of the infectivity associated with some of these agents.

Included for NIOSH could be new laboratory and field-base detection capability, as well as development of new assays; laboratory assurance and certification activities and development of training materials for laboratory technologists.

Thank you for the opportunity this afternoon. It's always fun to appear before colleagues.

Verbal Comment 2006/01/17: I`m Betty Ann Cohen. I`m a physician with Central Washington Occupational Medicine so I`m in Yakima. I`m in the middle of the agricultural communities there. And one of the things that -- you know, the Holy Grail of occupational health is prevention. We don`t want people getting injured. But the truth is we can -- we can go for that goal of zero, but across all industries, we`re not going to reach zero. And I think one of the things that needs to be addressed is how are these people educated and taken care of after they are injured.

There`s a huge lack of information amongst the physicians and clinicians out there providing care to these people. They`re not informed in a way that helps them to get better, that helps them to get back to work, and there`s a lot of research that could be done in this area. Thank you.

Verbal Comment 2006/01/17: Thank you, George, and thank you to NIOSH and the Northwest Center for convening us to provide input and to exchange ideas, which is a wonderful forum. So greetings from New England. Do I get the prize for coming the farthest? I hope so, and so my name is Ann Backus. I'm an instructor in occupational safety and health at the Harvard School of Public Health and director of outreach there in the Harvard ERC.

Over the past five years I have worked with the fishing community and the U.S. Coast Guard in New England, and organized with George and the NIOSH Alaska Field Station Anchorage the first International Fishing Industry Safety and Health Conference, which was held in Woods Hole in 2000. And I currently write for Commercial Fisheries News a column called "Fish Safe", which appears every month or every couple of months. And also I'm an active member of the Maine Commercial Fishing Safety Advisory Council which -- the members of which are appointed by Governor Baldacci.

I bring you comments from a variety of people of the Harvard School of Public Health and from the fishing community. I would like to make five points, and many of them you've heard from Jerry and Ken this morning, so I want to echo the importance of their remarks as well.

Number one, the NIOSH-funded centers are a very important infrastructure and funding source for research and agriculture and fishing sectors.

Number two, there's a need for generic, which I'll -- what I'm calling generic research -- research agenda that crosses the industries within this sector.

Three, there's a need for fishery-specific research to reduce traumatic injury and fatalities.

Four, there's a need for research on exposures of bacterial origin and associated antibiotic resistance.

And five, there's a need for toxicological research on pesticides, volatile organic compounds, hydrogen sulfide and other compounds and chemicals that revisits the (unintelligible) and time-weighted averages and brings them into line with exposure levels and types in today's workplaces.

First infrastructure, so the NIOSH-funded education and research centers, of which I'm one -- an employee -- and the centers for agricultural disease, injury research, education, and prevention are extremely important, especially for the success of research in rural and non-urban settings such as farms, forests, and coastal villages. The ability of our researchers to gain the confidence of prospective research subjects and to be seen as having a substantive hypothesis, integrity relative to the research process, and competence for the analysis and interpretation of research is greatly enhanced and supported by the presence of these centers and by coming from them.

Melissa Perry, who is a colleague of mine, is doing hearing loss research in the Vermont farms, and I've been doing some work with the fishing community. Both of us have been funded by NIOSH pilot project money.

In terms of NORA research areas, the area I called generic, some of the research needed is common to agriculture and fishing. One, work-related hearing loss from exposures to tractors, conveyors, engines, and winches; two, particulate matter, PM 2.5, and ultra-fines associated with grain dust and pot buoy sanding and branding; three, polycyclic aromatic hydrocarbons, PHs from diesel exhaust and heat-branding styrofoam pot buoys; four, endotoxin from cotton, grains, and algae-covered rope; and five, volatile organic compounds such as paints, degreasers, and solvents.

In both industries -- that is agriculture and fishing -- there is a major concern about child labor and childhood exposures. Kids on farms and in fishing communities are often pressed into service at an early age. And very young children -- in the fishing communities, anyway -- are often in their parents' workshops working right alongside the sanding and heat-branding of styrofoam pot buoys and the painting and being exposed to particulates, PAHs, VOCs, and endotoxins. High school students who are apprentices often sleep above the workshop and are exposed during the night as well.

Is that a one-minute sign already? Okay.

So fishery-specific work is very important and the work platform, as Jerry Dzigan told us this morning, is very dynamic in the fishing industry so we need fishery-specific research to help us understand that work platform.

In terms of the biologics, the warming of the oceans, bacterial infections once confined to tropical latitudes are going to be with us in the temperate zones. And we have had deaths -- one death, anyway -- in Chesapeake Bay from vibrio vulnificus, which is an exposure that we noticed was in the Gulf Coast during Hurricane Katrina.

And in terms of toxicology, the researchers at the Harvard School of Public Health are very interested in having this be a decade in which we relook at the (unintelligible) and TWAs and try to put those in line

with what`s happening in terms of the current day technology and research on low level exposures. So thank you very much.

Verbal Comment 2006/01/17: Thank you. I'd like to thank NIOSH for the opportunity to talk today and also to work with you over the last five years on your deck safety project. I'm a naval architect, which means that I provide engineering work to boat owners. My company works with the majority of the Bering Sea fishing fleet that is based in Seattle. There's an awful lot of boats here that go up to fish up there and then come back in the off seasons.

We've heard a lot about issues earlier. Two I'd like to focus on are traumatic injury and fatigue. And then I have a couple of other items to talk about as well.

When we talk about traumatic injury, one thing to remember is that these are distant water fleets. If somebody's hurt on a boat in the Bering Sea, if they're lucky there'll be Coast Guard fixed-wing plane overhead in about three hours. If they're -- the nearest person with first-aid treatment on Coast Guard cutter or helicopter may be six to 12 hours away. The nearest hospital may be a day. So we're talking -- a traumatic injury that may be painful and causing damage locally when you're near a hospital could be disabling when you're out on the ocean.

My last comment is that if you`re providing anything to an industry, it needs to be in the language that the industry can understand. Most of the people in this room are scientists and you can -- it`s really easy to talk to scientists. It`s easy to talk -- for an engineer to talk to engineers. What we need to do is learn to talk to the workers.

Thank you.

The other issue is fatigue. On one of the boats I was on, the crew told me the captain's really nice to us; we sleep four hours a night. They had about three half-hour breaks for meals in there; the rest of the time they were working doing heavy manual labor.

Categorized comment or partial comment:

Now onto the other issues, the first of them is stability. About half of the fatalities on board fishing vessels are from stability issues, whether because the boat capsizes and rolls over; or because of watertight integrity, the boat floods, the water gets where it's not suppose to be and the boat goes down. We need to focus on training as far as making sure the people are following their stability booklets.

We also need to make sure that stability instructions are within the reach of the fishing vessel owners. We heard Ken Laurencen this morning talk about how he has about 2,000 fishing boats in his district. Virtually none of those boats has any kind of engineering plans that we can use to develop stability instructions. If we have to do a stability tests on those boats so that we can give them instructions, we have to recreate those plans. And that drives the cost of the stability tests and instructions up to about the same as it would be for a factory trawler. So the cost of stability instructions for a 50-foot boat is about the same as it is for a 300-foot factory trawler.

And I don't know how you tell -- I've had people who say to me I can't afford that; I'm sorry. And we have to say I'm sorry, we can't do it for less money than that. We can't give you a good answer. There are probably ways we can get that within -- the stability instructions within their reach, and we need to look into how we can do that.

Another third of the fishing vessel fatalities are from man-overboard incidents. NIOSH has done some research on factors that influence survival of crew members once they go in the water. But there's been little research into what separates the near-miss from the accident, and even less research into what

separates the accident from the fatality. Knowing these differences is key to reducing the fatalities from man-overboards.

Finally, we also heard about the issues of using high-tech fiber ropes in -- from the people in the forestry industry. These are also moving into the fishing industry. But one of the problems is that there's no retirement criteria for these ropes. And on fishing boats these could be lifting anywhere from 10,000 to 200,000 pounds. They're under a lot of strain and if they break and there's someone in the way, there's going to be an injury or fatality. Right now the only way to look at whether these boats (sic) need to be retired and replaced is a guy looking on and saying yeah, that looks like it's okay. That's not going to do it, especially with fishermen who are known for reusing things well beyond when they're supposed to be. We need to do some research into when we should be replacing these -- these ropes and when they need -- if they can be spliced, if they can be repaired, or a -- damage means that they just need to be replaced.

Verbal Comment 2006/01/17: Well, thank you, and indeed INND is the Institute for Neurotoxicology and Neurological Disorders. INND is much easier. So thank you very much for having me here, and I wanted to thank NIOSH and the other representatives for coming here and listening to us.

Like I said, my name is Stephen Gilbert. I have a PhD. in toxicology. My research and professional activities are focused on ensuring that people live and work in environments that allow them to reach and maintain their full potential. In addition to be a researcher, I've owned and operated a biopharmaceutical contract research company, so I'm very familiar with a lot of OSHA and NIOSH regulations, which is very good, very helpful. And I'm currently an affiliate associate faculty member at the University of Washington. I left my full-time academic pursuits, in part because I wanted to put more effort into translating research findings into policies and practice that protect public health. You know, for example, advances in the knowledge about the adverse health effects of low-level lead exposure have implications not only for our children, but for also workers in the lead industry. Lowering the Center for Disease Control blood lead action level from 10 micrograms per dust liter reflecting the current scientific understanding of the effects of lead on childhood learning has implications for lead industry workers and take-home. It's a great example of translating our scientific knowledge into relevant policy matters, and it's real interesting that it's not happening.

I'm also a member of the Washington State Pesticide Incident Report and Tracking Panel, commonly referred to as PIRT. The PIRT Panel was formed to ensure that the state agencies responsible for pesticide regulation coordinate their incident investigation reporting and educational activities in a timely manner to protect worker and public from pesticide misuse. Mostly recently Washington state -- and you heard a little bit about this -- established a cholinesterase monitoring program for farm workers exposed to pesticides, and found that a significant number had depressed cholinesterase levels. A number of commonly-used natural and synthetic pesticides, and indeed weapons-grade nerve gases work by blocking the activity of cholinesterase, which is essential for normal nervous system function. (Unintelligible) monitoring effort demonstrated that some workers are being exposed to pesticides despite applications, regulation, and efforts to reduce exposure and spray drift. The unintentional exposure to pesticides from drift following aerial and ground-based applications are of particular concern to applicant workers, communities, homes, and schools. Policy makers, such as the PIRT Panel or the Washington State Legislature and DR agencies, need more information on the (unintelligible) of exposures, such as the work done by Drs. Rich Fenske and Michael Yoth* at the University of Washington, which examined community exposure to pesticide drift. We need to know how to translate this research into best practices and to evaluate the effectiveness of regulations and guidelines once they're in operation.

NIOSH has an important role to play in encouraging research in program evaluation methodology, translating research to best practice techniques, and procedures that can be implemented to reduce or eliminate exposure.

The challenge of pesticides is evident in that there are about 900 pesticide active ingredients currently registered. Approximately 88 million pounds of active ingredients were used in the United States in 2001. Our experience with pesticides indicates that NIOSH should invest in research that moves beyond the classic risk-assessment approach to ensure workers' safety and community health and safety. NIOSH can be a leader in the paradigm shift away from the standard hazard evaluation toward research and effective exposure prevention. Workers and community members receive multiple chemical exposures that are not well characterized by the classic hazard and risk-assessment approach. The uncertainties related to the hazards of multiple chemical exposures will not resolve soon, which argues for preventive approach. We have a vast amount of knowledge from the biological and toxicological sciences. We need to heed the lessons learned and take a precautionary approach to pesticide as well as the potent compounds, such as those emerging from the biopharmaceutical industries and more recently from the nanotechnology materials. So I think we have a lot of work to do, and I really think we need to work on translating research into good best practices and prevention in this area. Thank you very much.

Pesticides Stewardship and Pesticide Worker Safety Programs in the Office of Pesticide Programs of EPA

Categorized comment or partial comment:

Verbal Comment 2006/01/17: My name is Kevin Keaney. I'm the chief of the Pesticides Stewardship and Pesticide Worker Safety Programs in the office of pesticide programs in EPA headquarters. The office of pesticide programs headquarters is a 900-person -- has a 900-person staff, which I think would indicate the importance that the agency places on concerns related to the use of pesticides, the safe use of pesticides. This program also has staff in ten regional offices.

My particular focus in our group's focus is driven by two regulations -- three regulations, I'm sorry. One a recent regulation related to pesticide containers and containment, a soon-to-be-proposed regulation on pesticide recycling, and two regulations that focus on the span of labor that work with and around pesticides and the health implications that are inherent in working with and around pesticides. The regulation governing the agricultural worker protection, the field worker, and the regulation that tries to establish standards for certification of competency of pesticide applicators.

We also have an aggressive grant initiative in the healthcare provider arena to better prepare healthcare providers to recognize and manage pesticide poisonings and to gain information from the field clinician level of the effects of working with and around pesticides.

My remarks today are focused primarily on the practice aspect of research to practice. And I would like the theme that NIOSH and those here would carry away would be the more aggressive collaboration between agencies on -- in these areas and capitalizing on scarce resources to better effect the changes that we think would be necessary to better protect human health and the environment.

We are about the business in my office of trying to establish competencies, competencies for applicators, competencies for workers, and competencies for healthcare providers that have to deal with both of these segments of labor. We do support financially a number of NIOSH projects. We are in a long-term grant relationship with -- recently established a long-term grant relationship with PNASH to better affect the way healthcare providers are trained and to establish essentially champions in the area of public health for better training in the awareness -- the raising of awareness of how to deal with the implications of working with pesticides.

We also support the Migrant Clinicians Network that you'll hear a spokesman for later today in their efforts to bring tools that would be developed and awarenesses that would be developed to the clinician level and feedback that information to us in the pesticide program.

What I work with are field programs, and the value of field programs is the information that can be brought back into the agency so that the registration of pesticides and the specific directions of use for pesticides and the mitigation measures that are incorporated in the training for pesticide users can be more realistically shaped and functioned by the field information that we get. To that extent we help, through an inter-agency agreement, the funding of the sensor network, the Sentinel Event Notification System of Occupational Risks, and the pesticide aspect of that. And we would -- we heartily endorse that project and are committed to funding -- helping fund the expansion of that project so that at some point we can have SENSOR network information coming from the agricultural -- the states where there is high labor working with and around pesticides. and we can get a better sense of the actual incident -- incident picture in the country, which we don't have at the moment, and we can use that then to better regulate pesticides.

We also have an extensive training network that we've established through grants under the umbrella of AmeriCorp. We have safety trainers -- bilingual safety trainers dealing with agricultural workers in a way that provides them with the basic principles of safety so that they can help protect themselves, but also tries to engage them in ways that would make them active participants in a safety net of safety training, safety -- safe clinicians services, and so forth. We would benefit by research in that area from NIOSH into methods that would better reach this -- into this community, it's a challenge, as -- as many of you know, the nature of the agricultural workforce is varied from the migrants coming in to work a seasonal -- a seasonal session to the resident labor to the fairly sophisticated applicators in aerial settings and ground rig settings. So it's a challenge to reach into that community and actively engage them in the matter of protecting themselves and by protecting themselves protecting human health and the environment.

So I would heartily endorse your move to bring research to practice, and we should be more aggressively collaborating in these -- in these efforts, and I hope that we will.

Cooperative State Research Education Extension Service through the Department of Agriculture

Categorized comment or partial comment:

Verbal Comment 2006/01/17: Thank you. I've got a lot more things to say than I have time for, which is why I've given you the comments there. I'm Mitch Ricketts. I am a Certified Safety Professional. I work for Kansas State University Research and Extension. One of the things that I would like to say -- and I think we probably all know it but maybe don't think about it enough -- is that there is a real disconnect between the way that we think and the way many farmers think, particularly in terms of safety and health. And to illustrate that I want to tell you a little bit of a story.

Last summer an agricultural worker that I know was using a PTO-driven auger to transfer soybeans from a grain bin into a truck. He and his coworkers started the auger and soon they found that it was not quite in the right position to dump the grain into the truck. They were in a hurry so rather than shutting off the PTO, the man in charge -- who was a middle-aged worker; he's about my same age, he had done this work all his life -- without shutting the power off, he leaned over the auger to try and move it by hand.

Now this same worker -- about a week before a pin had sheared off the drive on this auger and about a week before he had taken the shield off and he replaced the pin with a long bolt, and he didn't have time to put the shield back on. So as you can imagine, he went to lean over the auger and as he did, the bolt grabbed his clothing -- I wasn't there, but there were two witnesses and what they told me is it flipped him head over heels and slammed him against the ground. Then something very fortunate happened, which probably saved his life. The auger ripped his clothing completely off. Had it not done

that it would have wound him up in there, and he probably would have been crushed or suffocated. To give you an idea of the power of this auger, he was fully clothed before this happened, but when he ended up on the ground he had two things on. One was the collar of his tee shirt -- not the rest of the tee shirt -- and the other was his left boot. Okay? Everything else was gone, everything but the collar of the tee shirt. He tells us he was wearing underwear and even those weren't there anymore. But that probably saved his life.

This -- as I said, this was a very experienced worker. He never would have let his employees do that. He knew better than to do that. As I visited with him the next week, you know, I asked him what -- what can we do to make sure that this sort of thing doesn't happen in the future, and he told us the kind of things that I'm sure every one of you in here have heard. He said, you know agriculture is a very dangerous business. He said sometimes we have to take risks in order to get our work done. Most of us would not agree with that. Most of us believe that there's no job worth risking our -- our health for in order to get the work done.

So I think the safety culture in agriculture is something that we really need to work on. One of the questions is how -- how can we deal with the safety culture among farmers. I think the only way that we're ever effectively going to do that is if we enlist farmers and laborers to help us -- or to help develop approaches that are practical and profitable in their own workplaces. Farmers are not going to adopt methods unless those methods make sense to them. It's not enough for those safety methods to make sense to us. Farmers will not adopt new methods for improving safety unless those methods are also efficient, profitable, and realistic in relation to the goals and resources on the farm.

In that regard, I would like to encourage NIOSH through NORA to encourage more partnerships with the agencies and organizations that are already set up to work with agriculture. In particular, the Cooperative State Research Education Extension Service through the Department of Agriculture has a system of local extension offices, experiment stations, and land grant universities throughout the United States. I know in Kansas, the state that I'm from, we have agents in every county of the state, and I think -- I think most states are like that as well. Farmers are already used to working through this network, and typically when rural people have questions, their first call is to a county agent or to the land grant university or to the agricultural experiment station.

This is a great resource that's out there. Most of the big changes that have occurred in agriculture have taken place through the efforts of the cooperative extension service, the agricultural experiment station, the land grant universities. It is difficult to imagine how we're going to make any major changes in agriculture without getting this group of people more involved. I realize that in some regions of the country that -- that group of folks has been very much engaged, but not in every region of the country.

So my challenge to NIOSH and to NORA is to go ahead and get this group of folks more involved in every region of the country. Thank you.

agricultural businesses and organizations, such as the National Council of Agricultural Employers (NCAE); USDA

Categorized comment or partial comment:

Verbal Comment 2006/01/17: I believe it's everything, yes. Hi, my name is Sharon Hughes and I represent the National Council of Agricultural Employers, which is the only national organization that's devoted to representing agricultural employers from the farm management viewpoint in Washington on labor and immigration issues. We represent the growers and producers interests before the federal government on -- on these issues and work closely with Congress, the Immigration and Customs Enforcement Bureau, the Departments of Labor and Agriculture, the Occupational Safety and Health Administration, and the Environmental Protection Agency. NCAE membership is open to growers, producers, processors, cooperatives. Other agricultural organizations at the state, local, and national level belong to the council, and we thereby have membership in all 50 states dealing with labor-intensive agricultural crops.

As NCAE's Executive Vice President I've had the opportunity to work with the Department of Labor's review of the hazardous occupations orders regarding children's work in agriculture, advised on the USDA's Hazardous Occupational Safety and Training and Agriculture Initiative. I was one of the employer representatives to the International Labor Organization when they developed their safety and health in agriculture protocol a few years ago. And I also served as advisor on several NIOSH-funded projects, including our current project with the Marshfield-based National Children's Center for Rural

and Agricultural Health and Safety where we're testing a strategy to motivate employers to improve the safety conditions for hired adolescent workers.

Our organization has a vested interest in the safety and health of agricultural workers.

For today's statements I have five key points to make. First, NIOSH-funded investigators should be required to partner with agricultural businesses and organizations, such as NCAE, to plan and implement studies; then disseminate the results that have practical application for agricultural producers and hired workers. Too often there's a disconnect between what academics want to study and what is of real importance to agricultural producers and/or their hired workers. Many papers and scientific journals have virtually no impact on the health and safety of agricultural workers.

Second, NIOSH research should identify effective health and safety interventions targeted for hired farm workers, especially those with short-term employment requiring skills and machinery operation. For many of our crops there's a brief window of time for planting or harvest. Workers circulate through quickly and may not return for a second season. We need help in providing effective training and safety interventions for these employees.

Third, the NIOSH agricultural research agenda should address cross-training of workers in agriculture. Skills building, including safety aspects, would improve worker options for promotion and longevity in agricultural work. Many of our trained employees have moved out of agriculture into construction, retail, and other occupations that offer full-time, year-round employment. Ideally, farm workers would be cross-trained and given opportunity for upward mobility within the agricultural industry, and we need help with this type of research into doing that type of skills training.

Fourth, NIOSH should maintain designated funds to test and disseminate effective programs that agricultural producers can use for promoting health and safety among legally employed young workers ages 12 to 17. Many employers flatly refuse to hire teen workers because of all the regulations, the liability concerns, the inability to get workers compensation coverage, et cetera. But agriculture can provide safe, meaningful employment opportunities for the local youth. The NIOSH children's initiative has ensured a focus on this topic, and we support its continuation.

Finally, new strategies are needed to bridge the research to practice gap. You may want to consider jointly-funded projects between USDA and NIOSH. As the speaker before me indicated, working with extension personnel at the state and local levels would be very effective in being able to actually implement the practices, you know, with the growers. The USDA HOSTA initiative for youth, tractor, and machinery certification might benefit from further testing, evaluation, and promotion via the NIOSH regional centers. And there are other health and safety issues that could benefit by linking NIOSH, you know, with the cooperative extension personnel.

I will go ahead and submit the written comments at a later date, but I do want to thank you for this opportunity to address.

Verbal Comment 2006/01/17: Good afternoon. It is indeed a privilege to be here. I am Jane Elam from Lexington, Kentucky, the horse capital of the world. I have been involved with Kentucky Farm Bureau for many years. I'm serving currently on the State Safety Advisory Committee. My husband and I farm a six-generation horse, cattle, and tobacco farm.

I introduced myself stating that I am from the horse capital of the world, but my state holds another record, being near the top for all terrain vehicles accidents and deaths. We have many reclaimed coal mines and fast, hilly country sides that promote ATV riding -- abundant tourists and locals riding at these sites that promote ATV riding and cause injury problems.

The sites are always glad to collect a few bucks from riders who use them. We have the largest ATV dealership in the nation located in eastern Kentucky. ATV accidents, which are usually head injuries, can be greatly reduced with proper use of helmets, especially on farms, but they are not widely used by ATV drivers.

Motorcyclists are another problem group -- a group that has gotten the lawmakers to rescind the mandatory helmet law in Kentucky. This is a problem in itself.

My message today is education and research, because that is the only way to reduce injuries and deaths. We were at the top of the nation's farm deaths and injuries before our Department of

Agriculture started an education program. Now we have cut these statistics in half since farmers are using roll bars and seatbelts on tractors.

Other ways we are educating are by holding safety camps, health and wellness camps for all the ages, and working with 4-H and FFA in pilot programs. Many people think farm accidents are inevitable, but they are preventable when children and adults are educated how to be safe on the farm.

Being from a top tobacco and coal mining state, we again hold another record as being near the top for lung cancer and related health problems. We are working on solutions through education and research. Results will be slow coming because of habits and peer pressure. We are asking our General Assembly, as they go into session this year, for monies for research and education to help deliver the health and safety story. Thank you.

Verbal Comment 2006/01/17: Good afternoon, everybody. I thank you for the opportunity to speak today. I'm Regina Cullen Luginbuhl from the North Carolina Department of Labor. I'm representing my agency and also ECU, the agrimedecine program.

I want to tell you a little bit about agriculture in North Carolina since we're on the other side of the universe in this kind of a different place. In North Carolina agriculture accounts for 22 percent of the state's revenues and employs 18 percent of the workforce. You probably know we're tops in tobacco, but also turkey, some really delicious healthy fruits, blueberries, and some good vegetables -- my personal favorite, cucumber pickles. And our Christmas trees go as far as Hawaii and Japan, and they usually end up in the White House for whoever is the President. It's going to be his tree, too.

But I also want to talk about the migrant labor workforce that puts all these things on our tables. It's an indeterminate number. Some people say it's a 100,000, and some people say it's 300,000, and some people just tell us to go and find out. We don't really know, but we do know they start -- they all start in the agricultural area pretty much. Most of them are from Mexico. Some of them now from Laos and Cambodia, and the ag start is at the bottom of the ladder. They might go on up into construction. We don't really care about that, either. We just -- our job is to make sure they stay safe on whatever step they're at.

I want to talk about three safety topics -- the ones we know about.

The first one has to do with injuries and death from heat stress and heat stroke. That's been addressed earlier, but I can tell you from our point of view it's pretty important. We had three workplace fatalities this past summer, 2005, and they were all heat stress/heat stroke. And these were guest workers, people that were guests in our country. They came here under the H2A Program.

At the time of their death they were working for the farmer that hired them, and they were doing the job they were paid to do. They were not alone when they died. Their fellow workers were with them, and in two of the three cases their employer was with them as well. I really don't think anybody ever intended that these deaths would take place.

So why did they take place? Studies point to work rest cycles, adequate hydration, job cross-training. My personal bet, recognition of the hazard. I think if anybody knew, any of the workers knew, if the worker himself knew, and the farmer knew that some of those symptoms were going to be life threatening, they wouldn't have put them at the end of the field to rest.

Our second pick is pesticides. That's also been a theme this morning -- this afternoon. Some of my colleagues in North Carolina are really convinced that we do need a reporting system that works. Right now we don't have one. We need chemical exposures that can be traced, understood, and prevented. We need to record exposures. We need a record. In California we have a state law that mandates doctors' reporting illnesses from occupational exposures to local health offices. So surveillance is important.

The Department of Labor takes care of the HazCom, Hazard Communication Standard, and we've noticed when we issue citations there's three of them that typically occur. Most growers don't have a written program. They don't post their Material Safety Data Sheets, and they fail to train their employees.

Third topic -- this actually is a -- it's going to end on a happier note. In North Carolina we've created a gold star grower program. Those are the guys who do it right. They would do it right whether we were there or not, and they sort of manage us. Sometimes I like to think we're managing them, but of course that's not the way it is. And in many of our conversations they told us what their most serious workplace safety issue was. How nice, and I didn't guess it anywhere close. It was driving their vehicles on the rural roadways. Everybody in the room I guess was on top of that.

So we got some government money, state government money, and got some slow moving signs out, and they promised not to put them on their mailboxes. And we educated the public, which was their number one issue. And the grant provided us with an intern so I think that's always useful, a useful way to put your money, and she got her MPH out of it. So I'd like to see that sort of effort continue and maybe move on in North Carolina to the roll-over protection.

So I think there's a few things that are important to us. One is that the education we have, we share it with farm workers and with farmers, and that we listen to both groups, and that we get additional help from folks like you. Thank you.

Farm Safety 4 Just Kids; Progressive Ag Foundation day camp program

Categorized comment or partial comment:

Verbal Comment 2006/01/17: Good afternoon. My name is Marilyn Adams, and as the spokesperson and founding president of Farm Safety 4 Just Kids, I take this opportunity to thank NIOSH personally for the past efforts that you have given to the child farm safety and health issues. The majority of our funding comes from agribusiness, but we also depend upon NIOSH. We depend upon the studies to justify ongoing corporate donations and to justify the categories that we need to address. We feel strongly that NIOSH should continue its dedicated and separate focus on children in the coming years.

The Children`s Farm Safety and Health Initiative was appropriated by Congress as separate funds and for the sole purpose to be sure children were not forgotten. I know because I was there. I was one of the members of the national committee that worked really hard to make this happen.

Collaboration and support from others in the agricultural safety and health field is crucial at this time. Networking and project funding provided by NIOSH centers, such as the National Children`s Center, the Great Plains Center, the Southeast Center, have really directly benefited the Children`s Farm Safety and Health. For example, the network created by the National Children`s Center has given Farm Safety 4

Just Kids the opportunity to work with under-served world populations with educational materials both for Spanish-speaking populations and for the Amish.

Community outreach programs that address the entire family and protect children are extremely vital to preserving the rural environment. Farm Safety 4 Just Kids has nearly a 140 grass roots volunteer chapters across North America that reach more than one million rural children, youth and farm families each year with life-saving educational materials based on research to practice principles. In year 2000, Farm Safety 4 Just Kids developed an educational packet called "Farm Tasks, When Are Kids Ready?" This educational tool is based on the North American guidelines for agricultural tasks created by the National Children's Center.

Farm Safety 4 Just Kids has also created a farm safety day camp manual in response to a two-year evaluation done by the Southeast Center on farm safety day camps. Some of our chapters who conducted these day camps were trained by the Progressive Agriculture Camp Program. I mean, excuse me, the Progressive Agriculture Safety Day Program.

ATVs are extremely important. You've heard that more than one time today. Along with the Great Plains Center for Agricultural Help, Farm Safety 4 Just Kids surveyed the attitudes and behaviors of youth on ATVs during the recent national FFA convention. Two educational sessions with peer to peer education were also conducted. The results are being used to shape up -- shape an upcoming educational tool that includes a community planning guide, paper and pencil activities, demonstrations, posters, presentation materials, a brochure -- and the list goes on.

Our vision at Farm Safety 4 Just Kids is simply keeping rural kids safe and healthy. For agriculture to continue as a viable and prosperous industry, we need to make sure agricultural safety and health outreach programs are researched, implemented, and evaluated on an ongoing basis. We also need to make sure our efforts are geared at reaching all generations within the family unit from the curious toddler asking for a ride with grandpa on the tractor, to the 12-year-old wanting to ride an ATV, all the way up to the teen that's working around the power take-off for the first time. Our education and awareness efforts are timely and effective.

In closing, Farm Safety 4 Just Kids is working to deliver grass roots programs based on research to practice. We take pride in creating programs and educational materials that are based on the foundation of networking, research, evaluation, and awareness about farm safety and health issues. Farm Safety 4 Just Kids is prepared to expand our organization to implement the intervention that has already been tested, while continuing to specifically address the needs of children, youth, and farm families through community outreach programs.

In addition to my verbal comments, I have a handout that describes our priorities in ATV safety, rural health, and tractor safety. And yes, we would love to partner with you on the tractor safety initiative.

Three key points that I'd like to quickly make. Children's initiatives should remain viable and separate. Recipients of NIOSH research funds should strongly encourage the partner -- to partner with organizations such as Farm Safety 4 Just Kids and the Progressive ag Foundation day camp program to ensure that the knowledge gained through research is implemented at the grass roots level. Even better yet, direct funding to the nonprofit organizations to be provided to organizations such as ours that have had proven track record conducting and disseminating educational programs based on the NIOSH funding -- funded research. Okay. I firmly believe that if steps are taken in this direction -- and I wanted

to say this most importantly to you, sir -- the modest reduction of children`s agricultural injuries and fatalities, together we can assure that agriculture will remain a strong, viable industry for years to come. Thank you, Sir.

Note: Verbal testimony provided to NORA Town Hall meeting in Seattle, WA, 2006/01/17.

Verbal Comment 2006/01/17: Good afternoon. As he just said, my name is Deliana Garcia, and I represent the Migrant Clinicians Network based in Austin, Texas. The Migrant Clinicians Network is the nation's oldest and largest clinical network dedicated to improving the health of the mobile under-served. For 22 years we have worked to prepare clinicians to meet the healthcare needs of migrant farm workers, those persons who cross a prescribed geographic boundary and stay away from their normal residence overnight to perform farm work for wages, and other mobile under-served workers.

Occupationally-related illnesses and injuries continue to be some of the most complex and frustrating healthcare events handled in the primary care setting. I am grateful for the opportunity to address you today with our recommendations for the agricultural section -- sector, excuse me -- of the National Occupational Research Agenda under development.

Your work will have enormous impact for many years to come. We have seen this in the critical pesticide-related research that has been conducted over the last ten years based on the previous NORA. The body of knowledge has greatly improved, yet those crucial advances must be taken to the next level. Understanding of the impact and effects of pesticide exposure must be translated into critical evaluation strategies, and treatment and management protocols for the clinician in the field.

Related to the research to practice initiative, our first recommendation would be that NIOSH-funded research include an applied component to swiftly translate findings into clinical practices.

We ask that future requests for proposal include requirements to seek to link research findings to programs or organizations that can apply the results. In this way, as studies are defined and executed they will have a specific aim, the rapid deployment of major findings into the settings where they will have the greatest benefit.

Categorized comment or partial comment:

Our second recommendation is that the agricultural sector of the NORA redouble its effort to study injuries and illnesses resulting from occupational insults to workers. When caring for migrant workers it is critical that the clinician look beyond pesticide exposure at incapacitating injuries resulting from rapid and repeated motion, awkward body mechanics, and the strain of supporting excessive weights. And it would be important at this moment to also highlight that this work has not been conducted looking at female farm workers and female workers in other occupations who are currently pregnant.

These work requirements result in a whole host of traumatic injuries and musculoskeletal disorders that greatly impact the longevity of workers in many segments of the agricultural industry. The long-term effects on the human body are not fully understood, yet due to these injuries we see a growing number of workers no longer able to maintain employment either in agriculture or in any other work setting. For many of these individuals their very survival, and that of their family, depends on the ability to work at whatever job is available to them. The field of workers compensation and rehabilitation has far to go. I would again urge that future research incorporate the identification of strategies for the prevention, as well as the treatment and clinical management, of these injuries. The NIOSH Northeast Center for Agricultural and Occupational Health, NICAM, provides an outstanding example of research in this area that has been translated into clinical recommendations, and more efforts like this are needed.

Categorized comment or partial comment:

While there is enormous concern about the impact of injuries and exposures on adult workers and the young children and their families, little attention has been paid to adolescent workers, older children ages 14 to 17 functioning as emancipated minors. Reports of studies looking at the changing face of migration repeatedly indicate that the migrant population is getting -- that is increasingly not English speaking and also non-Spanish-speaking, is getting younger. These young workers are not yet fully developed either physically or physiologically -- or psychologically, excuse me -- but life circumstances have required that they function in the adult world of work. They are, however, children unfamiliar with worker protections and often incapable of requesting assistance, and additional research is needed to understand the impact of occupational injuries and illnesses on the adolescent worker.

Our third recommendation is that research funding targeted at children remain in place, with a special focus on an older child because we do not believe that this population can be adequately addressed in adult research. We have benefited enormously from our partnership with the NIOSH National Children's Center in Marshfield, Wisconsin and our active involvement in the Childhood Agricultural Safety Network. This partnership led to the development of highly sought-after resources to help educate farm worker families. Continuation of this kind of intervention is critical. Again it is important that research work to assist the healthcare provider in understanding the effects on the developing body and identify strategies to prevent and clinical management.

So as I'm closing I'd like to reiterate linking studies to organizations able to translate the findings into critical strategies -- clinical strategies, broadening the research agenda beyond pesticides, and

expanding the child-focused initiatives to include the adolescent worker who is functioning essentially as an adult. Thank you.

Verbal Comment 2006/01/17: I've already said I might sound like God with this and so I hope you listen appropriately. It's -- we pronounce it "Petrie," but I've had Greeks and Romanians both tell me that they know people in their countries with that name and gave me that pronunciation. I asked my dad about it, and he just said I'm American, so -- I am Chip Petrea from the University of Illinois at Urbana-Champaign, the Department of Agriculture and Biological Engineering. I also have an appointment with the Centers for Environmental and Occupational Safety and Health at the University of Illinois Chicago, which is an ERC center for NIOSH.

I would like to speak about older farmers, that being those farmers older than 55. I know lots of places older farmers -- or older guys, and older white guys in particular, don't get a lot of good press, but there's a lot of them out there. The average age in Illinois is something over 55 for farmers, going up. So I have four particular factors related to that category of farmer that I'd like to address.

One is the physiological changes of aging. We have a lot of data on lots of things that takes place as the body ages. However, related to farming we do not know how these changes may interact with the continuing workload and the long hours that farmers tend to do. I served on a dissertation committee

of farmers in northern Illinois, and they routinely put in 40 to 60 hours, which is similar to what my dad does and he's 74.

There's lots of information on chronic diseases and the increasing prevalence of those diseases as individuals age. However, we do not know what the impact of those may be on the older farmers. We know that lots of farmers, particularly the older generation, are not typically preventative health oriented. They only go when they need to to a physician or clinic, and sometimes not then, and whether -- the suspicion is that there's lots of undiagnosed chronic diseases out there that are -- in fact there are some of them that have been diagnosed but may be under-medicated, and so there's -- their relationship of those factors to injuries and fatalities is not well understood.

The relationship between prescriptions and over-the-counter medications with farming and farm health and safety, in Illinois we lose 10 or 12 older farmers every year from tractor overturns, and it would be nice to know what kinds of medications those individuals were taking and whether there was any impact of that on their particular situations.

And also the role of stress and mental health problems such as depression and anxiety. We know that farmers spend more of their times being humans than they do being farmers, but they do have a particular set of circumstances that bears to be better understood.

I would recommend that there be a specific NORA research target of older farmers in production agriculture to assess the role of physiological changes of aging, health status, chronic disease, mental and physical health effects, and the effects of medication as they relate to occupational injury and mortality. I would like to see the continued work on better mechanisms to document farm and farm-related injuries and fatalities. We of course recommend a collaborative approach between nursing, medicine, agrimedecine, agricultural safety and health, agribusiness, public health, and of course the farmers, their spouses, and their family members. And NIOSH has a nice publication on community-based participatory research that I think offers a model that we can follow. And I would also offer that the -- related to older and aged farmers that something similar to the current previously work related to the rural and agricultural children's efforts would provide a good model, and also the USDA cooperative states research, education and extension service AgrAbility project, which relates to disabled farmers and their families, are both good models for furthering the research that we need and the appropriate mechanisms for guiding both preventative as well as facilitative programs. Thank you very much.

extension service professionals

Categorized comment or partial comment:

Verbal Comment 2006/01/17: Glad to see there's so many people still here, and thanks for the opportunity to speak this afternoon. I am Dee Jepsen, the director for agricultural safety and health programs at Ohio State University. I am also the President of the National Institute for Farm Safety, which is the leading professional organization in the nation that's dedicated to occupational safety of agriculture workers.

When asked about the topic of my session I simply chose to speak from an extension perspective, so I may be echoing some of the remarks from my colleague, Mitch Ricketts. For those of you who are not familiar with extension, oftentimes referred to the cooperative extension service, let me just briefly summarize it as an educational research and service organization that receives funding from federal, state, and local budgets to address issue-based initiatives.

Extension receives financial and programmatic support from the stealth government agency familiar with ag, that being the USDA. From a historic perspective the extension service came about in 1913 through the Smith Lever Act. This Act called for the information generated by the research and the academic communities to be disseminated to the citizens and put into use. So with no disrespect to my NIOSH officials who I know and who developed that R2P logo, I would like to say that extension and the federal land grant institutions are the original crafters that the research to practice model.

Now in all seriousness, I do want to acknowledge NIOSH and their efforts to incorporate R2P in the current research expectations. Basic and applied research findings through the R01, R21, and feasibility studies are much needed in the ag sector. Each study, whether it's farm-related asthma, injury

surveillance, noise-reduced hearing loss -- I could go on and on -- these studies are just bricks that help form the wall of research in the agricultural workplace.

But this wall that we built can also be a barrier between the researcher and the workforce. Perhaps the findings are there, but the common practitioner does not know what to do with them.

This is where extension comes in. Extension professionals can take those findings and transform them into a more palatable format for teaching and training. Utilizing the R2P model, researchers can be sure that the occupational workforce, including farm families, are getting the most current findings and strategies for prevention of illness and injury. Extension is comprised of four major program areas, not just agriculture, but also family, youth, and community development. Extension has a presence in every state of the nation and often in every county or parish.

Extension professionals work directly in the communities that they serve. They are faculty members of their state land grant universities and are familiar with methodology, program planning, and systematic evaluation. I heard this morning and then again this afternoon that the NORA agenda will encourage partnerships. I recommend that extension be that logical and effective partner when it comes to the agriculture sector.

The regional agriculture centers have the ability to work directly with the extension professionals in their area. These professionals have access and the rapport with the agricultural workforce.

The mission of extension program is to take information to the people. Extension can effectively target the appropriate audience and utilize research findings in their local communities. On the local level, extension professionals have community linkages with the veterinarians, the public health departments, and local clinics or hospitals. Including extension in the R2P process ensures that the researchers that have valuable occupational findings -- that their findings are being put to use. In a nutshell, extension can be those wheels for research, knowledge, and safe workplace practices.

Let me conclude by saying that long after the grant dollars expire, and we all know they do, extension offices will still have a presence in the communities. and can keep the information and the best management practices set by NORA progressing. Thank you.

Verbal Comment 2006/01/17: Good afternoon, everybody. And I certainly would like to thank NIOSH for organizing this opportunity for listening, and for myself for learning from many of you from the audience, and also an opportunity to contribute to the next ten years of research with regards to agricultural health and safety.

I am Anne Greenlee, and I'm an Associate Professor with Oregon Health and Science University within the School of Nursing. I have a secondary -- that's my primary appointment. My secondary appointment is with the Center for Research on Occupational and Environmental Health, and I am located on the LeGrand Campus. That's about four and a half hours away from the Portland Campus. And I'm developing a new program of research there within the School of Nursing, so I've had an opportunity with over the last year and a half to talk with some of the producers and veterinarians in the area. So I have kind of a short message that underscores really what has already been discussed with regards to beef production and dairy industry in northeast Oregon and southern Idaho.

And essentially the issues as far as health and safety, traumatic injury, really stem from animal handling issues, understanding the animals and moving the animals about, bull/human interactions and yard maintenance with regards to heavy equipment. So many of -- I guess what I'm -- what I'd like to underscore is just the need for translating the message of safety and how to get it into the more remote areas of efforts that are occurring in northeastern Oregon and Idaho.

An area in which I am more familiar in that I'm more of a laboratory-based scientist and I have not heard yet today, sort of two areas that are emerging as far as knowledge gaps, that I think need to be on the agenda. And that is the fetal basis of adult diseases, those exposures that occur in the workplace with regards to heavy metals and solvents and agrichemical exposures; and those exposures that pertain to or have the possibility of trans-generational effects, those heritable changes that occur during in-utero exposures that are -- not only affect the offspring but also have the potential for affecting future generations as well.

And there's increasing evidence that some of the environmental agents, especially those with hormone-like activities, may alter developmental programming. They do not result in overt malformations, rather they alter the developmental program and result in functional deficits. And the functional deficits are expressed later in life as an increase in susceptibility to disease and dysfunction. And the mechanism proposed for this phenomenon, i.e., the fetal basis of adult disease, is believed to be epigenetic alterations in the genetic -- in gene expression; that is, altered DNA methylation. And in some instances these exposures may result in transgenerational or heritable changes in the germ line.

So I think my point is, my suggestion is with regards to the agenda, the future agenda, is to look at those exposures, those low-dose, chronic exposures that don't result in an overt malformation but yet may lead to the risk of the interaction with those exposures and later susceptibility, or increased heightened susceptibility to cancer, to reproductive changes, fertility, decrements in fertility, and neurological health. So I think there's a lot -- just having my foot in the arena of toxicology and reproductive health and agricultural health, it's becoming very obvious -- this -- this is a hot topic. This is what is really on

the agenda of many upcoming meetings and is going to be building over the next few years. And I think that low-dose, chronic exposures really need to be kept at the forefront as far as disease susceptibility.

Thank you very much.

Categorized comment or partial comment:

Verbal Comment 2006/01/17: Perhaps the most important change in U.S. agriculture during the past 30 years is the dramatic increase in the importance of labor-intensive agricultural production and the associated greater reliance on hired workers.

Three major factors account for this greater utilization of hired workers. First, there's been a steady increase in the proportion of U.S. crop farm cash receipts derived from the sale of fruits and nuts, vegetables, nursery and greenhouse products. In 1974 that total was about 17 percent of total crop farm sales. By 2002 that share had more than doubled, and is now 40 percent.

Second, increased farm size often requires supplementing farmer and family labor with hired workers. Among fruit and vegetable producers there has been a dramatic increase in size concentration in recent years, and correspondingly a greater reliance on hired labor.

Third, the labor supplied by hired workers on U.S. farms today probably now exceeds the labor input of farmers and unpaid family members. The 2000 U.S. Census of Population indicates that just 587,000 persons said their occupation was farmer or rancher, down from roughly 830,000 ten years earlier. In contrast, the number of persons reported in the census of agriculture working 150 days or more directly for farmers -- these are regular hired workers -- was reported to be 928,000 in 2002. That's up from about 700,000 25 years earlier. Of course the latter figure does not include the one million or more short-term or temporary hired farm workers who labor on U.S. farms.

What do we know about this population? First, most U.S. hired farm workers are characterized by low socioeconomic status, long associated with adverse health outcomes. The National Agricultural Workers Survey of the U.S. Department of Labor finds that the typical hired crop farm laborer today is a young, low-income, foreign-born, mostly Mexican male with low educational attainment and who has only recently migrated to the United States. In California the most significant development in the farm labor market is the sharply increased flow of indigenous migrants from the southern Mexican states of Chiapas, Oaxaca, Guerrero, Puebla and Veracruz. Approximately 20 percent of California farm workers today are believed to be indigenous migrants. Many speak only their indigenous language, not Spanish, not English, languages that very often doesn't even have a written form.

The seriousness of farm labor occupational hazards was underscored in California during the past summer when a statewide attention was directed to multiple deaths among workers who suffered heat illness while hurrying to pick crops in the San Joaquin Valley. My belief is, and this underscores something that Bill Krycia said earlier, that there is persuasive evidence that vigorous enforcement of occupational safety laws can reduce workplace injuries and illnesses throughout industry.

An economic -- an econometric multi-varied analysis of non-cumulative injury, Workers Compensation claim frequency for all industries in California conducted by the Workers Compensation Insurance Rating Bureau, showed that Cal-OSHA enforcement and education was the single largest factor contributing to reductions in paid claims. But unfortunately there's been relatively little progress in the recent past among hired farm workers. In particular, the number of fatalities on California farms among hired workers in the ten-year period 1988 to 1998 was 442, an average of 40 fatalities per year, and that rate has not decreased subsequently.

I believe that hired farmers are a special population based on the unique demographic features, the lack of access to care, the lack of health insurance, the high rate of occupational injury, and the poverty status. A major factor of course is the extent of poverty in this group. This has its impact in different ways, including lack of access to healthcare, limited nutritional choices, decrease in preventive health services, dental/vision care, vaccinations, and poor housing conditions.

If we're going to understand the pattern of disease and illness in this population, we can't only look just at the occupational exposure. So here's my recommendations.

One, I think we need to support prospective cohort studies of this population that includes workplace and living condition exposures, as well as acculturation and risk behaviors.

Second, I think we need to insist that future cross-sectional studies in this population should include comprehensive physical exams. We are seeing a pattern of infectious disease, tapeworm, tuberculosis, and other illnesses endemic in the sending countries now appearing in our state.

Third, NIOSH should add a periodic occupational health supplement to the National Agricultural Workers Survey, perhaps every three or four years, and take advantage of the wonderful work that that organization has done.

And fourth, and this I'll end on, NIOSH should immediately provide public access to raw data files already collected, such as the 1999 Occupational Health Supplement to the NAWS, subject of course to privacy protection, as is the standard practice in the Census Bureau's PUMS files and the NAWS has recently put on the web all of the raw to data files for the past ten years. Thank you very much.

Verbal Comment 2006/01/17: Good afternoon, everybody. My name is Dick Dressler, and I'm speaking to you on behalf of AEM, the Association of Equipment Manufacturers. We appreciate the opportunity to speak today on agriculture and forestry, and will briefly highlight some of the recommended -- recommendations we have for the agenda.

AEM is a nonprofit manufacturers trade association, headquarters in Milwaukee, Wisconsin. We also have offices in Washington, D.C.; Ottawa, Canada and Beijing, China. AEM serves the agricultural, forestry, construction, mining, and utility equipment sectors. We have over 700 corporate members with 375 original equipment manufacturers and the rest suppliers of goods and services for the industry.

Agriculture, as you've heard today, ranks among the most hazardous industries. In addition to adults, children and teenagers are regularly performing work on many family farms and are exposed to potential illnesses and injuries. NIOSH currently supports research and prevention programs, but more can be done.

The following topics are recommended for the NIOSH agenda. One, high productivity equipment. Ag equipment working and traveling at higher speeds requires special consideration for steering, braking, hitching, lighting, marking, and training the operator.

Two, global positioning and other automated systems. Automated functions allow machines to perform complicated tasks with minimal or no operator assistance. Unexpected movements or occurrences must be addressed in the operator's training and re-training.

PTL, drive lines and other hazards. Guarding and warning for preventions of entanglement, crushing, or cutting industries have improved dramatically over the last 20 years. They must continue to be evaluated and tested for safety, functionality, and comprehension.

And as we talked before, training. NIOSH needs to identify the most effective means for operator and technician training. Examples could be classroom, web-based, or interactive training. Consideration also needs to be made for the non-English-speaking individuals.

Operator visibility studies. NIOSH has supported visibility studies for the construction and mining equipment sectors. This should also be done for ag equipment.

Run-over, backing injuries and fatalities continue to plague the ag industry. Closed circuit monitoring is available. A human factor study needs to be done in an ag environment.

Public acceptance requiring cultural changes. The public must be educated to accept that ag equipment manufactured in recent years, probably since the mid-1980s, is inherently safe. It should be investigated whether further reduction of injuries and fatalities may require cultural changes in addition to improved standards.

NIOSH should also become an advocate encouraging OSHA to have -- to base their regulations on modern standards rather than developed in the '60s and '70s. An example is the reinstatement of the Roll-over Protective Structure Standard.

Finally, research is suggested to study the benefits and risk of injecting manure into the soil to minimize run-off and contamination. This should be compared to the common practice today of spreading. The process may be regulated by the EPA, but we do not believe there is sufficient data available to make an informed regulatory decision.

Categorized comment or partial comment:

Forestry is another hazardous -- hazardous industry and there's clearly a need to prioritize efforts intended to make this occupation less dangerous. Forestry per man-hour worked in many states is the most hazardous industry.

The following two topics are recommended for the NIOSH agenda. One, fire prevention. The Society of Automotive Engineers is currently working with the insurance industry to prepare an informational report on fire prevention practices. Collaborative research with NIOSH in validating these practices would be a worthwhile effort. A specific area of study is the total loss of machines resulting from the misuse of forestry and construction equipment in firefighting applications.

Two, operator protection. Forestry equipment generally provides excellent protection, but some conditions are more challenging to the manufacturer than others. Topics for investigation could be (a) additional protection from falling objects; (b) durability of polycarbonate window material that may be bullet proof, but it may react differently to a heavier mass, lower speed object; (c) effectiveness of add-on roll-over protective structures on forestry conversions; and (d) safety research for ground personnel, such as fellers, choker setters, and even truck drivers.

There are other research topics but these are some of the higher priority issues we believe should be placed on the NIOSH agenda. Thank you for your time and the opportunity to speak.

Verbal Comment 2006/01/17: Thank you very much for the opportunity to make just a couple of comments on behalf of some of the folks that I work with. My name is Charlotte Halverson. I am from eastern Iowa. I am employed by Mercy Medical Center. We have a rural health service through that hospital. Half of my time is contracted to the National Safety Council where I work with the National Education Center for Agricultural Safety. My background is occupation health nursing, and I have done a focus study on agriculture, so sometimes I have to look at my name tag to tell you where I'm working today.

I really, really want to commend NIOSH and NORA and most of you here for your emphasis on the importance of collaborative efforts. None of us have a lot of time and a lot of money, and so all these things are precious to us. I think collaborative efforts are going to be especially effective in a lot of areas, and we need to be working very closely with researchers in university centers and NIOSH centers - the importance of having the media involved in a lot of what do. Looking at those collaborators that we don't oftentimes think about, such as the community -- community colleges, working with producer groups; involving rural practitioners in not only looking at what are the issues to be researched, but in getting the word out when we do have the materials.

I very much represent the P in the R2P. As an occupational health nurse, I spend a tremendous amount of time with farmers, with farm families, with very young workers, and very much the older working population.

There are some issues that I think that we have a particular interest in and see a need for research time and dollars, and we have hardly scratched the surface on some of the issues around respiratory -- chronic respiratory issues. I have, believe it or not, driven down the highway and seen farmers with their oxygen tanks driving the tractors -- you know where I'm coming from.

Those of us that are nurses in agriculture -- and I am actually representing the Agrisafe Network. We are a group of occupational health nurses with a focus in agriculture, and that's where we are trying to devote most of our time. But we have really seen that there is a need for agricultural focus in the occupational health programs and in the community health portion of nursing and medical training.

Now that being said, I know that the schedules are extremely tight. There is no room for any additional information to be put into these programs. But the sad part of it is the majority of nurses that are working in the agricultural community have less than a bachelor's degree, very oftentimes out of your two-year programs where there is no time to put any community health issues in. So I think we need a challenge for those of us that are in the arena is to look at how can we get information and training to people that are the healthcare providers.

I preceptor some of the master's degree students in the occupational health nursing program for the University of Iowa, and there is a direct -- a definite interest in the agriculture arena in these people. And they really have a passion and a caring and an interest in working in agricultural health and safety. But we all know that it is definitely not a revenue-producing area. It is very rarely third-party reimbursed, and we need to be looking at how can we integrate this practice into a model that will give us a paycheck.

Providing research information on the continuing education front. NIOSH alerts are a wonderful tool and we have really -- really used them and -- and look forward to them. But I think that these alerts not only alert those of us in the agricultural health and safety industry, but they also can be a way of getting to our colleagues who don't always interact on a day-to-day basis with agricultural workers. So any kind of information that can be disseminated that we can have available to physicians and nurses that don't

always see people in the agricultural arena. And my emphasis story on this is I worked with an occupational health physician. I put him into a training program at the University of Iowa that we took, and he came back and he said Charlotte I've been misdiagnosing. So that's where the value is in the NIOSH dollars that go into the research.

Thank you.

North Pacific Fishing Vessel Owners Association (NPFVOA) Vessel Safety Program

Categorized comment or partial comment:

Verbal Comment 2006/01/17: I want to thank NIOSH for the opportunity to participate in this forum. I -- I've learned a lot today, and I wish there was a little bit more time. But hopefully as a follow-up we can look together at some of the commonalities between the ag and the -- particularly processing industry for -- in our fishing sector.

I am Leslie Hughes. I'm the executive director of the North Pacific Fishing Vessel Owners Association better known as NPFVOA Vessel Safety Program, and this program was started 20 years ago. I've worked in the commercial fishing industry for 31 years, but with the safety program for 20. And it's been an amazing program where we've seen huge improvements, but some of the comments that have been made today about disconnects are a constant challenge with trying to get a culture to understand that they are at enormous risk. The fishing industry is regarded as typically the most dangerous occupation in the United States.

So I think we've been very effective as an organization because we're nonprofit, we're totally dedicated to safety education and training, but we have a membership base. We're not exclusive to our members, but it gives us a population that we continually communicate with and they communicate with us. And they will come to us, for instance, if they have say a pneumonia incident where their people are exposed. They'll come to us and say we've just discovered we need training. So I think we're in

excellent forum for collaborating with NIOSH, and we've appreciated the opportunities where we've been able to do that, because we have the trust of an industry over many, many years, and so we're just very unique. There's nothing like anywhere in the country, and there's actually nothing like us in the world. The International Labor Organization had me come up to Geneva because they couldn't figure out how fishermen would do anything on a voluntary basis.

So some of the things where I think NIOSH has -- could work further to have the kinds of positive impacts they've had already -- and for the shortness of time I'm not going to identify what some of those were but we would like to see them continued. And some new projects that you might consider would be having some assessment of some of the things that the Coast Guard, which is the agency that has the predominant authority over fishing industry, but to look to see where some of their interventions have been really effective. And recently the District 13 and District 17 -- which is Alaska, Washington, Oregon -- Coast Guard has had some real hands-on interventions. It would be interesting to look and see how that compares to dockside exams and some other things they've done.

Also we see that 30 percent of our fatalities are caused by man-overboard incidents. NIOSH in 1997 did some initial work in that, but I think we really need something much more in-depth and stronger, and we would very much like to participate with you in working on that.

We are seeing an increase of foreign population in the workers that we're hiring. Many are third world countries, and there's a lot of concern about how an epidemic that would break out on a boat in the kind of conditions Eric Blumhagen described to you, how you would deal with that. Would you quarantine the vessel? You would have very limited means of quarantining people as individuals. So I think that's something that there -- could be very, very helpful in the future.

And I would say that the comments that have been made about being able to communicate with an industry is totally critical and industry participation is critical. If you don't involve industry, I don't think you'll ever hit the mark. It's industry that knows where the problems are. If you can identify a risk, then they will work with you to try to mitigate it because no one in our industry wants to have people killed or maimed. And I think that's how you get the buy-in, and the work that you've done in the past has been very much appreciated because you've had the respect for the workers that you're addressing. And again, I thank you.

Verbal Comment 2006/01/17: It won't take me long at all, but it's late in the afternoon and we all need to hear the wrap-up. It's been a very interesting session, so thank you very much for this opportunity.

My name is Deborah Reed. I'm from the University of Kentucky College of Nursing and the Southeast Center for Agricultural Health. Although I'm here as an occupational health researcher, I really come from a long line of farmers. My sisters, ages 73 and 71, are still full-time farmers in the fields every day. My brother, age 60, just retired from a career at Lexmark to take over the family farm. They're worried sick about their future. And as Forrest Gump would say, that's all I got to say about that. Except that I echo what Chip said earlier about issues of aging farmers.

And I would tell you, though, that young people on a farm are worried sick, too. A child psychiatrist told me at the University of Kentucky Children's Hospital -- seeing an increasing number of farm children. And one example the physician said the teenage girl felt that she would quit eating because she felt if her dad had one less mouth to feed perhaps he could hang onto the farm. In my own experience conducting research in high school agricultural classrooms, I've overheard countless stories by teenagers who use extremely, extremely risky behaviors to deal with their stress, particularly on weekends.

While all of the topics covered today are worthy and salient to the health and safety of agricultural workers, I feel there's a basic risk to health that has not been mentioned very much this afternoon. The person is really more than an entity that bleeds and breaks. The many cascading pressures faced by

farmers today -- competition in global markets, the disappearance of their family-based industry, rapidly advancing and expensive technology, and a marked shift in the labor force -- creates stress and psychological strain on farm families that is absolutely enormous. Research is needed to identify precipitating factors and the effects of this stress, not only in the workplace but within the families that work together. There is limited, albeit very limited, evidence that supports the negative health effects experienced by children in struggling farm households. There is documentation of the direct link between stress and injury. We need epidemiologic studies to examine this issue and to develop research-based strategies that can help children and families deal with the increasing stress in agriculture and related work.

We've had this in the past with adults. We've looked at it with the adults. But let's not forget that family farms are made up of children, too. Thank you.

Verbal Comment 2006/01/23: Buenos dias.

(Whereupon, the speaker continued a greeting in Spanish, without an interpreter.)

And I am the same, Martha and Soledad, so the title of my presentation is Advancing an Occupational Health Agenda for Farm Workers. NIOSH is the only agency that can adequately address the occupational health and safety of migrant and seasonal farm workers in this country. If NIOSH places priority on applied research designed to yield practical results for this population, researchers will be responsive to that lead.

The National Agricultural Workers Survey is the only national information source addressing this population. It reported that 62 percent of the farm workers live in poverty and they represent almost half of the population employed in seasonal agricultural work. Spanish was reported as the native language for 81 percent of those farm workers, 41 percent they cannot speak English and 53 percent they could not read English at all. The average annual individual income for those farm workers was between \$10,000 and \$12,000, and the family incomes was averaged between \$15,000 and \$17,000 every year. Fifty-two percent of workers reported that they would not be covered by workers' compensation for a work-related illness or injury, and only 23 percent said that they were covered by health insurance.

Culturally appropriate interventions are needed for all Spanish-speaking farm workers. In my years working with migrant educators, the potential avenue for occupational health and safety curricula is an avenue to reach those young farm worker programs. This partnership approach is demonstrating the building capacity for promoting occupational health and safety education and to develop sustainable

programs that are workable and effective. In my experience, many agricultural employers welcome partnerships with researchers. They are willing to collaborate to find out what practices work better to prevent occupational diseases and injuries at their workplace. These types of collaborations are a genuine opportunity for researchers, for employers and for NIOSH, but they will be much more likely to occur if NIOSH specifies these types of projects in their call for research.

The National Occupational Research Agenda recognizes that no single organization has the resources necessary to conduct occupational safety and health research to adequately serve all the needs of this diverse work force in the U.S. Partnerships and coordinating addressing the scarcity of bilingual resources in occupational health and safety research are required to determine the efficacy of intervention techniques and strategies. The research initiatives set forth in NORA should be applauded, but they could be strengthened through integration of a specific call for applied collaborative research projects targeting Spanish-speaking farm workers

Verbal Comment 2006/01/23: My name is Eva Shipp and I`m a recent graduate in the occ-epi program here at the UT School of Public Health, and currently I`m working at the Texas A&M School for -- School for Rural Public Health. And today my comment is going to be on back pain in farm worker youth.

Many of the one to four million hired seasonal and migrant farm workers in the United States are children. Unfortunately, enumerating this population is difficult because of their mobile nature. In 1996 the USGAO estimated that there were 290,000 farm workers ages 15 to 17 alone. This population is largely foreign-born and unauthorized. Although they play an important role in our agricultural economy, many are impoverished, and few have employer-provided health insurance.

Despite the hazardous nature of agricultural work, very few studies focus on back pain in farm workers, and even fewer include adolescents. However, agricultural tasks may be particularly harmful to the musculoskeletal system of growing youth. Hazards include sustained bent, stooped and awkward postures; repeated bending and twisting; and heavy lifting. These are very common in tasks such as harvesting from the ground. An assessment of farm chores performed by youth indicated that the physical demands were comparable or even greater than those associated with high-risk industrial jobs that we have deemed inappropriate for adolescents.

While the consequences of back strain during adolescence are unknown, injury at such a young age is a concern because the musculoskeletal systems are not yet fully developed. Therefore these young

workers may be more vulnerable to injury, or more likely to sustain injuries with lasting effects, including back pain in adulthood.

I recently completed my dissertation here at UTSPH. Working with investigators at the Texas A&M School for Rural Public Health we began to address issue-- gaps in the literature. Using data from a project funded by the Southwest Center at Tyler, we estimated the prevalence of severe back symptoms among high school students from Starr County, a population that includes many migrant farm workers. During a nine-month period the prevalence of severe back symptoms among 345 farm workers was 15.7 percent, compared to 12.4 percent among 1,547 non-farm workers.

During this same period I was somewhat surprised to find that well over a third also held a non-farm job. A third of the farm workers. The prevalence of severe back symptoms on these workers increased to 19.1 percent. We also found that farm work exposures remained significant in a multiple logistic regression model that adjusted for the effect of non-work factors. Our results are similar to those reported by Park* and colleagues on a study of adult male farm workers. They also recommended further investigation of the relationship between back pain and working both farm and non-farm job simultaneously.

In 2002 NIOSH sponsored a conference that focused on the prevention of MSDs in children and adolescents working in agriculture. But many of the research gaps identified during this meeting remain and require our attention. Among others these include identification of the most pertinent risk factors for targeted interventions. Further research could also guide legislation that addresses the health of farm worker youth specifically. This includes legislation such as the Children`s Act for Responsible Employment that seeks to provide the same protections to youth agricultural workers, as well as young workers employed in other industries.

In summary, since the livelihood of many of these young workers depends on their ability to engage in physically demanding work, both now and in the future, more research is critical in this population of young disadvantaged workers.

Thank you.

Verbal Comment 2006/01/23: Thank you very much, Dr. Felknor. I`d like to try and make ten points in five minutes. Who`s my timekeeper here? Can you give me a one-minute warning, and I may talk really fast in that last minute.

My name is Bobbi Ryder. I`m with the National Center for Farm worker Health, and I am going to try and give you my life`s work in five minutes. The first point about current demographics, we estimate that there are about three and a half to five million farm workers and their dependents in the United States currently performing either migratory or seasonal agricultural labor where they don`t move from one place to the other. We include in that group folks who are residents who`ve been farm workers for many generations, citizens, as well as immigrants, both documented and not documented. They`re doing work as defined by the Department of Health and Human Services as agriculture which, in a broad sweep, does not include animal husbandry nor packing nor slaughterhouses. Other than that, anything grown in and on the land is their definition of agriculture.

They are a hard to reach and hard to serve population. And as a result, they`re also hard to research. Their mobility, the inaccessibility of their living arrangements in rural, country labor housing and crowded into back lots in semi-urban areas makes them very hard to serve. And as a result, if we do manage to reach them for some basic research, very, very hard to go back to to follow up to see what the outcomes are. That was my second point.

Third, let`s make a leap here and instead of just looking at the occupational risks and illnesses, let`s look at the patient as a whole, because there`s a direct implication between access to care and their ability to

perform their jobs. I would like to suggest a partnership between NIOSH, the Health Resources and Services Administration, and the Agency for Healthcare Research and Quality, otherwise known as ARQ. There are 150 grantees funded by HRSA to deliver services to farm workers in approximately 500 service delivery sites around the country. They're currently serving approximately 700,000 patients -- user patients, unduplicated. So where do the rest of the three and a half to five million patients go? Well, they don't all go anywhere. Many of them use the emergency rooms. Many of them go across the border for their healthcare. But an even larger number simply have no access to healthcare at all.

My fifth point, we have a lost opportunity to create -- to have created greater access to care for farm workers in this Presidential administration. There was a Presidential initiative to increase access to care for all populations, including farm workers. And that Presidential initiative had the goal of increasing access by 100 percent. In order to do so and compete effectively to set up a new access point for delivery of services to migrant farm workers, we needed national data that's not available for the population. We've increased services to this small segment of the overall community health center user population by less than ten percent in those five years.

And how did that happen? It's because of what we don't know about the population. There's a deal breaker in the front part of the application process. It's called a need for assistance worksheet. You have to have national data. You can't use your own practice-based research data. It has to come from somebody else. And so where else do we turn? We've heard about the NAWS, thank you very much, Dr. Acosta. We didn't hear anything about health status in the NAWS. We heard pure demographics. The Bureau of Vital Statistics is no help because there's not one in the country that documents death or infant mortality by occupation. So we don't know.

The U.S. Census made a significant effort to reach out to include farm workers in the population in the last census, but they still didn't document occupational status in that census data.

There's several ways of collecting research. The one that I'm most fond of is practice-based research. And there is a national sampling that exists of existing records of registered patients that can give us a lot of data. That was conducted in 1989 and it was only a midwestern sampling. This is the model that we would like to see replicated on a national basis. I appreciate your point, Dr. Howard, that this is a national occupational research agenda.

Okay, I've made six of my ten points, I've got a one-minute sign here. I guess I'm going to blend the rest of them altogether and simply say that the fabric of our society is woven with an interesting tapestry of ethnicities from many waves of migration into the United States. Someone once asked me -- excuse me, someone once said to me that slavery was our most expensive mistake in this country. I prefer to think of it in human terms, but if you want to look at it in economical terms, education, lack of education and health disparities among African-Americans has been a significant problem in this country.

Likewise, we have imported workers from Mexico for many, many decades to do work in this country, and we have a significant health problem among this population, which is not documented.

My last comment, in presentation to the Surgeon General's Conference on Occupational Health in I believe 1989 or 1990 I talked about the significant health problems that we were seeing on the front line. And after that presentation an academician came up to me and kind of looked down his nose at me and said well, we're not seeing that in the literature. And I said you know what, you're not looking in the right place.

Please, let`s look in the right places together. Thank you.

Verbal Comment 2006/01/23: My name is Ron Sokol. I'm executive director of the Contractors Safety Council in Texas City, Texas. And I'd ask our panel to kind of leave the farm and now come into the industrial environment. I'd like to talk to us specifically about the process safety management compliance for the petrochemical industry, including contractor operations during turnarounds and maintenance activities.

As many of us know, the Occupational Safety and Health Administration promulgated safety management standard in 1992 as a result of two catastrophic incidents that occurred here in the Houston Area, specifically the Phillips Chemical complex and the ARCO Refinery in Channelview. As a result of this -- these two incidents that caused over 40 lives to be lost, the process safety management outlined a systematic process for the industry to evaluate catastrophic events within their own industry.

Within the process safety management standard, 14 elements were identified. One of the principal concerns addressed in the standard was the use of contractors for maintenance and turnaround activities. As a result of this standard, many in the petrochemical industry have initiated programs to evaluate the safety performance of contractors used in both turnaround and general maintenance activities. The result of this is that many of the contractors working within the industry have achieved accident and illness rates that are far superior to the permanent plant workers. One of the areas that I would like to see NIOSH be involved with is to evaluate many of these best practices that have been developed within the industry, and there's a need to be able to review, communicate and share these best practices with the rest of the petrochemical industries for others can share in these results.

Consequently, though, the fatality rates of contractors within the petrochemical industry is higher than that of permanent plant workers. One of the initiatives that I would like to see evaluated is a -- not only

a compliance effort, but within our organization we have instituted a process within our petrochemical industry to assure that every contract worker is drug free, security background checked, safety trained and skill assessed. These four cornerstones of contractor compliance needs to be implemented throughout the whole industry. The events of September -- or the events of March 23rd on 2005 only involve contractors at the BP facility in one area, and that was in the area of fatalities. There was not one contractor man-hour that was spent in that unit that exploded. The only event was regarding contractors' locations within the facilities for facility siting and location of trailers. This also needs to be an area that needs to be investigated and researched within this initiative to ensure that we have safe distances, determine what those distances are to ensure that these people are not placed in harm's way in the event of catastrophic explosion.

Secondly, the process hazard analysis requirement within the standard needs to be evaluated. Over ten years have passed since the initial PHAs had to be completed. It is imperative that we review the effectiveness of these PHAs to ensure that it is not just a checking the box once we completed the initial PHA in 1995. What effectiveness do we have to ensure that we've incorporated management of change activities into these PHAs? How are the information being communicated, not only to the operators, the maintenance personnel and the contractors, but the effectiveness of this communication is imperative.

The events of March 23rd, 2005 at the BP refinery in Texas City needs to be a catalyst to use the resources of NIOSH to be able to evaluate these issues and share the findings with the rest of the industry.

Lastly, other issues involve the effectiveness of the mechanical integrity processes for the petrochemical industry, and the need to conduct research on the best practices on mechanical integrity and share these throughout the industry and with other trade organizations such as API, NPRA, Texas Chemical Council, and other industry trade associations. Thank you.

I am a manager in an operating room and have three employees who are in their first trimester of pregnancy. They are concerned about exposure to radiation

(C-Arm X-Ray, fumes from methylmethacrylate--bone cement polymer, and gases from anesthesia sources). we (management and co-workers) have been trying to arrange scheduling to avoid exposing the pregnant staff to these cases which impacts the amount of people to take call in a smaller OR. When on call the possibility of doing one of these cases is quite high.

Are there any regulations to help guide us? Most of the other OR's that I have questioned do not provide any provisions for the pregnant worker. My theory is that a safe pregnancy ensure a happy employee but I want to do the correct thing for all of the staff.

I appreciate any assistance that you can provide.

Comments offered to NIOSH, as NORA is revised Carol Rice, Ph.D., CIH Professor University of Cincinnati

Under Section 21 of the Occupational Safety and Health Act, NIOSH shall

provide for the establishment and supervision of programs for the education and training of employers and employees in the recognition, avoidance and prevention of unsafe and unhealthful working conditions in employments covered by this Act.

These are very specific phrases in the Act--phrases that characterize the outcomes of training and education: recognition, avoidance and prevention. This comprehensive description given to NIOSH extends the responsibility well beyond the creation and dissemination of information. Information understood and retained is essential to any increase in knowledge--the foundation for activities that lead to recognition, avoidance and prevention. However, knowledge alone cannot provide the vital skills, abilities and attitudes to fully recognize hazards, or to design and successfully implement actions or programs to avoid and prevent unsafe and unhealthful conditions. Identifying meaningful outcomes and the success of the outcomes in the work setting requires research.

In the current climate of smaller regulation and even smaller enforcement, it is increasingly incumbent on employees to take improving their safety and health into their own hands. Increasingly, a union or active joint labor-management committee that might provide effective health and safety training resources are absent, especially at small companies. NIOSH can, and is in fact mandated, to address this

need. Certainly the crafters of Section 21 intended that the change to a more healthful and safer work environment would be successful—a result that can only emerge from continued research, and then research to practice.

Currently, the need is enormous.

In dimension it exceeds that of improving science literacy—which has been identified by President Bush as a national priority.

And the easy approach of providing information is a fundamentally flawed and failed system, as illustrated by a situation we have each been subjected to or witnessed:

The struggle with written directions to operate any one of the wide array of electronic devices now on the market.

(This has been reviewed recently in a strictly academic mode by Burke et al, AJP 96:315-324.)

While the task is large, it must also be recognized that the benefits are also large. Workers participating in training designed through research in one sector to increase knowledge, skills and abilities and to develop attitudes that support continued diligence and improvement are able to make changes that improve working conditions. Four anecdotal reports follow:

We now use cameras in confined spaces—camera goes in, people remain out.

We had not had an ammonia release in our facility for many years. Because of the skills my team members had, we were able to isolate and abate the ammonia leak efficiently and were able to keep anyone from getting hurt.

Training was helpful in siting and setting up a decon line for a spill of chlorosilanes caused by equipment failure. A portion of the hazardous material formed hydrochloric acid fumes when it mixed with moisture in the air. Even though it was a very hazardous situation, only one person received minor injuries and was treated and released.

Training changed our work behavior and made us think about working safe.

(See final report, Midwest Consortium for Hazardous Waste Worker Training to NIEHS, October 2005).

The economists can put dollar figures on these examples; they are essential to documenting value to employers and insurance companies. To the workers and families of the workers who benefit from the training, the dollar value is not relevant. They are guided by the expectation that each day their family member will return from work with no diminution in health.

Most importantly, the benefits of avoided exposures are meaningful on an individual level—and the individual is our foremost constituent in occupational health and safety.

The following are some steps to consider in addressing this mandate of quality training to achieve recognition, avoidance and prevention:

--. Update and supplement the NIOSH review by Cohen and Colligan, 1998 to identify models of worker training and education that have proven to accomplish the NIOSH mandate. This will be very useful in identifying gaps and sector differences.

--. Identify targets for improvement and design research to identify why current approaches have not met the need, such as:

a. training programs needed: industry sectors or cross-sector operations where increasing workforce skills, abilities and attitudes in “recognition, avoidance and prevention” would have substantial impact on health.

b. better use of existing media: For those who will be workers, NIOSH might conduct research to identify effective methods of implementing the NIOSH school checklists as part of the science literacy initiative in teaching programs.

--. Define knowledge, skill, ability and attitude goals resulting from the research

--. Conduct intervention research to evaluate the impact of training

Evaluation of the impact of each element will necessarily include feedback from participants after the return to work.

These ideas are not new to NIOSH leadership. They are articulated here because I believe Section 21 must be at the forefront of a comprehensive approach focused on research that will benefit workers during the next decade. In both large and small workplaces, the workers are central to the reduction of unsafe and unhealthful working conditions. They need this research, and it is the legal mandate of NIOSH to identify through research the determinants and elements of both educationally effective and cost effective programs to increase health and safety at work.

Support development of a computer program that will automatically code industry and occupation information. Industry and occupation information is captured by many public health records systems. These include death certificates, cancer registries, and birth defect registries. However, this information is rarely utilized to its full potential. Coded data is the most electronic-friendly form of industry and occupation information. NIOSH developed an automated coding system to assign 1990 Census codes to industry and occupation. However, the program was prone to coding errors and the codes it assigned are now outdated. A new automated coding program needs to be developed to improve and expand collection of useful industry and occupation information. Surveillance data that may be grouped by industry or occupation is critical for the growing number of hard-to-study occupations or industries that do not keep centralized personnel records. It is needed to improve the quality and quantity of injury, illness, and exposure data for prioritizing safety and health research for these industries. These data may be used to track progress and evaluate prevention efforts. Development of an automated computer program that will automatically code industry and occupation information is the next step in closing the gap between work and health.

I encourage NIOSH to consider broadening the scope of funding to Health and Safety Groups that work directly with workers, including vulnerable workers such as youth and immigrant workers. Groups such as COSH Groups [Committees on Occupational Safety and Health] have been working closely with these populations for many years. NIOSH needs to support an increase in the level of funding for these activities.

Verbal Comment 2006/01/23: Good morning, Director Howard, members of the NIOSH NORA team. Thank you for the opportunity to speak. I would also like to thank Dr. Sarah Felknor for bringing this town meeting to Houston. Thank you, Sarah. My name is Ben Amick and I'm associate profession of behavioral science and epidemiology, and a member of the Southwest Center for Occupational and Environmental Health.

First I would also like to take the opportunity to congratulate NIOSH on the success of NORA I, and your vision for NORA II as a sector-based approach. I would like to speak to you today about injury prevention and control in the healthcare sector. I will use broad brush strokes to paint the picture today, but will provide more well-documented written comments.

My comments are shaped by my own work experiences. I had the privilege of working for five years in the U.S. Congress as a policy analyst. I have collaborated with industry and labor on the first large-scale chair* intervention study and -- that demonstrated both health and productivity effects. And am now intervening in a variety of nursing homes, hospitals and social service organizations with a new program we've developed, the (unintelligible) vocation program, to change work. And finally, I am the co-developer of the most commonly-used presenteeism (sic) scale, the work limitations questionnaire, and

a new series of scales to assess organizational policies and practices in injury prevention, disability management and return to work.

My messages are simple. We must scale up our intervention efforts to create scientific knowledge that can provide the evidence base needed for scientifically credible recommendations. Pre post-only test interventions with no control groups are unacceptable. We can no longer continue to support interventions that have fatal flaws in them and therefore are subject to the criticisms, both by labor, employers and the scientific community with respect to the evidence.

Multi-site interventions are critical. We must no longer do single-site interventions, but multi-employer, multi-site interventions to demonstrate that interventions can be conducted and implemented at multiple sites and multiple companies and in both the public and private sector.

We must recognize that health promotion and health protection are integral in the successful implementation of interventions. They are synergistic. We often go into work sites assuming that everybody that's in the work site is willing and ready to change. This is wrong. Many people exist and live in our society and they are constantly told that they cannot engage in any successful change, and therefore we must engage in both health promotion programs to bring everybody up to the same place, and then the health protection programs. They act in synergy. These are critical to provide the types of information necessary for systematic reviews.

We must ensure our valuable research dollars are effectively used by developing consensus on the outcome measures. When each scientific group uses different measures, we are faced with difficult challenges in research synthesis. We have just finished a research synthesis of the office ergonomics intervention literature, and unfortunately we were unable to integrate the scientific -- the published information into a single set of effect measures because there is no consensus on the outcomes used. We must have consensus and part of NORA II has to be developing consensus panels on the measures to be used in large-scale intervention studies or we will not be able to leverage our science.

We must measure outcomes that are meaningful to all stakeholders, including measures of productivity and human burden of occupational injury. While there has been a clarion call for measures of objective productivity and measures of presenteeism, which I think are very important for many people, we must also remember many workers work with injuries and absorb a burden. So we must also capture the burden of those injuries on the individual worker, their family and the household. Those are a different set of measures. They need to be measured differently, but they're equally important.

We must transfer knowledge by conducting systematic literature reviews that meet acceptable scientific standards for research synthesis, but also answer questions that are relevant to all stakeholders. To produce a literature review which answers a question which a group of scientists find interesting but nobody else finds interesting is really not enough anymore. We must engage stakeholders in the questions that we answer in our literature reviews. We have just finished one on office ergonomics and are just starting one on nursing homes, and liter-- systematic reviews provide a public face to our science. And we must be engaging in them in a continuous process where they get re-reviewed every other year, and this is the type of knowledge that allows us to engage in work with workers.

Zero? Okay, let's see, one last comment. We must recognize that employers and labor are not passive receptors of scientific knowledge, but active agents of change that should be studied. We have left this organizational context out of most of our research, and I would just remind you all that if you go back to

Barbara Silverstein's original paper on force and repetition, the exposure effect was equally as large as the five plants that were implemented as indicator variables in the studies, so there's something going on at the plant level that matters. And we should be studying that context because how we -- understanding that will help us succeed in doing interventions. Thank you.

Note: Verbal testimony provided to NORA Town Hall meeting in Houston, TX, 2006/01/23.

Verbal Comment 2006/01/23: Thank you, Dr. Felknor. Much of the -- I am an occupational medicine physician also. I work and teach at the University of Texas School of Public Health, Dallas Regional Campus. I want to talk to you about brominated flame retardants, worker safety and health.

Brominated flame retardants, especially polybrominated diphenyl ethers, are widely used in the United States to reduce fire injuries. They are found in television sets, computers, fax machines, in some textiles, styrofoam in chairs and mattresses and in carpet paddings. These brominated flame retardants are currently found in all people studied in the United States, whether blood, milk, fat tissue or fetal liver.

Levels of one of these types, the polybrominated diphenyl ethers, or PBDEs, are orders of magnitude higher in the US than found elsewhere worldwide. High levels have been reported in U.S. household vacuum sweepings and on office computer and computer monitor wipes.

There is both structural and toxicological similarity of PBDEs to PCBs. Animal studies with PBDEs show similar health outcomes, cancer, reproductive and developmental toxicity, endocrine disruption and central nervous system alterations. No human health studies have been published at this time.

The only occupational study worldwide is from Sweden. There are no U.S. studies on worker safeties. Worker studies in Swedish electrical recycling workers showed elevated PBDEs in the blood of workers.

After worker protective measures were instituted, levels decreased. The elevated PBDE levels reported in exposed Swedish workers, the exposed Swedish workers, were lower than the general population levels for the United States.

It is believed that some U.S. workers are at risk from PBDE and other brominated flame retardant exposure. Exposure and health studies are urgently needed to document exposure and possible adverse health consequences from such exposures, as well as to take preventive measures.

Workers at risk include those involved in manufacture of brominated flame retardants, including the one type that's still being manufactured in the United States; those involved in putting brominated flame retardants on or into electronic, textile, styrofoam; those involved in recycling such materials; first responders, such as firefighters, police and emergency medical specialists; as well as garbage disposal and incineration workers.

Since PBDE levels in humans have gone from not detectable in the 1970s in the USA to the highest in the world in the early 2000s, while at the same time dioxins, dibenzofurans* and PCBs have declined -- government regulations are working with respect to these persistent organic pollutants -- that it is of considerable urgency to determine which exposures (sic) are exposed, how such exposures can be decreased, and what the health consequences are of worker and general population exposure.

Hopefully NIOSH, the National Institute of Environmental Health Sciences and EPA, along with partners in university and industry can work together to decrease this potential human health hazard. Thank you.

Verbal Comment 2006/01/23: Good morning. Thank you. Again, my name is Dave Coultas. I'm a pulmonary physician and chairman of medicine at the University of Texas Health Center at Tyler. As a pulmonary physician and epidemiological researcher I've had a longstanding interest in occupational and environmental lung diseases, health disparities and prevention of chronic lung diseases.

During my training as a pulmonary physician over 20 years ago, my perspective on occupational lung diseases was largely limited to the classical dust-induced diseases from inorganic dust, including asbestos, silicosis and coal workers' pneumoconiosis, and organic dust such as farmers' lung. Subsequently my knowledge about occupational lung diseases was greatly influenced by my clinical and research work with miners in New Mexico and Colorado. Over the past 20 years we have learned that many more workplace exposures are associated with a much wider range of acute and chronic lung diseases than these classic dust-induced diseases. Occupational exposures are associated with non-malignant diseases such as asthma, chronic obstructive pulmonary disease known as COPD, and idiopathic, quotes, interstitial pneumonias and malignant respiratory diseases.

First, chronic airflow obstruction from asthma and COPD has huge public health and economic impacts in the U.S., and a substantial proportion of morbidity from chronic airflow obstruction is attributed to

workplace exposures. Of the over 16 million adults with asthma in the U.S., up to 33 percent of over five million are estimated to have work-related asthma, either caused by or worsened by exposures at work. And of the 12 million persons -- estimated 12 million persons with COPD, growing evidence over the past ten years strongly suggests that up to a quarter, or about three million of COPD may be attributed to workplace exposures. In addition, of all the causes of death in the U.S. such as heart disease, stroke and cancer, COPD is the only one with rising rates of mortality in the U.S.

While these estimates for the number of persons affected by chronic airflow obstruction from workplace exposures are large, these numbers are probably underestimated because the true number of affected persons with asthma and COPD are frequently under-diagnosed. Furthermore, the proportion of persons with chronic airflow obstruction affected by workplace exposures varies between racial and ethnic groups, estimated at 22 percent among whites, 23 percent among African-Americans, and strikingly 50 percent among Mexican-Americans. A wide variety of workplaces have been associated with increased risk for chronic airflow obstruction including the armed forces, rubber, plastics and leather manufacturing, utilities, textile product manufacturing, construction, metal and automobile manufacturing, food product manufacturing, and agriculture.

Well, the -- now, switching gears from chronic airflow obstruction to the chronic fibrotic lung diseases, including asbestosis, silicosis and coal workers` pneumoconiosis are among the classic occupational lung diseases, there is growing evidence that other fibrotic lung diseases also may be associated with other occupational and environmental exposures. For example, the "idiopathic" interstitial pneumonias, chronic pneumonias with no known cause, may in fact result from a wide variety of occupational and environmental exposures including farming, metal and wood dust exposure, silica and cigarette smoking.

In a meta-analysis that I conducted recently of six case-control studies of idiopathic pulmonary fibrosis, also known as IPF, the population-attributable risk for cigarette smoking was estimated at 49 percent, and 20 percent for farming.

While the idiopathic interstitial pneumonias are not as common as asthma and COPD, there`s no effective therapy for IPF, and this evidence suggests that there may be an opportunity for prevention.

Similarly, effective treatment for lung cancer -- switching gears again -- is very limited and prevention offers the greatest hope. Nearly 60 agents found in a wide variety of workplaces are established or suspected human carcinogens, and it`s -- the estimated attributable risks range from five to 35 percent, and it is estimated that in the U.S. over 16,000 lung cancer deaths may result from occupational exposures.

So in summary, we have strong evidence that combined chronic respiratory diseases from workplace exposure in the U.S. result in a substantial public health burden. Moreover, workplace exposures that cause respiratory diseases disproportionately affect non-white and lower socioeconomic populations who have traditionally been overexposed in hazardous industries. Thank you very much.

Verbal Comment 2006/01/23: Good morning. My name is Michelle McHugh and I'm a doctoral student in Environmental and Occupational Health Sciences here at the University of Texas School of Public Health. I'd like to thank NIOSH for coming to Texas to gather our contributions for the second National Occupational Research Agenda. I'm pleased to say that this is my second time participating in NORA, having been on the other side of the microphone in 1995 when I helped organize the town hall meeting in Seattle, Washington with staffers from Dr. Rosenstock's office.

I would like to focus my comments on answering the question of how I can make a difference for workers. Without the graduate traineeship I receive in industrial hygiene through the NIOSH Educational Research Center we have here at the University of Texas School of Public Health, I'd have to say not as big as I would like. My comments today focus on the importance of continuing to fund the 16 NIOSH ERCs located throughout the United States. Funding for these centers to train occupational and environmental health specialists through graduate-level academic programs and continuing education courses is vital to conducting the research that will reduce work-related illnesses and injuries, as well as the promotion of safe and health workplaces. I need to caveat that and say the research and practices.

I've had the opportunity to directly benefit from two of the ERCs in the last 12 years. My first association was as the program coordinator for the University of Washington's occupational and environmental medicine residency program, and later as a continuing education coordinator in the Northwest Center for Occupational Safety and Health. Both programs are components of the University of Washington's ERC.

My time at the University of Washington introduced me to the field of occupational health and safety, and ignited my desire to work to protect the health, safety and well-being of those in the workplace and community. While at the University of Washington I truly worked with professionals dedicated to this mission, and their commitment to the field is what led me to pursue graduate-level training in occupational and environmental health.

My second association, with another ERC, is through my funding as a doctoral student in industrial hygiene at the University of Texas Southwest Center for Occupational and Environmental Health. My NIOSH-funded traineeship enables me to focus on a field that is truly my passion, and contribute to progresses in occupational safety and health. I am able to work and learn from another set of professionals equally as dedicated as those I worked with in Washington.

In closing, I sincerely hope NIOSH will continue to fund these centers, as the individuals trained in the graduate-level programs and continuing education courses are going to be the ones who can answer the questions posed here today: Who is at most risk? How serious is the issue? What research is needed? Who are the stakeholders and partners, and how we can make a difference. Thank you.

Verbal Comment 2006/01/23: Actually I`m -- I`m splitting; I have a split personality today, so if you could give me a zero after the first one, then a second one. I have two topics, actually. You can look on your list.

I`d like to thank Director Howard for the opportunity, sir, for putting this together, School of Public Health. I`m Lawrence Schulze. I`m from the University of Houston and the School of Public Health. I`m an adjunct professor here.

My first topic is regarding the petrochemical process workers on the heel of Ron Sokol. I`m not sure which sector this fits into. You may consider a ninth sector as the petrochemical industry.

The average age of a petrochemical process worker in the United States is about 55 years old, predominantly male, predominantly overweight or obese, and deconditioned. Injury distributions are about 50 percent back injuries, 20 percent shoulder, 20 percent wrist, and about ten percent head, face and neck injuries.

Where do these injuries come from? The most common factor is opening and closing manually-operated valves, either by hand or by using -- the most common is either a pipe wrench or the new aluminum valve wrench. When putting an aluminum valve wrench on steel, aluminum loses out, they tend to slip. And then there`s reaction forces that the worker has to deal with.

We conducted a pilot study funded by NIOSH -- thank you very much -- looking at rotational force capabilities of males and females between the ages of 35 and 55. We simulated the opening and closing of valves using actual valve hand wheels, heights taken from the workplace, using a rotational force transducer that allowed us to adjust height, pitch angles, et cetera. We also compared these results to standards that are published by the American Bureau of Shipping, published in books by Kodak, Van Cotton, Kincaid, which is typically the most referenced references that people use for designing workplaces, and compared the 35 to 55-year-old data to the data in these standards which was collected on 18 to 24-year-old military personnel straight out of boot camp.

What did we find? We found that every measurement that we took for pitch angle, height and distance was nowhere near the capabilities of these young workers that we have established as our standard.

What do we need? We need to collect data from workers, the deconditioned worker out in the workplace. We don't have any of this data. We need to do that, or we're designing systems for 18 to 24-year-olds that 55-year-olds are working. I don't know about you, I'm 48 and I know I can't do what I used to be able to do at 18.

Verbal Comment 2006/01/23: So my next topic. This is healthcare related, and because I was told I couldn't do one in the morning and one in the afternoon, I'm doing this in the morning. This information is fundamentally related to many of the healthcare presentations that you're going to hear this afternoon.

New demographics addressing the nursing shortage in the United States is being affected by Filipino, Indonesian, Malaysian populations, as well as Latin American populations. These Latin American populations happen to be mostly from Costa Rica, Honduras and Nicaragua.

What does that mean? This is similar to what we saw in the early '90s, for those who have been in the healthcare industry around the Texas Medical Center back then when we had a nursing shortage crisis. We had an influx of nurses from other countries, which essentially brings down the average height of the workers.

What do we know also that's going to happen in the next ten years? About roughly 65 percent of the U.S. population is going to be 55 years or older. Here comes the baby boom population.

What do we also know? That for women the average dress size in 1989 was eight, and now it's 16 to 18. Which means that our populations are heavier -- that's from the textile industry, by the way. Our population is -- two-thirds of our population is overweight or obese.

What does that mean for someone who is five foot tall or five foot two trying to move a patient that's 165 pounds? You have the potential for musculoskeletal injuries that you're going to hear about, other

injuries, back injuries -- and we know the lifetime back injury rate for nurses is 80 percent. Some -- 80 percent of the nurses will suffer some type of back injury in their career. What does that mean for the shorter-statured worker?

We've also looked at the data that we've been using for years, the NASA 1024* standard, which by the way, the most popular standard that we use. And we've also looked at the CAESAR data, the Civilian Anthropometric and European Surface Anthropometric Resource, that was funded partially by the government and military, the car makers and the textile industry. CAESAR has 2,400 usable individual people in it. When you stratify (sic) that data by the socioeconomic level that they talk about, age and gender, you roughly get 15 people per cell.

So what did we decide to do? One of my students getting her master's degree is from Peru, so she decided to collect some data on Latin American nurses. She'd collect data for 30 nurses and compared it to that 15, and what did she find? She found that no anthropometric data point matched any of the CAESAR data. So we are using CAESAR data -- the car industry, the textile industry, the patient industry like the Hoyer lift, et cetera, for all equipment being used, and they're using the CAESAR database. Doesn't match what's out there. We've got a problem.

Also on top of that, the human factor's an ergonomic society and you hear the United States has endorsed the use of the ISO-7250 standard, which is the European standard for anthropometric measurement. By doing that it negates many of the data points that we're using in the CAESAR database or in the NASA 1024 database -- any database pre-2000 negates and makes them obsolete.

What do we need to do? We need to collect some real data on real people that are out there in the workforce. Not the people who volunteered, like myself, to go get measured for the CAESAR database. We need to measure nurses. We need to be designing the workplace to protect the nurses, using real nursing data from real nurses, not from the general U.S. population because that population does not appear to match the data that we're using to design.

I'd like to thank you for the opportunity for this short brief moment to present these two -- what I feel are very important issues with the petrochemical process industry, as you know, and also with healthcare topics that you'll be hearing more about this afternoon. Thank you very much.

Categorized comment or partial comment:

Verbal Comment 2006/01/23: Good morning. My name's Larry Whitehead and I direct the industrial hygiene program here at the Texas ERC. I spend a lot of time in national academic activities, various committees and such, where the programs try to figure out what it is we're doing as we educate industrial hygienists, but the data also suggest that we still need industrial hygiene education and graduates, but should be broadening the scope of that education.

Graduates in environmental science in schools of public health dropped by 29 percent in the ten years 1994 to 2004, according to the Association of Schools of Public Health. Many industrial hygiene programs observed the same pattern. Other public health majors were steady or grew in number. So why is this? Well, no one in the various school programs is completely sure. Answers most likely include lack of awareness of graduate study in environmental and occupational health among the undergraduates who might be coming here; not realizing the jobs exist, although I tend to doubt that many undergraduates are aware of the IH job market directly; an increase -- and I think this is a big one -- in attractive jobs in other areas. For example, the growth of molecular biology has suddenly made biology majors look very seriously into that direction, and there is a lot of employment. And perhaps reduction in social focus on environmental issues.

To address these issues among undergraduates the American Industrial Hygiene Association recently published a video on the profession that's really very good, as well as a PowerPoint and a number of print materials, all of which they have available on-line and have distributed to the identifiable academic programs in the country for industrial hygiene. The schools are present on the internet, as they must be, but they need to be efficiently found by search engines. That's our problem to figure it out, but we're working on it. Our ERC and our Division of Environmental and Occupational Health Sciences, for example, have redesigned our web sites, and also this fall e-mailed information on our programs to just about all the science departments we could find and student clubs -- which is a useful means -- in biology, chemistry and pre-med at approximately 25 four-year colleges and universities within a

reasonable driving distance because we offered to speak at these and made about a half-dozen campus visits.

We're just getting started on figuring out how to recruit (unintelligible) graduates. You'd think -- been doing it for 20 years. No, we really didn't need to in industrial hygiene, and now we have to figure it out. We'll know very soon if the applicant pool was increased.

There are jobs in industrial hygiene, but the situation is complex. Many industries have mature occupational health programs but basically have only a replacement employment market that is not expanding or is shrinking somewhat. Consulting appears to also be at a replacement level.

Why do I mention that? Well, a third of hygienists are consultants. The IOM/NIOSH monograph, *Safe Work in the 21st Century*, discussed the need also for occupational health services in the service industries and in small and medium-sized businesses which is not being addressed. I don't think that's solved yet.

Data suggest the job demand is changing. A thesis here by Virginia Rodriguez examined trends in utilization of Certified Industrial Hygienists since 1990. The number of active CIHs is down about five percent from its peak just a few years ago. This may not yet be a trend, but it's the first substantial drop in almost 20 years. Consultants make up about a third of the profession, but that group has leveled off.

Industries that traditionally need many hygienists show little or no growth -- excuse me -- little or no growth in the numbers of hygienists, or are shrinking, and these include chemicals, refining, insurance and transportation equipment. For example, Ford this morning announced cutting 14 North American plants in the next few years, and 25,000 to 30,000 jobs over roughly the period 2007 to 2012. Only the industries of, quote/unquote, consulting and educating -- and educational services were both among the top ten in numbers of hygienists in 1990, and have grown at at least five percent per year on average since then. But consulting is now flat. It depends on everyone else needing industrial hygiene services, and that's gone down.

So where are we? Manufacturing demand is flat, averaged over the last 14 years. Some major industries are dropping. Industries that utilize consulting are not currently expanding that need. The service sector grows, but in most portions of this sector, one IH supports many more workers than in manufacturing. Possible exceptions to this include educational services and healthcare services.

Okay. In closing, industrial hygiene is changing. Our education includes more safety, environmental and management content. These are converging. Traditional industrial hygiene I think is shrinking if you define it the way it's been defined for 50 years. But as we redefine what it means to practice a broader field, I think industrial hygiene will not be shrinking, but it will be changing, and the academic programs need to figure this out. NIOSH training will continue to be vital to this future, as it has been for 30 years. Thank you.

Verbal Comment 2006/01/23: I understand. I'll stay in the vicinity. All right?

How are our workers getting hurt in the construction industry? We looked at this problem within our company and did a little bit of research. We took three years where 100 injuries had occurred, and we analyzed how they got hurt. And I've also subsequently done this in several other construction companies or in conjunction with them, and I'll offer this graph in evidence that -- it's of -- where -- how injuries occur in the construction industry. What it says is 84 percent are primarily behavior. The employee knew better, but he chose to do something different. Another 12 percent of those involved a behavior and a condition that caused him to get hurt, and generally speaking that's where the most serious injuries occurred. And only four percent of our injuries were conditions or miscellaneous type injuries that we couldn't quite account for because of the data may be in improper reports. But I found this to be within five percent of all the five different -- four or five different times we've done this.

So this kind of tells me that maybe measuring -- and please, don't anybody take offense by this -- the amount of sand that we breathe every day is not where we need to spend out time, but maybe in how to get the worker to want to work the way we train him to work.

We analyzed our incidents and came up with a graph showing where people got hurt. The highest frequency came in eyes on their path, not looking where they were going, making a quick step first before they thought about it or planned it. Line of fire, getting between a fixed and a moveable object. And lifting and carrying was probably one that maybe needs a little more work, but the person knew how to lift; he just chose to bend his -- bend at the waist as opposed to bending the knees. He knew -- he knew how to lift. When you'd ask him, he'd say yes, but it didn't look that heavy so I just picked it up. Okay?

Does this work in the construction industry? I spoke of behavioral safety now back in October, and I knew I was going to get that question so I put together a few statistics. We invoked a behavioral safety system where we do have workers doing observations of one another and giving one another feedback and developing the communication at the job site level. And being (unintelligible) behavioral safety now, I thought I'd throw them a curve ball and I said Tom Krause doesn't know anything about workers getting hurt. And -- my God, I don't want to say this; I'm having one of those moments -- Scott Geller's a fool and the consultant that we used to develop our program, Terry McSween, doesn't know how to spell safety so he calls it value-based safety.

We did our first observation and feedback session on the 15th of July, 2003 and we had three pilot projects for the remainder of 2003 that were doing behavioral observations. We had 272 observations per month during that -- remainder of that year at only 37.6 percent participation, but they were 97.3 percent safe.

2004 we rolled it out across the whole company to see how it would work across a commercial construction company. Okay. We turn over employees about as fast as anybody -- let's just put it that way; I'll be polite with this crowd -- and in 2004 we jumped up to 784 observations per month at 58 percent participation across the whole company, and 97.5 percent safe.

2005 up through the beginning of the conference I ran it per month again and we jumped even farther to 876 observations per month with 73.1 percent participation, and a rate of 97.8 percent safe.

These numbers seem to indicate that the workers will do this, even in an environment where it had never been tested before, the commercial construction environment.

Is this important to us? Well, from my perspective, 18,179 times safety was talked about on a Linbeck project by peers. And to me, that's important.

Verbal Comment 2006/01/23: My name is Chip Carson. I`m a faculty member here at the UT School of Public Health in the Southwest Center for Occupational and Environmental Health. I`m also the director of the occupational and environmental residency program housed here at University of Texas in Houston. I`m the incoming director of the National Association of Occupational Medicine Residency Directors. And I am myself a recipient of a NIOSH traineeship during my doctoral training at another ERC in Cincinnati some years ago, and have benefited greatly from that.

What I`d like to talk to you a little bit about today is education of occupational health professionals and the needs we have for that -- a continuing need.

Recent reviews, analyses and published opinion papers have pointed out there is a dramatically-changing landscape in occupational health practice in this country. It`s very different from what it was back in 1970 at the passage of the Occupational Safety and Health Act and when the concepts of the roles of occupational health professionals became really fixed.

Injuries and illnesses in the American workplace are addressed by a number of systems. One of those notable of course is the workers compensation system. Well, who staffs the workers compensation system in terms of occupational health professionals? It`s primarily primary care professionals -- primary care physicians, nurses --with no occupational health training -- retired surgeons, various other professionals who get into this who have really no formal occupational health training.

So where are all our occupational health trainees going? They're being absorbed by the system to perform management, administrative, oversight functions for programs within industry or the healthcare industry, as well, or in academia -- which is a true need -- but they are not able to provide services. And this is because there are so few of them. There's been an identified shortage for many years of occupational health professionals, and this continues to exist. And very few of them are now getting directly into occupational health practice.

These trained people are now absorbed to do designing, monitoring and directing of the programs that are in existence, and to manage those programs that exist. This defines a true manpower shortage in occupational health professions. The shortfall comes in part from the limited funding for training that's provided in this country, most of which is provided by NIOSH and I think this agency deserves a great gratitude from us for being able to consistently provide such funding. But it's not enough, and it's not doing that job that we need to do and the job that we have consistently, in writing, identified as a big need for this country.

It is critical in our future to generate scientifically-valid needs analysis and productivity research to highlight not just the need for occupational health professional education, but also its value to our country as a whole, to its value to the productivity of business, and to its value for the maintenance of health of our human resources.

The American workforce is a prime laboratory for this kind of research. Practice-based research is an ideal mechanism for generating this kind of information, and there is also an opportunity for which we as occupational health professions are in a unique position to provide translational research for basic science research that is being generated in the academic setting, and put that into practice in the workplace in saving lives, preventing illness and injury.

I think we should take advantage of this to generate the necessary research that will provide a background to show this value, will leverage additional training elsewhere with currently existing funding in occupational health content, and establish liaisons of research agenda between not only NIOSH and practicing occupational health professionals, but also basic science research throughout the United States. Thank you.

More research is needed in the areas of low-level chronic exposures, exposure to multiple agents affecting the same target organ, and molecular epidemiology. Workplace exposure to some substances have decreased, however workers today continue to be exposed to unstudied combinations of hazards present at low levels. We are unaware of the adverse health outcomes of chronic low-level exposures to industrial materials, processes, and stressors.

Categorized comment or partial comment:

I agree in that the sector-based approach will allow NIOSH to address OHS problems in the industry effectively. However, I feel strongly that more emphasis needs to be placed on cross-sector issues. I strongly recommend that OHS surveillance needs to be strengthened. Data needs to reside in NIOSH, and more partnerships need to be formed to have access to data from other agencies. There should be a comprehensive national surveillance system. In-depth studies assessing particular issues should be carried out for factors identified by the comprehensive surveillance system.

Healthcare workers (HCW) are at great risk of illness and injury. I urge that researches should integrate surveillance and prevention intervention in the healthcare setting.

I recommend that more emphasis needs to be placed on Hepatitis C Virus exposures, infections, and diseases. There is neither vaccination nor treatment for HCV disease. Surveillance of exposures, adverse outcomes, and prevention interventions need to be implemented.

I also recommend to focuss on the ageing working population, pregnant women at work, and children entering the workforce.

Categorized comment or partial comment:

We support the effort to integrate state government partners into NORA II and agree with the recommendations made by Dawn Castillo regarding state-based surveillance at the NORA Town Hall Meeting on March 21, 2006 in Morgantown. To further illustrate this, we would like to point out a fundamental difference between surveillance research and state government public health surveillance programs that makes this distinction critical. State agencies rely very heavily on federal funding for surveillance programs. However, these agencies are generally not in the business of conducting research, and do not have sufficient infrastructure to plan, design, and apply for new research grants. Most state governments are reluctant to devote or hire appropriate staff for this purpose without program funding in place.

We do not dispute the importance of improving and enhancing occupational surveillance research. However, state-based surveillance should be considered separately in the research agenda, specifically in terms of funding mechanisms for surveillance efforts. As stated in Dawn's comments, state agency-based surveillance can provide data unavailable to nongovernmental researchers that is critical to guiding the national research agenda.

Verbal Comment 2006/01/23: Hi, thank you very much for folding me into the schedule. My name is Bronson Frick. I'm with the organization called Americans for Non-smokers` Rights. We're a national member-based organization headquartered in Berkeley, California. Our sister organization, the American Non-smokers` Rights Foundation, is our 501(c)(3) arm that does public education around a smoke-free workplace policy and the benefits of smoke-free air.

I'm here today to encourage NIOSH and NORA to conduct further research into occupational exposure to second-hand smoke. This research is incredibly important for helping point the way to solutions to that problem in a variety of workplace settings. Although many workers throughout the country are now protected from second-hand smoke, thanks to either corporate policies or the growing number of smoke-free workplace laws and ordinances, many other workers are left behind, particularly those in the manufacturing sector or in the hospitality sector, especially venues like casinos, restaurants, bars, bowling alleys, hotels and pool halls. Those workers are typically left behind, and they have one of the highest cancer rates of any occupational sector in America.

According to the Centers for Disease Control, at least 38,000 Americans still die every year due to exposure to second-hand smoke, and thousands more suffer disease. It remains a leading cause of preventable death -- leading cause of preventable death and disease in the United States, and it's all too preventable.

The new 2005 California EPA report now finds a causal link to breast cancer in pre-menopausal women from exposure to second-hand smoke. The California Air Resources Board will be voting in a couple of weeks to -- whether or not to make -- classify second-hand smoke as a toxic air contaminant, putting it in the same category as diesel fumes, so that relates to NIOSH's mission.

ASHRAE, the American Society of Heating, Refrigeration and Airconditioning Engineers, which is meeting right now in Chicago, they issued a board policy statement in 2005 reaffirming that ventilation systems are not a solution to second-hand smoke because there is no known safe level of exposure.

The U.S. Society of Actuaries issued a report in 2005 finding that second-hand smoke costs the U.S. economy about \$10 billion a year in lost productivity and higher healthcare costs, so it remains of vital interest to the economy for having a healthy workforce -- a healthy, productive workforce and a way to control spiraling healthcare costs.

NIOSH is prepared to do air quality and second-hand smoke-related studies in two casinos in Las Vegas this month -- I believe it's this -- actually this week -- based upon the complaints of two casino workers that were exposed to second-hand smoke and -- so we're grateful for NIOSH -- for responding to their complaints. Unfortunately the casino workers have been fired for having filed the complaint with NIOSH. After the original two filed their complaint, 200 other casino workers joined in the complaint and so the casinos obviously have acted against the original two as a way to scare off other workers.

Other workplaces -- like I said, factories, we still hear about like car manufacturing plants where people smoke on the line, and particularly other kinds of hospitality sectors. Our organization receives calls every week from casino workers, bar workers, they're hospitalized because of their exposure to second-hand smoke. But they're caught in this awkward place where if they quit their job then they're not able to feed their kids, or they might become homeless or unemployed.

Okay. So that's all I have. So thank you again to NIOSH for looking into the ongoing problem of occupational exposure to second-hand smoke. And we greatly value and appreciate your research that helps to quantify the health problem and point the way to solutions. Thank you.

Verbal Comment 2006/01/23: Hi, my name is Walt DeFoy. I'm a disability medical director for Aetna Insurance Company. I've come here through several channels, but the main reason I'm here is that I serve an advisory committee for Social Security through America's health insurance plans and I'm a member of the American psychiatric task force to develop guidelines for return to work assessment for behavioral health professionals.

We have reached a point in all of these areas where we don't know how to assess whether a person can return to work based on a behavioral health issue. That is, can they persist in a task; can they take supervision; can they supervise others; can they work collaboratively with coworkers. The need for the development of an assessment tool to evaluate these areas is extremely important, and I think it cuts across all the areas we've talked about today. But it's particularly important in returning to work and returning workers to work who have behavioral health issues.

That's important because now Social Security's behavioral health cases represent 50 percent of the new disability case log -- huge amount. In our organization behavioral health cases represent about 12 percent of all disability cases, but they take up to 40 percent of our resources. So this is a major area. I'm hoping that NIOSH might be able to impact or help with a research agenda in this area. Thank you.

Verbal Comment 2006/01/23: Yes, ma'am. I work for her. One of the things I'd like to address is I used to have an occupational safety engineering program grant and recently lost that due to our university not hiring another faculty member, which was one of the major comments, that I was a one-man show. However, I think NIOSH needs to reconsider this approach, simply because we can make up that difference -- if we cannot hire another faculty member -- through adjunct faculty members.

Mayor Consatti's* safety engineers` Gulf Coast chapter, which I'm the president of, we have 1,400 members in the Gulf Coast area, all within driving distance of our campus. There is a huge need for safety professionals with advance degrees. We cannot provide that in this area. The only place that they get to go is Texas Tech, and there's no school around here that allows us to do that in the engineering area.

So I think, and I would like to encourage NIOSH to reconsider their position about funding one-man shows. We were doing a great job. We had a lot of students that were interested in that. We still have students who are asking where they can go to get an advanced degree in occupational safety engineering, and the only place we get to tell them is to go to Texas Tech. And I don't know if you've ever been to Lubbock or not, but they're -- the industry availability in Lubbock for getting students to see what's happening in industry and actually putting to practice research and activities where they can actually do something and get their fingernails dirty and their hands dirty is not that available in Lubbock. It is in Houston. We have lots of industry, have a wide variety of industry. We have healthcare, we have petrochemical process, we have manufacturing, food processing industries here -- we have the gamut, and I'd like NIOSH to reconsider that position. Thank you.

Verbal Comment 2006/01/23: Thanks for your invitation to comment. I'm Barbara Smisko, director of national environmental health and safety for Kaiser Permanente. We are a healthcare services on an in-patient and out-patient basis to over 8.3 million members in nine states and the District of Columbia. Kaiser Permanente includes over 12,000 physicians and more than 148 (sic) non-physician employees. We operate 30 medical centers and more than 430 medical office buildings.

In 2004 hospitals reported more non-fatal injuries and illnesses than any other industry, and healthcare retained the fourth largest non-fatal incident rate compared to other industrial sectors. We have identified three issues -- cultural, ergonomic and hazardous exposures. These issues cut across all the aspects of healthcare systems that include hospitals, medical office buildings, laboratories, pharmacies and radiology.

First the cultural issues of healthcare. We have a good picture of what current injury risks are, although unique cultural challenges make reducing workplace injuries extremely challenging.

The biggest challenge is creating a culture of safety within the complex hierarchical structure.

Healthcare is predominantly practiced by individuals with a high degree of autonomy, and a willingness and openness to give and receive feedback needed in behavioral-based safety programs is not the norm.

Creating a culture of safety in healthcare is also challenging because of a rapid and constantly-changing environment, with new priorities arising that take the spotlight off workplace safety. New regulation is quite frequent and can consume an organization's efforts.

Recent revelations (sic) about prevalence of medical errors have shifted more focus on patient safety, which may directly compete with worker safety. The link between healthcare occupational safety and health and patient safety will be a critical component of moving the two fields forward together instead of in opposition.

The ability of an organization to maintain a productive and health workforce is becoming increasingly difficult in the United States. The aging workforce and the prevalence of chronic diseases resulting in lost productivity and higher costs to American workforce, including our own industry.

Categorized comment or partial comment:

The second issue is ergonomics. Ergonomic-related injuries are a primary contributor to the overall injury rate in healthcare. Sixty percent of Kaiser Permanente's workplace injuries are related to strains and sprains, and ten percent are attributed to work-related musculoskeletal disorders.

In addition to existing ergonomic risks, new medical technologies and electronic data systems are being introduced at a faster rate than ever before, creating new and more numerous exposures.

The changing demographics of the United States population introduce new ergonomic concerns as well. More chronically ill and obese patients who may not be able to assist themselves need assisted transfers in greater numbers than before.

Categorized comment or partial comment:

The third issue is hazardous exposures and unknown hazards. Healthcare is unique in that not only are workers exposed to known hazards like chemical disinfectants and waste anesthetic gases, but there is also a possibility that exposure to an unknown biological respiratory hazard could occur at any time. Respiratory protection continues to be one of the most difficult safety programs to implement. Healthcare specific evidence-based science is needed.

There are challenges in evaluating exposures to known hazards as well. The research on exposure and health effects does not always move quickly, so in some cases we truly do not understand what the exposures actually mean to our employees.

There is substantial evidence that hazardous drug exposures during preparation and administration may be more prevalent than previously thought. However there are few established methodologies available to measure airborne or surface concentrations of hazardous drugs, and very little dose-response information available to evaluate exposure data.

High level disinfectants pose similar exposure concerns, with new products being frequently introduced with little or no exposure data or sampling methodologies available to assist in evaluating potential health risks to healthcare workers.

In conclusion, healthcare faces many challenges in maintaining a safe and health workplace. The biggest challenge is creating a safety culture that is adaptable to the complex hierarchical structure and multiple

priorities of healthcare. In addition, the industry needs to create new ways of reducing ergonomic risks and assessing hazardous biological and chemical exposures.

We appreciate the opportunity to comment on the National Occupational Research Agenda. Thank you.

Verbal Comment 2006/01/23: Thank you. Good afternoon. My name is Linda Lee and I'm the executive director and chief safety officer at M. D. Anderson Cancer Center. And I'm also in the interim acting associate vice president for patient care facilities for the institution.

M. D. Anderson has about 16,000 employees, faculty and staff, and about \$2.5 billion of operating funds, 9 million square feet under roof, as well as about 1,200 research labs. So we have a pretty large facility and we, as environmental health and safety professionals, have some concerns and I think that they've been voiced in some aspects.

We're certainly concerned about personal protective equipment in relation to pandemic flu and emergency preparedness and availability should we have a flu outbreak in this country.

We're also concerned and would like to see some research on patients with infectious diseases and their exhalation from patient ventilators. There are filtrations on some of them, but some of them do not.

We're also looking at assessing chemical and biological hazards from exposures to manifolded exhaust systems. In the old days you used to have a dedicated exhaust system. Your lab went out. Now because of money and concerns, we have venti-- we have ventilation systems that are manifolded together, except in the highest hazards of BL3* laboratories.

And then finally, one of the drugs we have major concerns of course is Ribavirin. There's a lot of information out there on Ribavirin, but we continue to struggle with protective equipment, protective environments for patients, particularly pediatric patients where the parents want to be in the room during the treatments or the patient can't stay in the room during the treatment, what -- how and how should we protect the parents of the children and what is appropriate? We focus mostly on occupational exposures, but what about the non-occupational exposures from the patients and the visitors and their family?

I'd like to thank you for this opportunity today to address you and hopefully these things will be considered in your future research. Thanks.

Verbal Comment 2006/01/23: Thank you. My name`s Melissa McDiarmid. I`m with the University of Maryland School of Medicine`s occupational health program in Baltimore. And my topic concerns chemical hazards in healthcare. They`re high risk and high hazard, but generally poor recognition as such.

It`s counter-intuitive that the healthcare industry, whose mission is the care of the sick, is itself a high hazard industry for the workers it employs. This industry sector consistently demonstrates poor injury and illness statistics, among the highest in the U.S., while it employs about ten percent of the U.S. workforce. This suggests a large population at potential risk of health harm. It is therefore most appropriate that NIOSH has chosen this industry sector to be included in the next generation of NORA activity.

While possessing every hazard class, the biologic and musculoskeletal hazards are those typically considered in workplace safety programs. However, under-appreciated are the diverse and novel chemical hazards also present in the healthcare environment in the form of sterilants, germicidals, industrial cleaning agents and pharmaceuticals, including the highly toxic anti-cancer drugs. Many of these drugs are themselves genotoxic, carcinogenic and/or reproductive and developmental toxicants.

In recent years they have been the subject of environmental monitoring campaigns, which have demonstrated troubling results, with widespread work area contamination observed.

Responding to these observations, two NORA I teams, the control technologies and reproductive hazards research teams, joined efforts to sponsor an enormously successful working group of stakeholders affected by the use of hazardous anti-cancer drugs in healthcare. Working over four years, this group considered these new data, and proposed solutions and promoted them. In a splendid example of research to practice, this groups work resulted in the publication of the NIOSH alert on the safe handling of hazardous anti-cancer drugs in health care, with a national rollout in October of 2004. The work of the group, however, is unfinished and ongoing.

As NORA II receives the baton of responsibility for the research agenda in healthcare for the protection of present and future healthcare workers, it is important to build on the strengths of NORA I and capitalize on its legacy. The task will not be easy. Biases within the healthcare industry and the safety and health community collude to limit both the awareness of hazards which do exist, and the successful application of classical approaches used to assure safe jobs. The unique mission of healthcare also adds obstacles to our efforts in that self-preservation behaviors which normally may protect workers are suspended in a culture of selfless commitment to patient care. This erroneous either/or mentality must also be addressed by our safety and health community, and changed to a both/and outlook during worker training efforts.

While daunting in scope, it is critical that NORA II address the high hazard exposures of healthcare and specifically tackle this enlarging use of highly toxic pharmaceuticals. Already underway is an explosion of technology growth in pharmaceutical applications. Noteworthy here is that about half of the present nanotechnology applications are for pharmaceutical or other medical use. But again, due to this disconnect between the hazard recognition of drugs and the traditional lack of safety and health expertise in healthcare settings, the growth in high hazard chemical use has not been accompanied by stepped-up safety programs in hospitals.

Add to this the increasing frequency of complex care delivery moving outside of the hospitals to clinics and patients` homes. The migration of healthcare hazards enlarges the potentially affected population to those transporting these hazardous materials and to patients` family members as well. There are also patient safety issues suggested by gaps in safe handling practices of drugs and other therapeutic products.

The challenge for NORA II resides in continuing the vital safety and health advances of NORA I in this complex, highly technical work sector. A comprehensive culture of safety in healthcare must be crafted and promoted that allows the provision of life-saving therapies to patients while protecting and ensuring the health, lives and livelihood of the caregivers who treat them. Thank you.

major pharmaceutical companies

Verbal Comment 2006/01/23: Let me step this up a little bit. Hello. Did that wake everyone up? I'm a little less vertically-challenged than most, so I'll try to get this up to the right size.

My name is Hank Rahe, although it's one of the most mispronounced four-letter words in the language, and I'm technical director for Containment Technologies Group, which is a small company nobody's ever heard of. Historically I spent a short 30 years at Eli Lilly & Company. During the last eight years I had responsibility for developing and implementing containment technologies to deal with hazardous compounds. I was also part, and continue to want to be part of the hazardous drug group. And in those roles I wanted to share with you a little bit perhaps of experience through describing a journey.

A journey starts with a definition of a pharmaceutical. All pharmaceutical compounds are hazardous. The issue is how much and how often, because if they weren't hazardous or were not creating an effect, they would not have any benefit in society. So given the fact that they're all hazardous, what we need to look at is how much and how often, and how do we prevent that coming to -- inadvertently to people it's not intended to come to.

Looking down that journey it's also important to understand the delivery mechanisms for those compounds. Approximately 80 percent of the drugs that are delivered are delivered in what's called solid dosage form -- tablets, capsules, a little bit of powders. The others are delivered in what I refer to as parental or injectable drugs. And as Melissa indicated, there are a lot of new and innovative forms coming which have in themselves a high -- high level of hazard to them.

So to continue on the journey, let's take a brief look at drugs and how they're evolved or developed from discovery to delivery to a patient, and what happens along that way as they're developed.

I had the pleasure and pain of being involved with the committee at Lilly that established exposure limits for -- internally for workers and will share in the brief minutes I have a little bit of that. But one of the important things in developing a drug was to determine whether it was therapeutically effective or not, because if it wasn't there wasn't any point in evolving the compound to a pharmaceutical product.

Once it was determined to be effective, the next issue was what levels is it therapeutically effective at, and what levels, if possible, is there no effect level. The purpose of the committee that I sat on at Lilly -- which involved industrial hygiene people, development, engineering -- was to look at those drugs and provide a safe level internally for the development -- or for developing facilities and handling techniques for those compounds. And as you can imagine, in the world of pharmaceutico (sic) we weren't talking about a 250 milligram delivery, we were talking about kilogram, so facilities have been evolved to safely handle these drugs to exposure limits.

In the developing of those engineering controls three things are identified in OSHA and pretty well practiced are the means of control -- engineering controls, work practices and personal protective equipment. Also to go with that is monitoring, because if you don't know where your journey's going to, you don't know where you've been. So you need to monitor not only the workplace for safe exposure levels, but also the people that are involved in that workplace. So developing those strategies for engineering controls, personal protective equipment and work practices, and evolving the monitoring, are extremely crucial.

That has all occurred with the major development of compounds. The major disconnect, and I think what many of us are here to express our concern over, is the communication of that knowledge base to the delivery segment, the hospitals (unintelligible) practices, the clinics that -- and the healthcare givers that provide the delivery of those compounds to the end patient. And there is a major disconnect there, for a lot of reasons that you can't cover in five minutes total time. I'll skip over those but would be glad to discuss those later.

How do we overcome those major disconnects? I think that's one of the things that we're certainly here to look at. One is there is a knowledge base out there that needs to be tapped, and that's the major pharmaceutical companies, because they do provide facilities for deli-- for manufacturing these drugs and getting them into final dosage forms.

As part of the alert group, there were over -- I'm going to be wrong in my exact number, but approximately 15 major pharmaceutical companies involved with that. I think we need to re-energize that and see if we can take advantage of that knowledge base and transfer it on to the -- to the delivery section of healthcare.

One mechanism that's been discussed many times is banning/banding* exposure limits because, as you can imagine, with -- I think in terms of just simply cytotoxics there are well over 100 drugs out there so you don't really want 100 different exposure limits floating around. It just gets too confusing, so that's one potential and an objective I think that should be seriously considered.

The art of negotiation. The other major objective is self-help within understanding what goes on in the delivery process because there -- there have been many things completed, but there's no target. And as an engineer, for me to design an effective engineering control I need to understand what the exposure

limit I'm trying to deal with. The typical transfer in healthcare is taking a material from a vial, using a syringe to transfer it to the mechanism that delivers it to a patient. It's not a complicated operation, but we don't understand anything officially about the exposure limits that occurs during that. We've got gross data, but what does it mean? What level of the three forms of matter -- solid, liquid and gas -- do we produce when we simply do that transfer? There's an important piece of research, if done, can help greatly.

Verbal Comment 2006/01/23: My name is Shelby VanMeter and I`m a registered nurse. The reason I`m here today is because not only have I been affected by an exposure at work, I`m also a patient who has to deal with this. When I was asked -- 11 years ago when I was working as a nurse-practitioner -- to help expand and develop a new stabilization area for our newborn intensive care, I was ecstatic. I thought this is going to be, you know, the best thing. I can get everything I want in that facility and, you know, it`s the dream job. And I never expected that the construction from that development would not only end my career as a nurse-practitioner, but it would also affect my life, you know, from that day on.

I was exposed to chemicals while they were remodeling. I ended up -- instead of running to a delivery of a premature baby, I ended up going to the hospital myself, and that was the first of many events where I was hospitalized or had to go to the emergency room. This is something that`s impacted my life every day. Even to this point 11 years later, I`m still affected by that.

When I leave my home I carry a backpack that weighs almost 20 pounds, so that I have my nebulizer, my medications, everything that I could possibly need in case I`m exposed to a trigger going to work, at work, on my way home. I now work in an out-patient clinic, and I never thought that I would have to kind of dodge my everyday job because I have to avoid cleaners, dry erase markers, microwave ovens, anything that can put a trigger into the air.

I also have to avoid construction. Even though the facility that I work at does an outstanding job in keeping that construction out of our work area, there`s still vapors. There`s still dust. There`s still things that trigger that, and it`s just an everyday event.

I ended up leaving my job as a nurse-practitioner, which is something that I'd always dreamed about. I left nursing for four and a half years and finally, after finding an occupational environmental pulmonologist -- which was something that my workplace originally had never heard of. You know, I was fortunate to have a friend who went to the graduate school here and knew someone. But through my physician's care and new medications, I've been able to go back to work.

But I can't work in-patient because of the constant exposure of chemicals, cleaning, exhaust fumes from ambulances, things that are just common every day in our hospitals. But I've pretty much found a safe environment in an out-patient clinic working with children that have cancer. But still, just these simple things cause me to have issues every single day.

Verbal Comment 2006/01/23: I'm Ann Malecha and I'm the director of research at Texas Women's University College of Nursing here in Houston. We have three campuses, one in Denton, Dallas and here in Houston. And I'm talking on the interaction between personal stressors and workplace violence. And I will say it's from a nursing point of view, looking at nurses as -- coming from a nursing student. Just so you know, I'm representing -- we have over 50 full-time faculty here in Houston teaching undergrad, master's and the doctoral program in nursing. And it's been overwhelming, when we started to form a research team we put a call out to faculty, would you like to meet to investigate personal stressors and how it impacts -- we know nursing students 'cause we listen to nursing students, but also nurses. And we consistently have over 20 faculty that show up for each meeting. So we know, as faculty, our students come to us with great personal stressors, and they take those personal stressors to the workplace.

What I would like to say is there is a great deal -- lack of research on what do we mean by personal stressors. And if I look a little bit disorganized, it's 'cause I am in the process of trying to put together a literature review. There was a study that was recently put out in September, 2005 and they were just looking at how R.N.s view the work environment in terms -- just generally. And what they found is 31 percent do complain of back or musculoskeletal injury, and this was compared to 2002 data where it was 34 percent, so there was a slight decrease.

The second was episodes of violence in the workplace, and it was 28 percent in 2002 and it remains at 28 percent in 2004. And at the end of that survey the -- the conclusions were this is still a problem in the workplace in terms of high levels of violence.

It -- mostly when we talk to nurses and talk about workplace violence, if you look at workplace violence on a continuum from incivility all the way to homicide, most of the workplace violence they are talking about is verbal abuse, harassment and emotional abuse. And there has been a literature review conducted and, again, over and over the verbal abuse is what comes out as the work-- in terms of the workplace violence that I'm talking about.

In terms of personal stressors, again, there's been limited research done on it. There's been one researcher here in Texas, and she has looked at who experiences workplace violence in terms of nurses. And the two studies that she conducted -- I have my literature review -- she looked at workplace violence -- and over and over, this is another thing that comes out in the literature if you talk about stressors, is a history of child abuse. She found 58 percent of nurses have child abuse, primarily sexual abuse, 89 percent of those childhood abuse; 41 percent witnessed adult -- witness currently adult abuse. She did a study looking at Hispanic nurses and what she basically found is 94 percent suffer emotional verbal abuse at workplace violence.

Basically, to summarize, there's a definite -- she sees a history of abuse. Nurses that report workplace violence verbal abuse have a history of personal abuse. So that's -- in terms of defining one workplace stressor is child -- a history of child abuse, as well as a history of adult abuse and current abuse.

The only other personal stressor that has been studied is finances, and that has come out as a strong personal stressor is the worry about personal finances.

And then we recently just finished a pilot study here in Houston following 99 students one year after they graduated, and we found the same thing with personal finances being a strong personal stressor. But interestingly enough, we're seeing an increase -- instead of child care being a personal stressor, that more and more nurses are taking care of other family members other than children. We find about 18 percent out of the group of nurses were concerned about not having adequate care for someone at home other than a child, compared to only 15 percent for child care. So that's a growing concern.

But I guess to summarize, the research that's needed is what do we mean by personal stressors. There's a lack of data on that, but we do know it does impact how a nurse views workplace violence. Thank you.

Verbal Comment 2006/01/23: My name's Ilise Feitshans and I -- I teach in this field, but I also write a treatise called "Designing an Effective OSHA Compliance Program", so my comments are going to be very broad-brush comments pertaining to the history of occupational health and the future of NORA and NIOSH in light of that history and facing the challenges on the frontier of science.

When the U.S. Congress wrote the Occupational Safety and Health Act of 1970 it sought to cover a lot of ground in one bold stroke of the legislative pen. It sought to reduce injury and illness at work, to preserve our human resources by protecting the health of workers -- of every working man and woman in the nation, and to force development of new technologies through research and implementation strategies that would ameliorate working conditions throughout the land. Several fundamental flaws in OSH Act undermine its effectiveness. The many compromises required to pass this important legislation are reflected, one, in the lack of jurisdiction over very important sectors of the working population, such as public sector, some parts of mining, agriculture, things like that. And also the failure to provide private rights to action by citizens to enforce its tenets when the citizens themselves are not the workers who are harmed.

But overall, OSH Act has done pretty well for a relatively young statute. Congress, through the authority delegated to the Secretary of Labor and to NIOSH in Sections 21 and 22 of the statute, did force new technology in occupational health and occupational safety, just as the Congress intended. If you look in contrast to 1965, which was a time when there were only a few non-profit organizations and trade associations groomed professionals who would create programs for workplace health and safety

training, the statutory scheme has an amazing track record in promoting a wonderful state-of-the-art understanding for occupational safety and health.

Successes have been talked about by other people here. My point is to say that NIOSH has been the linchpin of these developments. NIOSH research goals provided the financial resources for thousands of investigative studies, and in turn generated the impetus for many research programs in academia that would never have existed but for the government interest in the subject of their work.

So this sounds really broad-brushed when you look back from 35 years toward a new century. But as my son would say, you know, that's about as long as it takes for God to grow a fingernail. It's not really much time in the history of the world. And when we're at the dawn of a new century we have the luxury, and maybe even the obligation, to think about that new century.

So there are three things that my remarks would like to underscore in the vital areas for the work in occupational health in the future. First, a renewed emphasis on safety now that we have better technologies thanks to NIOSH research and the new types of jobs that are out there such as genetic technicians, nanotechnology and such.

Two, outreach to all populations. We need a classless model that embraces service industries, professional workers such as doctors, architects, engineers, lawyers, leadership people in business and government. Outreach using health promotion that embraces the special needs of changing demographics of our populations to include working moms, older workers who will use their experience beyond the seventh or eighth decade of their life, minorities who are assimilating into our workforce and have special linguistic needs. And of course across all of these categories there are people with disabilities who, that's to the Americans With Disabilities Act, have now an equal opportunity to education and will enter our workforce, regardless of the causes of injury, having a life experience of disability. This is really very different than the model at the time that OSH Act was written. And they will take their rightful place as employers, employees and taxpayers, raising that ever-thorny question of how do you provide reasonable accommodations.

The third area is that OSH Act itself needs reform. Yes, the old statute has served us very well. And some people in Washington, D.C. do say if it ain't broke, why fix it. But in truth, 35 years, it's time for a little bit of a renewal job. Thirty-five years without modification for a statute is really an extremely long time. We need a provision in the new OSH Act statute that will provide for citizen suits and the right of individuals who are not under contract in the particular work site but may be present in that work site to complain about harms in the workplace that nonetheless have an impact on health for all.

So I speak of this from an academic perspective. I have never worked for either labor or management sides, always worked in academia. And one of the books that I've written for non-lawyers is available to the panel for your review if you need it for anything.

I really appreciate NIOSH's extremely pioneering work, but I think that the emphasis really has to be on looking very closely, first, at the old question of safety, which is very much a changing notion. When OSHA and NIOSH were born there were consensus standards, there were organizations that were sort of loosely defined -- created standards, but there wasn't a process for doing that. There wasn't a functional analysis of what goes into a standard. Our courts have taught us subsequently through the benzene decision and other cases what that's supposed to look like, and we need to use that in looking at safety with new eyes.

As I said about demographics, it`s not just that we have a different population, but we need to approach it in a way that`s classless and available to groups that we have really overlooked in the past.

Verbal Comment 2006/01/23: Okay. All right. Hello, my name is Lisa Pompeii and I'm an assistant professor here at the University of Texas, and my background is in occupational epidemiology and occupational health nursing.

I signed up to talk today about return to work issues among healthcare workers, specifically nurses and nurses aides. However, in the interest of time I would like to focus specifically on return to work issues among nurses aides after sustaining a work-related musculoskeletal injury, or specifically a back injury.

I'm currently conducting a NIOSH-funded study called "Back Pain and Work Disability Among Healthcare Workers", and the setting for the study is a tertiary care medical center in central North Carolina. And the purpose of the study is to examine risk factors for back injuries among nurses and nurses aides and the impact of work disability resulting from those types of injuries.

While working on this study, differences in return to work issues between nurses and nurses aides started to become apparent. I'm reticent about not focusing on nurses right now because I don't want to in any way minimize the experiences that they have trying to return to work or the difficulties that they have. I just want to focus more on how these two groups are really different.

And when you dig through the literature, the occupational health literature, looking for information on nurses and nurses aides, typically these two work groups are analyzed together. They're combined. And what happens is I believe that they're portrayed as being similar, when in fact they're very different. As a result, aspects of nurses aides' jobs that may contribute to disparities in their health have not received adequate attention.

A handful of studies have reported what injury rates reflect, and that is that nurses aides lift more, they - they twist, they bend. Their jobs are more physically demanding compared to nurses. I have seven years of workers comp injury data, and the nurses aides have a rate of 8.4 injuries per 100 FTEs, that's occupational back pain injuries, compared to nurses that are at 4.0 -- they're still high, but nurses aides are twice that. They have higher rates of lost work day injuries, they have higher rates of restricted work day injuries.

Some fundamental differences between these two work groups, the first is latitude. When a nurses aide is not able to perform their job in the hospital setting, their ability to move to another job is very limited, compared to a registered nurse. Registered nurses have more years of education, formal education, and they may have more latitude. They can transfer within the hospital setting possibly to other jobs.

The hospital setting where I'm conducting my study, nurses aides can move to a housekeeper position, they can go to dietary, they can go to laundry or they can go to a secretarial position. One only out of those four is a -- is a desk job, and that's if they meet the educational requirements for that job.

There's the reporting structure within the nursing unit. Typically nurses aides have to manage their own work restrictions and they have to manage -- or negotiate with the nurse manager in order to do that and they may not feel comfortable. They may fear retribution or job loss if they refuse to perform work duties that are difficult, placing them at further risk for injury.

Disparities in health already exist among nurses aides with regard to significantly high rates of occupational back pain compared to the general work force. But they're at risk for further health disparities if they incur additional injuries and loss, or lose their job and the benefits of employment because of these injuries. Workers who sustain occupational back pain or have occupational work-related -- excuse me, work-related back injuries have been found to be less likely to return to work, or they have delayed return to work if they have to go back to a job that's physically demanding. We already know this.

And we also know that return to work strategies, including modified work and physical therapy, assist workers to getting back to work. But when we conducted focus groups with nurses compared to nurses aides, we found that nurses aides didn't have that ease of returning back to work. They had a harder time negotiating with their managers. They had a harder time negotiating work restrictions. They felt isolated.

They also felt like they couldn't go to their fellow nurses and ask them for work because they felt like their jobs are very different than the nurses' jobs. So on a typical nursing unit in a shift you've got two nurses aides. And so if one of those nurses aides doesn't show up, the other nurse aide has to pick up that slack. So I asked them a question. When you -- is there ever a time when you go to work and you have back pain and you feel like you can't work but you work anyway? All of the nurses said no, that they just take time off if they can't go. The nurses aides, all of them said yes, I still go. And they go because they feel obligated. They feel committed. It isn't just because they can't afford it, but they go because they feel like they need to be there.

I know I only have a few seconds left. I would just like to recommend that future research separate these two occupational groups so that we can find out more about how to return nurses aides to -- back to work post-back injury. Thank you.

Categorized comment or partial comment:

Verbal Comment 2006/01/23: Good afternoon. I`m George Delclos. I`m on the faculty here at the University of Texas School of Public Health. I`m a professor and I direct the division of environmental and occupational health sciences. I`m also a practicing occupational and pulmonary physician, and I have submitted my detailed comments to -- to the group. Thank you for allowing me to speak today. Good afternoon.

There are approximately 16 million people in the United States with asthma, and the incidence and prevalence of asthma have been increasing in the general population, both worldwide and in the United States, for the past two and a half decade. Prevalence estimates vary widely, depending on race, ethnicity and geographic area, with some estimates as high as 19.6 percent having been reported.

Now the annual economic and social consequences of asthma are staggering, as evidence by more than 100 million days of restricted activity yearly, nearly 500,000 hospitalizations, over 5,000 deaths, and

more than \$27 billion in costs. Various factors have been implicated in explaining these worsening epidemiological trends, including contaminants present in workplaces.

In the United States it's estimated that there are over 20 million workers potentially exposed to occupational asthmagens, 9 million of whom are exposed to established asthma sensitizers and irritants. Work-related asthma is currently the most frequently reported diagnosis of work-related respiratory disease in developed nations, and the U.S. is no exception. In a study conducted by our group based on the adult population data from the NHANES III, we estimated that the prevalence of work-related asthma in the United States to be around 3.7 percent, and that of work-related wheezing, which is a cardinal symptom of asthma, to be about 11 and a half percent. Estimates of just how much asthma in adults is attributable to the work environment have varied widely, probably due to several reasons, including geographic area, lack of recognition, differential reporting, absence of statewide surveillance systems for asthma and variations in what we actually call occupational or work-related asthma. However, in the review and synthesis of 43 studies, Blanc and Toren found that the median attributable risk for asthma -- for workplace asthma to be about 15 percent among the best-designed studies.

Now certain groups of workers are well-known to be at particularly high risk of developing workplace asthma, including red cedar workers, isocyanate chemical workers, construction workers, and farmers. However, whereas the magnitude of the risk and etiologic agents are well characterized for many of these occupations, this is less well studied in the case of healthcare workers, where data are largely derived from case series and relatively few population surveys.

Healthcare workers comprise eight percent of the U.S. workforce, and are one of the fastest growing sectors of that workforce, projected to increase to more than 15 million by 2012. In other words, a 30 percent increase from about 2002. The greatest growth is occurring in out-patient settings, with average annual increases more than double those of the remainder of the U.S. economy. Healthcare-related occupations represent 50 percent of the top 30 fastest growing occupations in the U.S. And within the healthcare sectors the professions that are expected to grow by more than 20 percent include nurses, physicians, respiratory therapists, occupational and physical therapists, the dental professions and pharmacy professionals.

Following the passage of the 1992 OSHA Bloodborne Pathogens standard, which resulted in a significant increase in the use of latex-containing personal protective equipment, cases of latex-related asthma drew attention to healthcare workers. Potential asthmagens in healthcare settings, however, do go beyond latex, and include disinfectants, pharmaceuticals, sensitizing metals, methacrylates, aerosolized medications and cleaning products, among others. Furthermore, since there are potentially multiple sensitizers in healthcare environments, it is possible that interactions among these various compounds could affect sensitization thresholds. Previous studies in several countries have described an increased occurrence of asthma among specific groups of healthcare workers, including nurses, respiratory therapists and pharmaceutical workers.

In the U.S. the health services industry is second only to the transportation equipment manufacturing sector in total number of reported asthma cases. Five of the top 11 industries and nine of the 22 leading occupations associated with significant increased asthma mortality were related to healthcare services. And recent surveillance data from California, Massachusetts, Michigan and New Jersey found that work-related asthma among healthcare workers represented 16 percent of the total reported cases, exceeding the proportion of the workforce made up of healthcare workers. Agents most frequently

associated with these reported asthma cases include, still, latex -- although we're doing a better job with that -- cleaning products, and poor indoor air quality.

Now in our own NIOSH-funded study of asthma prevalence and risk factors that we've been conducting in a large representative sample of over 5,600 Texas healthcare workers, analysis of which is still ongoing, the overall prevalence of a physician diagnosis of asthma was 14.7 percent, ranging from a high of 17 percent among respiratory therapists to a low of 12 percent among physicians. These asthma prevalence figures are substantially higher than those reported for the general Texas and U.S. populations. Furthermore, the prevalence of asthma with onset after entry into healthcare -- into the health professions, which could be used as a surrogate for work-related asthma, was likewise high. In addition to latex and based on self-reported exposures, the preliminary analyses showed elevated odds ratios for women, obesity, years as a health professional, exposure to aerosolized medications, and exposure to glutaraldehyde and cleaning products.

In summary, there's evidence that workers in healthcare settings are at an increased risk of work-related asthma. However, important gaps exist in the healthcare worker literature with respect to risk characterization of healthcare worker subgroups, identification and assessment of specific exposures to asthmagenic compounds, estimation of the impact of asthma on work patterns and productivity among healthcare workers, and implementation of proper preventive measures.

I urge NIOSH to support and expand continued research into this important topic, and I thank you for your time.

Verbal Comment 2006/01/23: Good afternoon. I'm Paul Rountree. I'm on the faculty at University of Texas Health Center at Tyler. I think I can speak with some credibility about aging among healthcare workers.

You know, the day that we have awaited for has finally arrived. We've come to 2006 when the boomers begin to reach age 60. So the question is, what will be the effect of this boomer generation on healthcare?

Now we know that as you age you have certain physiologic changes that occur that we call normative aging. In addition to that, we also know that you have higher prevalence of chronic conditions like arthritis, heart disease, lung disease and the like as you mature. So I think that it's fair to assume that we're going to have a burgeoning increase in the demand for healthcare services in our country.

This comes at a time when we have currently a shortage of 126,000 registered nurses in the United States, and it's projected that this increase is going to continue faster than we can in fact replace them. And we also are dealing with an aging nurse population. The projection is that the average registered nurse in the United States by 2010 will be age 50.

So we basically have a changing workforce, and we have a workforce that's aging, and we have an increased demand. What does this mean for the registered nurse, then?

We know that registered nurses already are working more hours and have more mandatory overtime. And we know that studies have shown that mandatory overtime impacts on job-related stress, as well as patient safety. We know that registered nurses have increased rates of injury, as do all healthcare

workers, but particularly registered nurses and nursing care assistants, and earlier speakers have alluded to that.

It's clear that older workers also have delayed recovery, and there's much data from the Bureau of Labor Statistics that would attest to this fact. So I think it's reasonable to assume, among the registered nurse population that's injured, that we need to examine causes of delayed recovery.

I suggest to you that we need to look at the interactions between job-related stress, between co-morbid conditions that nurses may have, as well as behavioral characteristics in an attempt to explain issues about recovery from injury in this particularly important group of people.

I am currently working with the College of Nursing at the University of Texas at Tyler, and we are involved in a cross-sectional study that's unfunded looking at registered nurses in a large number of institutions in rural health communities in east Texas. It's really been remarkable that we've had support from a number of large hospitals -- from the chief nursing officers at a number of these large hospitals, who are actively supporting our research because of their issues and concerns about nurse retention as a result of the various influences that I've described. And I hope that NIOSH will take an interest in the -- in the synergism that exists between these varied influences, work-related injury and recovery. Thank you very much.

Verbal Comment 2006/01/23: Well, thank you very much. I think, like everyone else, I appreciate the opportunity to provide input to NIOSH as they form their agenda for the coming decade.

Just by way of quick background, I'm a physician whose practice is devoted exclusively to occupational medicine. Within OcMed, most of my encounters involve healthcare sector workers. For example, I'm a medical director at Baylor College of Medicine. In all we have about 10,000 employees. I also serve as an out-source director, basically, for other healthcare entities. So most of my dealings are with health -- healthcare sector employees.

I have two primary themes to consider for developing a research agenda, the first of which entails new diagnoses and novel problems within healthcare. Medicine invariably is responding to new challenges all the time. Some of these things are conditions or problems that have never been described or discovered, whereas others may be known problems but are merely being approached in a new way. If you consider even recent events, physicians, nurses, paramedics, everyone within the healthcare sector has been called upon to respond to various things such as natural disasters. New conditions such as SARS, bird flu, which for all practical purposes really has not developed into a problem but might, and yet we're all expected to know how to respond, how to take care of others, while at the same time we incur risks.

And we incur health risks largely to the unknown, especially when you're dealing with a new condition, a new problem. It's hard to tell what long-term problems are going to arise from being exposed to it, or

working with patients who are exposed to it. So invariably there need to be mechanisms to help define what the problems are going to be and to properly define exposures in the present so that we can properly assess people in the future.

And this issue of new problems, new diagnoses, new conditions goes beyond even the clinical realm. It's as prevalent, if not more prevalent, within the setting of medical research. We like to think of medical research as always being on the cutting-edge, as developing new techniques, new strategies, dealing with new technologies. But again, we're also dealing with problems that have not been described before.

We have healthcare workers exposed to various things like oncogenes, adenovirus vectors, and yet we know very little about the long-term effects from exposure. We're not sure of morbidities that may arise. And yet there's very little in the way of appropriate guidance for what to do to protect people. There's certainly little that's known as far as any outcomes in working around these entities and what types of tasks pose the biggest problems. So I think definitely the new -- the new, emerging conditions that we're faced with in society are also some of the new, emerging conditions that we're faced with in research.

The second theme I just wanted to hit upon briefly as far as the research agenda is being sure to consider healthcare trainees within the scope of any sort of research project. We think of trainees traditionally as students. In many ways we're all students throughout our lives. But the trainees are often disenfranchised from the rest of the system. If you think about a typical employer/employee relationship that occurs, there's perhaps more accountability that goes on. Some of it is legally prescribed, some of it is -- just occurs through tradition. Yet healthcare trainees often don't share in the same protections that employees share in.

And there's some practical issues that arise in trying to account for trainees. This includes the fact that many of them are transient, for example, in institutions that they rotate in. Institutions may not be very well aware of their presence. They may know in general that they're there, and I think for a large part a lot of institutions try to incorporate them to the extent they can within safety programs. But the bottom line is that a lot of trainees don't have access to the same resources employees do -- things like training, PPE, certainly ongoing healthcare and surveillance. A lot of that, when it does occur, is pushed onto the employee, meaning they have to follow up through their own health plan or they have to buy their own equipment. This is something that's almost unheard of within the employment sector. Not to say that we need a workers comp system for students, but they definitely need to be considered within the context of any sort of medical surveillance.

Just as important as far as their vulnerability, if you will, is the fact that a lot of them are pursuing second careers, third careers. A lot of them have been engaged in healthcare for quite some time by the time they hit a -- quote, a career goal. So often we're picking up healthcare employees, we're roping them into some sort of surveillance program or workers comp or risk management program

because they just started employment with us. But by virtue of the fact of what they've been doing the last ten years, they've really been healthcare employees for ten years. So if you consider a nurse or a medical aide who has -- who is just starting work, this is a person who may have been working as a paramedic or an aide for several years before becoming a nurse. And yet on day one when they develop low back pain, we measure their exposure from the time of employment and we often overlook their, quote, pre-employment exposures. So the relevance of a person's student status as their career, if you will, just can't be downplayed enough.

Verbal Comment 2006/01/23: Hello, my name is Stephanie Tabone. I'm a registered nurse and director of practice at Texas Nurses Association. As a representative of Texas Nurses Association I'd like to thank you for the opportunity to provide input into the future research agenda for occupational health and safety in the area of healthcare.

Registered nurses constitute the largest healthcare occupation group in the country. Then-NIOSH director Linda Rosenstock testified before Congress in 2000 that nursing personnel have one of the highest job-related injury rates of any occupation. And she related in that same testimony that the rate of injury specifically for R.N.s was greater than that of workers in construction and agriculture. In fact, construction and agriculture work is safer now than it was a decade ago. Not something that can be said for healthcare.

Moreover, characterization of the nursing profession by the Bureau of Labor Statistics lists hazards, including ergonomic injuries and acquisition of infectious disease, exposure to chemicals, shocks from electrical equipment, and hazards posed by compressed gases, not to mention emotional strain from

close contact with critically ill patients. The statistics and characterization of the work of nurses reinforce the perception that providing patient care is hazardous and that nursing is undesirable work.

Because R.N.s make up such a large component of healthcare delivery system, hazards to nurses in the workplace constitute a serious public health concern. This is true not only in terms of real injury, but in their potential to impact the capacity of the healthcare system to deliver essential services to those whose health is compromised. It is also the case that most hazards that accompany the delivery of patient care are preventable, or at least can be mitigated by improving safety processes.

Texas Nurses Association would like to commend NIOSH for its research in the area of healthcare and in particular in resulting guidance in the areas of violence prevention and recent guidelines for lifting in long-term care settings. This work has enabled Texas Nurses Association to advocate for and get enacted legislation that requires nurses and healthcare organizations to work together to produce increase -- policies and procedures that increase safety in these areas.

Safe patient-handling initiatives decrease injuries that cause harm to patients and result in increasing cost of care, while violence prevention has the compassionate outcome of helping to limit persons in moments of crisis from hurting themselves or others. So not only do these efforts protect nurses, they also have the added effect of helping patients.

Evidence-based guidance and best practices provide essential components when nurses seek to improve the delivery of care. The need for continuing research in healthcare in the area of workplace safety cannot be over-stated. As the population ages, the need for provision of care is projected to increase, while the number of persons available to deliver that care is projected to decrease.

It is essential for us to develop safety processes that increase the desirability of nursing as a profession by eliminating, to the extent possible, unsafe practices in all delivery settings, as well as identifying ways that an aging healthcare workforce can continue to deliver that care safely. To this end the American Nurses Association and Texas Nurses Association have brought talking points to this -- to this session, and they are listed in the written testimony.

As we review how each of the issues -- I'm going to go over the issues just briefly -- that impact the nursing profession, we must always remember that those things that are unsafe for nurses have equal, and sometimes more profound, effects on patients.

Safe patient handling itself, by looking at that as a patient safety issue, has allowed nursing to now start to get some very important things into the workplace to help with lifting. And another speaker I think will speak to that.

Others have talked about chemical exposures, so I won't go into that, either. I think the things that have been said are very good and important.

There's two things that I'd like to add. One is in the area of worker fatigue. There's a lot of work -- we know that worker fatigue has an impact on omission of care. What we do not know is how long it takes someone to recover after they have become fatigued. Neither do we know the additive effects -- just one second more -- the additive effects of things like emotional strain to that fatigue, so we don't have those add-on things.

And in the area of infectious exposure, what we don't look at often is how many opportunities there are to do something -- for example, hand-washing being a simple example. There may be many times or

many more opportunities in a -- in a time of care to do hand-washing than there are minutes in the day. So when we ask somebody to do something that's more safe, we sometimes do not look at how much time that takes in relationship to the actual process the person's involved in. And that's something I think really needs to be looked at when we ask people to do things that are safer. And I'll end my comments there. Thank you.

Verbal Comment 2006/01/23: Good afternoon. Thank you for the opportunity to present today and have input into the agenda. My name is Nancy Crider. I'm a master's-prepared nurse, currently full-time doctoral student here at the UT Health Science School of Public Health in management, policy and community health with a minor in occupational and health safety. I've been a registered nurse for over 25 years. My primary background is nursing administration and education. I've been a past president of the Houston Organization of Nurse Executives and on the board with the Texas Organization of Nurse Executives.

Much of what you heard today I want to repeat and emphasize with a couple of additional factors. As you know, it's well documented that the hospitals and healthcare organizations present a wide variety of biological, chemical, radiological and musculoskeletal hazards. Employee health and safety for those of us in administration are key issues in maintaining a viable workforce that's able to meet the healthcare needs of our populations, and also to be prepared on a whole-hazards approach for emergency preparedness that we're currently gearing -- been gearing up to, even more so since 2001.

Many safety initiatives have been initiated from the NORA I. Bloodborne pathogens is clearly -- are getting attention. They create new hazards as we do the personal protective with -- with gloves. Issues that are still out there as far as airborne exposures to both infectious disease, and particularly the occupational hazards as we do new construction and renovations in our hospitals. The air handling and exposure there are still issues that need to be addressed in practice.

One issue that I have heard this morning, but not this afternoon as much, is the changing demographics of the workforce is creating new challenges. Many employees have -- both at the professional and the unlicensed level are not native-born and English is not their first language. We have a challenge here I think in the research to look at the cultural competency, a culturally-appropriate training strategy to look at where we have opportunities for safety. We have literacy issues. And even those who are fully literate in their own native language, when you get into the nuances of health and safety in the United States hospital and healthcare organization are not totally fluent, and that creates a great deal of misunderstanding. So I would adhere to this needs to be additional behavioral and social research as far as the culture of safety and training for both licensed and unlicensed personnel as to how to bridge the gap between knowledge of safety -- knowledge of safety practices and the behavior in the workplace.

Additional time I want to do is the workplace fatigue and safety. We know from aerospace and transportation that the effects of fatigue are similar to alcohol in the bloodstream. And not only do we have employees working long hours, again we have multiple -- the economic conditions are multiple jobs, and they come from work to the work site without adequate rest. So the timing of what it needs to recover becomes important, not just for scheduling in our own institution, but knowing whether you have contract workers in, knowing whether you have trainees in, people who are going to school full-time and working full-time. It's created a additional need for training there.

Finally, ergonomic studies, as you develop -- the development and manufacture of assistive devices, I will reiterate -- looking at the workforce, who are the workers using it. We have an aging workforce, in many cases deconditioned and suffering from chronic illnesses themselves (sic) who are caring for obese patients. They are -- arthritis, the musculoskeletal risks, and we also have the foreign workforce who may be, as a speaker this morning said, a petite Filipino nurse who clearly cannot manage the same as a strapping 18-year-old, five ten, 180-pound male.

In summary, I'd like you to continue the NORA initiatives. Look at the multi-cultural, the training issues, the literacy issues and the gap -- bridging the gap between knowledge and practice of PPE. Thank you.

Verbal Comment 2006/01/23: Hello, I'm Nancy Menzel from the University of Florida College of Nursing. I'm an occupational health nurse-researcher in musculoskeletal disorders in direct patient care providers. I also received a NIOSH traineeship 25 years ago to attend the Harvard School of Public Health, so thank you, NIOSH. And I also graduated from the University of South Florida College of Public Health Sunshine ERC with a Ph.D.

This morning Dr. Howard spoke about relevance of research, and I can't imagine anything much more relevant than the nursing shortage the previous speakers have spoken to. This is a problem where by 2015, in fewer than nine years, they predict a 20 percent shortage of nurses. And we really must do something to prevent their leaving the workforce.

The University of Florida graduates 180 new baccalaureate-prepared R.N.s every year, and within two or three years most of them have left the bedside. So the problem really isn't supply, it's keeping the workforce at the bedside.

Part of that is the healthy worker effect. They realize that they're going to get injured if they continue, because being a nurse is very hazardous to your health. The solution is not to go to developing nations and steal their supply of R.N.s with better wages and bring them to the United States and hurt them as

well. Nurses are not hatched like eggs. However, if they were and the farmer noticed that 75 percent of them were being broken during production, there would be something done about it. Instead we continue to injure our nurses.

I prepared a summary of gaps and needs for further research which I distributed earlier, and I'd just like to go over some of the main highlights from my vantage point. One of them is the pathogenesis of work-related musculoskeletal disorders in nurses. How early does this start? Does it start in nursing school? Where -- what are the exposures there? What are the biomarkers of musculoskeletal damage that's occurring to these nurses?

Exposure assessment, the methods that we use now are observation. I think NIOSH has used things where they put little clickers on machines to see if the lifting equipment is being used. But we must develop more sophisticated methods than that.

Under-reporting of work-related musculoskeletal disorders, we're using as a metric occupational injuries. That's rather like counting the number of planes that crash each year as our metric. I think we can do better than that.

Contributions of psychosocial factors to these disorders in nurses, what is the contribution of stress or organizational factors?

Patient handling technology, although we've seen research that demonstrates that injuries are lowered, with this technology many nurses continue to resist its use because it's awkward to use and it's inconvenient and it takes a long time. We still don't have any equipment that assists a nurse to turn a patient from side to side, and that's one of the biggest exposure points.

Adoption of technology, I've alluded to some of the reasons why nurses don't use the technology, but what is the reason that employers are not wholesale adopting this? They complain about the nursing shortage, and yet they fly recruiters to the Philippines to bring Philippine nurses back, but they don't invest in the technology. What can be done?

And the relationship of work-related musculoskeletal disorders to quality of care and patient safety. When I did my dissertation at an unnamed facility, I worked with nurses who were working 12 and 16-hour shifts, and I followed them around and wrote down what they did, and it was pretty exciting for me. But many of them stopped turning patients and ambulating them toward the end of their shift because they were physically exhausted. So I know that there's a relationship between patient safety and nurse safety.

These issues need to have further investigation and funding by NIOSH. Thank you.

Verbal Comment 2006/01/23: I'm the executive chair of my organization's -- of continuing education for AOHP, and that organization is the Association of Occupational Health Professionals in Healthcare. On behalf of AOHP organization, I thank you for allowing our input at this public meeting of the second decade of NORA.

AOHP is the primary association for occupational nurses and other professionals providing occupational health services to workers in healthcare. The occupational health nurse, usually called employee health in a hospital setting, performs a multitude of services that evaluate, screen and monitor the environment and the worker in healthcare settings. Prevention of injury, illness and disability is the primary practice objective. Health promotion, wellness, is one method to those objectives. But realistically, the practice objectives become more challenging due to the everyday hectic pace in the healthcare facility. The patients are sicker, the healthcare worker works more hours with less support from their administration, and the outcomes can be seen in the loss run data. And we can see these in benefits, dollars being spent for more medical and mental health care.

This presentation is focused to the following broad issue that we feel NORA could include in the next decade:

Examining the research on health habits and attitudes, then apply and expound them specifically to the healthcare worker. Seek the answers to why so many healthcare workers are basically unhealthy, and what can be done to improve the mental and the physical human factors of the healthcare worker. For this healthcare worker, continued research is needed in behavior modification, mental health management, coping with work stressors, and how the practice of motivation factors can lead to optimal health maintenance. Examine the employer's medical benefits incurred costs. They have continued to climb year after year. Is that because the healthcare worker is inappropriately using their medical benefits? Is it because the worker is less healthy and requires more medical prescriptions and services under their employer's medical benefits? Is the solution better case management? Should the employer and/or the insurance company be held more accountable to provide strategies around prevention versus continually raising the premiums to the healthcare worker? More facilities can take what has been learned about managing injury under the workers compensation systems in all the various states and apply those learnings to case management of their employees' medical benefits.

Secondly, AOHP commends NIOSH and NORA for your research, and we want continuation of strategic research to gain an accurate picture of the environment inside healthcare setting -- its stressors, hazards, potential exposures -- mentioned by many of my colleagues this afternoon -- and inherent risk. Continue to advise on risk avoidance, disease detection and the disability limitations that can be integrated into work practices. Provide research to practice on the human factors of disease and disability. Thank you very much for this opportunity.

Verbal Comment 2006/01/23: Good afternoon. I'm Mary Willa Matz and I'm with the Veterans Health Administration. I am an industrial hygienist and an occupational safety and health researcher, so I'm not a clinician so I'm coming from a little bit of a different vantage point.

Representing the VHA is certainly something that I have also talked with some of our -- our -- excuse me, I'm getting off-track here. I should just read my notes here.

As the largest healthcare organization in the United States, VHA has a unique vantage point for identification of important occupational safety and health issues. On an annual basis the VHA records more than 25,000 injuries, which afford us a really vast database from which to determine issues in need of study and intervention.

The VHA injury data consistently finds the following types of injuries as top ones, and you should have a pie chart on that. But if you don't, I can read them to you. Slips, trips and falls are consistently the number one source of injuries in the VA for about the last four or five years, at around 20 percent of our injuries. Struck by/against, approximately 13 percent, as well as bloodborne pathogens and body fluid-related exposures, also 13 percent. We show approximately 12 percent from lifting and repositioning patients, 8 percent from manual materials handling, and 6 percent from assault/workplace violence.

Due to the limitations in time I'm going to briefly discuss some of the recommended research topics. Full descriptions and supporting data for our recommendations, as well as research and partnership suggestions, will be provided separately through the on-line submission process.

The VHA recommends and requests the continued focus on sharps injury prevention, especially use of technology in that prevention.

Under-reporting of injuries, this is a huge issue. We don't really know what's going on out there. OSHA has estimated that for every musculoskeletal injury reported there's a similar one that's not reported. The 2001 VHA task force on workplace violence prevention showed that there's a factor of under-reporting of five. And similar under-reporting can be seen in blood and body fluid exposures, et cetera.

So each of these areas have unique considerations and conditions surrounding them, therefore unique issues may be related to their under-reporting. And in order to know the true state of injury incidents, under-reporting must be addressed.

Continuing on to another topic, emerging pathogens protection. There`s concern that the respiratory protection standard as written in the pandemic flu plan may not adequately protect healthcare workers from transmission of disease. The plan recommends wearing, quote, a surgical mask or a procedure mask for close contact with infectious patients. N-95 respirators or surgical masks do not adequately defend against penetration, nor the airborne nature of viroparticles. Much higher levels of respiratory and other protection are needed until scientific evidence -- including volume and virus produced per cough, size of particles, aerodynamic properties, et cetera -- is generated that can be used to identify control measures such as respirators that will reliably protect healthcare workers from the organism in question. We recommend that NIOSH, OSHA and CDC and CID/NCID* collaborate to review and determine a scientifically-defensible posture regarding airborne pathogen transmission issues. We also suggest testing existing N-95 respirators and surgical masks for protective capacities, as well as developing new technology that will control transmission of known infectious diseases, and from this information develop criteria that can be extrapolated for new pathogens encountered.

Next topic, slips, trips and fall incidents -- can I have another few minutes since I have so many more and I'm the last --

MS. PALERMO: (Off microphone) (Unintelligible) time, so --

MR. WEISSMAN: (Off microphone) Yeah, we have to (unintelligible).

MS. MATZ: Okay. Thank you. Slip, trip and fall incidents. Slips, trips and falls are the leading cause of occupational injuries among hospital workers. The national average for falls on the same level per 10,000 FTE in hospitals in 2003 was 31.6, as compared to 19.9 for general industry. BJC Healthcare, a large private healthcare organization, reports 26.3 falls on the same level in 2005, with over a million dollars in workers comp claims. Very significantly, as I reported earlier, the majority of the injuries for the Veterans Health Administration come from slips, trips and falls. And once again, these are reported injuries, though.

Small, sort-term intervention studies dealing with behavioral aspects of STF incident causation rather than large studies that have been difficult to manage and track are suggested. As well, cost effectiveness of existing and new strategies would be beneficial, as would continuation of descriptive studies.

Next topic, and the last one -- excuse me, it's the next to the last one -- is workplace violence. Violence in the workplace, both physical and psychological, is a major concern. Almost two-thirds of non-fatal assaults at works (sic) happen in hospitals, nursing homes and facilities that provide health or social services. Our VHA task force on violence prevention showed that nurses and nursing assistants were most likely to be victims of injurious violence, and incidents were most likely to occur in in-patient and nursing home settings. Among other topics of research, the effectiveness and cost benefit of existing strategies is important to determine. Organizational factors and unit organizational cultural influence on the risk of workplace violence may also shed light on this subject.

And the next and last issue, and it's been addressed elsewhere, is patient handling. And I won't go into statistics on this, but I will say that continued innovations in technology are needed for control of risk. As well, program implementation facilitators and barriers need to be identified for improvement in safe patient handling compliance. As well, with the new -- new construction and renovations going on in the healthcare industry, it's critical to have acceptance and inclusion of ergonomic design by architects and engineers. But the science behind ergonomic recommendations for safe patient handling, especially for bariatric and total dependent care patients is lacking. So we see that science is needed to support ergonomic design criteria.

And I will say that we have also -- have a list of recommendations for these topics that I provided to you earlier, and we also will be addressing these -- these issues on-line -- through your on-line process. Thank you.

Verbal Comment 2006/01/23: I'm not really prepared to talk on this topic but I don't think it was mentioned this evening and I would just like to express this issue personally. I do feel a bit like we have a choir here and that we preached to the choir on occupational health issues. And I did want to say that since we're talking about the healthcare sector that at least in my mind there remains a relative lack of awareness or recognition among the healthcare community itself of the implications of work on health, whether that is from an economic perspective in terms of trying to maximize the number of patients that a nurse has to care for, how to manage a case of occupational illness and how to deal with the employment implications of that illness, how to search for an occupational pulmonary physician who might recognize that there is a relationship between an occupational exposure and a disease, so I think it would be prudent to at least raise the issue that we have to focus on what our role and responsibility should be to make sure that the healthcare community itself is more aware of occupationally-related issues.

Transportation - Urban Bus Drivers

Irwin Lum, President Transit Workers Union Local 250 - A

irwin@twusf.org

In past studies conducted by noted researchers Drs. Fisher, Ragland, Krause and Greiner, they found that urban bus drivers experience poor health as a result of work. In San Francisco, they found that rates of hypertension among our drivers increased over age (30% hypertensive in the 20-29 age groups, to 98% in the 60-64 age groups). Musculoskeletal problems also increased and accounts for 25% of all workers' compensation claims and 33% of all costs associated with occupational injuries. Hazard exposures includes workload, work organization, poor ergonomics, violence, bus maintenance, increased traffic, lack of rest and recovery breaks, bad press.

Funding for public services, such as transit, is declining while the demand has increased (high gas prices, parking fees and traffic congestion). While studies show that our drivers are at high risk for illness and

injury, and that maintaining things as they are is not cost effective, effective prevention measures are scarce. We need research that helps us identify solutions that address the sources of transit hazards and eliminates or reduces these exposures. Options that only look at driver behavior and health practices are not adequate.

We recommend the following:

- Research issues of workload, violence, ergonomics, work organization, labor/management health and safety committees, public awareness.
- Identify and or develop intervention strategies that address sources of workplace hazards.
- Involve drivers, union and employer representatives in the development of intervention strategies.

Verbal Comment 2006/02/13: Good morning. I am Brian Hennessy. I am an assistant area director in the Tampa OSHA office. The Tampa OSHA office encompasses 20 counties in central Florida. So we're really the central Florida area office.

We believe that there are two areas worthy of NIOSH research relating to workplace falls that result in fatalities.

The first area would be the feasibility and incomplete structures of the use of conventional fall protection. The second is more effective implementation of fall protection systems and plans. Falls continue to be a major cause of occupational fatalities in the nation and in Florida. According to the 2004 published BLS data, falls accounted for 14 percent of nationally reported occupational-related deaths and 17 percent of the deaths reported in Florida.

During 2004, BLS reported 422 occupational fatalities in Florida, 75 of which resulted from falls. If one bears in mind that the BLS data indicate that 256 of the fatalities were transportation-related or violence/assault-related, one gains a better perspective of the ranking of falls.

If one removes the transportation and violence/assault categories, falls account for 45 percent of the remaining 166 occupational fatalities.

Of the 75 fall-related fatalities in 2004, four were from scaffolding or five percent of the total, 18 were from ladders or 25 percent of the total, 26 were from roofs or 35 percent of the total with the remaining 27 being from other surfaces.

As this sophisticated group is well aware, OSHA mandates the use of conventional fall protection while working at elevations in excess of six feet in most construction activities and at four feet in general industry activities. Conventional fall protection is defined as one, standard guardrail at perimeters and floor openings or two, safety nets or three, personal fall arrest systems consisting of a sound anchorage, a lifeline connecting the anchorage to a person wearing a harness; all of which is joined by appropriate hardware.

A major challenge to the implementation of the use of conventional fall protection has been the issue of feasibility, especially in the construction of roofs and the framing of residences. It is very common for the residential constructor, especially in the framing phase, to assert that there is no structurally sound location that will safely support anchorages for personal fall arrest systems. Furthermore, the employer often asserts that the incomplete structure will not safely support nets or that surface areas are so incomplete that guardrails provide no meaningful fall protection.

Despite the introduction of new fall protection equipment and technologies, their use in residential construction activities has not gained not widespread utilization in Florida. Typically, the residential constructor is a small employer who lacks the engineering expertise or the resources to hire the services of an engineer who can determine when a partially-built structure can safely support fall protection systems.

Research is needed to establish proven data that addresses the application of fall arrest systems to specific materials at specific phases of the building process. Such data needs to be published and made widely available. Since so many of our structures in Florida are of masonry construction, specific data needs to be developed regarding masonry buildings.

When OSHA implemented its excavation and trenching standard in the early 1990's, the standard allowed for shoring systems to be designed using recognized tabulated data. Much like the trench shoring systems, fall protection systems can be developed from common and accepted engineering values. The values need to be determined and publicized so as to be far more user-friendly to the small employer.

Beyond the feasibility of fall protection issues is the challenge of assuring work crews properly utilize fall protection technologies and properly implement alternative fall protection programs in cases where conventional fall protection is genuinely not feasible. This challenge is enhanced by the fact that the workers performing such activities, both roofing and framing, are often Spanish speaking. Research needs to be conducted to determine an effective means of educating the Hispanic worker whose cultural background may differ from the traditional worker in the proper methodologies in using fall protection systems.

A better understanding of when conventional fall protection is feasible and conversely is not feasible needs to be established. More effective means of implementing fall protection systems and programs

need to be developed. Both topics are directly related to fatal workplace falls and are worthy of detailed research. Thank you.

Verbal Comment 2006/02/13: My name is Sherry Carberry with URS Corporation. In preparing for this statement, I have had conversations with John Henshaw, the former Director of OSHA and he is also representing the Florida section of the American Industrial Hygiene Association. Things that we would like to state today is that we know that a lot of the existing occupational health and safety regulations are not being followed and we would like to encourage NIOSH to consider other means of having people have safe workplaces other than having more regulations or trying to enforce the existing regulations.

Some means that we think that will help to accomplish this are to have partnerships with industry groups, if industry groups can participate and then see that there is an occupational hazard. That will lead to a solution that can be acceptable to all parties to make the workplace safer. We believe that industry groups would do it. We also would like NIOSH to consider partnering with manufacturers of equipment. If manufacturers are given some guidance on how to design equipment that would make it safer, we believe that they would follow those designs and there's many things that could be looked at. Noise, the ergonomics of it, can they add a safety feature that would not increase cost considerably, but increase the safe use of that equipment.

We also would like NIOSH to consider to look at vendors. We have a lot of different vendors out there selling equipment and products, but in general we have some big ones. For small businesses, Home Depot is a major provider of equipment, supplies, and so forth. If NIOSH could work with people such as Home Depot and say these products that you're selling create hazards in the workplace. Can you only sell these products here that are very similar, but have safety controls on them and will not create such hazards in the workplace? Or if you are going to sell a product that has a high risk to it, can you somehow educate your buyers that this product has high risks associated with it, so therefore they can take the steps to protect themselves?

So this is basically going to create a different way of NIOSH for doing their research. We're suggesting that they look at communication skills. How are they going to communicate these things to the public and to the workplace and to the owners of the businesses? Modifying behavior, getting the public and owners and workers to buy into safe behavior. That's basically it. We're just trying to look at different ways of achieving a safe workplace.

The Wood Truss Council of America;

Truss Plate Institute; manufacturers; WBC Construction

Categorized comment or partial comment:

Verbal Comment 2006/02/13: Good morning. My name is Luis Moreno. I'm the director of risk management for WBC Construction. We are shell contractors building for residential homebuilders throughout the State of Florida.

What a shell contractor is is a company that gets contracted by homebuilders and builds the shell of the structure, meaning from the slab to the sheeting of the roof. The reason I'm here today is to address and give testimony of the imperative need of research and the necessity to have clear and concise guidelines for roofers while setting trusses and during sheeting operations within the residential construction industry.

From data collected in 2005, the Bureau of Labor Statistics shows that falls to lower levels are the leading cause of construction-related fatalities and injuries requiring hospitalization. The study conducted by the University of Florida shows that roofing operations were found to be the most hazardous task performed in residential construction; with nearly 88 percent of the roofing accidents ending in a fatality or serious injury that required hospitalization.

In 2003, roofers suffered 21.1 fatalities for 100,000 full-time employees nationwide. This represents six times higher than the average rate of 3.6 for 100,000 full-time employees. These results are certainly unacceptable and need to be reduced.

Now, most of us know that the federal OSHA requirements for fall protection mandate that the employer provide fall protection to residential workers who are subject to falls of six feet or greater to a lower level. This condition exists to all workers installing trusses and sheeting roof systems.

In '96 the interim fall protection STD 3-0.1A was introduced to the residential construction industry. Until 2003, this interim fall protection was utilized here in Florida. Many have questioned its effectiveness in reducing falls from roofs, since the fatality and injury rate of roofers has been consistently in an increase or has stayed constant.

The interim fall protection may lead to improvements, but offers no recourse for a worker who loses his balance. In 2003 and 2004 the office of the director of construction of OSHA put forth some letters of interpretation disallowing the interim fall protection 3-0.1A to be used in dwelling structures that were constructed with masonry concrete walls. This means that here in Florida all workers on roofs needed to have conventional fall protection as prescribed in the OSHA standards 1926.

WTC, the Wood Truss Council of America, in the guidelines found in the BCSI 3-01, strictly prohibits the use of an anchorage system on a single-truss member. Therefore, an employer in residential construction in Florida must find other means to protecting workers while setting trusses and sheeting the roofs.

Because of eventually adopting the WTCA guidelines under NC/TPI 2002 and the employer's responsibility to adhere to governing guidelines in 1910.6 incorporated by reference, the employer must find other means to properly protect their workers.

Other systems include a scaffold system that is placed on the beam or a scaffolding system erected around the structure of the building, a net system or possibly a system with a cable running from one end of a roof to the other. Unfortunately, none of these resolve the issues. The scaffold system, although would relieve some of the exposure, exposes the worker while installation procedures and do not protect the roofer from falling within the structure. In some cases, it could be several floors.

A supportive tubular scaffold around the structure will be completely infeasible due to the time to erect and the time to dismantle the scaffold system around a multi-level structure. The net system cannot be used in all cases because a span between the window and/or door openings is too great that would not allow proper attachment of the net. Also, the workers are exposed to a fall on the outside of the structure.

The cable system cannot be used while setting trusses, therefore the workers are once again exposed to tremendous dangers. It is also questionable as to how many personnel could utilize the same cable without exceeding the 5000-pound threshold.

Currently, WTCA in unison with TPI, Truss Plate Institute, are reviewing the guidelines set forth in the BCS 3-01. This is an opportunity for NIOSH to partner with these two organizations as well as manufacturers and of course a private industry like WBC Construction, DMHC and so forth to be able to come up with some conclusive answers. I humbly suggest and request for you and others within NIOSH to seriously consider funding a project that will find concise solutions for employers of roofers within the residential industry. Thank you.

Verbal Comment 2006/02/13: Thank you. I'm Pat Stark, safety and health compliance specialist at the University of South Florida, the OSHA consultation program. Good morning. According to the data available from the OSHA Region Four office in Florida falls in construction were the highest accident type for fiscal year 2003, making up 36 percent of all fatalities in construction in Florida.

In Florida, in fiscal year 2004 falls in construction accounted for 47 percent of all construction fatalities. In Florida, in fiscal year 2005 31 percent of the fatalities were fall-related.

In each of these fiscal years the type of construction and industry work that appeared to make up the majority of these fatal falls was the roofing industry. Although it was a bit difficult to determine from available data, it appears that a considerable number of these fatal falls were residential-type construction. Presently in Florida, which is covered under the Federal OSHA Standards, the fall protection height for nonstick framing-type residential construction is six foot. Unless an employer can demonstrate that it is infeasible or creates a greater hazard -- at which time a fall protection plan -- basically passive fall protection, can be used.

It is interesting that CALOSHA's trigger height for fall protection is 15 foot and 20 foot depending on the type of construction. I'd request that NIOSH research this available accident fatality data -- these Florida fall-related construction fatalities, both commercial and residential.

This research would be to determine if existing Federal OSHA fall protection standards appear to be in line with the fall-related fatalities in the construction industry and possibly to determine if fall trigger heights for commercial and residential construction need to be increased, such as with CALOSHA, decreased, or if other non-passive active fall protection systems need to become part of an updated

OSHA construction standard; a standard that incorporates more detailed fall protection systems for residential construction and residential roofing. Thank you.

Verbal Comment 2006/02/13: Thank you, Dr. McCluskey. My name is Jim McConnaughay and I am a workers' compensation attorney. You don't have many of these in safety and health meetings, I'm sure. I practice in private practice in Tallahassee. I'm also chairman of the Florida's Workers' Compensation Institute and the Florida Safety and Health Institute. Both Institutes being nonprofit associations devoted to trying to educate persons in regards to the general areas of workers' compensation and safety.

I take a little different slant on workers' compensation and a different slant on safety. I consider safety and health in workplace the same as workers' compensation. Each is dependent upon the success of the other as to the relevancy in workplace.

I primarily am concerned about the impact on employers versus a feel-good impact on trying to resolve accidents that occur in the workplace. In other words, I'm more interested in looking at the savings that result to industry with a competent safety and health program versus more of an esoteric look at a feel good presence and trying to reduce the number of accidents in the workplace.

Unfortunately or fortunately, industry's attention is frequently devoted to what kind of bottom-line savings are realized as to profitability of their business in regards to the attention they give to safety and health. Based upon my experience in the area of safety and health as it relates to workers' compensation, I can see that it is in fact the case, especially in the field of workers' compensation.

I've been practicing workers' compensation law representing insurance companies and employers for 30-plus years. If you look at the history of workers' compensation in Florida you see a cycle of problems that we've experienced that have resulted in systemic changes in our workers' compensation systems in an attempt to control cost.

Going back to 1973, originally there was a systemic change in our workers' compensation system. Again, you saw it in 1979, 1990, 1994, 2000, and 2003. It's not unlike every other state in the Union dealing with workers' compensation. Every five to ten years the legislature of a particular state looks at their workers' compensation law and addresses what they perceive to be the runaway costs that are associated with delivering benefits under the workers' compensation system.

The common theme that seemingly always occurs is trying to reduce costs by reducing benefits to injured workers. Unfortunately or fortunately, this is the only way seemingly that industry can estimate potential savings to the system.

In 1989, I was chairman of the Florida Governor's Commission on Workers' Compensation. I again served in 1990. In that particular taskforce we were looking at alternate ways of saving money in our workers' compensation system, not just reducing benefits to injured workers. At that time as chairman of the Governor's Council on Workers' Compensation, I quite frankly was sold that the emphasis on safety and health was the remedy to reducing costs in the workers' compensation system.

In 1990, indeed, we passed legislation creating the Division of Workers' Compensation in the State of Florida. Quite frankly, that turned out not to be the answer because approximately ten years later the Division of Safety in Florida was dissolved.

So we in Florida don't have a regulatory agency relating to safety. This is pretty consistent with what you see in the industry when there is a need to cut back the jobs in a particular industry; it's always safety that goes first.

What I would like to do and what I would like to see a study on in the timeframe that I have left is the answer to several questions in regards to the effects of safety and health on the workers' compensation industry. Obviously, the creation of a regulatory agency is not the answer. What I would like to see is the answer to basically five questions.

What impact, if any, does a strong safety and health program have on overall workers' compensation costs? Quite frankly, consistent with my thoughts back in 1989, I would hope that we could find some proof rather than anecdotal answers. How can we as an industry create a strong workers' compensation program through the use of increased safety and health emphasis to create the related savings? Finally, how can we convince the legislatures in this State that safety and health is indeed the answer to our problems in workers' compensation versus reduction of benefits to injured workers?

Thank you.

Verbal Comment 2006/02/13: My name is Robert Pavlik. I'm the industrial hygiene supervisor for the OSHA Consultation Program, which has its headquarters here at the College of Public Health at the University of South Florida. Employee exposure monitoring conducted by state agencies in Michigan and Washington have shown that employees that perform spraying of truck bed liners are routinely exposed to airborne concentrations of methylene diphenyl isocyanate, or MDI, that exceed the OSHA permissible exposure limit. Cases of exposure-related asthma have been reported in the literature, as well as a fatality in Michigan in 2003.

In conjunction with Federal OSHA compliance, the OSHA Consultation Program here in Florida has initiated a special emphasis program to visit employers who spray truck bed liners to identify hazards and recommend corrective measures. Our employee exposure measurements so far have also shown that employees are routinely exposed to airborne levels of MDI that exceed the OSHA permissible exposure limit.

In cases reported in the literature, and in our survey results, employers rely almost entirely on respirators to protect their employees. Spray enclosures have very little ventilation or not at all.

At the present time, OSHA allows the use of air purifying cartridge respirators for protection against MDI as long as the elements of a respirator program are in place, including the implementation of a cartridge-change schedule. NIOSH recommends that only air-supplied respirators be used for protection against MDI. This lack of agreement between OSHA and NIOSH is confusing for employers, as well as safety and health professionals. I recommend that research be performed to determine definitively whether air purifying cartridge respirators can be used for protection against MDI.

Associated with this question is the uncertainty of calculating cartridge-change schedules. In both the OSHA and manufacturer's formulas for calculating cartridge-change schedules there are disclaimers that both high temperatures and high relative humidity can drastically reduce the time that cartridges can be safely used, but give no way to calculate how much the time is actually reduced except to say that employers should determine this by experimental methods. Research is needed to determine how to calculate cartridge-change schedules more accurately in areas of high temperatures and relative humidity as found in Florida and other areas of the southeast in the summer.

Approximately half of the spray-on truck bed liner employers that we have visited in Florida use air purifying cartridge respirators to protect their employees. These same employers are finding increased applications for the same polyurethane coating for garage floors, decks, boats, and other surfaces. In order to protect the employees for MDI, research is needed to determine if and under what conditions air purifying cartridge respirators can be used to protect employees from exposure to MDI. Thank you.

Verbal Comment 2006/02/13: My name is Charles Lankford. I am an engineer and a certified safety professional. I work for a company that does primarily excavation work in construction in the Tampa area. I'm here to request from NIOSH to develop a recommended standard for excavation safety. The competent person that is required for by OSHA excavation standards is a person that needs to have the ability to recognize hazards in excavation and trenching, as well as have the authority to take corrective action; however, many demands are on this competent person. This person needs to be able to judge whether heavy equipment is too close to an excavation and trench to pose a hazard to employees in the trench. The person is supposed to make judgments whether the surface encumbrances, such as the sidewalks, utilities, foundations are too close or can pose a hazard to the employees in the excavation.

At the same time this person is also supposed to make judgments whether loads on the surface adjacent to the trench are excessive or pose a hazard to the employees. Such loads may be heavy equipment, may be vibration of heavy equipment, or may be just moving traffic on an adjacent roadway.

The problem is that a typical competent person is a person that may be a foreman with a couple of years of experience on the job and the class that is supposed to qualify this person as a competent person by the OSHA standard typically is a four-hour class. Now, we are to believe that this four-hour class will qualify this person and that OSHA does not require him to have any technical knowledge in soils, engineering, or any other calculations of safety factors to be able to make these judgments that can mean the difference between the life or death of employees that are in these trenches.

So typically this four-hour class is just barely enough to cover basically what the OSHA standards are and to give an idea what these hazards might be, but OSHA does not presently require that this person have

any training or experience in soil analysis or soil engineering. Basically, this person does not have the ability to make these kinds of judgments.

The typical competent person class has a basic review of soil analysis, which is required by the OSHA standard. The OSHA standard currently requires both a visual and a manual soil test. The brief four-hour class is not sufficient to equip this person with the knowledge required to properly classify soils in order to make a determination what protective system is necessary for an excavation or trench.

The OSHA standard makes a reference to the USDA classification system as well as the ASDM D-2488 standards to refer the person for a proper soil analysis technique. No class that I've ever seen to qualify a person as a competent person actually includes the text of these standards and covers all of these soil testing procedures. The soil analysis is key for the competent person to properly decide what kind of protective system needs to be installed for the protection of employees.

Thus a competent person typically employed by construction companies such as mine is not going to be able to make these types of technical judgments, even though we would be in compliance with the OSHA standard by sending a person to a basic four-hour class.

Now, even three-day classes that I have been to failed to address the detail needed to make these kinds of judgments that are basically engineering judgments. This in my view presents a problem for excavation safety. As we might know, there's about 50 fatalities a year in the United States and about 1,000 injuries each year as well from cave-ins and other excavation hazards. That's where I see a problem. We need a more detailed curriculum for these excavation courses that are supposed to be qualifying these people as competent persons in excavations. Yet OSHA does not require anything particularly special about these competent persons that they require of competent persons in other areas of the construction industry.

Therefore, I recommend that NIOSH take the decade -- hopefully, a little sooner than that -- to develop a recommended standard for excavation safety in which competent person qualifications may be spelled out or the class standards themselves might be approved.

Also, a log of inspections by the competent person, as well as what visual and manual tests have been done needs to be included as a requirement. Thank you very much.

Verbal Comment 2006/02/13: There are three major issues affecting farm safety, regulations, education, and engineering. My focus will be on education. Some needs that my colleagues and I see include a survey of workers separated by commodity and job categories that describe the level of knowledge workers currently have with respect to workplace safety. Such an effort could help document an overall need for safety programs and perhaps target where the priorities should be placed.

Since nearly 91 percent of the farm labor in the United States are of Hispanic origin, we should strive for research on how to improve Hispanic agricultural workers through education. Number one, a study of teaching methods to improve instructional effectiveness. A, how do farmer workers learn? B, are there differences in learning styles between Hispanic and Anglo workers? C, what are effective teaching methods for an adult audience with less than a fifth grade level of formal education?

In 2001, the University of Florida began a program addressing the needs of Hispanic workers and it was designed to provide education in farm and pesticide safety. Approximately 10,000 workers have been trained in south and central Florida. One big challenge is to measure the impact of this extension program and this may constitute an important area for research and extension.

Number two, how does safety training influence job performance and overall economic performance of an agricultural operation? A, how effective have educational programs been in reducing farm accidents

and injuries? B, which workers are more vulnerable to farm accidents? Is that related to education, age, or number of years in the country? C, what is the relationship of frequency of training and farm accidents? D, what education techniques are most effective to train agricultural workers? And finally, E, it would be necessary to improve farm equipment and manufacture training manuals in order to lessen this rate.

One possibility might be an analysis that would measure the impact of educational programs on farm safety and identify what we need to improve to be more effective in transferring agricultural farm equipment safety to workers.

Number one, a possible strategy would be to set up a cross-sectional study of agricultural operations. B, describe safety programs and training activities by company. C, construct an index of training intensity or create some other measure that could objectively rank companies by their training efforts. D, collect statistics, such as accident rates, worker sick rates, worker turnover rates, and worker productivity by task wherever available.

Finally, E, survey worker attitudes towards the company, looking for a connection between safety training efforts and worker morale.

Verbal Comment 2006/02/13: Good morning. I'm Rosanna Barrett. I'm the coordinator of the pesticide exposure surveillance program at the Florida Department of Health. I'm here to speak on pesticide-related illness and injury. I'll first start with an overview of the program and then go into the problem and the solutions.

There's several occupational indicators that relate to different illnesses and injuries. Unfortunately, a lack of funding has restricted the Florida Department of Health's abilities to conduct surveillance on most occupational diseases and conditions.

Currently, the Department of Environmental Health Division focuses surveillance activity on adult lead poisoning and pesticide-related illness and injury. A pesticide exposure surveillance program was established in 1998 through the funding from the National Institute of Occupational Safety and Health, NIOSH. The funding source was discontinued in 2002. The program now operates solely on state funds, which supports one full-time position. DOA continues to contribute aggregate data to the NIOSH sentinel event notification system for occupational risk and supports prevention and intervention activities at both the state and federal levels.

For several years, data has been collected to determine the rates of work-related injury and illness in Florida. The 2000 census data estimates that 79 percent of civilians are in full-time employment in Florida. The BLS data indicates in 2004 that 70 percent of these workers were employed to occupations of high risk for occupation morbidity and 15.5 at high risk for occupational mortality.

In 2002, the Florida health status data indicates that the rate of work-related hospitalization with primary pay encoded as workers' compensation was 180 per 100,000. These rates, though significant, are based on estimates made from the occupational documented workers and for illness and injury that have been presented to healthcare facilities for treatment.

The situation, however, is more complex when looking at pesticide poisoning. The population at risk for pesticide poisoning are mainly comprised of farm workers who are migratory, usually undocumented, and generally are not recipients of workers' compensation. Most farm workers also do not seek medical care for pesticide poisoning.

In 2001, the test data, which is supplied by the Florida Poison Control Centers, reported an annual incident rate of two percent for acute work-related pesticide poisoning. This, however, is an underestimation of the problem since only a few cases are captured by the FPCC. More accurate figures can be obtained to act as surveillance and through investigations of incidents.

The pesticide program currently operates a passive surveillance system and relies mainly on evidence and personal testimonies to substantiate pesticide poisoning. For the period 1998 to 2004, the surveillance program received 1600 pesticide exposure incident reports with less than 40 percent being work-related. Only 55 percent of these reports resulted in classified cases as guided by NIOSH. Also, more than 80 percent of the cases are classified. These cases are classified mainly by evidence provided in the exposed person's testimony of the exposure and health effects.

Pesticide illness and injury is a reportable disease in Florida. Although the Florida statute 64-D3 stipulates that healthcare providers and laboratory personnel should report the existence or suspicion of the disease, less than five percent of all cases are reported by these two entities.

Underreporting is likely the result of the non-specific nature of symptoms of pesticide poisoning leading to difficulty in diagnosis. This is further compounded by the reluctance of physicians to report cases of poisoning without clear exposure history and conclusive laboratory findings.

In Florida, the absence of a state-wide monitoring system poses a challenge and a determination of pesticide poisoning cases. A monitoring system would provide consistent analytical data on the level of pesticide and other chemicals in the tissues and foods of persons suspected of being exposed to pesticides or chemicals. Such data would assist healthcare officials in the early detection of disease, support diagnosis, and allow for appropriate treatment and management of cases.

For cases where low-level exposures were not detected immediately, epidemiological studies should be done to provide more complete understanding of the health impact. Resources, financial or otherwise, are needed to support the operation of monitoring systems and to conduct active surveillance on epidemiological studies. Monitoring pesticide poison in workers should require the collaboration of stakeholders such growers, state agencies, universities, laboratories, healthcare facilities, and community organizations. It may also require statutes, as well as a working agreement between partners to ensure compliance. The combination of expertise from these areas and state or federal funding support should ensure the implementation and success of such a venture.

In summary, the DOS Pest and other state-operated surveillance programs require the financial support from both state and federal governments to ensure that these programs remain viable. There's also great need for bio-monitoring to test the level of pesticide in the bodies of persons exposed to pesticide and for the treatment of workers who have been overexposed to pesticide. Epidemiological studies

should be conducted to determine causal relationships between pesticide exposure and health problems. Thank you for your time.

Verbal Comment 2006/02/13: Good morning. I'm Lora Fleming. I'm an occupational medicine physician and epidemiologist at the University of Miami where I am a professor. First, I want to thank NIOSH for this opportunity and also for supplying me with much of my training and education. I am part of a research group and I'll be presenting some of our findings concerning health disparities and U.S. workers.

In the U.S., race and ethnic differences and socioeconomic differences have a substantial impact on many aspects of health status, especially in terms of prevention and intervention. The reduction of health disparities is a key objective of the U.S. Healthy People 2010 to quote, eliminate health disparities among segments of the population, including differences that occur by gender, race, ethnicity, geographic location, or sexual orientation.

However, you will note that occupation has not been identified as a significant factor in health disparities. With NIOSH funding, the University of Miami research group has been exploring the health

of all U.S. workers using the National Health Interview Survey or the NHIS. It's a household survey of the U.S. population conducted annually since 1975 by the National Center for Health Statistics.

The NHS has collected demographic health and employment data on over 600,000 workers age 18 years and older representing 130 million U.S. workers annually from a sample of the entire U.S. population. This is a unique resource. Thus this uniquely representative and large data base from 1986 to 2003 -- we are using it to evaluate the issue of health disparities among all U.S. workers, particularly among the poor and minority worker sub-populations.

In general, the results of our occupational health disparities research can be summarized as the following.

Poor, less educated workers, particularly workers in minority sub-populations are at a major disadvantage in terms of their health and resources in the U.S. For example, we have already shown that obesity rates have greatly increased over the past two decades among all employed workers irrespective of race and gender, but particularly among black women workers. Furthermore, average obesity prevalence rates and corresponding trends vary considerably across occupational worker groups, particularly among many blue-collar workers. Cigarette smoking, a preventable cause of cancer and heart disease -- morbidity, and mortality is very high in blue-collar workers. For example, 58 percent of roofers are current smokers and are not decreasing over time while white-collar workers report lower rates. For example, four percent of physicians are smokers who have correspondingly downward trends over time.

These same blue-collar workers are also less likely to have health insurance. In the NHIS study population between 1997 and 2003 representing 130 million U.S. workers annually, the annual prevalence of having medical and dental insurance among U.S. workers was about 83 percent. However, the majority of U.S. workers during that time period had downward trends of insurance prevalence particularly among blue-collar workers. So for example, construction and extractive workers went from 64 percent to 55 percent with health insurance during this only six-year period, and all of us bear the burden of those costs.

Furthermore, using this same database, morbidity and mortality rates tend to be higher and health interventions are lower among blue-collar workers and minority workers. Those minority sub-populations reporting the worse self-rated health are also in the most racially segregated and lowest paying professions, such as private household cleaners and servants, maids and housemen, laundry and dry cleaning machine operators, nursing aids, orderlies, and attendants. With respect to health interventions workers, for example, with high ultraviolet or UV exposure are less likely to receive skin examinations. For example, only six percent of farm workers report a skin examination from a physician in the past year, while 29 percent of health diagnosing professions report getting a skin examination. And even though 41 percent of construction workers report smoking, only 57 of them reported being told by their doctor to quit smoking.

Not only does our research illustrate the value of the surveillance of the health and resources of the U.S. workers, these negative trends and health indicators and health resources, particularly for certain sub-populations of the U.S. workforce are alarming. Specifically, I just wanted to add with regards to the new sector-based NORA recommendations that are being proposed, my fear as both a physician and epidemiologist is that cross-cutting health issues which cut across these sectors will not be studied in an effective and consensus collaborative way. Thank you very much for this opportunity.

Verbal Comment 2006/02/13: Thank you. I'm Stuart Brooks. I'm the director of the Sunshine Education Research Center at the University of South Florida. NORA involves a transition from NORA I, which consists of 21 priority areas of research emphasizing disease and health to a sector-based process.

As part of this process, NIOSH will recruit as many stakeholders as possible and establish numerous partnerships. By adopting the approach of multiple stakeholder inclusion and partnership development, NIOSH believes there will be better achievement of a consensus on important research initiatives.

I wish to offer caution that a process devoted mainly to building sector-based consensus by itself may not be successful. The EPA's bold experiment, the Common Sense Initiative of regulatory reinvention that was conducted from 1994 to 1998 relied on consensus building. However, it proved to be relatively ineffective in the final analysis and other approaches were found to be more important.

Purportedly, NIOSH's sector-based approach would permit the building of partnerships that lead to research to practice applications in the workplace. I wish to voice a concern that a consensus philosophy needs not be the major criteria in making the final NORA II decisions. I am concerned that the change to a sector-based research approach will often emphasize safety issues, workplace interventions, and less effectively foster basic biomedical research, including biochemical and toxicological studies, but also diagnostic, clinical, and epidemiological approaches to important occupational disorders.

I wish to illustrate my concerns by focusing on one of NIOSH's NORA priority diseases, that of occupational asthma, a condition that I have studied for more than 30 years.

Now, throughout the world and especially the United States, occupational asthma will continue to be the most important occupational lung disease during the 21st century. For about eight to twenty million workers in the United States there are workplace exposures to agents that cause occupational asthma.

Perhaps two-and-a-quarter million workers in the United States have or will develop workplace asthma. In fact, occupational asthma is the most frequent occupational respiratory disorder in westernized industrial populations. Unfortunately, effective surveillance systems and epidemiological studies for occupational asthma are limited in the United States. There's a scarcity of validated epidemiologic and surveillance research studies in the United States that examine incidences of occupational asthma in various industrial sectors and job categories.

Many informative epidemiological studies originate from outside the United States. While NIOSH has sponsored a variety surveillance programs including Sensor Programs, the number of states with this program is limited. In Florida, the fourth largest state, we don't really have a good surveillance program like Sensor looking at conditions such as occupational asthma. Thus, I urge NORA II to emphasize a need for surveillance for occupational asthma in order to provide the critical link to practicing physicians and professionals and to translate research findings into interventions that prevent occupational asthma in the workplace.

Now, there may be an advantage using a sector approach since certain industries report greater risk for occupational asthma. There are over 250 causes of occupational asthma. There are many different jobs associated with its development. I wish to emphasize four important industries or jobs that might need further study in the future.

An increase risk for asthma is found in the dental industry. It's found among household and industrial cleaners. It's found in spray-on truck bed lining. We talked about that earlier. It's also found among food processing and manufacturing.

I also want to in the time that I have just to mention some other areas. That would be the role of irritants in the workplace and how further research is needed in that, particularly with susceptibility. I want to talk about the issue dealing with the perception of chemicals and the risk for chemicals and odors in the workplace and how that affects individuals. I want to mention that there are no good diagnostic approaches for occupational asthma. That specific inhalation challenges are fought with legal and liability issues, and really there are no methods for providing that.

So I'd like to say that in conclusion that an expectation for NORA II brings about excitement for new advances and ideas, and with NORA II there will be an opportunity to open new research vistas and make significant inroads into important occupational disorders, such as occupational asthma and in accordance with advances in medical research for other specialty areas major breakthroughs have their origin from findings derived from basic research. And it's important that there be emphasis on basic research with the introduction of NORA II. Thank you.

Verbal Comment 2006/02/13: Good morning. I apologize for my laryngitis. I'm going to do the best I can to get through this quickly so you don't have to listen to the scratchy voice. I'm with Chastain-Skillman here in Tampa. We provide environmental occupational health services. My topic of concern is mold impacts and remediation services in Florida; a hot, humid, and hurricane impacted state.

As a result of hurricane-related impacts to both the Gulf Coast and across Florida, mold is a pretentious four-letter word for many of us. Such as, but not limited to, emergency first-responders, law enforcement, rescue teams, and primarily workers in the cleanup and remediation field, not to mention the homeowner, construction and renovation contractors, the insurers, industrial hygiene, public health and safety professionals, laboratories, physicians, and last, but not least, the attorneys.

There are a few federal and state and generally agreed upon peer-reviewed scientific-based guidelines for the evaluation of potentially hazardous mold conditions or exposures. Not to mention the lack of governmental regulations, health-based or otherwise, at any level stipulating how alleged mold impact and the result on exposure should be handled. Subsequently, from this cascade of conflicting mold

exposure and potential health-effect information -- or more times than not, misinformation -- an unregulated industry of mold assessment and remediation has been illegitimately spawned.

Consequently, the need for sound defensible scientific, academic, medical health risk-based information as it relates to exposure, assessment and remediation guidelines or regulations coupled with appropriate levels of professional training are paramount to protect our workers from potential mold exposure.

The time is now for NIOSH through the NORA program and process to take a page out of the lesson books and learn from the torrid history and early days of the knee-jerk reactions of the asbestos inspection and abatement industry to the current manageable and level of appropriate asbestos guidelines and regulations and management programs today. Such an effort is crucial to ultimately protect those who are most at risk and those typically taken advantage of way too often; the less informed labor work force worker as well as the general public and community.

In closing, again, now is the time for NIOSH to act through NORA and to act decisively with sponsorship of appropriate peer-reviewed scientific, academic, and medical research, professional certification, and training programs, governmental guidelines and regulations, and an adequate financial funding that will be successful in carrying through this effort to its complete and beneficial fruition for all parties involved. Thank you again for your time. I appreciate your consideration regarding this request.

Verbal Comment 2006/02/13: I'm Joan Watkins. I'm an occupational medicine physician based in a hospital. I trained at the Great Lakes ERC. My concern is we recently have diagnosed in a hospital worker a case of erythema nodosum majora. This is documented first by a private dermatologist with biopsy and then by the head of dermatology here at USF. I removed this person from the hospital. It's a reaction to Capozide.

My concern is we've already sent her to the FDA and I'll send it to NIOSH this afternoon or in the morning. Once hospitals decide to use an agent, it's everywhere. I just want to see if there's other people who've had exposure to that or have had any experience that's similar.

Verbal Comment 2006/02/13: Good morning. My name is Dr. Prakash Patel. I'm with the Florida Department of Health in Tallahassee. I work with Rosanna Barrett. This morning on the slide show, the doctor from NIOSH -- he showed me the study and the information - as Dr. Brooks mentioned we don't have a central occupational program. Actually, this year we applied for occupational funding from NIOSH, but irregardless of whether we get the funding or not, we're going to start reviewing some of the data from workers' comp, hospitalization data, and mortality. We have some data regarding cancers caused by some of the chemicals and so we reviewed some of those data for applications.

Anyway, we will continue doing some of the basic things and in the future when we get more funding we will conduct more research within the programs. Thank you.

Verbal Comment 2006/02/13: Good morning. I'm Bob Nesbit, the program manager for the OSHA Training Institute Education Center here at the University of South Florida. I'm going to keep my comments real brief because three or four speakers before me have already talked about this subject. It's to develop a fall protection best practices for use in the residential construction industry.

From my experiences as an authorized OSHA trainer and as a consultant in the Florida Consultation Program, I find that the general building contractors in the residential housing construction industry could use a best practices guide for fall protection in residential construction. We see lots of different fall protection systems in use by this industry, but nowhere can we find a guide that outlines the best practices for specific types of residential construction.

There are numerous vendors of fall protection equipment that will tell you that their system is the best; however, that's not always true. We need for NIOSH to add this topic to the NORA intervention effectiveness research agenda and perhaps do some job site intervention research. Let's look at what vendors offer for fall protection throughout the nation and determine the most effective -- determine what most residential building contractors use on their construction projects. We need to see what most residential building contractors are willing to use and finally, determine how effective the devices are at preventing falls and share that information with us. It would also be good to know how easy and how the most effective devices are setup to use and maintain.

Maybe, your research could be the basis for an industry best practices guide. Such a guide can be used as a tool to encourage residential building contractors to adopt procedures and equipment for preventing falls. A best practices guide for fall protection in residential construction could also be used as a classroom manual for teaching new general contractors, superintendents, project managers, safety directors, and supervisors and workers. Most often we hear builders tell us that there's no good way for them to provide fall protection for their trades, or that trades are responsible for providing their own fall protection equipment, or that they are exempt from providing fall protection for one reason or the other.

In any case, there were 1,224 fatal accidents in construction in 2004. Of these, 441 were in residential construction or remodeling. One hundred and ninety-seven of these fatal accidents were from falls. There were 84 fatal falls out of a total of 364 fatal accidents in residential construction in 2003. The numbers are similar for the past ten years.

So we hope with NIOSH's help and the NORA intervention survey that we can make some difference in the next ten years. I appreciate you giving us the opportunity to speak and thank you very much.

Verbal Comment 2006/02/13: Good morning. My name is Jessica Bohan. I'm from the University of South Florida OSHA Consultation Program. My proposal for NIOSH this morning is to study the impact of applicable and accessible training for those workers who work in the highway work zones.

I brought my safety vest today to ask you when you see this color, what do you think? I think construction's coming, I'm going to be late, I'm going to be delayed, and a lot of feelings of frustration come up. I bring this up because roadside construction is a way of life. Wherever we go or what state we're in, we could be on a federal road, a city or county road, it's a widespread industry.

I'm concerned about it today because the truth of the matter is 100 people a year and 20,000 people a year are injured -- I mean, 100 people die and 20,000 are injured. The emotional and economical impact of this industry is something I can't even fathom. You may wonder how are they dying? Is it the motoring public that are killing these workers? Well, that's half of it. The other half is the workers are dying in the work zone, not from the motoring public, but from work practices that they're facing every day.

Historically, we have approached roadside safety from the motoring public point of view. We've increased the efficiency of the personal protective equipment. We've looked at improving the barrels and engineers have worked to design the actual traffic flow better to reduce confusion. We've also included law enforcement here in Florida to help inspire people to slow down.

Even though these changes are very positive, we still have people dying each year. Heinrich's Law of Safety basically says that unsafe acts are the reasons we have injuries in near misses. So I ask you today if you don't know how to do something properly, then how can you do it right?

I was at a hockey game over the holidays. I love ice hockey, especially the fighting. The zamboni driver came out and he went around the ice and he cleaned it. I've been to hockey games all over the country and I thought how does the zamboni driver know always to clean the ice in that direction? Well, he or she obviously has been trained. So why aren't we training the workers inside the work zone?

The current regulations that we have on the Manual of Uniform Traffic Control Devices, otherwise known as the MUTCD, and the Occupational Safety and Health Administration OSHA standards. They really only apply to flagger training. There's really no guidelines or regulations for those workers inside the work zones.

Donald Trump once said I only work with the best people. What he meant was in his organization he's the general in command, similar to an army or the Marines. He knows that every decision he makes will affect the lives of those people working for him. Although Donald Trump is a financial and real estate man, I think it's applicable to the roadside work projects. The crew leaders typically are the Donald Trumps of the construction site. They make decisions every day that affect the lives and safety of their workers.

So my proposal for NIOSH is to look into why don't we have any specific guidelines for these workers. Workers on foot are the ones who are being killed. They're being run over. They're being rolled over. They're being crushed. All of these, I believe, are preventable through knowledge and education. Knowledge gives us tools, tools give us the ability to make good decisions and help those who can't. So let's give them the opportunity to also work with the best. Thank you.

Verbal Comment 2006/02/13: Good morning. I'm Rosa Webster with Tampa Electric Company. I'm the coordinator of safety and health there. This morning I come to present to you one of the challenges that Tampa Electric Company is facing and that has to do with the aging workforce.

Within our work environment we have longevity. The average worker for Tampa Electric Company has been there 25 years. The average age of our employee is 47 years of age. As a result of that we would like for NIOSH to look at studies having to do with ergonomics and focusing on body mechanics as it's related to the aging workforce.

As a result of our workers' age and their decline in flexibility, there's difficulty as far as them being able to maneuver into some of the confined spaces that we have at our facilities. Also, the American worker no longer averages 170 pounds. It's well above that. So when you start looking at ladder safety, handrails that are rated at 200 pounds, it no longer meets the sufficiency of what our average American worker looks like.

So as employers we are faced with challenges of trying to provide a safe workforce within the guidelines that the federal regulatory agencies have given us; however, within the manufacturing sector, they may not be producing that equipment that is necessary in order to maintain that.

The individuals that we feel that should be involved as a part of this is not only the private sector, as well as the governmental sectors -- the engineers that are designing new equipment, new generators, new power lines throughout the industry. There needs to be an engineering design taking place as a part of this.

The best person that tells you how to do a job is the person that does it day in and day out. I think we need to look at the average worker. We need to reestablish what does the American worker look like in today's society and where is America going over the next 10 years, over the next 20 years, over the next 50 years. We need to provide safe workplaces for those individuals to be able to come in day in and day out and leave in the same state that they came to work in. Thank you for your consideration.

Verbal Comment 2006/02/13: Thank you. Before I make my statement I'd like to say that my comments are going to address all sectors and I have a one-page written narrative in the back if anybody would like a copy of it. Conventional means of managing workplace aggression have failed us. To this end we hear comments or topics like conflict resolution and anger management. There are individuals who express their conflict with a demonstration of violence. So if we truly want to prevent violence we must also prevent conflict.

Conflict resolution and anger management are fatally flawed. You see, conflict resolution presupposes conflict. You're already reacting. You're past any chance to prevent it. If all you do is react to aggression, eventually you're going to come upon that individual who does not communicate verbally. This person communicates physically and they strike out. Worse yet, they could have a weapon.

Everybody says well, where did that come from? It came because no one was observing prior to conflict. I see a lot of nodding heads out here.

Anger management is equally as flawed because you and I can experience and express the same anger differently. Therefore, the great universal axiom is if you can't measure it, you can't manage it prevails.

Thirteen years ago, we discovered and developed the means to measure human aggression. Through our ability to measure aggression in others and in ourselves enables us to manage aggression in others

and in ourselves, but here's the key. It enables us to measure aggression even prior to conflict. Thereby enabling us to even prevent -- I repeat -- prevent the conflict in the first place.

When you look at the last four shootings that have occurred; the ConAgra shooting, the Jeep plant in Toledo, Ohio, the U.S. Postal Service experience, and of course, the Martin Marietta shooting, these were individuals who came into the workplace and expressed their conflict by shooting and killing people. If you're relying on conflict resolution, you're already way too late.

I particularly like the Martin Marietta circumstances because here's an individual who left his sensitivity training class, went out and got his weapons, came back in and shot and killed six people. This man had taken anger management only six months before. These programs are not working.

Have you ever wondered why when you have an incident and you've got people standing around and why these people never got involved. Oh, I knew that Bob was that way. I knew that Bob was eventually going to attack someone. Why didn't they get involved? Well, the answer is simple. They didn't perceive it as in their best interest to do so. Well, the ability to measure aggression enables us to foresee conflict coming. Because we can foresee conflict coming we can now see ourselves becoming a victim. Now there's the reason or impetus to get involved.

Over the last 13 years we've actually seen this paradigm shift occur. Why would an employer get involved when they know that there is a cost of time and talent, but also the cost of this kind of training? That's brought me to Aon Corporation in the first place. They conducted a survey in the United Kingdom of the Royal Mail where they identified the cost of employee friction. Now, we're not talking violence or human crisis here. We're talking about simple employee friction which was costing them 247 million pounds a year. What they identified and more importantly measured was when you have an aggressor in your organization nobody else wants to be there. People come in late. They go home early. They stay longer at lunch. There's even a new term called presenteeism. It means you've got someone present, but they're so distracted, in this case because of aggression, they're not productive.

So we're able to demonstrate a direct link between aggression in the workplace and productivity based upon tardiness, absenteeism, and then ultimately turnover. People would rather go somewhere else making less money so they can feel safe.

Over the last 13 years, we have been measuring aggression anecdotally. We would like very much to be able to measure it empirically, to set a standard that all can build from. So we are very interested in a grant research partner to start doing this measurement so we can put it out to all sectors of the industries. So that way we can start to prevent conflict, prevent violence, and ultimately increase productivity by the diminishing of that tardiness and absenteeism linked to this aggression. Thank you all very much.

Verbal Comment 2006/02/13: Good morning and welcome to all of our visitors. I'm a native Tampa person here and so it's just really exciting to have you here with us in such a nice situation and where we can learn from everybody out here.

I'm Mary Matz. I'm with the Veterans' Health Administration. I am a patient care ergonomics consultant with them, as well as an occupational health science researcher and industrial hygienist. I will be speaking on behalf of the VHA, although I've already done this one other time in Houston. We have a lot of things that we want to get out on the table. So I'm fortunate enough to be here again.

As the largest healthcare organization in the United States, VHA has a unique vantage point for identification of important occupational safety and health issues. I'm going to briefly discuss three of them today. The other five I already discussed in Houston.

First topic, strategies for implementation of evidence-based programs and best practices. Change strategies are needed to facilitate management and employee acceptance of new research findings and best practices, not just in the healthcare, but other areas also. This lag in implementing evidence-based strategies has been noted across healthcare. In fact, it is estimated that it takes over 17 years for healthcare facilities to adopt new evidence, and it's been found that only a moderate proportion of nurses use research as a foundation for their nursing practice.

Studies that increase the understanding of management barriers and facilitators for adopting patient handling evidence-based practices would provide essential information for use in marketing efforts to overcome implementation obstacles. And because of the unique nature of clinical specialty areas, studies to determine barriers and drivers specific to each clinical specialty are needed.

Due to the significant costs associated with evidence-based controls, such as patient-handling equipment, cost benefit and return on investment studies would be helpful in persuading management to institute ergonomic programs. As well, research into patient handling productivity will assist in comprehensively defining cost benefits when justifying patient care ergonomic interventions and evaluating equipment for adoption by healthcare organizations.

Successful implementation of evidence-based programs in healthcare is also affected by the widely accepted belief by nurses that nursing safety should be sacrificed in favor of patient safety and quality of care. This belief diminishes nurses' acceptance of interventions and interferes with safe patient handling program intervention. Suggestions for research include determination of causes of the sacrificial mindset and the resulting non-acceptance and compliance with new safety strategies and best practices. Intervention studies using knowledge-transfer mechanisms that promote empowerment such as use of After Action Review are also suggestions.

Finally, implementation of evidence-based programs may be facilitated if data can positively relate patient handling to patient outcomes and quality of care, such as using falls, skin integrity, sprain strains, and others.

My next topic is workplace violence in healthcare and I previously spoke on this in Houston, but we actually came up with some new data and some new findings so I wanted to address it again.

Violence in the workplace, both physical and psychological, is a major workplace health hazard in the United States. Almost two-thirds of non-fatal assaults at work happen in hospitals, nursing homes, and facilities that provide health or social sciences. A recent survey of nurses in a VA Medical Center found that the majority of both physical and verbal assaults were client-to-staff and that the safety climate may be an important element in the potential for assault and abuse. The study of organizational factors and unit organizational climate influence on the risk of workplace violence may shed light on this subject. What is the effect of the unit culture on reporting incidents as well as the opposite, the impact of zero tolerance on the culture of the unit, including perceived stress and job satisfaction? How does the accepted paradigm in healthcare that patient/staff abuse is part of the job affect risk and how does personal abuse outside of the work, including intimate-partner abuse affect care giving and tolerance for abuse at work?

Patient handling musculoskeletal injury prevention. We are lacking in many of the indicators that we need for determining thresholds for cumulative injuries, as well as indicators for when patients and workers actually get to the point where they know that they need to report their injury. So this is another concern of ours and you will get it in written form.

Thank you.

Verbal Comment 2006/02/13: I'm Richard Johnson and I do occupational health in the Tampa Bay area. You may think that this is actually a vest for highway construction, but it's actually a required deer hunting color vest from Wisconsin that you have to wear so that people don't shoot you. They only had 1800 people in Wisconsin shot during deer hunting season in 1910, and they thought that was a good year. I'm not here to talk about that.

Although, it somewhat relates in that what we struggle with every day in our practice is trying to identify what is degenerative versus what it's an injury. With the aging workforce and your aging nurses, and with the stock market up and down and everybody lost their retirement a few years ago, nobody is able to retire when they wanted to. We have older and older workers having more expensive injuries all the time, which most of the time, at least in my medical/scientific opinion, are degenerative conditions, not injuries.

In the area of lung disease, we have B readers who will tell us what certain lung conditions are according to X-rays because they have criteria. We now have CT, spiral CT, MRI, X-ray, all kinds of sophisticated ways to evaluate a knee joint, yet we can't determine if it's a knee strain that the employer should pay for that new knee versus a degeneration, which is actually the major contributing cause. It goes with shoulders, too. A great example is a guy laying down and tightening a bolt and he experiences a shoulder strain. The end of case is total disability and big settlement for the employer because he has Parkinson's disease. Clearly, the neurologist says it's not work-related, but the compensation judge says he was working, he got hurt, now he can't work and therefore it's comp. So the problem isn't just a medical definition of what's degenerative and what isn't, but it's in the court system as well. Without

the help of good scientific research to say no, based on this CT finding, this MRI finding your knee is degenerative and it's not work-related. You may have had a little strain on top of it, but then we get into the whole cost issue of who's going to buy his new knee when he isn't ready for Medicare yet and he doesn't have insurance because he works for one of those contractors who can't afford to buy it anymore. Those are all of the kinds of issues.

Cumulative trauma is another one. That, in my opinion, is often just degeneration again. The employer is buying the medical care, which otherwise couldn't be afforded. When you think of this, think of deer hunting. Thank you.

Verbal Comment 2006/02/13: I might use that if I go quail hunting. Good morning. I'm Joe Doyle. I'm the regional medical director with Aetna Disability Services here in Tampa. I'm going to make three major comments -- a lot of them actually related to some of the ones you've already heard. The first one is about workplace wellness programs. During the past decade, several health insurers, including my own, and our vendors have developed wellness programs and disease management programs. Many of our larger employers have onsite fitness facilities and occupational clinics and health clinics. Dr. Francois kind of alluded to Citigroup. This encourages people to tend to their health and wellness activities during the workday. However, with more of the economic growth in recent years occurring in small and medium-sized businesses, access to these wellness and disease management programs may be problematic for employees in these settings.

Additionally, workers are being exposed to more stress and physical activity due to longer commutes and engagement in sedentary knowledge-based occupations. Disability claims, we've noticed in our claims experience, are increasing for depression, stress anxiety, and obesity.

Research is needed to assess the scope of this issue, as well as creative suggestions for insurers and employers to increase worker participation in these programs and to reduce time lost from work for mental health and obesity problems.

My second comment involves disability leave and graduated return-to-work programs. For some workers returning to the workplace after a disability leave -- graduated return-to-work strategies such as midweek restart, part-time hours, and reduced physical demand, also known as light-duty, can be useful in affecting a successful return to work.

However, some employers are reluctant to make accommodations or to accept less than a full-duty medical release based upon a fear of a possible on-the-job injury and potential workers' compensation claim. Here we feel that research is needed to assess the validity of employer concerns about the potential workers' comp claims and to develop best-practice guidelines for graduated return to work.

Categorized comment or partial comment:

My final comment deals with the aging workforce, lifelong learning, transferable skills, and productivity. Due to the natural aging process, some workers are unable to meet the physical demands of a medium and heavy occupation later in life prior to retirement, and may find themselves in a situation where it is unsafe for them to perform their own regular occupation. Often they are forced into disability retirement with the private sector, long-term disability, or Social Security disability, or as Dr. Johnson suggest even workers' comp.

Here we feel that research is needed to address the best manner of assisting the U.S. workforce in the acquisition of skills that would enable them to transfer into sedentary and light physical demand occupations, if and when their physical capability for their usual and customary occupation diminishes.

Some solutions may involve public policy initiatives, such employer and employee tax incentives, onsite education, and distance learning.

Thank you.

Verbal Comment 2006/02/13: Hello. My name is William Tomlin and I'm with the University of South Florida. I'm an industrial hygienist working with the 21(d) Program here. I'd like to suggest that NIOSH needs to look at exposure to silica at our construction sites, specifically looking at masonry tile workers and block masonry cutting workers over there.

Everybody understands the hazards associated with silica. It's one of the most studied toxic materials that NIOSH has looked at. We know that a restrictive and obstructive lung disease associated with that - and there's a 20-year latency period before the onset of some of the diseases.

As a personal note, my grandfather died of a restrictive lung disease associated with the construction industry. He was a cement worker. They called him the mud man. He mixed the cement there. Towards the end of his life he couldn't walk across the room. I'd tell training classes that he suffocated in a room full of oxygen based on his exposure to silica.

In the south Florida area, we're seeing a lot of masonry tile work going in with the explosion of the housing boom. A lot of the local communities and some of the builders are requiring that masonry tile be used. To install a masonry tile roof it has to be trimmed. Therefore the workers there are trimming the masonry tile while working in an elevated situation, exposing themselves to fall hazards, but more importantly exposing themselves to a significant amount of silica.

Our studies that we've done working with these workers show that every time we monitor those workers in that situation, they've been overexposed; both in masonry block cutting and in the masonry tile situation.

Currently, the only control method that they're using to reduce this exposure is personal protective equipment. We see that a lot. NIOSH has talked about different methods, but the only one we see out there are the filtering face pieces. With that filtering face piece, we're seeing a lot of misuse or not use of the material.

Therefore, I'd like NIOSH to get together with the roofing manufacturers and some of the local exhaust manufacturers and come up with an engineering control that they can use in that situation to reduce their exposures or at least come up with a best practices method. We feel like the use of personal protective equipment to reduce this exposure is not doing what it needs to do. Thank you for your time.

Verbal Comment 2006/02/13: Good morning. My name is Linda Horner and I work for Safety Products, Incorporated as a field products specialist. I assist our customers with product information, training, and sales. Prior to my employment with Safety Products, I worked for the Florida Safety Council and the National Safety Council for about nine years. As manager of the central Florida Occupational Safety Division I was responsible there for membership services, program development, and class coordination.

It was during my time with the Safety Council that I became very aware and concerned about the volume of violent threats and incidents, which my members were experiencing.

Our members consisted of a broad spectrum of industries in the public and private sectors. We offered a safety management class at the time called Preventing Workplace Violence. I made it a practice to routinely ask our members about their workplace violence concerns. One hundred percent of employers asked responded that they had experienced either a violent incident or the threat of violence from an employee, from a coworker, or a coworker's acquaintance.

I'm still dismayed and surprised that I did not find a single person at that time who had not been affected by this area of concern. In 1993 I had my own experience with the threat of violence during my workplace at a medical bill review company. Unbeknownst to anyone at our company, one of my coworkers was a cocaine addict. When she didn't pay her drug dealer, he shot her. When she was released from the hospital she didn't return home, but she did return to my workplace. We ended up hiring an armed guard to sit outside our office door after the dealer made a threat to come to the office to finish the job and kill her and whomever happened to be nearby.

I tell this story not for drama, but to make a point. Statistics right now do not tell the full story, and many incidents are still not reported to public authorities. This incident wasn't reported to the Bureau of Labor. It wasn't reported to OSHA. It wasn't reported to any other agency. Yet it occurred and it was a very serious threat to the lives of an entire group of office workers.

According to a 1998 Reuters' article titled Homicides are now the second cause of U.S. jobs deaths it also reported that more than half of all workplace victimizations were not reported to the police or to any other authority. I believe that new training and best practices would make a difference. Statistically, workplace homicides and violent incidents have decreased since 1998. I would attribute that to greater awareness of suspicious or concerning behavior, as well as the development of training programs like the one offered by the Safety Council.

Numerous public agencies and large employers like DuPont and the Post Office are including workplace violence prevention in their internal safety programs. Also, post 9-11 more companies began evaluating their security risks and international threats beyond the threat of just a disgruntled employee or family member.

Proactive employers can now easily obtain similar programs and support through agencies like OSHA, Bureau of Labor, and numerous Internet sites and services. Without a doubt, these efforts have contributed toward a decrease in the number of workplace homicides. I would like to request that NIOSH take a look at doing some research into effective safety training programs and best practices that employers can implement to decrease the risk of their workers in the workplace. According to the 2004 Bureau of Labor report, homicides have moved from the number two cause of workplace fatalities to number three now; behind transportation incidents and contact with objects and equipment. This decrease is a great thing, but it's still a non-regulated hazard and it's still a contributing factor to a large number of workplace fatalities every year. As a non-regulated factor this means that unlike some other high fatality hazards, employers are protected and prevention measures are enacted only at the whim of their employer, even though workplace violence affects every industry and even though it is a major contributor to workplace fatalities and even though it's very cost-efficient for employers to take a proactive and preventative stance with training and supervisor awareness programs.

I want to make one final point on that. Workplace fatalities are often accidents. Most of the things that we're going to be hearing about today or talking about are considered accidents. Tragic accidents, no doubt when fatalities are involved. However, homicides are not an accident. They are deliberate and often premeditated. Homicide is still the third largest cause of on-the-job deaths. Its hand is now reaching into our schoolyards and our churches. Many times after a high-profile workplace shooting you hear on the news people acknowledging they'd noticed warning signs, but they ignored them or their upper management ignored them. Many employers will not take the initiative unless some sort of training regulation is implemented and enforced.

I believe that workplace violence prevention training should be as important for supervisory personnel as a respirator class is for fabricators or forklift class is for equipment operators. Without some sort of research and presentation, I don't believe a regulation will be enacted. Employers will still choose to ignore the risks and these horrible kinds of fatalities will continue.

So again, I would ask that NIOSH consider applying some research funds and some efforts into coming up with ways for the employers to reduce this risk in the workplace. Thank you.

Verbal Comment 2006/02/13: I'd like to go ahead and jump ahead of the clock a moment or two and be the first to wish everybody a good afternoon. My stomach is starting to tell me it's about that time. My name is Keith Brown and I work with the OSHA 21(d) Consultation Program operated out of the College of Public Health here at the University of South Florida.

I am not a medical professional. I've never had any type of medical training outside of a very basic first aid course, usually at the spur of the moment to remedy a minor cut. However, in working with employers throughout the state and exchanging conversations with my colleagues, not only in the state, but also in other parts of the nation as well, we've identified what seems to be a disparity in the level of medical treatment provided for seemingly minor work-related injuries and similar type injuries sustained in an other than work-related environment.

This disparity places a burden on employers who participate and are required to maintain the Occupational Safety Health Administration's log of work-related injuries and illnesses. This disparity contributes a major burden on these employers, as well as OSHA to a degree in the fact that annually OSHA collects data and targets certain employers for enforcement inspections based on the data that they are reporting to OSHA. This disparity creates an undue burden on these employers and the federal government by targeting employers that perhaps should not be targeted for these enforcement inspections. This is an issue which frustrates employers and in some cases employees alike. No one wants to be second-guessing the medical professional in the type or level of treatment that they provide a minor injury, but at times it becomes somewhat curious as to why a cut that we might receive at home would only require a bandage, but a cut that we receive at work might require a couple of stitches as opposed to a butterfly bandage and subsequently, prescription-grade medications from antibiotics to painkillers. These are things which toss the employer into that position of having to report these issues to OSHA.

Unfortunately, I do not have any suggestions for resolving this type of an issue, but I sincerely hope and request that NIOSH and the medical industry work together to satisfactorily resolve this and remove this burden from the employers and employees alike. Thank you.

Verbal Comment 2006/02/13: Thank you, Dr. McCluskey. I do want to thank you for being here this morning. My story really cannot be told unless you're out there in the field and you see it. I want to congratulate our department and the College of Nursing and our program in occupational health nursing, which has had the wisdom to suggest that in this coming semester all of our graduate students will go to the field.

The story I want to tell you about is a product called d-limonene. Now, d-limonene is a very fragrant and very pleasant odor that is found in the citrus manufacturing industry. In fact, it is manufactured in tons. The interesting thing about it, even though it does represent an inhalation problem, there is no OSHA PEL. There is no NIOSH REL. There is no ACGIH TLV. That is very interesting, isn't it? Especially in view of the fact that animal studies have shown that it can be a potential carcinogen. In fact, in one study that was species-specific for rats, that's exactly what has happened.

So my story is simply that if there is great potential for exposure to d-limonene in the workplace in citrus production then why don't we have the information to support and to document a safe exposure level? So therefore I would ask NIOSH to consider this and do whatever it can to provide such a level. Thank you very much.

Note: Verbal testimony provided to NORA Town Hall meeting in Tampa, FL, 2006/02/13.

Editor's note: The erroneous "delimining" in the transcript has been replaced with "d-limonene" here.

Verbal Comment 2006/02/13: Good afternoon. My name is Roy Wood. I'm with the Division of Workers' Compensation for the State of Florida. We're part of the Department of Financial Services. Formerly, we were an entity in and of ourselves. We're renewing our interest or our thrust in this area of safety and look forward to working with USF in that area.

Dr. Brooks, I submit to you that another form of occupational asthma is speaking in public. That's probably something else to study in that area. The beauty of being last is I get to hear everybody else and get to rewrite my points several different times and find out that others have the same interest in mind that we at the Division do.

I have three basic topics to briefly discuss this morning.

One is the area of natural disasters. Around the southeast we are all very familiar with the hurricanes that have been taking place over the past five years. We're concerned about workers returning to a workplace where the infrastructure is down; where the employer may have damage to the workplace. They may be dealing with their products and services in a much different way. They may be thrust into a role that is much different than what they're used to. Overall, the environmental landscape has changed for these workers and their new work roles in many instances.

From our experience in Florida we believe there should be research into the ability to promote a safe workplace in an environment that is post-disaster; whether it's hurricanes or some other disaster. Research could be done on the safety issues concerning structural damage, enlightening workers

towards that area. What is the impact on medical resources in the area? What is the impact on the environment that people need to be made aware of? What can be done in these areas to prepare people for this obvious disaster that is to come? The impact of occupational hazards, the pollution in the water, the release of sewage, things of that nature are normal and should be expected, but to what extent can we prepare and be cognizant of those issues.

Finally, many workers are exposed to driving hazards that didn't exist before; the loss of power; the loss of traffic lights and just street lights of that nature. How to prepare workers for that. Which leads me also to my next topic, which is the extended driving periods that workers may have to go through because infrastructure has been damaged.

Categorized comment or partial comment:

My next topic is transportation incidents. Historically, transportation incidents are the leading cause of workplace deaths. On average in Florida it varies from 40 to 47 percent of all fatalities in Florida are transportation-related. Ms. Bohan probably pointed out one of the most important areas that transportation-related incidents occur and that is in the work zones. But there are many other cases and to my knowledge there is no definitive research that has been done on what other factors may come into play on other types of transportation-related accidents. For instance, are there distractions that we don't know about or that we do know about that may help us prevent further accidents?

Just imagine for a moment if you will that if we were able to reduce transportation-related accidents just by ten percent. That would be a significant amount of savings, both emotionally and financially. Are there safety programs that employers aren't taking advantage of in the driving arena? What is the impact of fatigue, cell phone use, drugs and alcohol? If you look at the BLS data it tells you that there were that many fatalities, but what needs to happen is we need to drill down into that information and find out what is really causing the accidents that occur.

Categorized comment or partial comment:

Finally, I want to talk about the aging workforce. January 1 of this year was the first year of the baby boomers turning 60. It became a very hot topic in everybody's mind and in all the press. When I went out and started looking for data and information in this area, I found very little. There was a lot of anecdotal information, but not a lot of concrete information that exists concerning the aging baby boomers; me being one of them. I did find a study by the American Society of Safety Engineers that suggested ergonomic changes that need to be made or considered. All of these things seem very obvious, but I think that it is probably time to begin considering what changes need to be made in the workplace that can accommodate this large mass of workers that we have a fundamental shift from a younger age to an older age. One research topic I would think would be the study of how to adjust the safety standards recognizing the limitations that may exist because of that shift.

Thank you very much and I appreciate being here.

Categorized comment or partial comment:

Verbal Comment 2006/02/13: Thank you. Once again, I'd like to point out that my comments are going to be directed to the retail and wholesale sector. I've got a one-page written narrative that's on the back table, if you'd like it.

Those in the retail and wholesale business often wonder why they miss the workplace predator all too late or until it's too late. We're talking about the individual who comes into the retail setting or the wholesale setting and shoots and kills people because they're either robbing from them or because they have some dispute with them.

This morning you heard me mention that how we had 13 years ago developed the means to measure human aggression. What was particularly interesting about this discovery was we realized that aggression wasn't just aggression, but that aggression was primal aggression and cognitive aggression.

Primal aggression is built off of the primal instincts of fight or flight. It is fueled by adrenaline. That is the connection between aggression, the production of adrenaline, the increase in the heart rate, and the resulting bodily language and behavior that we can identify and measure. This is what most people think is aggression.

However, what about conscience, deliberate aggression? Here, we've developed what we call cognitive aggression. This is built off of intent; malicious and hostile intent. In other words, what is your intent with this person? Is it in your interest and theirs, therefore a win/win as it ought to be or is it in your interest and their detriment? In other words, you're going to victimize this person. You're becoming a victimizer or at a slightly higher level of cognitive aggression, the predator. The person who doesn't care

who they're going to get, they just know they're going to get someone like in a robbery and often with criminal intent.

The highest level of cognitive aggression is the terrorist; someone who wishes to invoke terror into the hearts and minds of their victim. Now, we often think of a terrorist in Iraq, but the individual who comes into your workplace with the intent of killing people and who has no regard for their own lives meets the same body language and behavior that we use to identify the terrorist. The same body language and behavior are utilized.

To this end, an example is the best way to illustrate this. We were invited to the FBI and we met with the directors of behavior sciences for both the FBI and the TSA in Quantico. The Director of the FBI said that out of every 200 people that request a presentation in front of us we permit one. That says volumes about our interest in your subject matter. At the end they gave us a publication of all the devices and apparatuses that were being developed or had been developed to identify a terrorist in an airport. After reading it I explained to them that the problem you have is you're identifying a primal aggressor. You're identifying stress, anxiety, orbital flushing. In other words, you're reading emotions, which is what we all do when we try to find this kind of an aggressor. However, a terrorist is a cognitive aggressor. This is a person who not only disconnects from their victim, but this person disconnects from their own wellbeing to the point where they find a profound calm. Why a profound calm? Because they are completely and totally disconnected from their own wellbeing. Ladies and gentlemen, this is a completely different behavior than the primal aggressor. If you're looking for the primal aggressor then you're going to miss the individual who comes into the workplace. If you look at the last four shootings, these are people who came in and expressed their conflict by shooting and killing people. If you're not looking for the cognitive aggressor, you will miss this person all together.

If we are to identify any effective means of preventing the workplace shooter, whether the intent is to rob from you or to satisfy some kind of a dispute with you, we've got to understand cognitive aggression. How to measure it, how to engage, and how to prevent it. We've been measuring this over the last 13 years anecdotally. We have a strong interest in an ability to find a grant research partner that we can measure this empirically so that this can be the basis of preventing workplace shootings. Thank you very much.

Verbal Comment 2006/02/13: Good afternoon. I'm from northwest Florida and I'm Charlene Grafton. I've been a nurse for over 50 years. Since moving back to northwest Florida, I began to write about some of my experiences with computer-related injuries. That's what my presentation is today, computer-related injuries.

The major cause in my belief is the right-hand side of the workstation is an overloaded system. We're all righties (*). I first became aware of computer-related injuries while managing workers' comp claims while living in Nevada. I was managing workers' comp office claims for workers in California, Nevada, and Utah. Then when I moved to Atlanta I managed claims in Florida, Georgia, and Alabama. What I found by managing a large number of workers' comp claims of bank workers -- I managed all the claims for one national company for all of their banks in Georgia, and for another company all of their banks in Alabama. So I have a pretty good idea of what type of injuries that happen because of not only the computer keyboard, but also the keypad and the mouse.

With that in mind, I wrote and have a patent that is in a pending process, which is a training method to develop the left hand. By developing ambidexterity, we can prevent a lot of computer-related injuries. In the performance highlights of the NIOSH research findings -- it's in this book and if you don't have it and you work with people with hands, you really need to get this book. From this book of relevance to 40,000 employees of the IRS and millions of workers in similar work operations, they determined the use of a regimen of hourly brief rest breaks would reduce musculoskeletal disorders without loss of productivity. The study was done ten years ago, according to Dr. Naomi Swanson, who I did speak with and I am requesting follow-up studies with these same types of workers; as many changes have been made in keyboards, keypads, and peripherals by business and industry.

Directionality of the keypad with the left side of the numbers -- this is what is very interesting. When you change to the left-hand side of a keypad -- and you can buy them, but no one can tell why to buy one or the other. That's why I wrote the patent. Directionality between the hands is the issue. So there are certain small tests that you can do that really don't cost any money to be able to determine this.

Most of the research that's been done about work with the hands, though, is with CAT scans and MRIs and you just don't have that in the workplace. Products have been made and sold, but no explanation of what to buy. The computer keyboard with modem bought in a box is generic. So my method is based on the human factor of dominance. We all have our dominance, but what do you do with it to your advantage?

In 2003, it was estimated that 73 million computer users of which 80 percent were actively providing data entry services at work using the numerical keypads. With competitive motion injuries toping the charts in workers' comp claims it's reasonable to assume that NORA would be interested in new answers for computer-related injuries. I know that only employers can change occupational environments to decrease its incidence, but scientific investigations should be provided by NORA in the coming years.

Outsourcing of computer jobs to other countries makes this even more important for the United States because we primarily developed Silicon Valley and now so many of those jobs have gone overseas that so much of the computer business is not just our problem anymore. What I'm requesting NORA to do is to conduct research on the same types of workers, train for ambidexterity, develop work-hardening programs in our occupational centers, and also training programs to eliminate computer-related injuries. Thank you.

Verbal Comment 2006/02/13: I appreciate the opportunity to speak to y'all today. I'm Gary Greenberg. I'm an occupational medicine doctor at the University of North Carolina, as well as at Duke University -- and yes, you can do that. I'm pleased to be able to come to Tampa and discuss how we might be able to modify or redirect some of NORA's future with this opportunity for a town meeting. I'm lucky that I flew in from the north and it wasn't that far north and my flight was not cancelled. This is a town that I know well. I actually practiced medicine down the street at University Community Hospital and had a faculty appointment at the school in the first months of its existence as a school of public health.

My point today is to try to gather some support from the audience and from NORA's planners to make sure that we include recognition of one of the more consequential and sometimes overlooked aspects of occupational health, which is disaster planning.

Disasters are a sadly recurring situation of massive public health consequence, and occupational health needs a seat at the table and a voice in the room when those issues are being discussed.

Disaster planning has been a problem within occupational medicine for decades; especially because many disasters originate with our own worksite. Where there is chemical, nuclear, or infectious hazards which are either stored or even produced we recognize that managing those situations are part of occupational health. Recently, disasters have occurred because the workplace is the target of the disaster. That's a different situation than that in which we were trained in the past. Terrorism has focused its assault in many occasions at specific workplaces. We should right now think about some of the past contemporary situations where disaster was appropriately used.

SARS is often used as a prototype. SARS was an occupational health crisis. We probably couldn't call it a disaster because so few cases occurred, but nonetheless this was clearly an occupational health event where workforces of healthcare workers were the most primary target of the disease and the greatest sufferers in the countries where that was manifest.

9-11, clearly the first domestic episode of major terrorism needs to be recognized that the target was a workplace. 9-11, Oklahoma City were both situations which were targeted because of their metaphorical importance, but the victims of that situation were people in their job. They had no reason to anticipate that their job was one where major consequences occurred.

Similarly, anthrax was a targeted terrorist event focused at workers, media, congress, and accidentally it was postal workers who suffered the greatest health consequences. Clearly, this is a situation of occupational consequence. We looked at the converse of this and we can talk about Katrina. Katrina was a situation where the consequences were generic. A civilization almost comprehensively was demolished. The shining light of the recovery and the response happened to be the worksite. The oil industry as the victim and retail as perhaps a rescue agent need to be recognized as a very consequential situation where disaster management was well-handled.

I was at a meeting last week where Wal-mart's director of crisis management described their war room of monitoring tools, full-time employees, disaster plans for every possible crisis from shootings to fires to earthquakes. And in this case it was a hurricane where they could plot the plans and bring their resources to bear in the perimeter, ready to work on the population as soon as it occurred. They had scramble plans and reassemble plans for their workers. It was quite impressive and better than anything our government was able to achieve.

If we stop thinking about the past disasters and think about what's the most likely threatening and impacting disaster of the future we really need to think about pandemic flu and how that affects workforce, in addition to the population as a whole. We have to recognize that the workforce is an opportunity to respond to pandemics. It's an organizing focus of society. We have to recognize that the workforce has to respond to the situation with plans of social distancing, institutional surge capacity, new arrangements for remote work, shifted assignments, and alternative work programs.

The main point of my remarks is to recognize that disaster management within occupational medicine is public health. The core discipline of what we all trained in. It's about planning for community-based response. It happens that the community is workers. It recognizes that we are a network of providers. We are a network of providers that mirrors and parallels what's going on in the other network of public health, the more classically considered county, state, and federal networks. We need to stimulate, initiate, and evaluate our response to disaster situations. There is a growing network now called the Occupational Health Disaster Expert Network. There is a handout in the back of the room and I have a few in my own hand. We're trying to stimulate a resource that will allow professionals in occupational settings to share plans and ideas with each other, recognizing that disaster response is a non-proprietary and non-competitive aspect of occupational health. I appreciate your listening and I'll be around for questions later.

Verbal Comment 2006/02/13: Good afternoon. My name is Rene' Salazar and I want to thank NIOSH for allowing me the opportunity to be here. I'm with a small firm in Tampa, Florida called Salazar Consulting Group. We are a small group of certified industrial hygienists. All of us trained with either master's or Ph.D. training. We do most of our work here in Florida. We provide consulting services in the field of environmental and occupational health. Although we're trained and certified the comprehensive practice of industrial hygiene, it appears that our practice causes us to be most involved in the issues of indoor environmental quality, particularly in non-industrial environments. Most of our clients that call into the office usually have that kind of work or service that they need. The client base is quite varied. We deal with building owners, building managers, lawyers, physicians; a variety of folks. They all have essentially the same interest. That is they're all connected by this issue of the workplace and so protecting the workers is a priority.

For the more traditional exposure characterization methods such as for noise or asbestos or for a variety of chemical agents, NIOSH provides us, the practicing industrial hygienist, with methods to do those assessments. We can go to the bookshelf and find NIOSH methodologies for the investigation of these kinds of issues and also sampling methodologies that might be available. Even for general IQ issues, which are really a subset of traditional industrial hygiene, NIOSH offers us some guidance. There is some information available for us to go out and get NIOSH documents to determine how to perform an investigation.

However, these days the unfortunate factor is that most of the general IQ requests that come through are no longer general in nature. They focus specifically on one agent and that is mold, and sometimes bacterial agents. With this, of course, you would imagine that it would present a problem. We don't have standardized methods of doing investigations for these mold elements. We don't have standardized methods of data collection, of data analysis, and of data interpretation. It makes our job quite a bit harder.

We find ourselves as formerly trained and knowledgeable individuals as others doing these kinds of exposure assessments having to argue issues with those who are less qualified, not properly trained, who basically have gained an understanding of some buzz words and phrases, which are thrown out there to the workplace or to the workers and to the general community at large. So we find ourselves having to debate these issues, which I would believe with good research and good opportunities to do assessment methods would not have to be discussed. This wastes time and money and also drags the individuals through this entire process. The workers usually have some validation of their complaints, sometimes there are legitimate complaints, many times there are not. They are just perceived hazards.

What we need from NIOSH and what we need from this NORA process is to aggressively research this issue of indoor environmental quality in non-industrial indoor environments. We as practicing hygienist or as practicing environmental professionals need to be able to assess standardized investigative methods, standardized methods of data collection, analysis, and interpretation. Ultimately, we would hope that we would have some sort of response data that can be generated so that we can see the development of threshold values developed at some point in the future. Thank you very much.

Verbal Comment 2006/02/13: Thank you. I'd to thank NIOSH for giving us the opportunity to let the community come together and to Stuart Brooks and USF for sponsoring it here at the University. Well, a little bit about me. I'm also with Aon, as Dr. Byrnes is. You're going say what is an Aon? Well, we're a large insurance brokerage world-wide and a large reinsurance company. That's what we are. It says that I'm with the Sunshine ERC, which I am as a member here with the community. Today, I just want to talk a little bit and I'm going to tell you a little story about one of the companies that we represent to get their insurance for and the problems that they have today competing in the global environment with the worker comp cost.

Before that, I've been with Aon for about five years and before that I was in the manufacturing, telecommunication, and public-service sector. I was actually a paramedic when I started. So that's how I started. I represent a number of clients in the retail and wholesale trade sector. They're always concerned about employee safety and health, and of course, what comes with that is the cost of worker compensation.

One company in particular has had a lot of rapid growth, as a lot of the ones in this trade sector have. With that, the additional worker comp claims come, sometimes yes, sometimes no. So they call somebody like me from the insurance broker to come help them. So we do an analysis of their accidents, find out what body part, what type of accidents, and those kind of things. We try to come up

with a game plan to come up with some job fixes, let's call it; either engineering or administrative controls. Of course, we follow NIOSH lifting guidelines, we go to the OSHA website, and we look at everything that's out there that we can use. We come up with a game plan. So we have these interventions, which may include controls that y'all have heard about; material handling equipment, raising and lowering work surfaces. I was involved with a big project with VDTs way back when and we were trying to tell a company that they needed 77 million dollars worth of equipment to raise and lower workstations for operator services for the telecommunication industry. That wasn't going to fly. We switched it to you picked out your own chair and you were happy, and that was the end of the game. All we did was buy chairs, but somebody else was trying to tell us that we had to do all this lifting and stuff, as you've seen. Modifying tools, some of that is pretty easy. Reducing weights, physical-demands testing, which unions get excited about. You get a post-offer, we send you to get a physical test and we find out your shoulders, and your knees, and your back can't do this particular job and we can't hire you. Then we implement all of these things and time goes by -- let's say a couple of years -- and they go Bob, this isn't quite working like we thought. Our costs aren't going down. Our musculoskeletal disorders aren't going down. What's the story? Well, I can always say well, you need to give it a little bit more time. It's not like that. For these companies, costs increase with this. We all know what's going on with manufacturing, it's not here very much and those kinds of things.

I've been following available research, as you heard from -- just before I came, I read the NORA MSD Team Agenda to find out what they were thinking about. At Aon, I also have an associate that works with me, Dr. Richard Roy, who's on the NAICS Committee. I've read where all the gaps are in the research from both those groups and came up with one that I think is going to work good for the trade sectors.

Similar to their findings, I have two interrelated issues that need additional research. One is the impact of these multi-factorial causes of MSDs, including psycho-social, which is really important. There's a lot of loose data out there. A lot of people are pointing fingers at things and nothing definitive. We have physical occupational and non-occupational factors and their interactions. With this, how these factors factor into the worker comp systems in all states. In fact, some states are different than others. I get this injury and am working in Alabama and they won't pay anything, but I go to Florida and this will be paid. So we need the factors in the worker comp system and the findings of causation, diagnosis, the duration of the disability, and other outcomes related to musculoskeletal disorders. Those things are tied together.

Research greatly assists the companies in this sector with managing their costs and sustaining growth. Thanks for the opportunity and if I had more coffee, I could have talked faster. Thank you.

Note: Verbal testimony provided to NORA Town Hall meeting in Tampa, FL, 2006/02/13.

Note: Supplemental E-mail submitted 2006/02/14:

I presented at the Tampa Town Hall Meeting yesterday afternoon. I just wanted to restate the particular need for additional research -

More studies are needed addressing the multifactorial causes of MSDs (i.e., psychosocial, physical, occupational, and non-occupational factors) and their impact on factors within the Workers' Compensation systems on findings of causation, diagnosis, the duration of the disability, and other outcomes.

Thanks again for the opportunity.

Bob

Verbal Comment 2006/02/13: Thank you for the opportunity to be here again. My comments are going to follow what Mr. Prior just said there. Basically, what I'm going to do is talk to you a little bit about the need to develop better safety and training programs for people in the retail/wholesale industry.

It would be helpful if NIOSH could develop some guidelines as how to best approach the training needs for workers in this industry. We need to determine if there's a relationship between the accidents and the lack of safe work-practice training for retail and wholesale workers and the managers. We also need to look at hazards involved in the tasks retail and wholesale workers perform in order to determine if their safety and health training is adequate. There appears to be a need for developing task-specific minimum training requirements that include safe work practices.

As this industry has expanded to the use of new technology and automation over the past two decades, workplace safety and health programs and training in those programs seems to have been left behind or has not kept pace with the change in technologies. Numerous contract companies develop safety and health programs, emergency action plans, and training plans for the retail business owners. Some of these programs are canned so as to fit a number of different types of businesses with a little bit of modification. The problem is that a lot of business owners don't look at the information to see if it really fits their situation. When an accident occurs owners often find situations that contributed to the accident, but were not covered in their safety and health training program. The result is that the retail and wholesale safety and health programs need to be evaluated for effectiveness in terms of reduction of workplace injuries and lowering workers' comp cost.

NORA could use the information gathered doing intervention research to develop a promising practices document for the retail and wholesale trade industry. This document could then be used by the retail and wholesale industry for developing custom workplace safety and health programs, training programs, and emergency action plans. I recommend that NORA look at the possibility of developing course materials that could be used to target specific retail and wholesale management groups. We have found in our consultation work and in our classroom training sessions that there is a specific need to develop safety and health program management materials for managers who have little or no safety and health knowledge. There is a real need for developing training materials that can be used to explain the importance of good safety and health programs and demonstrate the need for effective emergency management plans. There is a need to determine adequacy of the emergency procedures and the knowledge of the managers and employees in implementing emergency action plans, as well as training programs. Again, I thank you for the time to give this presentation. Thank you.

Verbal Comment 2006/02/13: Good afternoon. My name is Rich Johnson and I work for Lowe's Companies and Lowe's Home Improvement. Great thing about working for an improvement company is we don't wear ties. Even our CFO and Chairman of the Board doesn't wear a tie to work, so that's pretty nice. A jacket is really dressed up for a hammer guy. I'm the director of safety for Lowe's. We're a Fortune 50 company. We have 1275 stores and building 150 more a year for the next five years. Our sales are going to exceed 42 billion in '05. We actually serve about a million customers a week. Our home is in Mooresville, North Carolina. That's where I came from today. We started as a little tiny hardware store 60 years ago in North Wilkesboro and it's grown to what it is today. We pride ourselves on actually developing our stores in a way that it attracts a customer that feels safe in our store. We have 175,000 employees that work at Lowe's. Of course, that number is growing at a pace of about 16 percent a year. So I'm not here to talk about a canned topic, I'm here to basically represent one of the biggest retailers in the United States and what our issues are.

The biggest thing for us is that we move about 70 percent of our products that you buy at Lowe's through our distribution network supply chain. That supply chain piece adds even more injury rates than the store does because everybody is driving forklifts and everybody is on power equipment when all the products get shipped. So you think about a 42 billion dollar company and 70 percent of our products coming through 11 distribution centers throughout the United States. It's quite a task. So that's what keeps me up at night, besides the fact that we have 5,000 deliver vehicles on the road. That really keeps me up at night.

The gentleman that talked about state-specific issues, we focus on California, Texas, Florida, New York, and New Jersey when it comes to work comp. Those are the states that cause us the most -- I don't want to say grief here in your hometown of Florida, but Florida is definitely one that is a real problem for us. So we focus on those states. We hold state-specific training every year for our HR and our loss-prevention teams and our store-management teams on how to deal with claims in those five states, and it's very effective for us.

I guess our biggest issue for us is really benchmarking. Our biggest issue with NIOSH and NORA is to set an agenda to benchmark with other retailers. Everybody kind of measures it all differently. There's a similar study that's done on our loss prevention side by Dr. Hullenger out of the University of Florida. He provides us a retail security study every year that measures shoplifting, internal theft, turnover, management training. He produces this and he's done it for probably the last seven or eight years. We need that same type of measurement tool for the safety side. What dollars are spent for safety, how much money is spent on safety, what other retailers are spending on safety? We're very fortunate at Lowe's to have a board of directors, and a CFO, and a CEO that believes in safety. So when those one million customers come in every week, they're going to leave the same way that they came. Our 175,000 employees are going to go home safe every night. They put forth a lot of money, effort, and time in those practices at Lowe's, and we're very proud of that. We truly believe that safety sets our company apart from our main competitor.

I think many of you, if you think back to your visits -- and this isn't going to be a soapbox about Lowe's. We have wider aisles. We have brighter aisles. Our customer is focused on the female. All of us guys that go in there to buy are being driven by the female in our lives that told us what we're going to buy. We recognize that at Lowe's. So we have a nice and safe setting for our customers to come in and shop. When you talk about all of those issues in safety, again, benchmarking is our biggest piece. We saw it on the slides earlier.

Back injury, ergonomic issues are a huge problem in retail, especially in big-box retail. It certainly drives our work comp. Our work comp and general liability combined is in the hundreds of millions a year. It's those customers and employees that get injured that concern us the most.

I appreciate the time. It's great to be here and to listen to everybody's comments and I appreciate it. Thank you.

Verbal Comment 2006/02/13: Thank you. I'm from your neighboring State of California. In fact, what brings me here is about three different projects that I'm involved with. One of things I'd like to share besides working in California for it seems all my life with occupational safety and health -- I started back in '76 with enforcement and now I'm responsible for the onsite consultative program. With respect to retail and wholesale, it's the programmatic effects. The changes that we have seen in California and the tools that we've developed is the focus that I'm bringing in today.

One is the displacement of manufacturing from service industries that have resulted in increases in retail and wholesale establishments. The focus here will be directed to the program and process element of preventing injury and illnesses in workplaces. Over a decade ago, California promulgated the injury and illness prevention program that's known as the IIP Program as a result of state legislation. Whether it's a private entity or a public agency that adopts the injury and illness prevention program or process, the question that I have here and hopefully that will stem some research would be that how can we effectively measure the programmatic or program process as far as its effectiveness in reducing preventable occupational safety injuries and illnesses?

What I am more interested in is something that's more specific and tied directly into the elements of an injury and illness prevention program or process. NIOSH and the CDC do have the publication, but again I would ask that we continue the research that would be a little bit more definitive.

I would like to request a study that will assess the injury and illness prevention program process through the systematic process of evaluation and developing evaluation tools and that will be specific to consistent factors, which I will go into detail about a little bit later.

Retail/wholesale establishments are experiencing major influxes that are progressive in time with the aging workers, young workers, Hispanic, non-English speaking, low literacy, and immigrant workers, and workers that have two jobs or workers from temp agencies. Increased workers in businesses lead to increased risks in exposures. From a proactive perspective, model programs have been developed and used throughout several states and include the injury and illness prevention for workplace security that I was part of many years ago. Best practice applications on ergonomic principles -- and we even have an ergonomic program in California.

How do we know which program elements work best? How can these program elements be assessed in fostering our efforts? For example, in the injury and illness prevention program we want to know if the company has a formal safety policy. Do they encourage or discourage (*) non-performance? Do they promote safety in the workplace? What about the individual responsible? Are they being identified? Who are the competent individuals? Do they have the authority with respect to the assurance of compliance? Are there methods and means to follow through with this? Are employees encouraged to report through communication? In other words, are they given it in the language that's clearly understood by those that certainly would be affected the most?

So I think that it's having a systematic approach; one that is consistent and that can be used to cross state boundaries. The research data can be used during the self-evaluation during consultative interventions to demonstrate the elements that work best. In other words, we can go from one industry to another and say okay, these elements are working in the prevention of workplace violence. They're working in ergonomics. They're working in preventing slips and falls. At least we have a data system and a process that will evaluate the effectiveness of the injury and illness prevention program and process. Thank you.

Verbal Comment 2006/02/13: I'd like to thank you first for the opportunity and the invitation to come and speak with you folks today. My name is Chris Mariner and I've been a loss control consultant with the FCCI Insurance Group for 12 years. The FCCI Insurance Group is a multi-line regional commercial insurance carrier. We conduct business in 13 contiguous states, from Florida all the way up to Indiana.

In these states we write just over 43,000 policies. These policies include workers' compensation and general liability coverage among others.

Throughout the nation and the State of Florida, roughly 80 percent of the businesses are classified as small businesses. From an insurance perspective, the clients that we deal with are almost entirely classified as small businesses. Our insurers represent a very broad scope of occupations, including manufacturing, construction, restaurants, and general mercantile-type risks.

While the NIOSH website is an excellent resource for safety and loss prevention professionals, one of the shortcomings that we see is the complexity of some of the information that's on the website, and that's available there for small businesses. Given the size of these businesses, the technical level of expertise is typically low. The percentage that have personnel directed to safety and loss prevention is also very low. I hate to say it, but the overall ignorance level with regard to the required standards, training programs, and worksite safety tends to be fairly high.

We would like to see development of some sort of a small business compliance section. We feel that that would be very beneficial to our policy holders. In addition to some basic safe work practices, web-based written programs. For example, respiratory-protection programs; a sample template program that perhaps employers or policy holders could go into and make modifications. Lock out/tag out, blood-borne pathogens, hazard communications, and having them be in layman's terms, so that the basic shop with 15 or 30 employees can understand. Web-based training programs to assist employers in meeting the training criteria of these programs. Somebody mentioned ergonomics, we need some sort of an interactive ergonomics section where employers can look at what sort of ramifications ergonomics have. What type of work station setup may be best suited for their type of work? Anytime an OSHA standard is cited on the site, possibly having a hotlink to that standard, so it takes you directly to the OSHA website would also be very beneficial.

In addition to the aforementioned items, certain trades in Florida have seen a deterioration in their labor pool as a very serious challenge. Statewide unemployment is hovering near 3.3 percent as of the December numbers; with certain areas of the state well under that mark. Sociologists indicate that at any given point in time, 1.8 percent of the population is incapable of working. You can begin to see the dilemma that is presenting itself to employers in this state. Employers are settling for employees that they would not have hired in the past or turning a blind eye to immigration issue so that they can have enough bodies to get their work done. This combined with the looming retirement of the baby boomers and the aging workforce spell real trouble on the horizon for employers here in the state.

Simple and easy to understand programs and training materials in several of the predominant languages including Spanish would be very beneficial to many of the employers that I represent. Thank you very much and I appreciate the time.

Verbal Comment 2006/02/13: Good afternoon. We got up at about 5:00 this morning and tried to get here as fast as we could. My name is Michael Wahl. I'm with the Wal-mart Stores, Incorporated in Bentonville, Arkansas. I've got a couple of my colleagues with me, Ryan Stanton and Joe Dial, who are two of our other directors. I manage the southeast area of the country. As you know, Wal-mart's growth is quite popular and it's gotten itself into quite a bit of areas within the country, and we continue to grow. I manage the southeast, which encompasses Louisiana all the way to Florida and then through to North Carolina.

I guess some of the things that we've been facing this year has to do with our propensity to grow. We have a lot of remodels, a lot of projects, a lot of expansions going on within our company. That in combination with turnover and the retail environment itself causes a lot of concerns for us and how can we maintain or sustain quality talent, new associates, associates that are willing to grow with the company, as well as keeping them safe from accidents.

We also in the retail sector have a concern for our customers as well. Cleanliness is going to be one of our mottos this year. How do we maintain cleanliness standards within our facilities to keep it a safe and healthful shopping experience for our customers? So that's some of the things that we're working on.

When you consider the retail sector, you also look at headline risk. As popular and as expansive as we are as a company, what is headline risk to us? You look at fires, catastrophic events -- we're constantly in the media. So there's always a lot of eyes watching us on a continual basis. We also have tire lube

express facilities, which is typically an oil-change facility, but we also change tires, and that can also lead to a certain catastrophic event.

We also have super centers that include grocery and the quality-assurance issues. With a lot of these undercover-type reporting that goes on we certainly want to maintain our integrity and not allow things to be placed at risk. We've got an aging workforce as many of all of us have. I think that's a concern for us as well. How do we sustain wellness programs? How do we maintain fit and healthy associates knowing that they're more susceptible to soft tissue-type injuries?

We're actually going to be attending a symposium over in the Orlando area in the next couple of days talking about off-the-job accidents. I think that's been somewhat of a concern or a possible issue with associate injuries within our facilities. How do we identify and understand the complexity of those types of accidents that are contributing to our bottom line? Within retail, I think some of the concerns that we have is how do you measure because you have that customer element. You've got associate man hours, but how do you come up with a simple measurement for the retail sector when customers are as important as our associates in providing a safe place for them to shop as well? So we're starting to look at some different ways of measurement and because we're kind of on a scale of our own in comparison to a lot of our competitors, we're actually looking at frequency of accidents per transaction, which we think will actually take into consideration the man hours worked as well as the customer exposure.

Probably the types of accidents in our stores are probably no different than anybody else. Some of the things that we're working to improve is our inventory flow process. There's a lot of technology that's used in the way we receive and freight merchandise through our stores and then out to the customer. So there's a lot of work and dedication involved in how we're going to ease that flow. Rather than bring merchandise on the sales floor and then expect it to go back into the back rooms, we're trying to figure out a way that we can just easily flow it through our counters or end-caps on a stack-basis, and then allowing the customers to check it out through the checkout and then exit the store. How you ease that process and reduce the amount of overstock is important to us. So those are just a couple of things that I've been thinking about as we flew in today. Thank you for your attention and if there's anything else we can do just let us know.

Note: Verbal testimony provided to NORA Town Hall meeting in Tampa, FL, 2006/02/13.

Verbal Comment 2006/02/13: Hi, I'm Cameron Brooks. I'm a senior at Plant High School. For the past few years I've been working as a summer intern as a contractor at the OSHA Training Institute Education Center at USF. During this time, I was involved in researching and developing training materials for teenage workers. I developed numerous safety and health topics in the OSHA general industry and construction industry regulations. I prepared Power Point presentations that were specifically aimed at the teenage audience. I also ran the USF OTI Education Center 10 and 30 hour OSHA card distribution office during the past summer.

What I'd like to see as my perspective as a teenager is I would like to see NIOSH develop a training intervention study to determine the effectiveness of teenage workers retail safety health. I feel that it doesn't target the teenage audience as much as it should. I found that there's a lack of adequate safety health and training materials designed for the teenage workers themselves.

My concern is that the currently available educational material may not adequately address all of the needs of this special and important risk population. Furthermore, teaching a teenager to be safe early in his career will carry over time and create good habits for when he's older.

A training intervention study could evaluate the type of training and information programs for injury prevention in a sample of retail injuries in Florida or another state. The results of the training intervention study could be used to estimate the effects that the various training programs have on reducing workers' compensation claims and on-the-job first aid injuries.

In addition, there can be publication of the best training practices of the retail safety and health training programs in peer-review literature to be made available by NIOSH for distribution throughout the rest of the nation. Thank you.

Note: Verbal testimony provided to NORA Town Hall meeting in Tampa, FL, 2006/02/13.

Thank you for the opportunity for comment. Rachel Kwapniewski, RN

Despite 20 years of data that characterize the hazards associated with patient handling, nurses and nursing personnel continue to have high injury incident rates: 7.6 cases per 100 full-time workers in hospital settings and 9.2 cases per 100 full-time workers in nursing and residential care facilities according to the 2004 Bureau of Labor Statistics (BLS) Report of Nonfatal Occupational Injuries and Illnesses (U.S. DOL BLS, 2004). Depending on their work setting, nurses and nursing personnel incur almost twice the risk of injury than the general working population that has an average incidence rate of 4.8 cases per 100 full-time workers (U.S. DOL BLS, 2004).

Nursing is a physically demanding job as one study illustrated that during an eight hour shift, the cumulative weight lifted by a nurse was equivalent to 1.8 tons (Nelson & Baptiste, 2004). The National Institute of Occupational Safety and Health (NIOSH) has determined 51 pounds the maximum recommended weight "under ideal conditions" for 99% of men and 75% of women (Waters et al., 1993). Nurses and nursing personnel are frequently required to work under less-than ideal conditions as a patient's status can be unpredictable, demanding workloads force nurses to rush through patient care, staffing shortages result in fewer personnel to assist with lifting tasks, and performing care in confined spaces such as small hospital rooms and bathrooms can be challenging.

In addition, the studies upon which a safe weight was determined were based mostly on men who were required to lift boxes from the floor in a vertical motion (Waters et al., 1993). This lifting scenario differs from nursing practice as in an adult setting, all patients weigh more than 51 pounds, the weight is unevenly distributed and patients are usually moved laterally and vertically simultaneously. In addition, females make up the majority of the nursing profession. For these reasons and more, manual lifting of patients has been widely cited as unsafe in the literature (Fragala & Bailey, 2003).

Musculoskeletal disorders (MSDs) involving days away from work among nurses and nursing personnel resulted in 49,500 cases for the year 2004 (U.S. DOL BLS, 2004). MSDs have enormous costs on the healthcare industry with direct and indirect costs approximated in the billions per year (Nelson, 2003). Long-term effects of back injuries include data showing that 12-18% of nurses plan to leave nursing due to back pain (Nelson & Baptiste, 2004). It has also been reported that 12% of nurses will change jobs to decrease risk of injury (Nelson & Baptiste, 2004). With the largest nursing shortage in history upon us, this can only accelerate the problem.

A change in legislation is critically needed for a profession whose numbers are dwindling and workers are sustaining injuries at unnecessarily high rates. Various hospitals and nursing/residential care facilities have responded by purchasing lifting equipment for their units, instituting "no-lift" policies, creating patient lift teams and performing patient care ergonomic assessments. However, the implementation of these interventions has been inconsistent and there is no national or mandatory approach to this problem in the United States.

The American Nurses Association (ANA) drafted a "Handle with Care" policy in 2004 which has recommendations for safe patient handling. The ANA is also currently working with NIOSH and the Department of Veteran Affairs Patient Safety Center to develop educational modules for nursing students (ANA, 2006). In 2002, OSHA drafted ergonomic guidelines for nursing homes (OSHA, 2006). However, these examples are all voluntary programs and wide discrepancies exist among lifting practices, equipment availability and training. To significantly reduce risk of injury and ensure a work environment free of recognized hazards for all health care personnel, a national comprehensive, mandatory policy is needed. For the next research agenda, NIOSH needs to investigate means for implementing safe patient handling practices on a national level.

Manual patient handling is a known hazard that continues to exist in hospitals and nursing/residential care facilities. From the literature, the hazards from specific lifting tasks have been well characterized. New equipment technologies have been developed to minimize the hazards but have not been employed uniformly throughout the U.S. At this time, research is required in the health services sector to integrate the existing knowledge about hazardous patient handling, effective policies, and available equipment into safe practice. Further work is indicated to formulate a national mandate to implement these safe policies in the most economic and efficient manner rather than relying on sporadic voluntary programs and educational programs in schools of nursing.

A national comprehensive mandated policy would require that hazards be minimized across all facilities in which patient care is provided by nurses and nursing personnel. Hospital units and nursing/residential care facilities would be required to allocate resources to complete a needs assessment for the type of patient handling program that is warranted. Based on the current literature and the needs of each entity, adjustments would be made to employ adequate staffing levels, purchase

lifting equipment, identify tools to assess patient handling needs, train staff on new policies and equipment, and evaluate their effectiveness.

Failing to implement a national, mandated patient handling program maintains work environments that are known to be unsafe to the worker as well as the patients. For instance, without a formal safe handling policy, patients are at risk for falls, joint dislocations and skin tears. We can not depend on voluntary programs as they currently have resulted in major discrepancies in work environments. In an ANA survey of 4,826 nurses, more than 50% reported that their facility did not offer devices to assist with patient handling (ANA, 2001).

Implementing a comprehensive patient handling program can decrease injuries dramatically (Fragala & Bailey, 2003). There are numerous studies in the literature showing reductions in injuries, lost work days, and workers' compensation costs among hospitals and nursing home/residential care facilities in which these programs have been implemented (Fragala & Bailey, 2003; Nelson, 2003; Nelson & Baptiste, 2004). NIOSH reports that an average claim for low back disorder is \$8,300 (NIOSH, 2006). Some hospitals, such as one in New York, have been able to cut their workers' compensation costs by 70% by implementing a comprehensive patient handling program (Fragala & Bailey, 2003). In addition, workers with back injuries/disorders will be able to return to work faster as this is a way to modify duty. Early return to work has been shown to further decrease workers' compensation costs and improve worker satisfaction.

With the threat of the worsening nursing shortage, sky rocketing health care costs and the aging population, it is imperative to improve the working conditions of nurses. Safe patient handling programs are one component of what is needed to improve these conditions.

Regrettably, this research will take time and thousands of nurses and nursing personnel will be injured in the meantime thus potentially contributing to the shortage of 1 million nurses predicted for 2012. However, to determine which programs are effective and merit modeling, the research is critical. The end result, a mandated, national comprehensive safe patient handling policy, will ensure a safe working environment for all healthcare personnel.

NIOSH needs to evaluate the safe patient handling programs that are currently in place to determine which ones are effective in decreasing injuries. The data from these studies can serve to identify models of safe patient handling programs which then can be applied to the variety of settings in which they are warranted. From this data, OSHA will have the foundation upon which to formulate a standard that specifically protects workers from hazards associated with patient handling and requires that all places of employment eliminate or minimize manual patient handling. From this mandate, nursing homes/residential care facilities and hospitals will be required to go beyond voluntary recommendations to implementing safe patient handling policies that protect all employees from the recognized hazards.

I am very concerned about potential health risks associated with non-ionizing radiation. With the establishment of extensive cell phone towers and now the emersion of wi-fi, the public is being subjected to vaster amounts of this radiation, with little to no research/concern re: any possible harmful effects. I strongly urge that money be allocated to fund serious research into this technology.

Thank you.

NIOSH conducted national hazard surveillance surveys in the past but it has been over 25 years since these surveys were conducted. Changes in the industrial and occupational mix in the American economy, the introduction of new processes and technologies, as well as changing occupational practices since these surveys were conducted have resulted in a need for more current occupational hazard and exposure information across all industry sectors. Hazard and exposure surveillance information, can be used to identify priority areas for further research and intervention, as well as to assess impact of these efforts.

The New York State Public Employees Federation (PEF) represents over 53,000 professional, scientific, and technical employees who work for New York State agencies. Many of our members face significant health and safety hazards on a daily basis. Our members include 7,500 nurses who work in state institutions, more than 5,000 criminal justice workers, and thousands of social service workers. We provide the services and programs that are required to care for society's neediest and most dangerous citizens. There are four hazards that impact the greatest numbers of PEF members: 1) workplace violence from patients, clients, and inmates; 2) ergonomic hazards in offices or patient care settings; 3) contaminated or inadequate indoor air; and 4) infectious diseases such as TB, HIV, and HBV.

Workplace Violence

Workplace violence is the most important hazard for our members. The largest state agencies are those that provide direct care to the State's most dangerous criminals and citizens with serious mental illnesses and profound developmental disabilities.

Office of Mental Health-17,250 employees

Office of Mental Retardation and Developmental Disabilities-23,643 employees

Department of Correctional Services-32,386 employees

Each year, thousands of our members are assaulted, many with career-ending injuries. While OSHA has produced useful broad guidelines for Healthcare and Social Service workers and for the Late-night Retail

sector, there is still no enforceable standard. Again, workers are dependent upon the beneficence of their employers, with no recourse. With cuts in social services and state budgets, prevention efforts are sparse. NIOSH should continue funding research that evaluates the effectiveness of interventions, the OSHA guidelines, and identifies "best practices" in a variety of settings.

Categorized comment or partial comment:

Ergonomics

Ergonomics hazards are a second major area of concern. There are two main groups of our members at greatest risk. The first are nurses and others who provide direct patient care in nursing homes, psychiatric hospitals, and similar settings. It has been proven time and again that a comprehensive ergonomics program is cost effective in reducing back injuries due to patient transfers. Excellent mechanical lifting systems and other engineering controls exist, yet they are rarely provided in our workplaces. Even when new construction or major renovation occurs, the State is unwilling to install patient handling systems, as is currently the case in a Department of Health-run nursing home being constructed by the State.

The second group of PEF employees facing significant ergonomic risks is office workers, most commonly due to repetitive keyboarding jobs. Without federal standards, there is nothing to compel employers to address ergonomic hazards. Additional research is needed to document best practices and to improve techniques for measuring and evaluating ergonomic risk factors.

Air Quality

As many state workers spend much of their work time in offices, indoor air quality is often a significant concern. With budgetary constraints, cleaning and maintenance functions are often cut, with a resulting impact on the building environment. With spiraling energy costs, there are renewed incentives to reduce the amount of fresh outside air provided. As there are no federal indoor air quality standards, this is an area largely left to the discretion of the employer. Further research should focus on collaborative efforts to implement state-of-the-art Indoor Air Quality Management programs, measuring effectiveness, documenting "best practices" as well as examining the relationship between "sick building syndrome" and stress-related factors.

Infectious Diseases

Thousands of our members work in healthcare or congregate settings. We are particularly at risk when outbreaks occur, whether of known or emerging pathogens. Hospitals typically employ infection control specialists, and hopefully have well-developed and implemented plans. Intervention research is particularly critical in non-hospital settings, where the expertise and resources for these programs may not exist. This becomes particularly critical with the potential emergence of a pandemic influenza. Underreporting of needle sticks and lack of access to training in newly available sharps technology continues to deter elimination of this potential for exposure to bloodborne pathogens.

Research Methods

We are firm believers in Participatory Action Research. Nobody better understands hazards than workers who are exposed on a daily basis. Similarly, nobody can better identify and evaluate potential prevention measures than those workers. Workers should be involved in all phases of the research, from framing the research questions, to developing study methods, to ensuring that the results are promptly and effectively disseminated.

The National Asphalt Pavement Association

Categorized comment or partial comment:

Verbal Comment 2006/03/13: Good morning. My name is Gary Fore. I am vice president for environment, health and safety at the National Asphalt Pavement Association. Accompanying me and also representing NAPA is Don Elisburg, well known for his ability to facilitate government, industry, labor and academia partnership. NAPA is the exclusive national trade association representing the hot mix asphalt industry, with about 1,100 members and representing the majority of highway construction and street paving in the U.S. As such, we and our membership have invested heavily in health and safety of 300,000 or more workers. Don and I are here today to talk about the Asphalt Partnership, which is now in its eleventh year.

Why have we come to this town hall meeting? As participants in the Asphalt Partnership, we and our partners in the Laborers International Union of North America, the International Union of Operating Engineers, the Asphalt Institute, the Federal Highway Administration, and yes, NIOSH, were the recipients of the very first National Occupational Research Agenda Award for Partnering in the area of worker health and safety. This partnership has been successful, successful in bring research into practice in the workplace, and we believe it could serve as a problem-solving template for other worker health and safety opportunities. We want to share both our enthusiasm for the concept of partnerships and hopefully some insights relating to the partnership process, and in the end to bring some reality to this thing we call partnerships.

A brief history of the Asphalt Partnership. The foundation for the Asphalt Partnership was laid in 1995 with the initiative to develop and implement engineering controls for paving machines. Participating were NAPA, the Asphalt Institute, the Laborers Health and Safety Fund, the International Union of Operating Engineers, the Federal Highway Administration and, last but not least, NIOSH. The result of this effort was the publishing of engineering controls guidelines for hot mix asphalt pavers in January of '97, followed immediately with the signing of a voluntary agreement with OSHA to install engineering controls on all paving machines manufactured after July 1 of that year. The result? A significant reduction in fume concentrations surrounding paving operations. What otherwise would have required years to accomplish through regulatory channels was accomplished in 18 months.

Why did it work? Well, first off, all participants in the partnership shared a genuine concern about health of workers. All participants share concerns about the paving industry. All participants share a belief in the value of trust and cooperation. And in this case there was a need for cooperation. Specifically, the uncertainty at the time of asphalt fume and occupational safety and health surrounding paving operations.

What has happened since 1995, the beginning of the Asphalt Partnership? We have built on the Asphalt Partnership foundation through a continuation of the collaborative process and inclusion of other important occupational health and safety opportunities. In addition, we have added additional stakeholders who bring the core set of values as partners, including academia. While we will not be exhaustive this morning in delineating the substantial numbers of partnership activities over the past 11 years, we offer just a few examples of recent and current efforts -- again, to bring some reality.

Last year we completed a major test program working with NIOSH and the Center to Protect Worker Rights to evaluate and validate the effectiveness of engineering controls for reducing exposures to asphalt fumes surrounding paving operations. We assisted Harvard with efforts to secure a National Cancer Institute grant to conduct mechanistic research relating to asphalt fume and human exposures. We provided funding support to the Harvard School of Public Health and worked with them to investigate potential dermal exposures.

We have worked together for the past four years in an effort to reduce injuries and fatalities in highway work zones by developing and delivering safety training materials for the asphalt paving industry. Having securing funding via a Harwood Grant, we extended the Asphalt Partnership to form an OSHA Alliance for work zone safety including NIOSH, the FHWA, and the American Road and Transportation Builders Association in this important endeavor.

Currently we are working together to complete targeted scientific research to fill perceived gaps relating to the evaluation of asphalt paving fume as we prepare for an eventual IARC Monograph review of that subject.

I am happy to report this morning that we are currently engaged in a partnership with NIOSH, the Laborers Union, the Operating Engineers Union, the Associated Equipment Manufacturers and others to evaluate silica exposures surrounding asphalt milling machine operations and modeled after the highly successful paver engineering controls effort.

Where to from here? We have just formed a partnership effort with the FHWA, the American Association of State and Transportation Highway (sic) Officials, the State Departments of Transportation,

the State Asphalt Pavement Associations, the National Center for Asphalt Technology and the unions and others to research and implement warm mix technology in the U.S.

Why? Because we believe that asphalt fume and its composition is driven by temperature. Our vision: No fume equals no worker exposure. This is perhaps the largest single challenge this group has undertaken.

What insights do we offer for taking research to practice? It is possible. It is possible to bring research into practice through effective partnerships between government, labor, industry and academia. The power of the concept involves an unwavering commitment to a set of core principles and values.

Facilitation knowledge and skills are important. For that I would like to introduce Don Elisburg, a long-time friend and I would say the key to the success of these efforts. Thank you very much as you approach your agenda for the 21st century.

Note: Verbal testimony provided to NORA Town Hall meeting in Washington, DC, 2006/032/13.

Verbal Comment 2006/03/13: Thanks, Gary. I just wanted to add a couple of notes to the process, but the -- I must say that one of the things that -- having been engaged in this activity now for about -- since the 1970 Act through the spring of `70, I always think about how NIOSH came to be. And as I listened to Sid Soderholm`s description and the charts and the detail of how you`re going to the NORA process, I got to tell you that NIOSH was created in far less time than Sid took to explain the process. Believe me, and I was there when we wrote it. It was one afternoon at a very interesting lunch.

But having said that, the other point that I want to make from my -- actually from listening and my perception of the last NORA, and perhaps having Dr. Howard as a captive audience and perhaps take these as my remarks, not necessarily NAPA`s, but I think you have to look at what you`re trying to do here with this NORA and not have the process become so ponderous that you can`t get it done. I`m a firm believer in the KISS theory of making some of these things operate, which is, you know, Keep It Simple, Stupid. And I think that there is a value in this NORA program, but I think that also in the effort to include everybody in everything in every possible thing, you can sometimes get lost in the process. And I think it`s important to keep your eye on what it is to make it happen.

And that was really what we did in connection with this Asphalt Partnership that Gary`s been talking about, which is that we -- we had some views and there was some interest in getting some specific results. Some specific things to happen originally was to do with the engineering controls, and the focus was on what do we need to do to get these engineering controls in place now. Not in the process of a regulatory scheme in 15 years, what do we do now. And each of these items that we`ve been talking about -- and I think our colleague Travis from the Laborers will be talking about them, too -- when you begin to get to highway work zones, what could we do now. What is it that gives you a result that is not so far down the road that it becomes an abstract proposition. And I think that was the important part of what we learned in trying to put together the process.

On the positive side for NIOSH, what we also found was that the NIOSH folks have been involved in this partnership with our people and various groups have been extraordinarily -- extraordinarily good in being willing to listen to what the -- what the industry, what the academic people, what the union folks, everybody had to say, because many of them came into this process with their little piece of the research that was assigned to their little unit, and they couldn't -- you know, and they had those blinders on and I think taking the blinders off has been very, very helpful both to us and to the partnership process. And I think it was the ability to have everyone together was -- was what made this thing an important success. As a matter of fact, Dr. Howard's predecessor, Dr. Linda Rosenstock, commented in the course of accepting one of the -- we were finalists I guess in the Innovations in Government awards one year for -- is it Ford Foundation, et cetera -- made the point that this was one of these cases where you had to make sure that you were -- you were dealing -- in the effort to get to perfect that you didn't keep the good from happening. And she thought this was one example of how you were able to get an important result in the process of understanding where you had to go with ultimately having something happen.

So with that, I will -- those were the only comments I wanted to make was that this was -- this was an example. We want to keep pointing out these partnerships and why this has been successful. As you saw, the whole range, from going from fumes to going from warm mix is an important part of what we see as the success of this research to practice notion of NORA.

Thank you.

Categorized comment or partial comment:

Verbal Comment 2006/03/13: Good morning. My name is Michael Thompson. I'm a safety -- certified safety professional in comprehensive practice and I work for BP America as the health, safety, security, environment training advisor located in Houston, Texas. I am, however, here today in my capacity as the senior vice president for the American Society of Safety Engineers and a member of the Board of Directors representing ASSE's 30,000-member safety, health and environmental professionals.

I'd like to say to Dr. Howard and Max Lum and Sid Soderholm, thank you and commend you and NIOSH for your leadership and allowing this type of town hall to take place over the last three months, and I very much appreciate that on behalf of the 30,000 members of the American Society of Safety Engineers. Those involved in NORA for this proactive and unprecedented approach in advancing the safety and health research our members rely on every day to do their work is very much appreciated. We know that without an aggressive safety and health research agenda, designed for the future, our responsibility for managing workplace safety and health risks will become increasingly difficult.

Today is the third time that ASSE has testified at these town meetings, and we are hearing reports that members of ASSE have been sharing their ideas in each of the town meetings across the country, talking about how more research is needed to provide a better understanding of behavior-based safety, to the need for better anthropometric data for use in designing tools, equipment and workplaces, to the need for better stability calculations for small boats. The time and effort our members have given to this process comes as no surprise to me, given the commitment to safety and health and the expertise and experience in virtually every industry that I've long-ago learned was the hallmark of the SH&E profession.

Today I'd like to talk to you just briefly about several issues uniquely important to our members. First, professionalism in safety, health and environment profession and practice. One area of occupational safety and health research that ASSE believes has been wholly overlooked is the role the SH&E profession plays in advancing safety and health. However much NIOSH-led research may help in addressing specific risks, if employers do not have properly-trained and assigned SH&E professionals in the workplace, perhaps the most important component of achieving safe, healthier workplaces will have been missed.

The time has come to advance research that will give the safety and health community and employers a better understanding of the professional preparation and accreditation needed for an SH&E professional to function appropriately as managers of workplace risks. A key to this inquiry may be to help define SH&E practice at various levels. This could begin with job analysis research to help define functions, tasks, knowledge and skills of the SH&E professional by level of expertise and responsibility. Quality SH&E professional certification organizations like BCSP, ABIH and IHMN already undertake this kind of analysis in order to meet stringent accreditation requirements. ASSE urges NIOSH to work with these organizations to develop a comprehensive understanding of tasks and capabilities throughout the industries.

Such research then can provide a basis to help examine other professional issues such as appropriate levels of SH&E education and training, the extent to which SH&E professional segments have converged across traditional job roles, and the role of technology on SH&E practice.

Also, like many industries, SH&E is facing growing concern over the graying of practitioners and declining numbers in some segments of the profession. A better understanding of the availability and distribution of SH&E professionals will help industries better plan for future needs.

Most important is a need for better understanding of the impact that SH&E professionalism has on health and safety performance. Employers especially deserve better information to understand fully the impact of their decisions on who has responsibility for SH&E management in a workplace.

A related issue is the need to help future academic leadership in safety. Only one Ph.D. program in safety exists today. If the safety profession is to continue to advance and meet the challenges of the future, finding ways to encourage more individuals to achieve the highest level of safety education will be necessary. Research to help determine how to achieve that is needed.

standards development community

Categorized comment or partial comment:

The second issue I'd like to speak about is involving the standards community. Following -- ASSE, following the lead of its ASSE Foundation's Research Committee, we urge NIOSH and NORA's agenda to better involve the standards development community in research efforts. Cooperation and involvement in the national consensus standards process will help ensure that NORA applied research findings become operational in the field. ASSE's more detailed comments which will be submitted for the record give specific -- a variety of ideas on how to achieve such an effort, including appointing standards committee officers to serve as co-chairs of the sector councils, and securing representation on the affected standards committees as active participants in liaison non-voting capacities. Voluntary consensus standards play an increasingly determinant role in company safety decisions, which safety and health research cannot overlook.

ASSE`s Research Foundation Committees

Categorized comment or partial comment:

Finally my third comment, safety and health management, ASSE and the ASSE Foundation Research Committee are concerned that not enough research is being conducted to examine the importance of broad safety and health management in the corporate and -- structures of organizations. Our members in many companies believe that effective safety and health management programs reduce injuries and illnesses and fatalities. Only NIOSH`s leadership can bring forth definitive data-driven studies.

In conclusion let me say that ASSE commends NIOSH and those who have made the NORA series of town hall meetings today. ASSE`s Research Foundation Committees and others look forward to working with NORA and NIOSH as they advance research to practice, and I very much appreciate the time and opportunities.

Thank you.

Verbal Comment 2006/03/13: I see her. My name is Jenny Schumann and I represent the Coalition for Safe Community Needle Disposal. We're a non-profit organization dedicated to change the way people dispose of their used needles at home, so this is out of the traditional healthcare setting.

On the behalf of the Coalition, we are requesting that NORA consider conducting a study to determine the rate of needle sticks in the environmental services industry, which includes waste workers, professional housekeepers, janitors and sewage treatment center workers. This study could also include other non-health industries, as well. I know that partnership is a big part of NORA and NIOSH, and the Coalition is already a partnership. We were formed a few years ago -- two or three years ago by the CDC. It was the brain child of the CDC and we have worked with OSHA, EPA, we're currently working with CMS -- those are some of the government agencies. We also have representation from the healthcare associations like American Medical Association, American Diabetes Association -- I could go on and on with all of those -- and we're represented by the -- by the trash -- or the -- trash, the waste industry, and we're represented by the other government agencies like the U.S. Conference of Mayors and National Association of City and County Health Officials.

Anyway, current estimates show that between eight and million (sic) Americans are injecting in their home, generating between two and three billion needles annually. Two-thirds of these people are injecting for medicinal purposes, ranging from arthritis to HIV to hepatitis to diabetes. The remaining one-third we believe to be illicit drug users, so that's two-thirds of the population that we can actually get our hands around. The other third we're working now on those with syringe exchange programs.

Unfortunately, the most common method of disposal for the household needle is the trash, a place that is becoming increasingly dangerous to environmental services workers, as well as the general public. Due to the nature of collection, waste collection waste workers are at risk for abrasions, cuts, small

puncture wounds, wounds and industries on the -- or injuries on the job. Because of the speed and physical activity of their job, many waste workers don't even know if they've been stuck by a needle. Therefore, the number of needle sticks in the waste injury (sic) reports on the OSHA 300 log is potentially under-reported and an appropriate estimation would be difficult to make. And that's what we're often forced to is try to make an estimation of the number of needle sticks in the industry, and it's virtually impossible.

The hospitality industry, which includes professional housekeepers or janitors -- those that clean hotels and motels, businesses, casinos, arenas, airports, restaurants -- often run across loose needles thrown directly into the garbage. We are especially concerned about these fresher needles for this -- for this group, and the potential for infectious disease carried on the needles and the high risk of transmission for housekeepers if accidentally stuck. Some hotel chains are starting to offer discreetly sharps containers for their -- for their guests, but those are often not used, as well, so the whole idea is to get them out of the waste stream and allow them not to be thrown directly in the garbage.

And finally, the sewage treatment facilities are still seeing a fair amount of needles being flushed down the toilet. These needles, like the waste industry, have to be hand-picked out of the whole process.

The problem of needle sticks injuries in household trash will continue to increase as our healthcare system continues to push medical treatment out of the hospital and back into the home. Four self-injecting drugs were introduced in the past two years for relatively common illnesses such as osteoporosis, arthritis, psoriasis and HIV, so people are injecting for HIV -- and again, hepatitis B and C -- at home and throwing those needles in the garbage.

We're sending a very unsettling message to environmental services workers and others by not requiring safer disposal laws for home injectors. The nation attempts to protect our environment from dangerous chemicals, oils, paints, et cetera, that -- with the household hazards waste program, but does allow -- continue to allow needles directly in the garbage.

Government agencies are beginning to treat the -- see the threat of these in the trash. The EPA wrote its recom-- rewrote its recommendations on safe needle disposal in the home in December 2004, so it does no longer suggest throwing needles in the garbage. A bill is currently -- currently in the House to provide needle disposal coverage under Part D of Medicare. And again, like I said, the CDC was very instrumental in forming the Coalition. So -- and we're also starting to see states move in that direction, so we are seeing the move and shift to getting it out of the garbage, but what is -- what is missing in all the piece is a needle stick study.

And so the threat of needle sticks to our environment work -- service workers is real, and to get our hands around the issue we desperately need a study to determine at what rate these workers are being stuck. With the information that is collected from the study, we believe we are able to protect our workers and encourage changes in needle stick study. We believe a needle stick study is long overdue for waste industry and the environmental services industry.

This comment for NIOSH-047, the docket for setting the NORA research agenda for the next decade, is submitted by The EMR Policy Institute, P.O. Box 117, Marshfield VT 05658 (www.emrpolicy.org). Links given in this statement refer to documents found on this web site.

Workplace exposures to electromagnetic fields (EMFs) from ELF (Extremely Low Frequency) up through the RF/MW (radiofrequency/microwave) radiation frequencies continue to increase and are becoming a ubiquitous environmental factor across all occupational sectors. Wireless internet networks in offices, schools, restaurants, and transportation terminals, i.e., airport terminal "hot spots", are commonplace and continue to expand. The job requirement that employees use cell phones, Palm Pilots, Blackberries and other wireless devices so that they can be in constant contact with their employers has become the norm. Many other jobs now require employees to operate electronic equipment and machinery that emit electromagnetic fields from the ELF range up through the RF/MW frequencies.

It is crucial that NIOSH include in the NORA funding agenda for the next decade research on occupational exposures to EMFs across all occupational sectors. No other federal agency is in a position to fund this important research.

US federal public health policy for long-term, low-intensity EMF exposure is inadequate. For example, the Federal Communications Commission (FCC), an engineering and licensing agency, is responsible for assuring the safety of the public's exposure to environmental levels of RF/MW radiation. A synopsis of the flaws in the FCC's safety policy for human exposure to RF/MW radiation has been outlined by science writer B. Blake Levitt in her book, *Electromagnetic Fields, A Consumer's Guide to the Issues and How to Protect Ourselves* (Harcourt Brace, 1995). This synopsis was updated by the author in 2005 and is used here with her permission:

The Federal Communications Commission (FCC) is a licensing and engineering agency that relies on other agencies to recommend and set safety standards for communications technology. It is not a health agency itself.

The FCC has traditionally adopted safety recommendations from the American National Standards Institute (ANSI). ANSI is an industry-based organization comprised of numerous committees representing diverse business interests, such as automobile manufacturers, chemical/pharmaceutical companies, the electrical industries, and many others. To create standards for radiofrequency/microwave radiation (RF/MW) used in telecommunications and other RF/MW-related activities, ANSI looks to a subcommittee of the Institute of Electrical and Electronics Engineers (IEEE) called C95.1 that is responsible for making recommendations for RF/MW exposures. The standards are referred to as ANSI-IEEE C95.1-1992; the date refers to the last year in which revisions were made to the original standard, which was put out in 1966. There is currently a subcommittee within C-95.1, called SC-4*, that is circulating a draft to relax the U.S. standards even further - at a time when the FCC is issuing more licenses for wireless technologies. This is a step in the wrong direction. The U.S. is already among the most lenient of the industrialized countries re: RF/MW exposures.

The National Council on Radiation Protection and Measurements (NCRP) also sets standards for diverse radiation-producing products, including RF/MW-emitting devices. The NCRP is the only agency mandated by Congress to set radiation standards. In 1986, it set a standard for RF/MW exposure levels for the general public that was five times more stringent than the ANSI/IEEE standard. Unfortunately, due to funding problems, the NCRP committee has not been able to review and update its current recommendation for RF/MW biological effects and it is doing no further standards work at this time.

The U.S. Environmental Protection Agency (EPA) is required by statute to provide guidance in formulation of all radiation standards to federal agencies regarding all matters directly or indirectly affecting health. In the 1996 Telecommunications Act, Congress – while preempting states' rights for environmental control over RF/MW health concerns – mandated that the FCC get its regulatory house in order. The FCC was widely expected to adopt the IEEE/ANSI standard again. Both industry and the U.S. military favored it and lobbied hard for that adoption. But for the first time, the EPA urged that the NCRP standard be adopted instead. What the FCC adopted was a two-tiered amalgamation of the two standards. Civilian exposures (called "uncontrolled environments") follow the NCRP standard while professional exposures (called "controlled environments") follow the ANSI-IEEE standard. The rationale for the higher professional limits is that professionals understand the risks.

While inclusion of the NCRP recommendation for civilian exposures was a step in the right direction, the standards are still seriously flawed.

The model used for both the IEEE and the NCRP standards is an adult male of average height and weight. Though safety margins are factored in, the standards do not take women, pregnant women, or children into consideration – all of whom absorb radiation differently than this “average” model. Nor does it consider the elderly or the infirm who are more susceptible to adverse exposures.

1. The model, and all of the research it is drawn from, is based solely on the thermal effects these frequencies can create. It has been known for decades that microwaves, at sufficient power output, can create heating. That’s what occurs in a microwave oven. The current FCC model presumes that nothing adverse other than heating occurs. Therefore, if heating does not occur, no other adverse biological effect does either. But a range of adverse non-thermal effects have been noted for decades as well – at levels significantly lower than the current FCC standard. This has been at the heart of the debate since the 1950’s.

2. The FCC standards do not take into account:

- Numerous research reports finding non-thermal effects.
- Long-term, low-level, continuous exposures such as would be found in schools, workplaces, and homes near RF/MW-emitting installations.
- The potential for RF/MW radiation to create standing RF/MW "hot-spots" near metal objects (water towers, other antenna towers, metal roofs, metal girders used in some architectural designs, elevator shafts, metal fences, metal in furniture, etc.)
- The distinction between digital (pulsed-wave) technology and the older analog (continuous-wave) technology. Pulsed RF has been found in several experiments to increase abnormal cell growth in tumorigenic cell cultures by up to 3000%. Digital technology exposures — such as the PCS frequencies used most widely today for mobile phones/towers — is the area where more lenient recommendations are expected to be made, despite research calling this into question.

3. The NCRP tier of the standards took no studies past 1985 into consideration; the ANSI-IEEE tier took no studies past 1986 into consideration. Therefore, although the FCC claims to keep track of the subject, the standards currently in place at the FCC are outdated by two decades of new research.

4. The FCC requires very little RF radiation monitoring from its licensees and does little of its own. As a result the aggregate of many co-located installations, and resulting RF accumulation, is poorly documented and remains unmonitored unless a community complains to the FCC about interference with other devices.

5. The IEEE is mainly comprised of engineers and physicists who deal with the non-living sciences. They have traditionally been charged with making these technologies work, not with understanding the health effects that are within the purview of the “living” sciences of biology and medicine. Yet appropriate funds for RF research in the living sciences have never been forthcoming. The FCC RF standards in place today are based on a faulty thermal model, designed by professionals from an inadequate range of scientific disciplines, and are drawn from research of an inappropriate kind (short-term, high-power designs models.) For many of the new personal wireless services, the FCC does not monitor any communications installations for RF compliance. They issue licenses for whole regions and

do not have a complete inventory list of actual installations and no idea where many are located. RF emissions levels are usually based solely on computer models done by the industry when applying for licenses, not on actual on-site measurements.

6. Meanwhile, the EPA has only been provided \$25,000 in the last 5 years for RF/MW radiation research. While the FCC sets the RF/MW radiation limits for wireless technologies, the FCC states officially that it is not a health agency and is not knowledgeable about human health.

*[IEEE's SC-4 has since been renamed the International Committee on Electromagnetic Safety (ICES).]

At the same time that the American workplace has become a place of ubiquitous EMF exposure, federal funding for research on potential adverse health effects from long-term continuous or repeated exposure to EMFs has dried up. Through the late 1980's the EPA had 30-35 full-time employees researching EMF environmental exposure. 1995 was the last year that the EPA budget included any EMF research funding. At present there is one EPA employee who devotes half of his time to tracking the EMF research. No other federal health agency has an EMF research program. Yet individuals in the federal health agencies recognize the inadequacy of the current federal regulations for EMF environmental exposures.

A prime example of initiatives undertaken by the federal health agency employees with expertise in EMF exposures is the June 17, 1999 letter written by the federal Radiofrequency Interagency Work Group (RFIAWG) to the IEEE's SC-4 committee delineating the inadequacies the work group finds in the IEEE's RF safety guidelines. (See: Exhibit A - Letter of June 17, 1999, from the U.S. federal Radiofrequency Interagency Work Group to Richard Tell, Chairman of IEEE's SCC28 Subcommittee 4 Risk Assessment Work Group, outlining RF guidelines issues.) The RFIAWG is made of RF experts from the EPA, the FCC, the Occupational Safety and Health Administration (OSHA), the National Institutes of Health (NIH), the National Institute of Occupational Safety and Health (NIOSH), the Food and Drug Administration (FDA), and the National Telecommunications Information Agency (NTIA). IEEE has yet to respond substantively to the issues raised in the 1999 RFIAWG letter.

Based on the issues in the 1999 RFIAWG letter, the EMR Policy Institute provided legal and financial resources to challenge at the commission level and subsequently in federal court the FCC's reliance on the IEEE's RF safety scheme. All of the filings in that legal process are found at:

http://www.emrpolicy.org/litigation/case_law/index.htm and Background on Citizens Brief Filed Against the FCC in D.C. Circuit Court of Appeals and NOI Background Page.

The FCC's reasoning in this case stated that because it is not a health agency, it does have a responsibility to address the issues laid out by the 1999 RFIAWWG letter:

If efforts to revise or update our RF safety limits based on research in the field or on other factors are appropriate, that determination should be made by these [EPA, FDA] or other federal agencies with primary expertise in and responsibility for ensuring public health and safety, and should not be made in the first instance by the FCC. Accordingly, any proceeding or inquiry should be initiated by and maintained under the auspices of such agency or agencies, and the determination of whether such an inquiry or proceeding is appropriate at this time should also be made by such agency or agencies. Accordingly, our dismissal of your petition should not be construed as a determination on the substantive merits of the matters it raises.

In its ruling on the EMR appeal, the United States Court of Appeals for the District of Columbia Circuit was satisfied with the FCC's posture of watchful waiting.

The EMR Policy Institute then provided legal and financial resources to appeal this ruling to the Supreme Court in May, 2005. The EMR Petition to the high court asked the high court to overturn the Court of Appeals decision concurring with the FCC order that refused to gather information and thoroughly investigate the consequences of 24/7 exposure to RF/MW radiation from antenna sites that power 180 million mobile phones across the country.

The problem is that no public agency really knows what the environmental impact of this blanket of RF radiation is on the people and animals in its path, especially the most vulnerable members of society – the elderly, infirm, small children, the unborn. The reason no one knows is that the one agency that has been given total pre-emptive control over this issue by the U.S. Congress is the FCC, which refuses to try to find out, as the FCC final Order in this case shows.

This is an “innocent bystander” case. EMR represents the interests of members of the general public who, as innocent bystanders, are continuously bombarded by ever-increasing amounts and higher and higher frequencies of wireless transmissions in workplaces, homes and schools, generating growing layers of RF radiation with the potential of long-term adverse human health effects that may not be discovered and diagnosed until long after it is too late to do anything to prevent them.

The Supreme Court denied hearing this argument in June, 2005.

Given this history of US federal policy on RF safety for the American public, it is crucial that NIOSH include funding for the next ten years of NORA for an RF/EMF research program studying exposures to American workers across all occupational sectors. There is no other federal program in place and no other agency with experienced staff who are showing any interest in investigating this ubiquitous environmental exposure. Research of occupational settings gives some ability to quantify the workers' exposures because of time sheets, employment records and job descriptions that may include information on what electronic devices were required in a particular occupational field. Research of exposures to the general public, especially in their homes, does not have this built-in head start on quantifying exposures.

Verbal Comment 2006/03/13: I work for the United Food and Commercial Workers Union. The UFCW represents retail grocery store workers, meat packing and poultry workers, and many other workers in both manufacturing and service.

I wanted to talk specifically today about meat packing and poultry, and three big issues in those industries.

But may I just put in a plug for the retail grocery store folks, musculoskeletal disorders remain the primary injury that is suffered by these workers, especially in grocery.

Categorized comment or partial comment:

The three issues are safety, line speed and immigrant workers. Meat packing and poultry remain some of the most hazardous industries in the U.S. The injuries include amputations, strains and sprains, lacerations, hearing loss; slips, trips and falls; chemical exposures, and MSDs -- musculoskeletal disorders -- again remain the number one injury suffered in those industries.

A brief history, this industry was targeted by OSHA back in the mid-'80s right up into the early '90s. A tremendous amount has been done in the industry on this issue of MSDs -- new equipment, new design of the lines -- really revolutionary, some of the design -- replacing workers with equipment that's drastically helped this. However, again, they still remain number one and so the issue of line speed, which I'll talk about in a minute, we believe comes into that.

The injuries are caused by dangerous equipment. They're dealing with live animals, very sharp knives and machinery, slippery floors from fat, grease, water, and a numbing pace of work and line speed.

When I go out and talk to stewards, the folks in the workplace that are responsible for all sorts of things including maintenance of the contract, but also safety, they will tell me that the number one hazard in these plants today is line speed. There have been two report-- in 2005 there were two reports, one by the GAO and one by Human Rights Watch. Both of those, independently, came up with line speed as a huge issue that needed research, and they actually recommended that NIOSH do that research.

Another part of this industry are the cleaning crews that go in at night. These fall right through the cracks in terms of statistics because they're not working for a meat company; they're working for a cleaning company, and that's a really bad SIC industry code because it includes cleaning, you know, an office building. So try to compare cleaning with 180 degree water at a very fast pace because you've got to have that plant clean by morning to have the animals be coming in to be slaughtered. Many of these workers are immigrant workers. Most of them, as a matter of fact, we're finding out. They're not covered by unions. They're almost -- virtually impossible to organize.

The GAO report in addition found that there's a standard sitting at OSHA around payment for personal protective equipment that impacts these workers -- low-wage workers and immigrant workers -- disproportionately, that in more sophisticated injuries personal protective equipment is paid for, but you don't find that in these kind of -- well, not -- not as -- that meat packing is underground, but sort of the -- what is that called, the -- the sector that's sort of -- oh, shoot, what is that -- what is the word that I'm looking for?

UNIDENTIFIED: (Off microphone) (Unintelligible)

MS. NOWELL: Yeah, something like that -- informal, there it is -- informal sector. The third point being -- and they also found under-reporting of injuries.

My third point, immigrant workers, they are the majority in most of these plants, many of these plants, especially the large ones. Both of the reports found exploitation of these workers because of their lack of English, because of their lack of knowledge of U.S. laws, and because of their perhaps lack of legal documents. They found discrimination of these workers. So my -- our recommendations are that NIOSH do research on line speed. I know that they're looking into that now, and -- and the contribution that it's having to injuries, and that there be a special emphasis on immigrant workers.

In terms of partnership, you have to have a willing industry to partner with, so I give you my blessing for finding that. Thanks.

Categorized comment or partial comment:

Verbal Comment 2006/03/13: Where do I look for the heavy? Good morning, I`m Seth Turner. I`m the senior director of public policy for the Association for Career and Technical Education. ACTE is the voice for roughly 30,000 CTE teachers, school administrators, guidance counselors and school principals across the country. ACTE and NIOSH have -- have a shared concern about young workers, and have participated in many ways for many years to improve occupational safety and health for young student workers. We look forward to our continued partnership for years to come.

The occupational industry`s problem for young student workers in the United States is a very serious problem. The 2003 NIOSH alert publication indicated that 70 to 80 percent of teens have worked during their high school years, and the Bureau of Labor Statistics reported in 2000 that 2.9 million students between the ages of 15 and 17 worked during the school year, and 4 million students in the same age bracket worked during the summer. U.S. students work at service jobs such as cashiers, gas station attendants, cosmetology assistants and entertainment and recreation industry, health services, in restaurants, in retail stores, grocery stores, manufacturing, agriculture and in construction. The

problems we face with young workers are lack of awareness, experience, training and risk-taking behavior which often results in industries -- I'm sorry, in injuries.

NIOSH estimates that each year in the U.S. 240,000 adolescent workers suffer work-related injuries; 77 require treatment in hospital emergency rooms, and unfortunately 70 student workers each year because of their work-related injuries. That's one occupational death every five days. In addition, an additional 100 teenagers die while working on farms every year. The direct and indirect costs of these injuries amounts to approximately \$5 billion annually.

To address these issues and reduce occupational injuries, NIOSH has been involved in occupational safety and health for years and has disseminated safety and health information to reduce the injuries of young workers.

I'd just like to summarize some ways that NIOSH and ACTE have collaborated over the years to address this problem. For years NIOSH and ACTE have worked to raise the awareness of occupational safety and health in schools, to promote a safe and healthy workplace, and to reduce injuries. NIOSH and ACTE cosponsored seven times in the last nine years the National Safety Competition and award for educators in career and technical schools. For safety -- the safety competition has been advertised in ACTE's technique magazine and on its web site, and NIOSH has promoted the competition on its web site over the last few years. Additionally, NIOSH has been presenting the safety award to the winning teacher at ACTE's national policy seminar's power breakfast in Washington, D.C. This year for the first time NIOSH also sponsored an exhibit booth at the national policy seminar. For the last ten years NIOSH has been invited to bring a NIOSH safety update during a one-hour session during ACTE's annual convention, and for several years NIOSH has participated at ACTE's annual convention with an exhibit booth -- with an exhibit booth that disseminated publications. ACTE has also helped during that event by selling NIOSH publications at its bookstore.

Some things that we can do to continue the partnership. ACTE has a trusted educational network of community-based training programs conducted and recognized educational institutions which place their students in predominantly local, small to medium-sized business enterprises. This trusted source of training and education is an ideal environment for better characterizing the need for safety training, and could serve as an important link in outreach to the small business community.

Young workers are at risk if not properly trained. ACTE could provide an important partner in developing realistic curricula and case studies and assisting and evaluating the effectiveness of outreach in training activities. It could serve as an important community-based resource.

Lastly ACTE hopes to work with NIOSH to rejuvenate and expand the teacher safety awards as a model for other educational organizations and institutions.

I'd like to take this final opportunity to thank NIOSH for inviting me to make these brief remarks today. Further, I'd like to commend it for its longstanding commitment to the health and safety of young student workers. ACTE appreciates your dedication and welcomes our continued partnerships for years to come. Thank you.

Verbal Comment 2006/03/13: Good morning. I`m Julia Storm. I`m a cooperative extension specialist at North Carolina State University, and I`m responsible for agricultural health and safety, education and outreach.

I`d like to make some recommendations for the agricultural sector.

First, I think we need to better characterize what health and safety practices are being practiced currently in agriculture. What are the barriers to those that are not being practiced, and what could be some economic or other incentives for adopting and sustaining good health and safety practices in agriculture.

Secondly -- and just for an example, we have some information coming out of the agricultural health study about this. We know that in North Carolina among farmer pesticide applicators the use of chemically-resistant gloves doubled in the ten years between the mid-1980s and the mid-1990s. So it would be good if we had those kinds of measures for all kinds of -- the whole -- the whole gamut of health and safety practices.

Agricultural Health Study (in Iowa and North Carolina)

Categorized comment or partial comment:

Secondly, I think that NIOSH should continue to capitalize and further capitalize on the opportunity to collaborate with the agricultural health study. This is a large ongoing comprehensive long-term health study of farmers and farm families in North Carolina and Iowa. I know there's currently some collaborative research going on there, but I think that's a great opportunity that should be followed up on, particularly with research that bridges toxicology and epidemiology to further characterize the chronic health issues that are associated with pesticide exposure. This would help in identifying susceptible populations and those gene/environment interactions that may be going on with chronic health issues associated with pesticide exposure.

Thirdly, I think that we need to better characterize and learn more about the actual pesticide exposure of farm workers in a variety of field situations. I know there's been some great work in the northwest in agriculture in identifying what is going on with pesticide exposure in field work, and also, along with that, identifying practical interventions that will reduce exposure where needed and protect workers.

Fourth, I think that there's some recent initiatives that have taken place to -- as consensus and stakeholder processes in the agricultural sector that should inform the NORA, and I've brought two of them here. They're published in 2003. One is the National Land Grant Research and Extension Agenda for Agricultural Safety and Health. That was prepared by a committee on agricultural safety and health research and extension. And also a very thorough consensus process also documented in 2003 by -- edited by Petrie using history and accomplishments to plan for the future, a summary of 15 years in agricultural safety and health and action steps for future directions. This is -- a tremendous amount of input went into this particular document and I think NORA could do well by -- by utilizing that information.

Categorized comment or partial comment:

Finally, I think it would be really helpful for NORA to be in a format similar to the healthy -- or at least an aspect of NORA be in the format of the Healthy People 2010 goals and objectives for each industry sector. We need to establish targets that we like to meet, to measure our progress, and then ongoingly (sic) identify the research, intervention and outreach and education gaps.

Verbal Comment 2006/03/13: Good morning, and how is everybody out there this morning? My name is Travis Parsons. I represent the Laborers Health and Safety Fund. I am the senior safety and health specialist for the Fund. We represent Laborers International Union, over 800,000 workers all over North America. We do health and safety services for them. Everything -- we're predominantly construction workers, which is your heavy highway workers, your building construction, about 600,000 of our membership is construction work. We also represent public employees, which represents another 200,000 or so, and that is everything under the sun, so you know, again, through other construction workers to janitors to maintenance workers to everything. So that's what we represent.

At our annual conference we had about -- I guess it was about three weeks ago, we had a very similar thing to this -- this workshop right here. We actually had a round table discussion with NIOSH's assistance at the conference, and what I'm going to do today is just summarize the things that came out of that meeting, with a couple of other things, so -- try to be brief. I could go on forever, but...

One of the big -- two-est (sic) big things that came out that we think there needs to be research in is more research in demolition industry when it comes down from (unintelligible) -- there's not a whole lot of stuff out there when it comes to demolition and it's a very dangerous work, very dangerous work. There's going to be more of it in the metropolitan areas coming up.

Also night work on the highways (unintelligible). Night work is increasing, especially in the metropolitan areas, and we need more research in that. Is it more dangerous? Of course, we think it inherently is because it's at night and the drivers at night are sometimes more dangerous but really is it and why are we doing night work? What research needs to be done?

And that alludes to work zones in general. Our workers are always concerned about working on the work zones and a lot of our workers work on the work zones and that alludes to also, which was discussed earlier -- earlier by Don and Gary about the partnerships with NIOSH's assistance and OSHA's assistance. Partnerships are very, very important and we definitely need to continue those and build on the successes that we've had. They spoke very eloquently earlier about the highway work zone lines so I'm not going to talk about that. We don't need to reiterate what they said, but we just need to continue those efforts.

Other areas of research that we see a need for is Hispanic and other non-English-speaking workers. It's increasing in our country, as we know, especially in the Hispanic population, especially in major cities. What differences do they have? Do they understand the rights? Do they have health and safety rights? Do they know that? What differences do they have in the workforce? Do -- are -- is that a concern to them? How do we get through to them? That's a big, big problem within our organization so it's -- Hispanic is the main one, and other non-English-speaking.

Let`s talk a little bit about training -- training in general. Health and safe-- there`s a whole lot of health and safety training out there now as -- that exists. But what really works? How do we impact our workers and how do we impact our workforce? Does the existing training really work? So I think there needs to be some research on the evaluation of current training methods, especially for adult learning. You know, adult -- the attention span for an adult is about an hour, I think, so after -- you know, what training are we doing and does it currently work and what can we do as far as new training.

And then to -- I'm going to be quick so -- to finalize things, in the end, does safety pay? And in this room -- everybody in this room, we all believe safety pays. How can we prove to our contractors, how can we prove to our owners, how can we prove to our workers that safety pays? So research to prove how safety pays, how does it affect the bottom line? How does it decrease your worker comp fees? Is there incentives to having a safe workforce?

And I have one minute left, so I actually finished early, so thank you for your time and I will answer any questions afterwards.

Verbal Comment 2006/03/13: Good morning. My name is Michael Rybolt. I'm the scientific and regulatory affairs manager for the National Turkey Federation. I'm here today representing the poultry industry Worker Safety and Health Committee, which is a joint committee between the National Chicken Council and the National Turkey Federation. The committee -- National Turkey Federation represents 99 percent of the turkey industry, and I believe the National Chicken Council represents about 96 percent of the broiler industry. Our joint Worker Safety and Health Committee includes representatives from each one of the companies. They're responsible for worker safety and health. Some are HR people, as well.

During our recent annual convention we had our joint meeting down in Orlando, and the joint committee decided to provide some research priorities to NORA. The poultry industry Worker Safety and Health Committee requests that NIOSH adopt the following three research-- or the following priorities for the national research agenda. I was asked to present only on one issue, which you see on your agenda is chloramines. This same presentation was given at the town hall meeting in Ohio recently. The committee asked me to discuss chloramines with you today.

During the annual convention back in February of this year approximately 50 percent of the companies attending reported that they had experienced a chloramine issue. Given the high percentage, it is likely that others in attendance have also experienced employee complaints about chloramine exposure, but have failed to segregate it -- the specifics of the exposure from the traditional chlorine usage.

Chloramines naturally result when chlorine -- chlorinated water, which is commonly used in the meat industry -- poultry industry, too -- to sanitize our products and equipments. The chlorine in the water becomes impregnated with ammonia. The source of ammonia can either be from the biological debris

that comes in on the products, or it can -- unfortunately, sometimes we have ammonia leaks that may drip into our chlorinated water supply, and then you have the chloramine formed. Ammonia has a great affinity for water and will therefore typically stay in solution. However, when it does combine, it -- when it is introduced into chlorinated water, they will combine and it will gas off.

The research priorities that were identified were that we do not currently have the physical means to measure chloramine levels in the air. When we suspect exposures of chloramine, expect exposures when employees report significant irritation, yet when we go out in the plant and monitor for our chlorine and our ammonia levels, our indicators are -- there's no issue or there's no significant levels. Permissible exposure levels, threshold limit values, et cetera, have not been defined so we don't know what, if any, level is injurious to the employees. And also that the degree of the problem within the industry is not understood.

And that's what the Committee -- our chairman asked me to come and present to you today. I would like to note that the -- the Joint Committee had recently, in January of '05, signed into a OSHA alliance, similar to some of the other industries out there. I did want to highlight that and to also mention the chlorine issue within the industry.

Told you I wouldn't take five minutes. Thank you.

Verbal Comment 2006/03/13: Good morning. My name is Shelly Heath-Watson and I work with ORC (unintelligible) International and I am representing the National Eye Institute this morning, and I have the pleasure of speaking with you about Healthy Vision Month in the partnership that we have with NIOSH for Healthy Vision Month. Healthy Vision Month occurs each May. This will be our fourth observance for the National Eye Institute and the national eye health education program. And what the -- what Healthy Vision Month tries to do is each -- each year it focuses on a different one of the ten vision objectives in Healthy People 2010, and tries to take what we know the research is telling us about the various eye conditions and eye disease and translate those into community outreach efforts, public health campaign messages and programs.

And this coming May, May 2006, our focus is on reducing occupational eye injury, and that's a completely new area for the National Eye Institute. NEI had not done any work in that area previously for its education programs, and so it reached out to NIOSH to partner and they jumped on board willingly and wholeheartedly. And because of NIOSH's participation and collaboration with us, we're very excited about the kinds of things that we've come up with for Healthy Vision Month 2006.

NIOSH came on as a cosponsor of the month. In so doing, it helped to form the direction of our campaign for this year, including the tag line in the slogan and the materials that were created and the content of those materials. So by virtue of this relationship, NIOSH has added credibility as far as being the expert in this area, and has extended the reach of Healthy Vision Month because not only do we have NEI's dissemination networks, we also have access to NIOSH's. And as far as making our voice louder, because we're saying the same thing and we're sharing the same messages, our tag line or our theme for this year -- as I said, for May -- is "Eye Safety at Work is Everyone's Business. Prevent Injury. Use Protective Eyewear."

About 2,000 workers are injured each year -- excuse me, each day. We see eye injuries that require some kind of medical treatment, and so we're trying to get this word out and we're trying to let employees and employers know what they can do to have a safer healthy work site and environment.

The kinds of materials and resources that we developed -- and I say we, NEI, NIOSH, the National Safety Council also came on as a cosponsor, the American Association of Occupational Health Nurses came on as collaborators, and so have all had a hand in the content and the direction for the Month.

The kinds of things we've come up with are promotional work site materials, posters, event posters. We've created a PowerPoint presentation for use of -- by employers or can be a self-guided work module for employees, just to give them ideas of what can -- they can do to make their work site safer, what they can do to protect their vision and that of their employees or their coworkers. We have magnets, we've got stickers, we will be sending out a monthly e-bulletin and in the e-bulletin it has links to more resources, either on the NEI site, the NIOSH site, the National Safety Council site. And so really looking to extend the reach of our collective voices, we're definitely making more of an impact working together than we could have done individually.

What else can I share with you -- the kinds of materials that we've produced and why they are for May, we've made them evergreen so that they can be used in the work sites year 'round. They're available to the public for no cost. If you come to the NEI web site you can order those materials. And so we're just encouraging people to try and help get the word out through their various -- their various sources.

And so special thanks to the NIOSH team that worked with us. It was Max Lum's office. We worked very closely with Fred Blosser and Christy Bowles. Dr. Larry Jackson was incredible; and from the National Safety Council with Elizabeth Wilson; and Bruce Lloyd from the American Association of Occupational Health Nurses. There's much, much more I can share with you about Healthy Vision Month. The site went live -- I want to say last week. I have sample materials with me. I can put them out in the front if you're interested in seeing them.

But I'd like to extend a thank you again for the invitation just to share with you briefly about Healthy Vision Month and all that NIOSH is doing and will continue to do to make eye health and safety a national priority. Thank you.

Verbal Comment 2006/03/13: Good morning. Before I get started, I'd like to apologize for a technical error here on the sheet. I will actually not be talking about OSHA this morning, but I will be talking about the occupational research health agenda for manufacturing for the next decade.

Again, my name is Sylvia Johnson and I'm working -- I represent the United Auto Workers, and we represent several entities within our organization. We do -- we represent workers who work in the manufacturing sector. We represent nurses, state employees, public employees, and so we don't just represent auto workers, but specifically today I will be talking about manufacturing and the occupational research needs for manufacturing.

Let me first say that on behalf of the UAW we thank you for the opportunity to voice our concerns and make recommendations on the future of occupational health and safety research over the next decade. The UAW has always supported NIOSH in its efforts to protect workers against hazards.

Having spent five of the last seven years of my career working as an occupational epidemiologist for the UAW, I've seen first-hand the devastation some occupational hazards have caused workers. On the other hand, I've also seen first-hand how concerted efforts between government, unions, academia and corporations benefit worker safety and health programs.

I want to speak about the priorities for occupational safety and health research in the manufacturing sector based on the experiences of the UAW at the national and local levels. Without a doubt, the UAW put our -- we've put our money where our mouth is in support of research. We negotiated jointly-

administered research funds from General Motors, Ford and Chrysler starting in 1984. Millions of dollars have been spent and around 100 publications have come out of this research. We also launched smaller efforts at International Truck, NUMMI and other locations.

In our view, the most important goal of research is identifying gaps in protections, meaning situations where workers are getting sick or injured under current conditions. This can be because an exposure permitted by standards is making people sick. As an epidemiologist who frequently made visits to the plant floor, I can't tell you how often workers complained of their eyes burning, headaches, skin irritations, and then the industrial hygienist would come and do an assessment and conclude that the exposures were within the OSHA standard. This clearly suggests that many of these standards need to be lowered.

Health effects research, including injuries, is the most important thing that NIOSH can do, and is something that only NIOSH will do. Industry only pays for health effects research after some other investigator has found a problem and industry is convinced it will make a cost go away.

Sometimes there is a gap in protections because the method of controlling exposures is not known, or a more efficient method of controlling exposure is needed. But this is much less a priority than showing an exposure is causing people to get sick or injured.

- Skyjack; aerial work platform industry

Categorized comment or partial comment:

Verbal Comment 2006/03/13: Thank you. Good morning, ladies and gentlemen. I'm very pleased -- my name is Brad Boehler and I'm very pleased to be here -- invited this morning to speak to you a little bit about the need for further corroborative research between the aerial work platform industry and NIOSH. I'm the director for product safety for Skyjack, a producer of aerial work lifts, and probably the largest manufacturer of scissor lifts in the world today. As such I'm a member of various standards organizations such as the ANSI Committee A-92 for Aerial Platforms, the CSA B-354 Elevating Work Platform Technical Committee, and internationally the ISO Technical Committee 214 for Elevating Work Platforms. I'm also a contributing member of various industry organizations such as the International Powered Access Federation and the Aerial Work Platform Training Organization. And as a manufacturer, I guess I'm feeling a little lonely here so far today, but I thought I would come.

Studies of accident data, some of which were done by Michael McCann from the Center to Protect Workers Rights, indicate that aerial lifts are associated with nearly four percent of construction-related deaths in that time period, and many more injuries. Aerial work platforms are designed and produced as tools to put workers and their materials at elevation in order to perform tasks. Now placing people at elevation, regardless of the method, is an inherently dangerous task and ultimately a great responsibility. I believe today that any manufacturers of aerial work platforms are aware of this

responsibility to safeguard the user, and these producers are actually pursuing methods in order to ensure that the machinery they create is practical and safe for use.

However, although this is extremely important, the design and manufacture of the lifts is just the first step in protecting the worker using this equipment. For a worker about to be placed at elevation, many other factors are involved in the safe completion of their assigned tasks.

Their lifting equipment must be the proper type for job site conditions, and it must be able to travel and elevate on that particular job site terrain, and it also must be of sufficient elevating height and load-carrying capacity for the task. The equipment must be properly maintained and ready for safe use, as well. Unfortunately, regular maintenance is not always a priority on many job sites, and in fact in some cases safety devices are deliberately overridden as they are deemed to hinder productivity. A proper pre-use inspection could eliminate many poorly-maintained lifts from immediate service. And finally, the operator must be properly trained.

I can't emphasize enough the training requirement. A properly trained operator is able to ensure that the equipment that they are about to use is truly safe for use and in a safe state of repair, that it is the appropriate tool for the task that they have been assigned, and that the surrounding environment is indeed acceptable for safe use of that lift. With complete and competent training, I believe an operator will understand that staying within those accepted limits will help to ensure that they go home uninjured that evening.

Skyjack and I have entered into a collaborative effort with NIOSH previously. Dr. Christopher Penn [sic] and his team in Morgantown, West Virginia are working on a project entitled "Fall Prevention for Aerial Lifts in the Construction Industry" and have thus far completed physical testing of a scissor lift and found that for the most part -- or actually for all parts, that it does exceed the requirements as set out in the ANSI standards for stability. They've also done human factors subject testing to determine the forces that may be imparted by a human being on that platform, and as well that testing's preliminary data seems to indicate that that is close to the 100 pounds as set out in the ANSI standard as well.

This collaboration has been a great benefit to both these -- manufacturer, myself, the scientific community and the industry as a whole, and I will endorse and support the continuation of this initiative in any way I can.

How can NIOSH continue to help the aerial work platform industry create the safest at-height work environment for workers? Well, the current project needs to continue, and will be used to ensure that the virtual lift -- or I'm sorry -- they're going to create a computer simulation to ensure that the virtual lift matches their physical data that they have found. They will then test that virtual lift in many different scenarios to determine what the limits of use may be.

As well, just to talk a little bit about what Travis said with regards to operator training, I would like to see that NIOSH could possibly evaluate and -- the requirements and effectiveness of operator training in the future. As well there is fall protection questions based on some issues in the OSHA regulations that are not quite clear to all professionals in the industry, and there are varying -- varying opinions on what type of fall protection is required. So certainly that would be another research topic that could be undertaken.

In conclusion, my personal goal is to ensure the safe work of aerial work platforms. There are a variety of different approaches to pursue and achieve this, and I feel that one of the best is having the brightest

research investigators various methods of mitigating these hazards associated with elevating personnel. Skyjack and the aerial work platform industry will cooperate and collaborate with NIOSH whenever possible to pursue this goal. Ultimately I believe education and elevation will create a safer workplace for performing tasks at height using aerial work platforms. Thank you for your kind attention.

Verbal Comment 2006/03/13: My name's Martin Cherniak. I'm a professor of medicine at the University of Connecticut Health Center and I'll be talking principally from the point of view of an academic investigator, which is mostly what I do.

You know, I started out at NIOSH 25 years ago. Marilyn remembers 'cause we were in the same EIS class in 1981. And it was simpler in those days. We had -- for a variety of reasons, the labor markets were stable, they were -- sponsorship was much more clear-cut, we had stable product categories and industries, and we had a couple of vehicles which were really gold standards. One of them was the Cohort Mortality Study, primarily geared towards cancer investigation, and the second was the Single Agent Classical Lab Toxicology Study, and nobody's talking about those today.

Now that gives me one lesson, that you have to be very wary when you're presenting an agenda and presenting a list. You know, political culture, research organizations, budgets, professional training priorities, they have a curious habit of upsetting lists and (unintelligible) disrespectful of tradition, so I'm not going to advise NIOSH on the ten things it should do because they won't have any meaning in five years.

But I do want to say -- talk about a couple of things which I think are important. One of them is that one of the strengths and the weaknesses of this field, and particularly one that NIOSH has encountered, is that in many ways we deal with -- in a multi-disciplinary field. It's evident in the study sections and our advisory panels. People come from a variety of different sectors with -- with cross-lapping concerns.

On the other hand, much of the research community is moving in a direction that's cross-disciplinary, which is to say that there's a great deal of detail and sophistication within subsets of fields which then integrate. This is a conceptual problem, and it's one that NIOSH is going to have to work through. And the reason that it's going to have to work through is that I really do believe that in this climate of very restrictive budgets and limiting resources, there nevertheless are many, many opportunities and it really has in a lot of ways to do with the -- what is a large breadth of investigative talent in this country and an

inadequacy of investigative funds. And that's a combination which, with the right expression and the right conceptual platform, can actually work well to the effect of the -- positive effect of the institution.

Now I want to give a couple of examples, particularly in terms of what I know are priorities here, which are research to practice and intervention. I basically direct something called the Ergonomics Technologies Center, which is largely a sound and vibration laboratory with biomechanics, and we deal primarily with physical hazards in this aspect of our work. There are other aspects of our work. If we look at the field of vibration, for example, hand/arm vibration -- which was an area NIOSH was involved in some years ago -- I can legitimately say that the physiologic and physical science understanding are sufficient that this is a historical problem we can well eliminate. We can eliminate it with engineering and we can eliminate principally with issues around design. But it's not happening here, and I think we have some lessons in terms of where it is happening.

And although it's not always popular, if we turn to our European colleagues we can see the way that they've dealt with this problem through the European community which is on a multi-national, multi-centric consortium basis with very clear goals, very clear directions, and a lot of attention to the organization of the process and its time scales. We've done it a bit here and NIOSH has with the musculoskeletal disease consortium, but that's only one start. And I think it requires, again, a different kind of platform than what we have.

This is also motivated by the issue of concrete problems that are large-scale problems that require cross-disciplinary work and -- and a concentration of resources which just can't be dispelled indifferently.

A second area I would raise is on physical acoustics. A number of people have talked in terms of sectors, particularly construction and mining, about problems of hearing loss. Many of you know there's been significant development in the field of physical acoustics and sound cancellation and moving away from bulky headsets to earpieces, and levels of integrating both the environment and personal protection, which are quite different from the way we've approached this in the past, and they can be effective while maintaining communications. Again, strong basis in physical sciences.

But occupational health is not the field that's making the contributions to these areas. We see it in other research areas, but it doesn't particularly cross over very well. We also see other institutions that are funding that research, and I have to say not always so effectively, largely in the military. But again, the platforms are there. They just -- doesn't necessarily spread in its current -- current milieu.

With that, I would say -- I know NIOSH has not used extensively and NORA has not used extensively the SBIR and STTR mechanism, but I'm not sure they are the best mechanism for much of this kind of work. This is a much longer discussion -- or maybe it's a shorter discussion than detailed about what might be the right mechanism, but I think if we look at the areas where they have not worked, what we can find is in fact a very different area.

Categorized comment or partial comment:

And finally -- I see the fist, so I want to talk about one area which I must do -- I'm sorry, but so many people have canceled you have to give me two more minutes and -- and that really is in an area that we don't do particularly well in this field and that is on healthcare and medical utilization. And there's been a number of discussions of the area but I want to mention just a few points that are important.

If we look at what's occurring within states in the insurance industry, we realize there's a merger going on, at least conceptually, of what would be called the workers compensation and the group health products. If you remove the term "products" what you can see is that there's a very different way of defining the field and a recognition that there is in fact a continuum, particularly with many degenerative diseases and the effects of disease on -- on performance, function and so forth.

Now one of the areas where I think we have failed badly is on the area of performance, and I would say medical performance within work sector. There's enough data to suggest that -- that treatments and the approaches that are taken towards the working population vary by sector and vary by region in ways that have nothing to do with disease, or if they do it's rather coincidental. Some of you are probably familiar with the work coming out of Dartmouth and Winbird's work on small -- local analysis and regional analysis. But if we're looking for huge effects in this society and huge risks which are addressed in rather erratic ways, healthcare utilization is one. And I'm not talking necessarily about coronary artery disease and processes, but I am talking about joints, musculoskeletal disease and many other areas where we see massive differences. And simply talking about practice guidelines or simply talking about a very high-risk sector is not adequate because in fact we see these massive differentials in the limited studies that have been done, and we don't have the information base. I think it's an important area which ARC and other agencies would be well interested in.

Dental Institute

Categorized comment or partial comment:

And finally as I sit down I just want to comment about one area that's been particularly bugging us, we do work in high frequency vibration. We do a lot of work on dental tools, medical instruments and so forth. There's several groups around the world (unintelligible) some very important and potentially consequential and poten-- and certainly controllable effects from high frequency vibration. We've gone to the various institutes, like the Dental Institute, and the response we always get is that's what NIOSH does.

Now the medical institutes will deal with -- with their workforces. You know, they deal with the aging of the healthcare population. They'll deal with the replacement of healthcare population. They'll deal with the inability to attract people into the -- into programs and into jobs. But they don't deal with many of the health problems which are intrinsic in those occupations -- except perhaps for backs. And I want to say simply that I think there's openness to it, but they really -- it's just something they just haven't conceptualized. So that would be my other recommendation by sector, that there are other institutes that have their own germane workforces that NIOSH could approach.

And thank you.

Verbal Comment 2006/03/13: Good morning. My name is Darryl Drobnich. I'm senior director of government affairs and programs for the National Sleep Foundation. Yes, there is such an entity in Washington, D.C. that's called -- called as the National Sleep Foundation. We're a non-profit organization. We're dedicated to raising awareness about sleep, sleep disorders and the consequences of fatigue. Most of the -- two of the most important of that being drowsy driving and workplace accidents. Eighty percent of what we do is public education. We also fund some post-doctoral research fellows and do advocacy around the issues of drowsy driving, school start times for adolescents and workplace education.

What I'd like to talk to you today about is I guess a cross-cutting issue. First of all I'd like to thank NORA for allowing us this opportunity to add some input. But we think sleep and fatigue is a cross-cutting issue and that a third of us -- we spend -- or all of us spend a third of our lives sleeping. And sleep and the loss of sleep has a tremendous impact on how we live, think and function during the other two-thirds of our day. Sleepiness affects vigilance, reaction times, learning abilities, alertness, mood, hand-

eye coordination and accuracy of short-term memory, all skills that we need on the job, obviously, as well as in other parts of our lives.

According to the National Commission on Sleep Disorders research, approximately 50 million Americans suffer from more than 80 different types of sleep disorders, and another 20 to 30 million suffer intermittent problems that are related to pain, stress, anxiety, depression and other ailments each year. Sleep-related disorders affect members of every race, socioeconomic class, and of all ages and genders, obviously.

Sleep is also related to other medical conditions. For example, problems like stroke and asthma attacks occur more frequently during the night and early morning. Lack of sleep appears to trigger seizures in people with some types of epilepsy. Sleep disorders occur in 75 to 98 percent of patients with Parkinson's disease. Sleep problems such as insomnia have also been closely linked to depression and other psychiatric disorders. And a recent study found that 69 percent of primary care patients in physician waiting rooms complained of occasional or chronic insomnia. Overwhelmingly the majority of these people are not properly diagnosed or being treated because of a lack of awareness and education, not only amongst primary care doctors, but other health professionals as well as oc. med. doctors and the patients themselves. They simply don't recognize the signs and symptoms of the major sleep disorders, that being insomnia, sleep apnea and restless leg syndrome.

Beyond that, America is chronically sleep-deprived because of lifestyle. Yeah, this 300 years of Puritan work ethic hitting now the 24/7 society and wreaking all kinds of havoc, not only in the workplace but also on the roads, or the medical wards of your local hospital. More than 63 million Americans suffer from minor to severe levels of sleepiness.

According to National Sleep Foundation's "Sleep in America" surveys -- and these are nationally representative surveys we've been doing since 1998 -- the majority of Americans, almost 60 percent -- get less than seven hours of sleep per day. Research says that we need anywhere from seven to nine hours of sleep to actually maintain proper alertness throughout the day. The survey also showed that 32 percent of Americans sleep as little as six hours or less per night during the work week. In total, 64 percent of Americans get less than eight hours of sleep that experts say that is needed to maintain proper alertness and health.

Sleepiness as a result of untreated sleep disorders or sleep deprivation has been identified as a growing number -- as a cause of a growing number of on-the-job incidents. At least 15 million Americans have non-traditional work schedules that conflict with their biological clocks. According to the National Sleep Foundation's 2000 national poll, 43 percent of adults believe that sleepiness negatively affects their performance at work.

While shift work has plateaued (sic) over the last decade, there is a rise in the number of people that work other alternative shifts outside of the usual 9:00 to 5:00, so you'll see a lot of those people working in the service sector jobs, working 12:00 to 8:00 shifts, and different shifts that might interfere with their sleep. NIOSH has done research on the effects of shift work and long hours, and we encourage them to continue these programs.

The other issue of concern that -- to us is the issue of drowsy driving. Drowsy driving is a very insidious public health problem. The National Traffic -- National Highway Traffic Administration estimates about 100,000 police-reported crashes are the result of driver fatigue each year. In NSF polls that we've been

doing over the last eight years, 50 percent of Americans say that they've driven drowsy at least once, and one in five, or almost 20 percent, say that they've actually fallen asleep at the wheel. In the new poll that we will be issuing in two weeks focus in on adolescents. Twenty percent of 16 and 17-year-olds say that they've actually fallen asleep at the wheel in the past year, and a large percentage of -- a good percentage of them, about 11 percent, say they actually do so a few times a week.

Really what we need at this point is better data and surveillance systems to fully assess how sleep deprivation and disordered sleep are linked to morbidity and mortality and other public health concerns. At this time sleep is under-recognized in most federally-supported surveillance systems, thereby limiting the inclusion of sleep-related factors from documents such as Health People 2010 and NORA and other managed healthcare systems. Sleep needs to be addressed in a more substantial way to reflect the importance in human functioning in order to produce a comprehensive safety -- health and safety agenda for the new millennium. Baseline data is needed to identify clear objectives and goals for subsequent educational programs and intervention models related to promulgating the good sleep habits, the treatment of sleep disorders and conveying the consequences of sleep deprivation. With that, I thank you very much.

American Industrial Hygiene Association

Categorized comment or partial comment:

Verbal Comment 2006/03/13: Good morning. I`m Mary Ann Latko and I`m the director of scientific and technical initiatives with the American Industrial Hygiene Association. On behalf of AIHA I`m pleased to appear here today in support of NIOSH and the National Occupational Research Agenda. I want to thank NIOSH for this opportunity, and to offer the views of AIHA on the important issue of occupational health and safety research.

As a leading association of occupational and environmental health and safety professionals, AIHA represents professionals who serve on the front line of worker health and safety. AIHA members and other professions -- professionals in the occupational health and safety rely on NIOSH to conduct research and make recommendations for the prevention of work-related illnesses and injuries. In 1996 AIHA was one of the earliest supporters of the development of NORA, and we remain a strong supporter to this day. AIHA has provided numerous liaisons to the different NORA sectors over the past ten years, and believes the research conducted by these sectors has worked to prevent serious disabling and sometimes fatal workplace illnesses and injuries. Now as NIOSH looks to renew the NORA project by announcing new research goals for workplace health and safety, AIHA again offers our support and assistance.

With the ongoing structure of NORA being focused on sector councils, each sector council should carefully consider if these topics are a concern for their sector. And if so, include the topic in their research agenda.

Again, AIHA appreciates the opportunity to provide our public support for NIOSH and the National Occupational Research Agenda. We offer our assistance in any way possible, and hope to continue to work closely with NIOSH and the many diverse individuals and organizations contributing to this important project. Thank you.

Verbal Comment 2006/03/13: Good morning. My name is Manual Anton. I am a consultant at the PanAmerican Health Organization, which is the regional office for the Americas of the World Health Organization. On behalf of Dr. (unintelligible) who is the regional advisor on worker health at the PanAmerican Health Organization, I would like to speak briefly about one issue that PAHO has been addressing intensively in the last -- in the last six years.

Given the fact of the fastest-growing participation of Hispanics in the U.S. workforce, almost 11 percent, the occupational safety and health of this population has become one of the priorities of our workers health program. As a response to this challenge, in 2000 PAHO decided to join other organizations in order to forge a strategic alliance, the Hispanic Forum. This initiative is focused on serving the needs of environmental and occupational health that the Hispanic community in the U.S. is facing. It is sponsored by several organizations, some from the U.S. government such as EPA and OSHA; private and non-government organizations such as 3M, the National Safety Council and the National Alliance for Hispanic Health; and also by multilateral organizations like PanAmerican Health Organization and the Organization of American States.

Among its general objectives we can point out the following ones: To prevent, reduce and eliminate the environmental and occupational risks that threaten the Hispanic community in the U.S.; to improve -
- number two, to improve availability and quality of information related to the occupational and

environmental health of Hispanics; to reduce inequality in the access to healthcare services in order to improve the occupational and environmental health status of Hispanic workers and their families.

During this six years the Hispanic Forum has carried out four international events that have brought together different relevant actors from community-based organizations serving Hispanic population in the U.S. to ministers of health and labor from Latin American countries. The main objectives of the first two forums were to identify common challenges, forge new associations, develop strategies and plans of action, and finally strengthen the capacity of these community-based organizations so that they could develop and use better tools to serve in a timely and effective way the needs of this population.

The last two events were focused on high-level decision-makers. A hemispheric meeting on occupational safety and health leadership was held in 2004 in order to outline the main issues that were presented in the 17th World Congress on Safety and Health at Work in Orlando in 2005 under the team agenda of the Americas. The topics included, among others, occupational safety and health of vulnerable populations, implications of foreign trade agreements on workers health, and corporate health responsibility and occupational health.

Within immigrant workers, Hispanic workers have specific characteristics and needs. Language barriers, psychosocial factors linked to the legal status, poor reporting on working conditions and inequalities on health care access are among the issues that make this group vulnerable or at risk. Within the PAHO -- PAHO's activities, workers health problem will get the commitment of working on this issue within the Hispanic Forum.

Finally, as one of our collaborating centers, we would like to thank NIOSH for inviting us to this meeting and allow us being part of this remarkable effort. Thank you.

Board-certified medical toxicologists; American College of Medical Toxicologists

Categorized comment or partial comment:

Verbal Comment 2006/03/13: Good morning. My name is Michael Greenberg. I`m professor of emergency medicine and professor of public health at Drexel University College of Medicine in Philadelphia, and I`m here representing the American College of Medical Toxicology. I`m a practicing medical toxicologist and a member of that College.

The American College of Medical Toxicology is a professional, non-profit association of physicians with recognized expertise in medical toxicology. For those who don` t know, medical toxicology is a formal medical subspecialty focusing on the diagnosis, management and prevention of poisoning and other adverse effects due to medications, occupational and environmental toxicants, and biological agents. Medical toxicology is officially recognized as a medical subspecialty by the American Board of Medical Subspecialties.

There are currently only slightly more than 300 physician members of the American College of Medical Toxicology, all of whom are Board-certified in medical toxicology. There are approximately 40 medical toxicology fellowship physician trainees currently enrolled in approximately 20 post-graduate training programs nationwide. Physicians enter the two-year fellowship training after completion of a primary residency in emergency medicine, pediatrics, internal medicine or preventive medicine. Board certification requires successful completion of an accredited fellowship and a comprehensive written examination.

Some examples of problems addressed by medical toxicologists include hazardous exposure to chemicals such as pesticides, solvents, heavy metals, toxic gases, alcohols and other industrial materials; unintentional and intentional drug overdoses; drug abuse management, including inpatient care for acute withdrawal from addictive drugs, as well as outpatient medical review officer services for industry and organizations; envenomations; ingestion of foodborne toxins such as botulism and marine toxins; independent medical evaluations assessing injury for possible disability resulting from potentially dangerous exposures; chemical, biological and nuclear and radiological weapons that may be used by terrorists; and protection of workers from chemical hazards at work. Medical toxicologists provide these kinds of professional services in a variety of clinical, industrial, educational and public health settings including emergency departments, intensive care units, outpatient clinics, poison control centers, medical schools, universities, clinical training sites, industry and corporations, government agencies and clinical and forensic laboratories.

Since 1999 the College has had a cooperative agreement with ATSDR supporting expanded educational activities for medical toxicologists in environmental health and toxicology, and that cooperative agreement has supported various educational symposia, internet-based teaching resources, multiple teaching monographs, and a national network of public health consultation for incidents involving mass chemical exposures.

There`s a current memo of understanding on collaboration between NIOSH and the College. The purpose of that memo is to facilitate collaborative activities between NIOSH and of the ACMT, including communication and exchange of technical information, consultation, professional education, document generation and review, and research in a joint effort to promote health and safety in the workplace and to enhance the capacity of healthcare providers and public health professionals to address health risks posed by occupational exposure to toxic -- to potentially dangerous substances.

I`m here today to tell you quite simply that Board-certified medical toxicologists and the American College of Medical Toxicology represent a group that is ready, willing and able to help NIOSH with respect to toxicologic hazards that may exist in the workplace. Specifically, medical toxicologists can be helpful in planning and conducting research in concert with NORA. Medical toxicologists can also be helpful in identification and generation of important research agendas and the evaluation of research proposals by participating in research councils as the new NORA focus and priority-setting shifts to an industry sector approach.

Finally, I would like to thank NIOSH for allowing us to speak and I`d be happy to answer any questions about medical toxicology at the next break. Thank you very much.

National Institute on Aging

Categorized comment or partial comment:

Verbal Comment 2006/03/13: Good morning. My name is Jim Mitchell. I`m director of the Center on Aging at East Carolina University in Greenville, North Carolina and associate director of the UNC Institute on Aging in Chapel Hill. And I`m really not representing anyone in particular except myself, I guess, but I`d like to make some observations about potential for partnering with NIOSH and other federal organizations such as the National Institute on Aging concerned specifically with issues such as older workers and aging workers; and secondly, those in occupations who serve older people that require assistance; and thirdly, the impact of occupational transition and job loss on family care-givers and the capacity of families to provide care for older people.

I want to offer an example of how NIOSH might partner with other federal organizations in the way of -- to enable them to gather better data concerning the problems of older people, particularly in rural areas. And I want to mention an example that points out interplay between the role environment and job loss and our knowledge of those processes and the effects of job loss on the quality of life of older people.

We really know very little in the research community about the effects of rural economic and demographic transition and change on the quality of life of older people living in those areas, particularly people who are left behind. To better address this, we formed a consortium between investigators at ECU where I work, UNC Chapel Hill, University of Kentucky, West Virginia University, and Virginia Tech. And we looked specifically at the feasibility of a project looking at rural transition and

quality of life of older people. And I began this process by looking at 55 rural counties that are non-adjacent to any kind of urban area, particularly -- some are adjacent to micropolitan areas, but none adjacent to metropolitan areas.

What I found when I looked at census data over a 40-year period was that there is considerable variability among these rural counties, and variables including economic and demographic transition on one dimension, and job loss in the other dimension. But the significance of this -- for me, anyway -- is that it represents the idea that there's considerable variability among rural areas or areas that we define as rural. And more importantly, that that variability has significant implication for the quality of life of older people through variables such as job loss.

Now what can we do about this? Well, I think it's important that NIOSH and other organizations and agencies reach consensus on definitions of, for example, what is rural. To me, rural has to extend beyond non-metropolitan and it has to extend beyond non-urban in order for the concept of rural to make sense.

I would also urge NIOSH, as it considers its job sector categories that were recently announced this morning, to consider compatibility with other job sector categories to enhance research capacity in the future, especially as we get into a longitudinal and long-term data-gathering. I think it's also important for me to, again, emphasize the critical nature of encouraging people engaged in research dealing with older adults and job transition and job categories to continue to work together. Thank you very much.

Note: Verbal testimony provided to NORA Town Hall meeting in Washington, DC, 2006/03/13.

Verbal Comment 2006/03/13: Good morning, ladies and gentlemen. My name is Mike Demchak. I'm with R. M. Wilson Company. My presentation this morning will be centered around ergonomically-correct seating on mobile equipment in underground mines. Seats in mobile equipment in underground mines is extremely uncomfortable. The road surfaces of most roadways in underground mines, especially near the face, are extremely rough and uneven. The shock and vibration that one's body receives or the operator receives are very intense. This abuse, along with constant attenuation of one's body, causes one to become weary, tired and fatigued. I experienced this first-hand while I was working in a mine.

At R. M. Wilson Company, upon my request, we decided to do something about this situation. We began by piecing together some different types of elastomeric foams which we acquired and piecing them together and -- and then we -- we were looking for somebody to manufacture these things, which was not an easy task. Then when we were into production, we started marketing them.

The mining division of NIOSH asked me if they could go underground to test our seat pads, as we were the only ones who were producing seat pads made out of elastomeric foams. We worked up an agreement with NIOSH whereby we would share ideas, they would introduce me to some new foams that they were using, and I would take them underground to test our seat pads. One pad that we made was -- proved to be 98 -- 95 percent effective in absorbing shock and vibration.

NIOSH is now working on several projects with which R. M. Wilson is involved. One is bulldozer seats on -- in surface mines. And they're checking on the breakdown of elastomeric foams in seating and they're

going to be -- be on -- they'll be working with new types of foams that'll be coming out, but this is in its infancy.

Upon request, R. M. Wilson Company produced and engineered -- engineered and produced what we call a throw seat. It is composed -- a throw pad, excuse me. It is composed of two seat pads approximately 15 by 15 which are sewn together. A person going underground, especially a mechanic, can take this seat pad with him. They can -- they can use it as a seat pad in any situation, even on a piece of mobile equipment. They can throw it on the ground. They can lay on it if they're working on something above, or they can kneel on it and they will feel -- feel comfortable when the work is done. Yes, it is ergonomically correct. And when they are finished, they just take the pad, pick it up by the handle that is con-- and carry it away -- carry it away like a -- like a suitcase.

These are some of the products which we're working with to -- to help to make the environment for miners healthier and -- and we're -- and I -- I wish to thank NORA for this invitation to come here to share these ideas with you, and I thank you for your attention.

Verbal Comment 2006/03/13: Sure. Well, I want to thank you all for allowing me to speak today. My name is Andrew Langer. I'm manager of regulatory policy for the National Federation of Independent Business, and actually I have a soft spot in my heart for occupational safety and health issues. My father's an occupational safety and health scientist, and as I was growing up as a kid my dad spoke a great deal about the research he was doing with NIOSH. He's a mineralogist, my mother is an epidemiologist, so if you can imagine growing up in a household like that, it was kind of hard for me to avoid going into regulatory studies. I tried desperately to do it; didn't happen.

Anyway, NFIB is the national small business trade association. We have 600,000 members. Our average member size is five employees. And that's really what I wanted to talk briefly with you about today because our members, our small businesses represent, you know, 90 percent of the firms that are out there. Ninety percent of the first that are out there have fewer than 20 employees. And our members deal with the regulations that come out of the research that's done by NIOSH and interpreted later on by OSHA.

Our members deal with those regulations differently, and they have a much different impact, and I'll talk very briefly about why that is. We know what the cost is for our members. For firms with fewer than 20 employees, the cost of regulation is roughly \$7,600 per employee per year. So for our average member of five employees, that's roughly -- almost a \$40,000 regulatory cost for them.

For firms with larger than 20 employees, that cost drops, and this is where the big difference is and why that is. Well, for the economists in the audience, if there are any -- and I apologize if I start to butcher economics -- the fact is that the economies of the scale change for larger firms. They're better able to handle the regulatory costs. They're able to pass those on. And the fact is that once you get above 20

employees, firms start hiring the professionals needed to interpret and design the regulatory meaning for the regulations that are out there.

So our members -- invariably it's the small business owner or someone that they've designated, in addition to their normal duties, who have to figure out what NIOSH is saying, what OSHA is saying in the Code of Federal Regulations. And I spend a great deal of my time dealing with that as an issue for my members, trying to find ways to make it easier for them to figure out what they need to do to be in compliance, and to protect the health and safety and well-being of their -- of their employees, because invariably they want to do that. These small business owners, they live and work and play in their communities. They become almost like family with their employees, and they want to make sure that they're healthy. It's just a matter of figuring out how to go about doing it.

So in essence what I would ask, as NIOSH moves forward with their research agenda, that they start to examine ways of making those regulations simple and easy to understand. You know, you start to talk about MSDs, my members start to glaze over. They can understand sort of repetitive injuries and they can understand trying to find ways to mitigate those. But you know, for our members it has to be simple.

I'll give you a real quick example. Last year -- or a couple of years ago, OSHA put out a new hazardous communications guidance system, and the book that they put out was literally bigger than my little portfolio -- it was about this big. And we went into OSHA and we said, you know, my members aren't going to use this. They're going to take a look at this, they're going to glaze over, go a little pale, and it's more likely they're going to use it as a backstop for a door than anything else. And the fact is -- the bottom line is, a document that -- that isn't used is a useless document.

And we're all after the same thing here. I just testified up on the Hill last week about this. We want small businesses because they represent that large sector of the economy. We want them to be in compliance with the law. We want them to understand what their responsibilities are. So what I'm asking is that we all move forward to find ways to make it easy, especially in light of all the regulations that are on the books.

I know most of the folks in the crowd are interested in engaging in new research to sort of expand the horizons of what we're out there protecting, because as we move forward in science we understand that there are more things maybe that we need to protect. But I really think we need to make a conscientious and concerted effort to figure out how to make it easier for businesses to understand how to comply with what's already on the books, what's already out there. Because as you begin to pile on more regulation, more requirements for them, it's going to make it harder for them to figure out what they need to do to comply with what's already out there.

So I leave you all with that. Thank you very much, and thank you for the -- allowing me the opportunity to speak today.

Verbal Comment 2006/03/13: Thank you. Good morning. My name is Marian Condon and I work at the American Nurses Association as a staff specialist in -- in the occupational environmental health center there. The ANA is a professional association that represents the country's 2.9 million nurses, and we have -- we have had members attend the town hall meetings across the country to present the occupational health agenda of nurses.

With the aging health needs -- with the health needs of an aging population and coupled with the aging nursing population and the continuing -- the continuing nursing shortage, all increase the urgency in addressing the occupational health needs of nurses.

There are six topic areas that our priorities can be broken into, the first being the musculoskeletal disorders. According to the Bureau of Labor Statistics in 2004 nurses had 8,810 reported work-related MSDs which resulted in an average of seven days away from work. This of course is grossly under-reported. Research to prevent back and other MSDs needs to promote nursing education and training in the use of assistive equipment and patient-handling devices. Research needs to be done on reshaping federal and state ergonomic laws to highlight the ways that technology-oriented safe patient-handling techniques benefit patients and the nursing workforce.

The next topic area is that of chemical exposures. RNs are routinely exposed to a variety of hazardous chemicals, including drugs, chemicals used in hospital labs, and chemicals used for hospital cleaning and sterilization purposes. And these have been associated with both chronic and acute health effects. Research needs include examination of health effects, employee surveillance and other efforts to protect nurses.

The next area of concern is worker fatigue. Available research shows that overtime and extended work shifts for nurses is associated with increased risk of smoking, alcohol use, risk for back, neck and shoulder disorders, vehicular accidents and increased exposure to biological hazards. It also affects safe patient-handling with slow -- by creating slowed reaction time, lapses of attention to detail, errors of omission, compromised problem-solving, reduced motivation and decreased energy for successful completion of required tasks.

Further research is needed to evaluate overtime and extended work shifts, and the relationship to productivity, quality of safety provided in hospitals, and the incidence of workplace accidents, injuries and stress-related illnesses among nurses. Research needs to be done on reshaping federal and state policy that will limit the ability of employers to mandate overtime.

Bloodborne pathogen exposure, a lot of progress has been made, but there's still room for improvement. Research is needed on the human factors and work practices of nurses related to safe patient-handling of sharp devices and compliance with other measures to protect them from these exposures. Further research is needed on facility-wide policies to promote worker compliance with safety practices, further research and development of safety-engineered devices is also needed.

Respiratory protection, research needs to be done on ensuring that federal and state pandemic planning policies include the use of N95 filtering disposable respirators to be annually fit-tested rather than the use of surgical masks, which are not protective of the nurse or the healthcare worker.

Verbal Comment 2006/03/13: My name is Ilise Feitshans and I'm a lawyer and a public health professional, and I've been writing about occupational health and lecturing on the subject for about 30 years. I write the treatise -- in case you've memorized it, I'm sure -- for WestLaw called "Designing an Effective OSHA Compliance Program", and in case you haven't memorized that, you might have memorized "Bringing Health to Work", I'm sure. But today I'm also a script writer for Digital 2000, who's going to do a 35-year retrospective on OSH Act and NIOSH, and I have been asked to submit a paper, which I did, for the Human Ecology Action League that's entitled "Nurses and Teachers, Worker Health, Worker Concerns".

I want to discuss very briefly something from the past that impacts workplaces today and in the future -- genetics. The (unintelligible) genetic propensities, even the very nature of the interaction between these genetic players and the work environment ultimately plays a role, if not controls, our individual ability to perform work today and tomorrow. My request is very narrow and specific. I perceive the role of genetic testing in the workplace as inevitable. And equally inevitable, a discourse that's fraught with painful questions -- painful social questions such as eugenics, social engineering, stigma, discrimination, liability and healthcare costs. And I request that NORA/NIOSH take the lead and research the role of genetics and genetic technologies at work.

Only NIOSH has the statutory permission to have a really open discussion about the hard choices that we will find in new genetic technologies. Genetics poses hard questions. Genetics is hard to

understand, but it's important. And perhaps the greatest challenge for NORA/NIOSH will be defining not the genetic materials of concern to workers and their employers, and not the criteria for the predictability and reliability of genetic testing and screening itself. The greatest challenge, and where I hope that my expertise might be of value to NORA/NIOSH, is the area of the definition of terms.

No one wants to make employers pay for problems that are inherited. And social policies such as the state-based funds for workers compensation when injury or occupational disease comes from a previous employer serves as a precedent that shows us this very point. But at the same time, we, society in general, and NORA/NIOSH especially, must reconcile this -- this fundamental notion that it might be unfair to make someone pay as a repository for third parties past with three very important factors that that must be weighed against.

First of all, employers remain responsible for providing employment and places of employment that are free from recognized hazards under Section 501 of OSH Act. And certainly genetic technologies will reveal the connections between workplace exposure and genetic transformations, and that would be studied by the scientific community. And this will inevitably broaden the scope of what we understand to be recognized hazards. NORA/NIOSH research must explore this new reality very keenly.

Second, ADA, the Americans with Disabilities Act, does apply to genetic conditions, so knowledge in the scientific community that can prevent harm from recognized hazards does not escape the requirement to provide reasonable accommodations at work to people who can perform the essential functions of their work despite these concerns about genetic factors in the workplace which were heretofore unknown or misunderstood.

Lastly, the convergence of new genetic technologies as applied through path-breaking research may redefine our collective societal notions of things like safety, health and disability. We must correct policies that incorporate the best genetic research without creating an underclass of people who lose their employability due to stigma, discrimination, insurance costs or potential liability.

This task is of millennial importance to every workplace and every worker in our society. That explains why genetics is hard, not easy. NORA/NIOSH must rise to meet this challenge to explore the best future path for applying genetic technologies and to make the best practices for work in the 21st century.

Thank you for your attention and time.

Categorized comment or partial comment:

Verbal Comment 2006/03/13: Actually I used to be with NIOSH. I retired October 1st, but somebody kindly put that in. My heart is still with NIOSH.

I want to bring your attention to a priority of NIOSH that you might not think of as being connected with NORA, and that is global collaborations, that the N in NORA is not intended to be a limiting term, only national. It was intended to mean bigger than NIOSH; i.e., National. So it's a national agenda. It's everybody's agenda.

Global collaborations is one of the cross-cutting programs, like ergonomics, that we -- NIOSH, we at NORA, all of us who are NORA -- will bring to the sectors. And I want to give an example of new opportunities that will exist if we're very clever about how to make use of them.

There is a international initiative that has been underway for about ten years, reasonably successful, called the Global Road Safety Initiative -- began ten years ago after the World Health Organization did some injury calculations globally. Just in December 2005 the U.N. General Assembly passed a resolution on Global Road Safety to acknowledge its reasonable success and to give impetus to countries to do better.

The World Bank, the National Academy of Sciences, the CDC, the Department of Transportation and USAID in February held a meeting on the international Global Road Safety Initiative which I went to for NIOSH, and it turns out that the -- as excellent as it is, it has missed the point of workers on roads, and also missed the opportunity of using workplaces as a way to try to deal with the problems. Right now

the -- and for the ten years the -- the priorities have been helmets, seat belts, general population activities.

So I think that it's time to advance the recognition and attention to both the problems of workers and roads and also use workplaces for action globally. Multinationals want their people to be safe in developing countries. Multinational manufacturers use trucks on roads, so they are -- have an opportunity to contribute to safety and also to have their workers be safe.

Another function of global collaborations with the NORA sectors will be to share good practices that work elsewhere. Our little scan of the European agency site on occupational health information pulls -- for road safety pulls up 180 documents, many of which are practices which are working in their countries and which could benefit workers in the U.S., as well. So by -- by tackling sector-based problems, both -- both for the U.S. and elsewhere at the same time, and also sharing things that work from one country to another, we can probably do more help for workers than we might have been able to otherwise.

Additionally, with some of these initiatives there is money available so that partnerships could be undertaken of multinationals, international unions, with the people in the countries because the World Bank and the other international development organizations are in fact funding activities of this type, and workers could then benefit from funds that are provided.

Another aspect for workers of these global initiatives is that sometimes globally -- and also we heard this morning about needle sticks in national initiatives -- the workers who carry out the initiative are often forgotten. The healthcare workers have been forgotten in the polio vaccination and the AIDS activities, the training of healthcare workers didn't seem to be recognized in the initiatives.

The road safety initiative has a comparable problem. The -- those -- one of the approaches to better roads in developing nations is to build good roads, so you put the trucks on the good roads and the people can walk on the little roads. In India millions of miles of roads are being constructed and there is now an additional huge silicosis problem because there are many mom and pop operations crushing stones and the whole communities have this exposure. So the development activities also need to take into account the workers carrying out the initiatives. And those of us who are working in the different sectors and therefore can become -- are or could become part of international initiatives, we could ensure that the working people get their due attention. Thank you.

ORC Worldwide

Categorized comment or partial comment:

Verbal Comment 2006/03/13: Good afternoon. My name is Scott Madar and I'm a consultant with ORC Worldwide. ORC Worldwide welcomes this opportunity to provide input and suggestions for the next decade of NORA. ORC is an international management and human resources consulting firm whose Washington, D.C. office specializes in providing occupational safety and health consulting services to businesses. Currently over 130 of the world's leading companies in diverse industries are members of ORC's occupational safety and health groups. The focus of these groups is to promote effective occupational safety and health programs and practices in businesses.

ORC member companies represent a range -- a broad range of industries and services, including aerospace, electric power generation, automotive manufacturing, telecommunications, food and beverage, household and personal products, petroleum, chemicals, metals, paper and pharmaceuticals. To a lesser extent, ORC also has members who perform or are involved in construction or maritime activities. These comments are solely those of ORC and may differ from the views and comments of individual member companies.

For more than 30 years, almost as long as NIOSH and OSHA have been in existence, ORC has worked in the occupational safety and health arena. ORC was intimately involved in the establishment of NORA a decade ago, and has been a strong participant in and supporter of the NORA process. We welcome the opportunity to continue to work with NIOSH in the coming decade.

In addition, ORC agrees that a renewed NORA should focus on areas of research whose results can have direct, practical and lasting impacts on safety and health in the workplace. To that end, ORC respectfully suggests that NIOSH consider the following items when crafting the research agenda for the next decade.

Data issues. NIOSH should examine the various occupational safety and health injury, illness and fatality databases in existence among federal agencies. NIOSH should categorize the data being collected, identify any gaps in the data, and ultimately seek ways to fill those gaps. In particular we encourage NIOSH to focus on improving the data collection and analysis related to occupational illnesses, as this is a major weakness of existing data systems. It simply will not be possible to have a significant impact on the reduction of long-term latent occupational illnesses without a better set of data. Lastly with regard to data, businesses are relying on contractors to perform various critical job functions more often. Despite increased reliance on these workers, little work has been done to evaluate the data regarding fatalities and serious injuries among this group, and the impact of these relationships on worker safety. NIOSH should develop a means to collect and analyze this untapped dataset.

Safety and health as a value to business. In order to justify non-regulatory reasons for increasing investments in occupational safety and health, NIOSH should examine management systems, metrics and risk reduction strategies in order to identify best practices among the various industrial sectors. This information, along with the analysis of safety culture, what makes a company successful, should also be the focus of future research.

Emerging issues -- emerging technology, excuse me. The impact of nanotechnology will soon be felt in nearly all industrial sectors. This cross-cutting topic must be a primary focus of NIOSH's in the coming decade. NIOSH must continue to take the lead in addressing occupational safety and health when working with nanoparticles. We suggest that NIOSH should also collaborate closely with the EPA and other government agencies, as well as with stakeholders. ORC is currently developing a matrix of business practices that address safety and health and nanotechnology, and would welcome NIOSH's involvement.

Categorized comment or partial comment:

Verbal Comment 2006/03/13: Good afternoon. Hi, my name is Ingrid Denis and I`m with the Association of Occupational and Environmental Clinics. One of our main concerns is building a cadre of occupational health and safety professionals of tomorrow. Many people have expressed concern about attracting students to occupational safety and health. Certainly this is a challenge that we all recognize and which NIOSH has committed resources towards through its training opportunities in the ERCs, medical rotations and internship opportunities at other non-profit organizations.

However, there`s always room for improvement. In light of our changing workplace and societal landscape it`s important that we shift our own occupational safety and health compass, as well. In addition to the training opportunities currently offered through NIOSH, there`s a need to develop a more comprehensive approach to recruiting people to the field. There`s a need to go beyond the four core disciplines of medicine, nursing, industrial hygiene and safety, and to include such areas as health education, health economics, health policy, toxicology -- it goes on.

There`s also a need to develop an approach to reach out to undergrads. This will have two effects. One is to extreme -- expand the stream of people applying to graduate programs in occupational safety and health, and also will have the effect of attracting more students from diverse backgrounds. There`s also a need to have special outreach to minorities, immigrants and people from under-served communities. And finally, there`s a need to be willing to devote resources to mentorship.

An approach that we`ve found successful at AOEC is the Occupational Health Internship Program. While it`s still a very small program, it contains some useful lessons that could be used to expand the program, or establish similar programs, throughout the country, perhaps through the ERC or the TPG structures. OHIP has two primary goals that are different from those of your standard internship programs. First, we want students to have a learning experience that is based on understanding the world of work from the point of view of the worker. This often involves a participatory research approach. And second, we

want the students to give something back to the workers. We want them to share what they've learned so that the workers can use this information to improve our own work environments.

These two goals are complementary. In the process of learning about the work environment from workers, students begin to formulate a product that will be useful to those workers. Students are motivated to work to solve real problems. And in the long run, we think, it helps produce a highly qualified and motivated occupational health professional.

OHIP is also unique in who it recruits. We have purposely broadened our recruitment beyond the core disciplines to include undergraduates as a way to recruit more students from immigrant and minority communities. This also helps to better serve those worker communities during the summer projects by having students with unique cultural and language skills.

For example, we had a Mandarin-speaking intern who played a pivotal role in a project with Chinese workers -- Chinese restaurant workers. We've also had Spanish-speaking interns work with hotel room cleaners, day laborers and retail service workers.

OHIP students are already making a difference -- entering graduate programs in occupational health nursing, being hired by university labor education programs and healthcare unions. This is important. Many OHIP interns still in school are volunteering as translators and health workers in community-based clinics.

NIOSH needs to continue its current program that supports graduate students in the core disciplines, but it also needs to fund other programs such as OHIP and other training programs that seek to broaden the pool of students who are eligible and interested in occupational health and safety.

In closing I'd like to leave you with a quote from one of our interns from the west coast. I didn't come to public health school thinking this would be my focus. A lot more people would be interested in occupational health and safety if they knew more about what it is. We need to do more PR. Occupational health and safety is not on people's radars. They think of work site wellness programs and don't think about how work affects people's health. Thank you.

Verbal Comment 2006/03/13: Hello and good afternoon. To its credit, in the previous NORA research areas NIOSH highlighted the needs and goals to define and implement a broad national occupational reproductive research agenda. To achieve this NIOSH has been involved in identifying critical research needs in the areas of surveillance, field studies and toxicology. But left out of almost all of these efforts has been a focus on exposure during pregnancy to one of the most dangerous and ubiquitous environmental exposures to which almost all pregnant women are exposed to, namely the risks from automobile crashes and trauma.

Recent research has shown that about one in every 25 pregnancies is involved in a police-reported crash. What appears to be driving this disconcerting statistic is an almost perfect storm of women are working more, working later into their pregnancy, and driving more and more distances. The result is that women commuters and women employed in the transportation activities are increasingly at risk of adverse reproductive effects from crashes and other occupational trauma.

The population impact of this increased exposure to motor vehicle crashes during pregnancy can be seen in the table that I've left with the panel that compares the annual frequency of fetal versus infant crashes, injuries and deaths. You will note that because the fetus takes on the risks of the mother that it -- that they're more likely to be exposed and actually suffer five times as many deaths than infants do from crashes, even though fetuses are exposed over a much shorter period of time -- obviously, nine months.

But fetal death is not the only endpoint of concern. Over the last two decades the medical literature has increasingly documented in larger and larger studies the range of motor vehicle crash threats to the mother, fetus and the newborns. The more important among the documented adverse birth outcomes for the offspring include substantially increased fetal mortality, neonatal deaths, placental abruption, premature (unintelligible) low birth weight.

Direct and indirect damage to the fetus from maternal crashes also leads to an as yet unquantified number of children that have suffered injury or damage to the brain and other organs. This can lead to acquired birth defects and many types of developmental problems. These types of disabilities are well-documented in case reports throughout the literature, but not through large scale population-based studies. In any event, these events leave the families to cope with the grief of the fetal loss, or the burden for carrying these young survivors who may be permanently impaired.

The potential factors, mechanisms and impact on the developing fetus resulting from maternal crash involvement are usually multi-faceted but as yet rather incompletely understood. From a clinical perspective, many things can happen to the fetus during and after a crash to upset the mother, the fetus or the delicate balance between them. There may be direct harm to maternal, fetal or shared organs. There may be indirect harm to the fetus from maternal physiologic adaptations to trauma, fluid loss and shock. There may be effects from maternal stress, common in serious traumatic events, known by itself to impact on the fetus. There may be effects from diagnostic regimens, medical surgical procedures or the wide variety of prescription medicines and self-medications taken by the mother. How all of these interact under different scenarios for different levels of severity at different gestational ages is simply not well understood. This is mainly due to a lack of study.

Therefore it's highly recommended that NORA include within its new round of occupational research priorities and within a continued focus on occupational reproductive research a priority on trauma and pregnancy that will, in general, identify research needs, assist in the development of reproductive health research, expand existing surveillance systems to include accurate information on maternal crash and occupational factors to identify research needs, to create new partnerships that expand resources, to encourage research that would encourage the understanding of biological and biomechanical processes under (unintelligible) abnormal reproductive outcomes after trauma, and to encourage the dissemination of results to the public to increase awareness and to encourage safety assurance.

Some more specific examples of suggested elements related to this priority are attached at the end of my statement. Thank you very much for your kind consideration to this neglected but very important area of occupational reproductive health.

USDA/Cooperative State Research, Education and Extension Service

Categorized comment or partial comment:

Verbal Comment 2006/03/13: Thank you. My name is Bradley Rein and I'm with the USDA/Cooperative State Research, Education and Extension Service. I've been working with NIOSH since I think 1991 in helping organize the first Surgeon General's Conference on Agriculture. I would -- am the USDA representative on NORA I and I applaud NIOSH for all of the things that they have done to help support research in the area of agriculture since the early '90s. Because of NIOSH we now have a lot better sense of what the issues and the injuries and illnesses and the occupational safety factors are in agriculture.

I applaud NIOSH for having the insight to include an agricultural sector in NORA II, and I think that's a move in the right direction and I look forward to working with NIOSH on that.

I would like to talk about -- a little bit about some of the ways we can work together. We've been doing a lot over the years. One of the things we do -- we're a very old agency. We have a very formalized structure in working with our land grant and university partners, and one of the things they have done is they have recently developed a national agenda for action on agricultural safety and health through the experiment station directors and the extension service directors. This agenda, I think, is a move in the right direction and I would like to have NORA con-- NIOSH consider that as they develop a structure for identifying their agricultural safety and health research and outreach efforts.

I applaud Dr. Howard for his initiative in research to practice. I think that's something that we can work together very effectively with. And with that, I think I'll leave it.

Some of the issues, again, we would like to see a little bit more engineering-related types of solutions to agriculture. Agriculture's changing tremendously in this country due to the influence of biotechnology,

the international competitiveness. There`s a lot of technology that I think can be transferred that helps agriculture compete, both internationally as well as produce a safer workplace. Thank you.

Verbal Comment 2006/03/13: Thank you very much. I'm with the safety and health department of the AFL-CIO, and first of all we'd like congratulate NIOSH on ten years of success with NORA I. We think that the initiation of NORA was important to focus what amounts to a limited amount of resources to address issues of safety and health and to address the most important research questions affecting workers.

Of course it's -- you know, it's important and critical to identify hazards and causes of injuries and illnesses among workers in this country. However, from our point of view, I think the most critical element ultimately is the bottom line for protecting workers is intervention. This is where you begin to intervene to reduce and eliminate exposure to those hazards and risks. It's where the impact of what we learn from research on hazards, causes and risks can be implemented to realize real benefits that benefit the employers and employees. Research -- NIOSH's research won't make a difference if we don't translate this into action in our workplaces, so from our perspective we think that intervention research is where the substantial emphasis in NORA II.

Categorized comment or partial comment:

We have several other suggestions I think that are deserving attention and consideration as NIOSH moves forward into its second decade in NORA II. Unlike NORA I where the -- where the -- the universe was -- was carved up by focusing on issues in safety and health, NORA II looks to address issue -- addressing sectors and -- and industries. And you know, logically, either one of those makes -- makes some sense and in round two the focus will be a -- a sectoral approach.

However, we do have some concern about losing some of the cross-cutting issues that cut across industries when you use a sectoral basis, and I know there's going to be a group that looks at these cross-cutting issues, but we really want to make sure and emphasize that we see this as really the central committee that's linking all of these sector-based researches together because we see that there's a number of issues that cut across that we don't want to see fall through the cracks when you organize in this fashion.

Issues of, for example, work organization and stress cut across a lot of industries. Minority and vulnerable populations, uses of PPE, ergonomics, nanotechnology -- these are all the kinds of issues that don't just lend themselves (sic) to using a sectoral approach, so we -- we -- I think we need to have some serious open dialogue and linkage among these industry groups to make sure that these cross-cutting issues don't -- don't fall through the cracks.

Two is we like to apply the lessons that we learned from NORA I and apply those to NORA II. What did we learn, what -- what worked and why, what didn't work and how to correct it, so that we don't reorganize ourselves and fall prey to making some mistakes that might have occurred as -- as NORA -- as NORA I was unfolded. So I think -- I think it would be important for NIOSH to summarize the overall experience of NORA I so that NORA II can -- can -- can benefit from that and move -- and move forward.

CDC National Center for Environmental Health; US Environmental Protection Agency; Department of Education; Healthy Schools Network, Inc.

Categorized comment or partial comment:

Verbal Comment 2006/03/13: Thank you. Thank you very much for the opportunity to provide comments today towards setting the agenda for the next decade. My name is Claire Barnett and I'm executive director of Healthy Schools Network, Inc. We're a national environmental health not-for-profit organization that seeks to ensure that schools are environmentally responsible to children, to personnel and to their communities.

Since our founding in the mid-1990s we have secured new policies, regulations and funding for schools in New York state and in New York City -- the nation's largest school district -- and federally, and advised and insisted (sic) scores of local, state and national groups on establishing reform agendas on school buildings.

We have a clearinghouse, a Healthy Schools/Healthy Kids clearinghouse, both on-line and telephone assistance, which we developed ten years ago in concern with adult occupational health and safety

experts, with parents and others. In that time we've worked with individuals in every single state. The volume of visitors now on an annual basis is approximately that of the federally-funded national clearinghouse on educational facilities.

Regarding the need for research aiming at improving adult health and productivity through better guidelines and standards for occupational safety and health in our nation's 120,000 public and private schools, it is a very timely research opportunity that NIOSH must seize. EPA estimates that approximately half of the nation's 120,000 schools have polluted indoor air. Asthma's not only a leading occupational disease among teachers and custodians, but the single largest cause of student absenteeism due to chronic illness. There are 54 million children in 120,000 buildings.

Indoor air can be five to 100 times more polluted than outdoor air. Americans spend 80 to 90 percent of their time indoors. The American Society of Civil Engineers believes that schools are in worse shape than prisons. Children, who breathe more air per pound of body weight than adults and who are especially vulnerable to environmental health hazards in their developing years, may encounter in school or in day care exactly the same or very similar exposures as the adults, and they vastly outnumber adults in schools.

Our research recommendation is that NIOSH, in partnership with CDC's National Center for Environmental Health and ATSDR, which carry the agency's priorities on protecting children's environmental health, establish a partnership with the EPA, U.S. Environmental Protection Agency, on a national research project to evaluate school environmental health. Such a pilot can rely on existing EPA guidance and regulations on healthy school environments. In fact there is a dedicated web portal now shared between the EPA, CDC and Department of Education on that. It should be advised by pediatric environmental health experts and by experienced parents and personnel, and occupational safety and health people as well.

Outcomes could impact studies on indoor air and help determine if assessing children's environmental and occupational health is a valuable way to determine overall adult employee health hazards in day care centers and schools where the children outnumber the adults by a fair ratio. My organization and many others would be pleased to partner with you on such a project. Schools really are an ideal workplace to study indoor air and low level chemical exposures.

At this time I want to add to this and place on the record several documents. One is a peer-reviewed document or report called "Schools of Ground Zero, Early Lessons Learned in Children's Environmental Health". There were seven public schools in the impact zone around ground zero. One of them opened very early before the fires were still out. The report documents the evacuations and cleanups of 9/11 impact zone schools. An informal backpack survey done in cooperation with the local parent associations indicated continuing health effects on elementary-age children as late as spring of 2002. No agency has reported such data. It was done through an informal community survey.

We're also putting on the record a new report called "Who's in Charge of Protecting Children's Environmental Health at School", and a data report on New York State school facilities and student health, student achievement and student attendance. I -- based in New York State, and New York is data-happy. We have a lot of good record-keeping on health effects. We have a good -- lot of good data reporting on standardized testing, as well as a lot of data on school facilities that a lot of states don't have. We recently -- our office, working with some outside consultants, recently completed a report showing that poor facility conditions are associated with lower test scores, higher absenteeism and

higher suspension rates. We did not have the research capacity to look at employee health or productivity.

I encourage you to consider schools as part of your research agenda. Thank you.

Categorized comment or partial comment:

Verbal Comment 2006/03/13: Good afternoon, my name is Shelley Davis. I'm the deputy director of the Farmworker Justice Fund. In 2003 -- 2004 the Associated Press surprised the nation by saying that Mexican immigrant workers in the United States had the highest fatality rate of any occupational group. As was just mentioned, immigrant workers have particular occupational health and safety needs. They often work in the most hazardous jobs and due to language, culture and other barriers, receive inadequate training.

I want to focus my remarks on a particular segment of the immigrant workforce, which is the nation's 2.5 million migrant and seasonal farm workers. Agriculture consistently ranks as one of the three most hazardous occupations in the nation. (Unintelligible) for example the combined category of agriculture, forestry and fishing had a fatality rate of 31.2 per -- cases per 100,000 workers. And with regard to non-fatal on-the-job injuries, they had a rate of more than six per 100 workers, including 3.7 per 100 workers

of lost-time injuries. (Unintelligible) fatal injuries with (unintelligible) leading cause was agricultural vehicles, both tractors and, for hired farm workers, the vehicles used to transport them to and from the fields. Here's the non-fatal injuries. Because of the kinds of work they do -- harvesting, pruning, sorting, packing -- they suffer a host of sprain and strain, musculoskeletal injuries, eye injuries from debris, cuts and lacerations from machetes, contusions, amputations from farm equipment, chemical-related illnesses from pesticides.

This workforce is primarily an immigrant workforce. The National Agricultural Worker Survey estimates that 78 percent of farm workers come from Mexico and Latin America. And 81 percent speak Spanish as their native language, and then only 25 percent understand English well enough to obtain information in that language.

There are also particular structural reasons in agriculture which make it particularly hazardous. The industry has gone to a great dependence on labor intermediaries or crew leaders that recruit, hire and transport the workers. And these crew leaders oftentimes are former farm workers themselves, with only a battered school bus or van as their assets to transport the workers, and they frequently don't receive enough compensation from the growers to provide adequate workplace safety.

The second reason is that the National Agricultural Worker Survey (unintelligible) 52 percent of the farm workforce isn't documented. And these, you know, (unintelligible) workers are loathe to complain about unsafe workplace conditions, even to their employers, let alone to government investigators. Also language, culture, mobility, short tenure at any given workplace all combine to make the conditions hazardous so that workers are not adequately trained, are often unfamiliar with workplace conditions, and don't have trusted sources that they can turn to for assistance. In addition, agricultural workers lack union representation. Only two percent are union members. As a result, few gain protections from collective bargaining, and most federal and state labor laws, partial or whole, exclude agricultural workers. In OSHA, for example, there are only seven OSHA standards that apply in agriculture, even though many other standards cover conditions that are equally prevalent in agriculture. For example, fall protection, (unintelligible), electrocution, et cetera.

So in these context researchers could play a very important role in identifying the causes of injuries and developing low-cost interventions that could really improve occupational health and safety in agricultural workplace.

We at Farmworker Justice have been participating over the last 18 months in a NIOSH-funded community participatory research project working with indigenous workers in Oregon, and we've really seen first-hand the value of that, the key role played by the workers themselves in voicing their concerns and identifying the kinds of interventions they're looking for and what they would use.

We've also been working across the nation over the last year with researchers and advocates and funders to try to develop an agricultural research agenda. And we've found that oftentimes researchers and advocates live in two very different camps and don't communicate. And so the research that's done is not really addressing the key issues and is not being utilized.

So from these experiences we'd like to just cull out a few recommendations for the NIOSH NORA. First, we think it's extremely important that NIOSH fund community participatory research projects, that researchers involve the targeted workers and their representatives from the outset in designing the project, in developing interventions and testing them, in making sure that this is the kind of issue the

workers think of as important, and that the solutions are low-cost and easy to implement and things that are likely to continue after the research project is done. That they involve community-based organizations that know where these workers are and are trusted by these workers `cause otherwise you won't get community participation and buy-in, and that is really critical to the usefulness of the project.

There are also particular areas that are worth focusing on. First, because of the primacy of motor vehicle accidents in workplace fatalities, that should be an issue that's -- that's given attention, as is musculoskeletal disorders, eye injuries, traumatic injuries, heat-related illness and the other major causes of occupational injury and illness in the agricultural workplace.

There's also a real paucity of data and the National Agricultural Worker Survey is one good example, but it's very limited in the area of occupational health and safety, in part because funding for safety issues has only been sporadic. So joining forces to put some money into the NAWS as a continuing datastream would be very helpful, as would be long-term epidemiological research that focuses on agricultural workers, even when they return home to Mexico, because many workers, once they become ill or disabled, do return home. And so the adverse health effects they suffer is lost to researchers who only focus on active workers or workers in the United States.

Finally, I'd just like to say that we really encourage you to continue supporting the environmental justice grants and other similar funding streams that allow you to tap into researchers that are working with community-based organizations that have close connections to the targeted workforce that can really involve the workers themselves in the projects. Thank you very much.

- Industrial Minerals Association of North America

Categorized comment or partial comment:

Verbal Comment 2006/03/13: Good afternoon. My name's Mark Ellis and I'm president of the Industrial Minerals Association of North America, which is a trade organization that represents producers and processors of industrial minerals. We also represent the manufacturers of mining equipment, railroads and trucking companies that serve the industry, law firms, consulting firms, media companies, and all of it is geared towards producing minerals that are essential for our everyday life.

These are such basic things as glass, ceramics, paints and coatings. They're the ingredients that are used in fertilizers, so it's basic building-block material and we're that silent part of the mining industry that you don't hear about all the time. Clearly you're familiar with coal or your crushed stone, sand and gravel. But we're more the commodity that are used in manufacturing and agriculture.

The Association has strong commitment to occupational safety and health. We have a board established, a safety and health committee that reports to the board, and they're involved in a number of occupational safety and health issues. Typical kind of things are broken down into task forces. Some of the kinds of issues we deal with are dust control and ergonomics.

We participate in a number of partnerships with research agencies and enforcement agencies. We have an alliance with the Mine Safety and Health Administration and we're exploring a similar arrangement

with the Occupational Safety and Health Administration. And we are engaged in numerous partnerships with NIOSH, including diesel particulate matter, noise, emergency mine communications and the like.

I think that what I'd like to draw your attention to is our biggest safety and health challenges, and this is obviously where we need to make sure that these subjects are covered in the occupational research agenda. The task -- the town meetings that have been held around the country -- we were unsuccessful as of yet in getting one held for the mining industry, and I understand that NIOSH is working hard to try to make that happen, so we will be a participant in that and we will encourage others to be involved as well.

But the challenges that we face are not unfamiliar. They're well-recognized occupational safety and health challenges. They've been around for centuries -- over-exposure to dust, over-exposure to crystalline silica, noise-induced hearing loss. Probably the biggest one that we're facing now and it is partly a testament to how well we've done in keeping the workplace safe and healthy is an aging workforce, but that presents new issues for us.

I think that NIOSH has done a lot of progressive things under Dr. Howard, and I think that one of the things that we feel is important for the National Occupational Research Agenda is something that focuses on the research to practice initiative. It's very important to take research and to translate that into something that's useable out in industry, and I know that that's something that Dr. Howard has moved very aggressively on in his tenure at NIOSH, and we applaud him for that and we encourage the agenda, as it's developed, to stay in that same line.

I think that the biggest problems we have right now are intervention strategies. We know what our problems are, but how do we break them. And so I think that any research that can be done to determine what is an effective intervention strategy would be of great assistance to us.

Also control technologies. People have been knocking metal picks against hard rocks for centuries, and it makes a lot of noise, it makes dust, and we have yet to figure out a way to take the metal and coat it and make it so that when you bang it against the rock it doesn't make a noise or doesn't produce dust. But that's where the research is needed, trying to get things that either control the exposure or isolate the person who's conducting the work, better PPE -- you know, these are the kind of things that would be of benefit to our industry.

So I think I'll just close with that, and thank you for listening to us and we hope that you'll support our agenda.

Categorized comment or partial comment:

I had earlier submitted a statement on the importance of research on non-ionizing radiation to occupational health. To document the extent of those exposures, I have used data collected by the INTERPHONE study of cell phones and brain cancer conducted by the International Agency for Research on Cancer (IARC) and epidemiologists from 13 countries (not including the U.S.). This case-control study has interviewed over 15,000 subjects on their full range of exposures to electric and magnetic fields (EMF), including workplace exposures. When fully analyzed, these interviews will provide excellent data on the prevalence of occupational EMF exposure.

For NORA, I have conducted a preliminary analysis of the introductory questions that ask about work in sectors where EMF exposure is likely. A table with the complete results to the NORA symposium organizers for entry into the docket, but here are some summary results:

- * 28.8% of the workforce (36.9 million workers in the U.S.) are potentially exposed to power-frequency EMF.

- * 23.2% (29.7 million) are potentially exposed to radio-frequency / microwave fields.

The exposures are reported from the manufacturing, service, transportation, utilities, construction and health care sectors. In other words, non-ionizing radiation is clearly a cross-sector exposure.

Research is needed on the relationship between pesticide exposure and birth defects, spontaneous abortion, and preterm labor. In February of this year, the News and Observer in Raleigh, North Carolina, chronicled the stories of three migrant farmworker women who reported repeated prenatal pesticide exposures while working in tomato fields in southeastern North Carolina. Subsequently, all three women gave birth to children with significant birth defects, one of whom died shortly after birth and one of whom has no arms or legs. Given that this is a routinely invisible population, it is unknown to what extent there have been other such cases, preterm births, or spontaneous abortion. Of interest is that although located in extremely rural areas of the state, health departments have no pesticide education protocols for any population. Even if these protocols were in place, a large number of the migrant farmworkers living in these areas do not speak or read Spanish but indigenous dialects that are not even written languages. The language barrier, along with access to health care issues, and fear of punishment if women are in the country illegally further complicates gaining information or providing health education to this population. Research is also needed into migrant farmworker women's knowledge about pesticides and beliefs about the use of personal protective equipment and pesticide precautions, particularly during periods of vulnerability such as early pregnancy. Your consideration in making this a priority for NORA's agenda for research to practice will help to ensure the well being of migrant farmworker women and children.

Wisconsin is currently the only state in the country with legislated medicaid reciprocity. When a migrant farmworker family enters the state and presents a valid medicaid card from another state, they are immediately given Wisconsin Medicaid until their current Medicaid eligibility expires at which time eligibility is updated. Lack of Medicaid reciprocity (or portability) for migrant farmworker families often results in families who are eligible going without medical coverage presenting a major barrier to health care access. Many barriers exist to reapplying in a new state including Medicaid eligibility office hours, transportation, language barriers, limited length of stay in a new area, and location of the eligibility office. Research to practice efforts are needed to examine the feasibility of Medicaid reciprocity or portability on a national level. In addition, feasibility of implementing a web based farmworker medical record that is accessible to the individual and to providers (with consent) such as the one being implemented in North Carolina are also needed.

Please consider noise in your review of occupational health hazards. Noise exposure in the electric utility is significant with little resources for engineering control measures. It is crucial that attention and funding for hearing loss prevention efforts be considered to protect the health and the hearing of 30 million working Americans.

Noise exposures and hearing conservation issues have the potential to affect a large percentage of the work force across virtually all industries and places of employment. As one who suffers from tinnitus and a noise induced hearing loss, I can also state that it affected my family too!!

I fear that cross-sector issues, such as noise-induced hearing loss, may lose some ground in funding and attention. Noise is perhaps one of the most ubiquitous exposures for working Americans. The potential for loss of research funding may have a serious impact on tens of millions. For this reason, I have trepidation about the whole industry sector concept. At the very least, I would hope for some form of reassurance that cross-sector issues, noise in particular, would not suffer in the NORA change.

Workplace Violence Prevention Research

Since the inception of a comprehensive occupational fatality database more than two decades ago, workplace violence (WPV) has remained one of the leading causes of occupational mortality. On average, each year more than 800 American workers lose their lives to workplace violence while they are doing their jobs. Additionally, an annual average of 1.7 million workers are victims of workplace violence incidents. The NIOSH Workplace Violence Initiative has strong intramural and extramural components that have made great strides in the prevention of workplace violence. Still these statistics on the tragic deaths and injuries of America's workers are compelling enough to warrant expansion of the prevention efforts within NIOSH.

In November 2004 NIOSH held a conference entitled "Partnering in Workplace Violence Prevention: Translating Research to Practice". Recommendations for a national workplace violence initiative were

collected from partners and stakeholders during the conference, which focused on workplace violence prevention strategies and research needs. Some of the overarching recommendations from this conference were that NIOSH should 1) develop a clearinghouse of information on workplace violence, 2) evaluate and identify model programs, 3) develop data gathering standards for disparate data sources, 4) provide public education in WPV, 5) coordinate the national WPV prevention effort and lead partners in the development of a national WPV strategy, 6) forge a common definition of WPV, 6) gather data on the Federal workforce, 7) ensure and maintain up-to-date WPV statistics, 7) adopt a partnership model to develop regulations addressing workplace violence, and 8) implement WPV prevention programs in the workplace.

Research gaps need to be addressed with regard to WPV prevention programs for all types of workplace violence. With regard to Type I, i.e. stranger on worker violence, research gaps include a) determining the effectiveness of environmental designs, physical measures, and work practices on injury and homicide during a robbery situation in convenience stores, b) developing a complete inventory of all state and local regulations and polices regulating WPV prevention measures for the leading causes of Type I violence such as in convenience stores and taxicabs, c) estimating the percentage of workplaces in compliance with federal, state, and local regulations and identifying reasons for non-compliance which can then be incorporated into the partnership model for developing regulations addressing workplace violence, and d) determine reasons why WPV-related homicides are decreasing in convenience stores and taxicab industries. With regard to type II, i.e. client on worker, and type III, worker on worker violence, research is needed to a) define the continuum from bullying to assault to injury or homicide, b) determine risk factors for bullying, c) evaluate and promote model programs to modify behavior for prevention of bullying, and d) evaluate program and promote model programs for prevention and response to workplace assaults. Additionally, for all WPV categories, research should continue in surveillance of fatal and non-fatal WPV injuries and an analysis of trends for person, place and time risk factors should be conducted.

These statistics and the recommendations from NIOSH stakeholders and partners for future research form the basis for a compelling argument that workplace violence prevention research needs to be a cornerstone in the new National Occupational Research Agenda.

Verbal Comment 2006/02/21: Good morning. I just wanted to share with you a quick story before I get into some other points I want to make. About a year and a half ago -- it's been almost a year, about a year or so ago, we had city-wide hotel negotiations in Los Angeles. And we put many is-- several issues on the table, but we really wanted to narrow down to the most important. And without a doubt, the workload -- especially of housekeepers -- was put on the table as an issue that had to be addressed. And that is because immediately after September 11th, which we all understand why the hospitality industry really went way down as far as business, that what employers had done across the board, throughout North America, was to take full advantage of the fact that they had to cut staff because business had dropped so dramatically. But as business was picking back up, they were failing to, at the same time, bring the staffing levels back up to correspond with the increased business. And so what was happening throughout hotels, union and non-union, was enormous overload of the work on the housekeepers and other changes. And so we put that on the table for discussion and to make changes in the workload for the housekeepers.

And the spokesperson for the hotels made some remark in front of the housekeeping and the other hotel workers negotiating committee, something to the effect of, you know, work isn't that hard for those housekeepers because we have a green program. And because of the green program, you know, their -- their workload is very light, so we see no problem, period. We don't want to discuss it. That's the end of the conversation.

Well, you can imagine -- if you're a housekeeper -- what their reaction was. They wanted to jump across the table and strangle him. First, it was a "him", who had never made a bed in his life, probably, and had no idea of what he was talking about. So the next negotiations all of the housekeepers in that hotel, plus housekeepers from many other hotels, filled the room because some of them were going to address him. And when he started walking into the room with the rest of management representatives and they saw the room full of housekeepers, they closed the door, left, and they called us saying that they were not going to start negotiations until we emptied out the room of housekeepers.

You know, the -- their unwillingness to even discuss this issue was so offensive to the housekeepers that work so hard every single day that they just couldn't believe that their employers would not even hear them out, would not even listen to them.

That's what's being faced, and there'll be housekeepers here today who will talk to you more importantly, more directly about what they go through every single day. That's what has moved us, in addition to all of the other working and -- working conditions of housekeepers and other hotel workers in the hospitality industry.

A couple of days ago I found -- something was sent to me or distributed on the internet about an L.A. County Health Department report that had just come out in January. It was talking about how chronic diseases had increased and \$48 billion in healthcare costs related to chronic diseases, and one of the points that they're making was that the hardship -- that the greater the economic hardship in a community, the greater the likelihood of the chronic diseases. And it went on about, you know, measured in every -- oh, that was quick -- measured every community and found that, you know, they really needed to make some changes. But the changes that they talked about all had to do with how to live a better lifestyle -- like stop smoking, eat nutritious foods, get regular medical care -- you know, things to do in the community. But there was probably just one sentence that referred to the hardship. In other words, we ought to do something about the economic hardship of these communities.

Well -- so two sentences on that is not sufficient to address what is going on in our communities. And we have got to be more direct and we invite and join the health and medical professional communities to join with these housekeepers as not only do we address the issues of housekeepers and the workload and the changes in the industry and the hospitality industry with, quote/unquote, heavenly beds and amenities and more mattress -- heavier mattresses and sheets on the -- and the heavier carts, but that we also address the economic conditions of our communities and of those workers.

It's real simple to say we recommend get regular medical healthcare. It's another thing when those workers, low-wage, mostly immigrant workers in these industries, service sector jobs don't make enough even to live outside of poverty, much less buy the health insurance that they need to be able to take care of themselves and their families.

I want to end -- I've been told to stop, but I want to end by saying we have materials here about a national -- North America campaign called Hotel Workers Rising. It'll be in the back. Invite you to join us. Join those housekeepers. Join those women -- join those women of color 'cause that's who works in these hotels as housekeepers -- as they struggle and they join across North America to say to the hospitality industry employers, you want us to do a good job, then we have to take care of ourselves. We have to be healthy as we do this, not to be pushed out and -- and abandoned when our back hurts, when our shoulders, when our knees, when our elbows, when we can't move anymore, abandon us. So

we`re creat-- helping to build this movement across North America, not only for hotel workers but all service sector jobs.

Eighty percent of the new jobs in this country are service sector jobs. And housekeepers and hotel workers are going to fight like hell, like manufacturing workers did earlier in the century, to say we want good middle-class jobs with health insurance to raise our kids, be healthy and have healthy communities.

And I thank you very much for the work that you do. Join with us as we do whatever we have to do to make life and work safe for those housekeepers. Thank you very much.

Verbal Comment 2006/02/21: Hello, my name is Alejandra Domenzain. I'm associate director with Sweatshop Watch, which is the statewide coalition of organizations focused on the rights of low-wage immigrant workers, including garment workers.

So first I think it bears reminding ourselves why focus on immigrant workers. First, when we talk about the future of our workforce, we are talking about immigrant workers. New immigrants contributed at least 60 percent of the growth in the nation's labor force between 2000 and 2004. And in California we know that Latinos alone account for about a third of our workforce. Looking into the future, if we assume immigration levels remain constant, immigrants will account for half of the working-age population growth between 2006 and 2015. And then looking even further into the future, they'll account for all of the growth between 2016 and 2035. So the health of the immigrant workforce is inseparable from the health of our immigrant workers.

Secondly, occupational safety and health is particularly important for immigrant workers. As Maria mentioned, they're less likely to have health insurance, and less likely to earn a wage that's adequate to have access to medical care. On average, low-wage immigrant worker in the U.S. earns \$14,000 a year,

which is probably a high estimate. And immigrants are over-represented in industries where there are predatory employers that violate the basic health and safety norms with total impunity.

Lastly, we know immigrant workers are disproportionately injured and killed. The Bureau of Labor Statistics concluded that Latino deaths on the job have been 20 percent higher than for whites or African-Americans. However, in my remarks I want to focus briefly on statistics from community-based research, closer to the ground, which I think really shows us even more rich details about the situation.

So for example, there was a study from the Korean Immigrant Workers Advocates here in Los Angeles that found 40 percent of Korean workers in garment, restaurant, retail and janitorial jobs had suffered workplace injuries that required medical treatment or resulted in lost work days. Seventy-six percent of these had no health insurance, and up to 75 lacked workers compensation insurance. About 90 percent never received any kind of health and safety training at all.

A UCLA study found that the injury rate among L.A. day laborers involved in construction work was twice the rate for construction workers as a whole. And a recent national study on day laborers found 44 percent were denied food, water and breaks; 20 percent were injured on the job; and more than half did not receive the medical care they needed for an injury.

Lastly, to focus on the garment industry, the Asian Immigrant Worker Advocates in Oakland found that 94 percent of garment worker patients that came to their clinic were experiencing pain severe enough to interfere with their daily activities. And the Garment Worker Center here in Los Angeles has found 97 percent of garment workers were exposed to concentrated dust and cloth particles, over one-half had experienced needle sticks or worked with pests such as rats and cockroaches, and one-third worked in shops with non-functioning bathrooms.

So in conclusion, I think we need to support these kinds of field-based research projects which are often the only detailed source of information we have on health and safety for low-wage immigrant workers. We also need to evaluate and promote innovative and effective intervention models for dealing with this specific population.

To do this it is essential to involve the community-based organizations that have the trust of immigrant workers and the ability to reach them. To this end I urge NIOSH to explore research models that build on the expertise of worker advocates in the field, to allocate funding for pioneering community-based organizations to document what they are seeing and doing regarding immigrant worker health and safety, and to prioritize this topic in coming years. Thank you.

Verbal Comment 2006/02/21: Good morning. Deanna Stover, and I represent the City of Los Angeles. With approximately 42,000 employees -- and actually it's growing I think day by day, our occupational health department's very busy -- we represent a very cross-section of employees, from recs and parks to firefighters, police officers, veterinary zoos and everything in between. I want to commend NIOSH and NORA for past practices, and I really encourage future endeavors in (unintelligible) research.

With our occupational health division we're very lucky that we have on-site psychologists, physicians and nurses to carry out the duties that we need to take care of our own employees.

A major issue of concern to us is workplace violence. We have experienced workplace violence incidence -- if you follow the news -- in the last couple of years. It very much concerns us. I know research has been done over the years on workplace violence, but we still find that it's very critical to look at prevention strategies and implementation plans, specifically to get to the small and large employers.

Very few of our employees that are actually out in the field have access to computers, so on-line training doesn't seem to be the way to go. They really have to have a handle on the warning signs and reporting mechanisms for workplace violence. Our employees are our number one asset, and we're very concerned about this area, so I would encourage that workplace violence remain at the top of the list for occupational safety and health initiatives and that research continues to grow in this area.

Another area that concerns us is with our commercial driver population, specifically with the area of sleep apnea. We have found just a paucity of research in the area of sleep apnea in applying it to the occupational health or employee population, what current modalities are out there for testing. There's several that we use, like the Inventory of Visual/Auditory Test. We call it the IVA. The TOVAA, which is the Test Of Visual and Auditory Alertness. What is the current mechanisms out there, the equipment out there to actually assess sleep apnea. How do you apply sleep apnea to your workforce that have commercial drivers. We have firefighters that have sleep apnea. They do 12-hour shifts, 24-hour shifts. Sleep apnea seems to be a field that appears to be, in our arena, under-researched and not funded to really look at the occupational side of the house, so I would like sleep apnea to be considered for the list, as well.

The other issue that I think really, in our arena, the number one of our employees, the largest volume is our police force and our firefighter force. Public safety initiatives need to give their due and need to get attention, as well. We find that medical standards for police in California are very good. It's the Peace Officers Standards of Training, they're called P.O.S.T. We use the national guidelines for National Fire Protection Association, NFPA, for fire. But those standards need to be researched in accordance with state and federal laws, like ADA and the Fair Employment in Housing Act specifically in California to figure out when can best evidence -- medical best evidence in occupational safety and health preclude an individual from going back to work that may pose a risk to public safety.

We try to balance this every day with the City of Los Angeles, and it's very difficult. We have looked for research, and again there's a paucity of research in the area of balancing federal regulations and state regulations with medical standards for police and fire, specifically looking at major illnesses, major disorders, MSDs, musculoskeletal disorders like hip replacements, amputations and things along that nature.

And in closing, the other area that I think needs current research and continues to be in the area of occupational health is what is the -- what is the research in the delivery of care systems using licensed vocational nurses, nursing attendants, registered nurses, physician assistants, nurse practitioners and physicians. What is the role -- the new role of a physician, given the other health care providers` level of expertise, certifications available, and training to enhance the field to make it cost effective and provide a high quality of care across the nation, specifically here in California.

Thank you.

Verbal Comment 2006/02/21: Good morning. My name`s Diane Bush and I coordinate the young worker project at the Labor Occupational Health Program at U.C. Berkeley. And I`m also here on behalf of our national OSHA-funded young worker safety research center that brings together agency partners involved in protecting and educating young workers from 13 different states in the country.

I`d like to thank NIOSH for the opportunity to talk to you about the importance of maintaining a focus on young workers within NIOSH`s work within specific relevant industry sectors, but also as a critical cross-cutting issue. And I want to start by acknowledging how NIOSH has really played a leadership role in focusing on this issue. They focused on this issue and then they maintained that over the last ten or more years, and have contributed in a very significant way to what we know about young worker health and safety, both through their own primary research, but also through supporting research by others.

We constantly cite NIOSH`s emergency room data, for example, because our own state injury and illness data -- it really isn`t sufficient to describe what`s happening. And I don`t -- I don`t want NIOSH to stop playing that role. It`s really because we have this information that we`re able to convince people in our own communities, both at the very local level, the school level, the community level and also in the

state agencies that we've been working with around the country, about the need to address this really important and critical issue.

And also because of the research that NIOSH has supported, we have collectively been able to begin to identify patterns of injury and potential intervention strategies. For example, the NIOSH-funded sensor project in Massachusetts has really provided a lot of rich information that we've all been able to use because it was well-funded and they were able to really look deeply at specific injury events, but also look at patterns of injury.

So there's -- there's been a lot of good work that NIOSH has done by focusing on this as a cross-cutting issue. And I want to just express my concern about this sector approach and encourage both that within each sector people look -- look for this in -- within the sectors where there's significant numbers of young workers working, that they really think about what the agenda should be in that sector, but also that NIOSH figure out a way to continue to look at this as a cross-cutting issue.

In addition, I want to really commend the NIOSH initiative now to really take research and turn it into practice and advocate for strengthening that practice role. There is a lot that we already know would make a difference, but getting it out there, getting employers to actually put things in place -- there's a lot more work that needs to be done there.

So just to name some of the cross-cutting research that I think would be helpful in this area, one, having better, more specific injury and illness data at the state-specific level would strengthen our work that most of us tend to do within our states.

We also feel that NIOSH did a great job looking at the existing work that -- that youth are doing and making recommendations to update the child labor laws, but they didn't -- they weren't directed to look at 14 and 15-year-olds, so we think we should -- they should extend that work and review the hazards and exposure for those under the age of 16 and develop a new set of recommendations to bring those laws up to date.

I also think it's important for them to look at -- or to encourage research on the consequences of early work experience injuries. There's really very little information or data on this, on the psychological impact on the young people as well as the long-term effect on their -- either their own disability or the associated costs, their loss of earning power, et cetera.

I also think it's critical to have innovative intervention research. How do we actually get employers to provide safer workplaces, including better supervision and training if -- if -- is there a way to make sure that young people are prepared at -- to go into their jobs ahead -- that they're prepared ahead of time because they work in such high-turnover, low-pay jobs, it's hard to get the employer to do what they need to do. What can we do in advance -- so I'm getting my 30-second warning here.

Also I do think within specific sectors there are critical issues. Agriculture, again, NIOSH needs to look at what 16 and 17-year-olds are allowed to do and make recommendations to improve those child labor laws. Within construction NIOSH's current recommendations actually say that young people shouldn't be working in construction before the age of 18, but what is the role of quality voc. ed. or apprenticeship programs in reducing injury.

So there are a lot of things to look at. I wanted to echo Deanna's concerns about violence in retail and the service settings where a lot of young people work. And I've got to stop 'cause Laurie's telling me to. Thank you.

Verbal Comment 2006/02/21: Good morning. My name is Michael Marsh. I'm a staff attorney with California Rural Legal Assistance, Incorporated, and I'm also representing California Rural Legal Assistance Foundation in Sacramento. CRLA has 22 field offices throughout the state, and we provide -- we provide no-cost legal services to low income persons in 25 counties. We represent -- or provide services to approximately 40,000 Californians each year.

Obviously the majority of our clients are farm workers and their families, and we conduct a wide range of occupational safety and health activities to help those clients. We have -- we conduct impact litigation to correct workforce-wide problems. We provide legal services on a one-to-one basis for clients. We do a lot of work in the area of community education, trying to act proactively to make sure that accidents don't happen. And we work at times very closely with Cal-OSHA or with the California Department of Pesticide Regulation.

Before I make a couple of specific comments, I'd like to make one general comment which I think echoes one of the comments that were made -- that was made earlier, and that is the importance of involving farm workers in the planning of these studies, of whatever studies are done. Farm workers, as we know -- I'm just stating the obvious -- are largely immigrants. The farm workers are largely from Mexico. Others are from Central America. The primary and native language of almost all farm workers in the state of California is Spanish. Increasingly farm workers are coming from southern Mexico, from the state of Oaxaca, and some of those workers do not speak even Spanish comfortably. And we find that many of our clients have very limited education, in some cases in the fourth to sixth grade level. Additionally, obviously, these individuals are culturally distinct from the majority culture of the United States, so you really have to -- or NORA really has to take into consideration these factors when it plans

studies. A study that was developed for farmers is not going to be effective for farm workers. NORA really has to work with study programmers to plan approaches and questions that are culturally relevant, that the questions are understandable, and they're really culturally appropriate for -- for farm workers.

One -- one area is there's a great need for additional study of the long-term impacts of MSDs. I think that there have been some studies, especially recently -- last few years -- that have shown farm workers suffer MSDs at very high levels. But there hasn't really been adequate research into the long-term impacts of those MSDs. Farm workers of course engage in a number of high-risk activities, from lifting and carrying heavy -- heavy loads to stoop labor, repeated bending, or to repetitive use of the hands such as pruning or picking or weeding. So we know that the problems are -- we know that the problems are there, but we need to look at the long-term impacts of that.

Let me move on to the next one, heat stress. Last year there were five verified heat stress-related fatalities here in California, four in agriculture and one in construction. The numbers were probably higher. Reporting's always an issue. But we need to look at the issues such as the effect of piece rate or incentive pay work on heat stress. We need to look at frequency and the duration of rest periods and how that might help -- how that might help alleviate heat-related illness. We need to look at the use of portable shade structures during rest periods and meal periods.

And finally, injury reporting. I think it's no surprise that there's a lot of injuries out there that occur in a lot of the different sectors that aren't reported. In farm work there's a lot of barriers to reporting, and a lot of the injuries that occur don't get reported either to employers or to worker comp carriers. And so we need to do more to look at what are the barriers to reporting, and how can we alleviate and eliminate those barriers.

Thank you very much.

Verbal Comment 2006/02/21: Good morning. My name is Vicki Beck, and I'm director of Hollywood Health and Society, a project at the USC Anenberg's Norman Lear Center. And I'm delighted to cross town today and come back to the campus where I spent six years in health sciences communications working with people like Linda Delp and others at the School of Public Health, and to see my colleague, Max Lum, at CDC where I spent five years working in Atlanta and knew Max well.

The question I want to pose to NIOSH is how do we reach special audiences of workers and find new ways to reach them more effectively. And we know how to use news media. We know how to use brochures. We know how to use pamphlets. Workplace information, even clinical places have information that could be helpful to workers. But I would like to challenge us to look beyond that and look into entertainment media that is so popular among special audiences and among all mass audiences.

What we have done at Hollywood Health and Society is conduct outreach to entertainment media, specifically TV shows, to inform them about the public health issues that are really big problems in our society; to educate writers about topics like HIV/AIDS, diabetes, heart disease, much, much more.

And I think what we have right now is a situation where worker safety and injury issues are a little bit invisible in television. You may see a storyline from time to time, but there's so much more that we can do to promote health and safety and to prevent -- and to offer messages about disease and injury prevention.

Some of the storylines that we have worked on in the past deal with topics like cancer, sexual health aids, violence. And what we would like to encourage are more storylines and working more closely on topics like construction, demolition, HazMat, manufacturing, agricultural issues. We just heard about farm workers.

We heard this morning about hotel workers. Well, I think if you saw the Jennifer Lopez movie you would think hotel workers lead a very glamorous life. They party a lot and they meet wealthy politicians. There's another side to that story that hasn't been told.

But we need to understand also what the audience takes with them from the storyline. And we have started to look at knowledge, attitudes and practices along some of these storylines on the HIV/AIDS topics, syphilis, diabetes. And what we know from our research is that people do learn about the health issue. They do learn and they do discuss, and we have the data to show that.

We know that sometimes people have higher intentions of a prevention activity or a screening activity after they have seen this in a health storyline. One example I can give you is a syphilis storyline that was on ER, and it was a storyline about an alderman in Chicago who came in to be treated for syphilis. As a matter of fact, he was treated secretly because he didn't want anyone to know that he had syphilis, and in the following episodes his partner came in to be treated for syphilis. And we did a study -- we worked with CDC, we worked with partners on this study, and we found that among men having sex with men who had seen this storyline, 64 percent were likely to be tested for syphilis in the next six months, compared to 34 percent who did not see the storyline. So we had a doubling of effect on intention to be screened.

We're starting to work -- we're just starting to work and we're delighted about that -- on a tele-novella project that will address a construction worker topic, and we will be doing some evaluation on that. We just hope that we can gain more understanding and that we can start to utilize this extremely powerful form of media to reach workers and their families with more health promotion, safety promotion messages. Thank you.

Verbal Comment 2006/02/21: Good morning. My name is Jacinto Lopez. I`m an organizer with KIWA, Koreatown Immigrant Workers Alliance, and we`re a non-profit -- and we organize workers in Koreatown, the local workers, and I think it`s important to talk about health and safety conditions in Koreatown in restaurants and supermarkets. And -- well, the common injuries in these places are from cuts, burns, back problems and working -- working with chemicals that make you feel sick and hurt your hands and eyes. But many of the injuries and accidents happen because people don`t get any training, and also there is no equipment. What happen is that when workers get hurt, they don`t get the right medical treatment. They just get fired. Or many times these -- they just don`t know what to do or where to go, and many times the owners send the workers to their doctors, but they -- they just -- sorry, but they just get Tylenol and then sent back to work, so they have to work again even with -- if they`re hurt.

And I want to talk about how probably health and safety laws -- and unfortunately, in places like Koreatown, I feel like there`s inspectors, but they don`t really talk to the workers and they don`t really help the workers. And I think the system is not working because no one knows about Cal-OSHA and no one knows what phone number they can call when there`s a problem -- and i`m talking about the workers in Koreatown.

And with this, I just want to present my concerns about our systems of workplace health and safety enforcement, and I think the researchers really need to think about how to address these problems. Thank you.

Verbal Comment 2006/02/21: Good morning. My name's Aleyda Moran. I work with the UCLA Labor Occupational Safety and Health program, also known as UCLA LOSH. The issue that I will be talking to you about today is young worker health and safety.

Youth face hazards at their jobs, and are at a higher disadvantage to protect themselves compared to adults. Teens under the age of 18 have been found to -- being injured two times that of adults. From national studies, youth have been found to report higher injuries during the first six months of their workplace, and the majority of these injuries are minor, such as burns and cuts. But there are also other incidents that negatively impact the youth, such as bigger injuries like concussions and other fractures which could have long -- severe long-term consequences since they are very young, and that could impact them from the long time -- for a long time.

We know that youth are working. Eighty percent of young people will have worked by the time they graduate from high school. Children from low income families are working more hours and on the average -- than the average child, and are more likely to be legally employed. It is estimated that 231,000 teens under 18 will be injured on the job each year, and 70 teens will die from a workplace health and safety injury.

The sad thing is that these injuries are happening and most of these injuries are preventable. But there's a lack of awareness, education and training on workplace health and safety for youth.

As UCLA LOSH one of our missions is to become -- is the development of youth leaders who learn about workplace health and safety becoming peer educators, then going on and spreading their knowledge to other youth in their wider community. The peer education model became established after a 3-year intervention program at Manual Arts High School. One of our most recent projects is the young worker leadership academy, which was -- which is coordinated and developed and implemented with LOSH and our sister program at UC Berkeley, LOHP. This model brings youth together from various areas of California, and they are there for three -- a 3-day intensive training on workplace health and safety and project management. The youth then go back to their communities and carry out educational campaigns and projects with their input and their ideas of how to reach other youth, which is the most important thing and vital thing with this project.

This is an outstanding model which is aimed to benefit the youth and their community. However, we will love to have former participants come back and actually be involved in a participatory research project on the issues that impact the -- on the issues and what the academy impact was on their involvement.

The statistics that I provided to you earlier are national statistics on young worker health and safety injuries. But California and local statistics are missing, and that's where the problem can be seen. Why is California's workforce important? Well, it's one of the largest states with the largest number of workers. One of the largest populations of immigrant and undocumented workers is here, and California has often been the model for strong and progressive support for workers in health and safety.

Why is research on young worker health and safety important? It is crucial to have markers to define the current state on how this -- on how programs like ours impact, to know the current state and measure this impact. Research is a valuable tool for workers on health and safety committees, organization programs, the workplaces. It is important to have that research to present to these places to identify what is the need, where is the need, and what is the proper way to address this need.

To conclude, I want to reiterate again the need for local statistics. We need to implement effective education programs. And I also want to highlight the commendations (sic) presented by the UCLA -- by UCLA LOSH to NIOSH in their report "A School-based Intervention for Teaching Workplace Health and Safety". These are the following:

Demonstration projects in several school districts in distinct areas within the U.S.; demonstration projects to get young worker health and safety as a component in the curriculum for youth; create collaborations and partnerships between the NI-- Department of NIOSH, Department of Labor, Department of Education and other relevant entities; and develop a national workplace health and safety campaign. And I feel the most important thing is that whatever research we do, whatever evaluation we're doing about different educational programs, bring the youth voice into it because, again, who else knows about how are youth going to learn more if we don't bring youth in it, as well. They have many invaluable things to share and we should take in consideration what their strategies are, also -- the strategies they're also presenting.

Thank you so much, and I hope you take into consideration all these things.

Verbal Comment 2006/02/21: Good morning. My name is Laura Podolsky and I'm a second-year student at the UCLA School of Public Health. I will be completing a master's degree this June. Also I have been working as a graduate student researcher at the UCLA Labor Occupational Safety and Health program since beginning my studies.

I am here today to speak about my experience last summer as a participant in the Occupational Health Internship Program, or OHIP. OHIP provides students across the county with hands-on opportunities to carry out occupational health and safety research. The program emphasizes direct collaboration with workers and worker organizations, focusing especially on low-wage immigrant workers.

Interns are encouraged to use community-based participatory research approaches. In addition to providing initial training in participatory research, OHIP supervisors and coordinators offer guidance and support to interns throughout the summer.

Of the four interns working in Los Angeles in the summer of 2005, three were from immigrant backgrounds, and three of us spoke fluent Spanish. All of us had prior experience working in immigrant rights, labor or health. And at the end of the summer all of us agreed that we had deepened our understanding of these issues, gained new skills, and strengthened our motivation to stay involved in worker health and safety.

Prior to beginning my OPIN internship I had learned about community-based participatory research in several public health courses. It seemed very much in vogue, something of a synonym for righteous research. The concept was frequently linked to other buzzwords -- empowerment, coalition building, collaboration, grassroots leadership. I was simultaneously inspired and wary.

Indeed, I had chosen to study public health because I believed in the potential for communities armed with solid information and skills to create positive social change. But I was also aware that facile slogans and jargon-laden idealism wouldn't get anyone anywhere. I wanted to know what did this community-based participatory research really look like. What could it actually accomplish. I was interested particularly in the role of such research in occupational health and safety. How, I wondered, might community-based participatory research contribute to efforts to improve worker health and safety.

OHIP gave me a chance to explore these questions. Along with my partner, Daniella Conde*, I spent ten weeks working with the labor union UNITE HERE Local 11 researching the occupational health and safety issues of hotel housekeepers. The housekeepers themselves were carrying out a survey on work-related pain and injuries among their coworkers, and participating in workshops to discuss the results. Daniella and I aimed to supplement this information through interviews and focus groups. Alongside the housekeepers, we wanted to identify the main types of injuries experienced, their possible causes and their consequences for workers. The union could then use this information to reduce hazards and improve conditions.

Over the course of the summer we faced both logistical and methodological challenges. We also enjoyed moments of real connection with workers. By the end of the internship we had carried out 19 interviews, attended five workshops and conducted several work site visits. We honed our interviewing and observation skills and discovered some of the challenges of survey research. Speaking with housekeepers in employee cafeterias and their homes, we learned about the benefits and difficulties of their work, and their ideas for making it safer. We explored different ways of returning this information to the workers, deciding in the end to create brochures to be used in union workshops.

Throughout we benefited from the support of our supervisor, Linda Delp, and OHIP coordinator Gail Bateson*. We also had the chance to collaborate with the other OHIP intern team in Los Angeles which was working with immigrant day laborers. Through discussions with them we gained a broader understanding of the range of health and safety issues facing low income immigrant workers in Los Angeles.

I still have questions about the connections between community-based participatory research and occupational health and safety. These are big topics, and an internship can serve only as an introduction.

That said, my experience with OHIP was an eye-opening, inspiring introduction. It has strengthened both my skills and my motivation to continue in the field of occupational health and safety. I know many students, both graduates and undergraduates, who are passionate about immigrant rights, labor issues, and reducing health disparities. But few of them even know what occupational health and safety is. I promise you, I'm the only student in the UCLA School of Public Health who focuses on occupational health and safety, and there's over 200 of us.

OHIP represents an opportunity -- an important opportunity -- to reach out to these students and train them to do good work. And as we all know, there`s certainly plenty of good work to be done. Thank you.

Verbal Comment 2006/02/21: Good morning. I'm Barbara Kanegsberg, President of BFK Solutions, and I also represent our non-profit Surface Quality Resource Center.

Well, I'm exclusive. I'm unlisted in the program. So if any of you would like copies of what I presented, please come see me, or would like information, we can exchange cards. This -- my -- my comments primarily impact the manufacturing sector, but I would say there's implications for all sectors. I have formal, written comments to present, as well, so I will summarize them here.

There is a regulatory witch hunt that occurs regularly in this country -- and throughout the world, I might add. I would like to propose some alternatives.

In my consultancy I help people who manufacture objects. I'm called the cleaning lady, and I help them with basically processes for everything from movie film to artificial hip implants to -- oh, I don't know, chunks of helicopters, the guts of this microphone, your camera, whatever. Everything that's manufactured requires chemicals, lots of them. And as we get into micro and nano, we're going to need even more chemicals.

Right now we regulate chemicals based on what I called the regulatory witch hunts. We manage individual chemicals or classes of chemicals. Let's suppose a chemical comes into widespread use, like for example the old freons, the ozone-depleting chemicals. Based on the use of freon trichloroethane, which is a chlorinated solvent, regulatory agencies got to know more about the safety and environmental impacts. They said bad, you can't use it anymore. Or sometimes they just put it on restricted lists, and it becomes more and more and more regulatory scrutiny.

So what does industry do in response? They say oh, we can't use hexamethyl death*; what should I do? Gee, there's tri-iotacatastrophe* over here, think I'll use that instead. Or hmm, let me look at this MSDS*, it says no hazardous ingredients. Hmm, must be chicken soup. The open the lid and -- pretty awful, but it says no hazardous ingredients; they use it. They also get very confused because they go through the lists and lists of lists, and I've got to tell you that private communities are confused, everyone is confused. Even the military, and the military are trying to talk with each other and actually systematize and good -- do good solvent substitution. They are very confused by all of the regulatory restrictions.

This approach is damaging to industry, to workers, to communities impacted by industry, and to the overall -- and it's also damaging to the overall environment. We need a paradigm shift. We need better approaches to managing the substances that we all work with. One thing would be process management, not more lists of chemicals that are politically incorrect, not more product bans.

We need simplification, nationalization, and globalization of standards and regulations. People in regulatory agencies down the hall from each other don't know what's going on.

I recently spoke -- was asked to address a group of inspectors for a local agency, and they were asking me to explain what was going on in regulations and restrictions at a nearby agency. I should know. They don't know themselves. If they don't understand it, how's industry supposed to get it? I did know a little about it, but we also need a holistic regulatory approach. And this is real revolutionary. I really think we need to consider both safety and environmental. Yes, they're separate -- they're separate issues, but they're related.

We also ask that industry have sustainable processes and sustainable products. I am here to ask for sustainable safety and environmental regulations, ones that we can all use, ones that we can all follow.

I have plenty of comments here designed to induce restful sleep if you read them in their entirety. I have more technical information for you. Please see me. Thank you.

Verbal Comment 2006/02/21: Hi, my name is Victor Esparza. I'm from International Union of (unintelligible) Engineers and I'm from Local 12, their safety rep. What I want -- would like to ask of NIO-- or of this NORA group is -- and I know our international has worked with NIOSH on -- just not -- on asphalt testing for air sampling, but I would like to see it on rubberized asphalt.

I also would like equipment for testing -- we crush and recycle old concrete. And pre-1980 concrete has asbestos in it. I'm not sure if all of it has, but a lot of it have it. And also when they crush and recycle material which -- if you guys know what the laborers -- a week ago or whenever, I think a lot of times in our industry we don't know that they're being re-exposed to, you know, airborne silica if they're around crushing operations or the construction part of it. I -- the reason I know is 'cause I have it in both my lungs and, you know, how short my life will be from it, I don't know. But these exposures are being set every day and -- you know, and I listen to and I can see where immigrants that -- on the low-wage scale are afraid to say anything, but also in the construction field that I work and the guys make great money are as scared of their jobs as the guy at the other end of it, and would kill himself instead of saying or doing anything about it. But I believe that if you guys could test it and make equipment that -- monitors that we could put on this equipment where they can come and face it and know that you are in -- exposed to either silica or asbestos at levels higher than what should be exposed to, then the guys could then change it by either adding more water spray or whatever. But they could see that they needed to change from either -- you know, even putting suits on or whatever. But without them knowing that it's out there, the guys are just going to keep on till they all die.

I know that I hit the perfect number about 25 years into the field. I got sick. I've just met two more men in the last two months that have now been diagnosed with a cancer of asbestos, and then other

gentlemen with the silica out of the Riverside San Bernardino area, and I came out of that San Diego, and only in two plants or two operations for 26 years.

So that's something that I would like to be able to be -- see 'cause like I said, the -- it's not only the risk to the guys running the equipment, but also the guys on the ground, which would be the laborers, and that could go all the way down to the low end of construction work.

I also know, or knew -- when I was first sick at home, I sent information to NIOSH. They did a study out of the Oakland area. It got big enough where they asked for more money. It got bigger, and then -- but I mean I was never -- and I tried to contact -- to the information that came out of there. I mean they gave me a little poster, but you know, there's got to be a way to relay to your doctors that hey, we're having exposures again to asbestos in California and silica because when I first came to this light about what I was sick, they were saying -- nobody knew. But I think it's my doctors misdiagnosing both from UCSD and Kaiser -- Kaiser, my primary people, and then when I was operated from UCSD. So you know, maybe NIOSH or NORA can relate hey, maybe we ought to start looking for these health problems out there 'cause to me it's an industry that we are at risk and will continue. Like I said, our international works with you guys all the time on -- you know, and maybe you guys can add to them and ask -- say hey, let's work with the rubberized asphalt and back at asbestos and silica because I know they'd spend the money to do it with you guys, so if you can address that with them. Thank you.

Categorized comment or partial comment:

Verbal Comment 2006/02/21: Good morning. My name is David Simmons. I'm on USW Local executive board. I'm a union health and safety rep for ConocoPhillips and I'm on the board of Kaiser, at-large member.

I'm here today to talk to you -- to explain to you how safety committees that I'm associated with helped to establish a climate of safety at ConocoPhillips' Los Angeles refinery.

At the best of times union and management had a -- have an adversarial relationship. But through negotiations we have agreed to remove one subject from the political arena, and that is safety. We have agreed to make this a common ground of understanding between the two factions. If we can't agree on safety, what can we agree on?

This caused a shift in attitudes in upper management, and pressure on middle-line supervisors to change their way of communicating with employees. When the old line of blaming workers first behavior model went away, root cause analysis took its place. Changes had to be made in order to stop repeating some incidents that was caused by equipment ergonomics, improper operating procedures and institutional shortcuts.

Labor and management both had to take a hard line to impose the new climate of safety in the workplace based on joint safety committee participating and having full-time union health and safety reps who work under the guidance of the committee -- joint committee to help promote safety and be a focal point for workers to get information and voice their concerns on issues of safety in the workplace. We have changed the old trinket-ology (sic) models that are prevalent in other industries to a more open strategy of full disclosure of every incident, with weekly audits, near-miss reports, management reviews for all incidents, and labor participation in all investigations so all can benefit from lessons learned from every misstep.

Now safety is becoming a focus in all work order management by everyone because they're being held accountable for their part in the work. We have a distance to go to reach perfection. Old habits die hard. There is still pitfalls we have to clear to get there, but we have mechanisms to reach their goals.

I'd like to talk about minimum staffing in refineries. Minimum staffing requirements should be set to ensure that worker safety is not compromised. Many refineries are so understaffed that during maintenance shutdowns workers are forced to work mandatory overtime until the unit is restarted. Some work as long as 20 days without a day off. This is one of the contributing factors in the Texas City incident. Worker fatigue keeps operators from being as sharp as they need to be. Computer controls has enabled companies to minimize staffing and require operations employees to have responsibilities to know more than one process area. As a result we have fewer experts and more operators that are only proficient. The workforce of our industry is aging and shrinking. Without minimum staffing I fear that there will be an increase in tragic incidents in refineries.

We're working hard to change this. At my plant we just, in the last year, hired 44 people -- operations and management. I'd like you all to research the effects of working continuous hours on -- on the operations people and how it affects their mental well-being to do their jobs.

Thank you very much.

Verbal Comment 2006/02/21: Good morning. My name is Ignacio Garcia. I'm a leader organizer with an organization called IDEPSCA, which is -- stands for Institute of Popular Education. Our organization has a program that concentrates with the day laborers. A little history of day laborers is it's people that are looking for daily work, and we have different sites throughout the L.A. County. (Unintelligible) concentrate to organize workers so they can work -- wait for people that are looking for day -- one-day person work. Okay? So these people -- myself, originally I've been in a union shop, but since I started working with this organization I came aboard and that is that the lack of safety is very much. Safety -- it covers a lot of grounds, but based on a study by our -- with LOSH, there was an occupational health internship program that we had with UCLA LOSH. They found out that out of 117,000 day laborers nationally -- they found out different problems with this. Okay? We have what we call is blunt trauma, lower back pain, general (unintelligible) pain, eye and respiratory irritation and body lacerations. All of this things are -- may sound very fancy, but is based on what a lot of people don't get on this day laborers on a daily basis. They don't get trained. They're -- they're confronting every aspect of safety issues out there on the -- on the workplace. When I say workplace, it can be a homeowner's place. Sometimes the contractors will come and take them to their job sites. And most of these times they don't even let them know the basic procedures on safety, as if you want to lower -- bend your knees or use your legs instead of using your back. So we need to find out -- or do some kind of research so we can protect all these 117,000 workers out there. They're doing -- most of the times works without PPE.

Most of you don't know what PPE is, personal protection equipment. They just go out there and use their hands, their bodies, without any kind of protection.

I can go on with a lot of scenarios where people can get hurt here, but we're trying to ask you guys to do some kind of research and find out how can we train these people better or -- so they can protect themselves 'cause in many cases these homeowners don't have the -- the capabilities or equipment for them to protect the workers. So very basic -- we need to protect these workers. There's a lot of people out there that are not being trained properly in all aspects of safety. Thank you very much.

(Whereupon, the following presentation was made through the use of an interpreter. Where presenter and interpreter were speaking simultaneously, separation of the two was difficult. This transcription represents the best effort of the reporter.)

Verbal Comment 2006/02/21: Good morning, everybody. Porfiria, I am Mexican. I work with IDEPSCA. I help housekeepers, baby sitters, and in addition to that make sure that they are protected and well-paid. I'm spokesperson for many of these women who come to this country. We are not conscious of our rights (unintelligible) of our (unintelligible). We work without fair pay. We go to work not knowing that we are not safe. We do not wear EPP (sic) because we are not provided with it. We are not provided with healthcare. We recognize many of our health problems, but we do not protect ourselves properly. Main accidents and diseases, product of our work, are burns, falls, back pain, arms, hips, eye irritation, respiratory problems, bone and muscle deformation, tendons and nerves, chemical exposure, asbestos and lead when we clean. We are not provided with proper training in health and safety in the workplace. Much less, we are trained in how to do properly our work. We housekeepers are practically (unintelligible) and ignored. And the worst is that there are not specific laws that protect us in the workplace. We are part of this society, and we believe we are indispensable. Without us doctors, lawyers, teachers, policemen, firefighters and many others could not function properly, much less be free in their -- during their break time because our work provides them with that leisure. Therefore I recommend that research is done to create laws of protection in the workplace that let us housekeepers and baby sitters to be visible people in this society and thus come out of the shadows. Thank you very much.

Note: [The preceding presentation was made through the use of an interpreter. Where presenter and interpreter were speaking simultaneously, separation of the two was difficult. This transcription represents the best effort of the reporter.] Verbal testimony provided to NORA Town Hall meeting in Los Angeles, CA, 2006/02/21.

Verbal Comment 2006/02/21: Hi, I'm Fran Schreiber and I'm with Work Safe. I'm also the executive director of the Cal-COSH legal services project and Cal-COSH is a project of -- of a non-profit agency and Work Safe is also one of those projects.

Work Safe began around 1980 as a coalition that built off of a number of the COSH groups around the state of California, Committees on Occupational Safety and Health. And in 1980 we came together as Work Safe and have been active in policy advocacy ever since.

I just want to -- it's not on my topic, but I just listened to the last two speakers and they were talking about how they're indispensable to this economy, and yet they are disposable as workers, and what the last speaker was just saying about the fact that there are no laws to protect them. I actually worked for Cal-OSHA for four years back in the early '80s, and she's absolutely right, there is no law that protects workers who work in people's homes. Cal-OSHA will not do inspections. They get no training. And then when they're injured on the job, they're completely disposable because the laws for workers comp don't cover temporary workers who work the few hours that these folks work in a particular setting. So they get screwed no matter which way they go, and I just thought I would point that out to you.

I'm here today, though, to talk about something else. I'm talking about kind of a California-wide problem which I think we face in the construction industry, and is also built off of what two -- the other two speakers said earlier. We're about to embark upon a big public works project here in California. The Governor was talking about \$222 billion worth of possible work. And even if that number isn't what we get to, there's going to be a lot of money on the table for doing public works job and increasing the number of construction workers. We've got 18 million workers here in California; 938,000 by last count did construction. That number has been increasing and will continue to increase.

And one of the earlier speakers said that of that group -- well, before I get to that, the incidence rate in terms of injuries for this population here in California is 7.2, which is far better, by the way, than what the national incidence rate is for construction -- partly I think because of the permitting system that we have, which I think is something people need to get some more information about because it should be exported to other places outside California. But it's still the highest number, that 7.2 rate, among all of the sectors that are here in California. And in addition to that, as one of the speakers said earlier, double that rate for the immigrant workers. So you're talking about a significant problem. You're going to have a lot of immigrant workers coming in to do this new construction, and we've got a problem on our hands.

I'm coming to this not as an academic. I am not out of that area. I come from a real life, real world perspective, and I think that NIOSH needs more of that perspective. People have talked about that earlier today. We need more research to practice work, projects that are going on.

And I'll also tell you that you have to change your criteria for evaluating these projects because the criteria you have is weighted in the academic arena, and you need to not do that. You need to have credits being given when there's community and worker involvement in these projects, otherwise the projects don't get funded and the research doesn't get done. I also would think that it might be nice to have some worker representatives in the team that evaluates these things, but I've been told that that's really stretching it a bit.

I come also from having seven years of working as in-house for the State Building and Construction Trades Council of California. Four years before that I did the criminal prosecutions of OSHA cases when I worked for Cal-OSHA between '80 and '84. I read every fatality in the state of California during a two-year period and I noticed something. In almost 99 percent of the cases somebody on that job knew ahead of time that that so-called accident was going to happen, and either they spoke up and were told to shut up, or they didn't speak up because they knew that was what was going to happen to them, and I prosecuted people criminally.

And it dawned on me as I started doing that that it would be better to prevent those injuries before they happened. And the way that you do that, I learned in the next job I had with the State Building Trades, which was with joint labor/management health and safety committees where we actually saved money and saved lives. And the gentleman here spoke before about the projects that they're doing with these committees, and I now want to just lay out very quickly -- I know my time is up -- a couple of research areas to focus on joint labor/management committees to determine, with research to practice proposals, how to maximize the effectiveness of joint labor/management committees to look at effective labor participation using training programs such as (unintelligible) which we have here in California, looking at what's happening with the Bay Bridge situation where you've got, quote, self-inspection by a company and you don't have enough Cal-OSHA inspectors to go after them and they

won't agree to have labor participation. And even if they did have labor participation, it wouldn't have trained labor participation.

We need information on cost savings offered by joint labor/management health and safety committees in order to encourage use of them. We need human costs and what kind of costs we can determine when a life is saved and how many lives and how many fewer injuries there are, and we also need information about construction savings for the construction owner and the contractors. We need to look at other worker participation models and promote them, as well, such as effective tailgate training meetings which are done with worker participation. We need to look at labor/management laws and regulations in other countries and in other settings where these are required by law to be done and to see what happens. We need to look at pre-qualifying contractors, both generals and subs, and requiring them to have labor/management committees in order to do -- do these big construction jobs. And we need workers comp discounts based on effective labor/management committees. We need to look at projects where those -- that kind of thing is happening, look at laws and regs where that's happening. And finally, look at contract language and determine what can be done via educating construction owners to include joint labor/management committees.

I know I've gone over my time, but we need some economics here to prove that these are the safe way of doing things and that they will prevent injuries before they happen. Thank you.

Verbal Comment 2006/02/21: Sorry, can you hear me now? (Unintelligible) Okay, I'll repeat again. My name is Jason Wang. I'm the research assistant from UCLA department of epidemiology. Today I represent our research team collaborate with UCSF (unintelligible) lab and also the California Department of Health Service. And we have conduct successful -- conduct (unintelligible) for garment worker so today the issue I want to speak is we will focus on the (unintelligible) musculoskeletal disorder for sewing machine operator.

Based on our finding, the -- most of the garment worker, they are immigrant woman and working for minimum wage, and also the most big finding we found is the -- about -- more than 80 percent of them don't even have health insurance. So musculoskeletal problem, based on our survey, we find out is the - really a big problem for them. Everyone -- all of the operator, even the shop owner, told us this is the - really serious problem for them and they want the help from us and they want immediately help -- to help them to solve this problem. And based on our finding about -- more than -- more than 60 percent of them are able -- have a musculoskeletal pain during at least a one day per week. And among them, about 30 percent of them have -- the pain is severe to -- moderate to severe pain. So we find all this -- this is really a serious problem in this under-served population. And during the year from 2003 to 2005 we actually received several phone calls from several garment shop that asked to help from us. They want us to help them to help their employee to -- how -- how can they do to help their employee to prevent the injury happen to minimum the musculoskeletal problem. So today we're here. We just want to help these garment shop to speak out and we want to help them to say this is a really a serious

problem. Musculoskeletal problem is a really serious problem for this occupation and we really need to spend more time and spend -- do more training and maybe (unintelligible) conduct more program to help this population -- to help them to prevent this injury happen. Thank you.

Verbal Comment 2006/02/21: Good morning. My name is Dr. Peter Schnall. I'd like to thank Cass Ben-Levi and Linda Delp for helping to organize this meeting. It's a pleasure to be here this morning. These are my personal views, but I should point out that I'm the recently-elected chair of the ICO scientific commission on cardiology and occupational health, and I'm hoping that the comments reflect the views of the people doing research in this field concerning psychosocial factors. I have six points I'd like to make this morning.

One, work is necessary, and yet can negatively impact on our health through the way that it is organized. Most people spend the majority of their waking hours commuting to and from work or at work. Work, so fundamental to a positive social identity, wealth and well-being, has its darker and more costly side. Work can negatively impact on our health, an impact that goes well beyond the usual counts of injuries and exposures to toxic chemicals that we think of when we think of occupational health. The way work is organized -- its pace and intensity, the space it allows or doesn't for realizing a sense of self-efficacy and self-esteem, the level of control over the work product or process, the sense of justice or injustice, and job security or growth -- the nature of social relations at work, it turns out, can be as benign or toxic to the health of workers as the chemicals one breathes in the air.

Scientists refer to some of these characteristics of work as hazards of the psychological and social work environment to which employees are exposed.

Point two, workers are experiencing significant stress at work. The problem is so pervasive that 60 percent of all workers at all levels and all sectors experience significant stress at work according to NIOSH's 2002 annual survey of the U.S. working population.

Point three, there are major categories of psychosocial stressors that cause physical and psychological illnesses. A number of work stressors, including objective features of the job such as long work hours and shift work, and psychosocial exposures such as job strain, effort reward and balance and threat avoidant vigilant work have been identified as playing a role in the development of psychological distress such as burnout and depression, the tip of the iceberg vis-a-vis the occupational illness, and contributing to chronic physiological arousal leading to hypertension and cardiovascular disease.

Existing research on occupations, including the service sector with its almost 65 million working people, have demonstrated the important role of work organization in the etiology of hypertension and cardiovascular disease. In the U.S. alone, cardiovascular disease is the cause of 41 percent of all deaths. An estimated 300,000 people die annually of heart disease in the U.S. By the age of 60, 60 percent of workers will have developed hypertension.

Based on available research in this field, job strain -- work characterized by high demands and low control -- would appear to account for 25 percent of all morbidity and mortality for heart disease among working people after controlling for individual risk factors. Some occupational risk studies say that the total burden of work on cardiovascular disease is over 50 percent.

Point four, we need to know a lot more. Still not enough is known of the exact mechanisms by which psychosocial stressors contribute to disease, and even less on how to prevent them. No major intervention study to reduce psychosocial stressors and to assess that impact on cardiovascular disease has yet to be conducted in the United States.

Point five, there is an imbalance in control between employer and employed. The scientific evidence suggests a connecting thread by which work organization and psychosocial stressors impact on health. That is through the mechanism of control. All of the fore-mentioned risk factors capture some dimension of the uncontrollability of the work environment or of the job. Ultimately work stressors reflect an imbalance of power between employer and employee, an imbalance which is growing under the pressures of globalization and economic competition, manifested by longer work days, decreasing vacation time, intensification of labor, et cetera. Overwhelming evidence documents that social inequality, characterized by the unequal distribution of wealth and opportunity, is increasing in the U.S. It is reasonable to conclude that one of the mechanisms by which social class contributes to ill health is through the exposure of large segments of the society to stressful working conditions. Powerlessness at work, at home and in the community is our society's greatest public health problem. Ultimately the rectification of this problem will require both a better understanding of the mechanisms linking the work environment to physiological risk factors as well as political action.

Finally, healthy work is a possibility. It is possible to design work that promotes health and well-being. It is not demanding work per se that's harmful, but work without control over how one meets the job demands or uses one's skills. Tomorrow's jobs will be deliberately crafted to allow the full development of human spirit through work which encourages, not discourages, human potential. This means creating a work environment that is conducive to human mental and physical health. And a key characteristic of a health-liberating work environment will be the full participation of all working people in the decision-making processes surrounding the organization of work. Thank you.

Sorry, that was a little rushed.

Categorized comment or partial comment:

Verbal Comment 2006/02/21: Good morning, everyone. My name is Mauritz Jauregui and I'm also with the UC Irvine Center for Occupational and Environmental Health.

In my presentation today I'd like to make three main points, the first of which is that work stress is important, but we should be focusing on sources of work stress that reflect the current nature of work in the U.S.

The second is -- excuse me, I'm -- can you all hear me in the back? Yes? Okay.

My second point is that work stressors do not exist in isolation, so we should be examining both the cumulative and interaction effects of multiple work stressors and their outcomes.

My third point is that we should be collecting data not on what it costs to make our employees well once they become ill, but on what it costs to keep them healthy in the first place.

Work-related stress costs the U.S. more than \$200 to \$300 billion a year, and is implicated in 60 to 90 percent of medical problems. Traditionally research in work-related stressors have focused on the concept of job strain mentioned by Dr. Schnall, which is the combination of high job demands and low control, and effort reward and balance, which is a mis-match between the amount of perceived effort put -- on the job and the perceived long-term rewards such as respect, income, promotional prospects and job security. Also examined have been design of tasks and organizational factors such as shift work and long working hours. And known traditional stressors such as work/family conflict and discrimination have been less prevalent in research. But given that the service industry now accounts for 80 percent of the U.S. economic activity, and that over 64 percent of dual-income wage earners have children under the age of 18 at home, it becomes even more important to examine non-traditional stressors such as those that stem from direct interaction with clients as part of one's job that could lead to harassment and emotional labor, which is the process of regulating your emotions in order to present a professional image, as well as stressors such as conflict between work and family roles.

In addition to the cardiovascular disease described by Dr. Schnall, work stressors have been associated with physical outcomes such as musculoskeletal symptoms, cancer, gastrointestinal problems and impaired immune function. They've also been associated with psychological outcomes such as burnout, anxiety, depression and PTSD. If you have any doubts, just ask any emergency rescue worker.

In addition to these are behavioral outcomes, the most commonly studied being excessive alcohol use, smoking and low leisure time activity. Less commonly examined are sleep disturbances such as the ones mentioned by Deanna Stover, accidents, and most disturbingly, violent behavior. In the U.S. almost 1,000 workers each year are murdered on the job.

All of these outcomes vary by socioeconomic status, gender, age, occupational resources and psychological and social resources, and all these outcomes can interact with the work environment and with each other, but we still don't know how.

Now if we include outcomes in a broader sense, such as the financial consequences of these stressors, we realize that these stressors are affecting not just individuals but the economy as a whole. Back in 1999 NIOSH estimated that these associated costs were over \$200 billion annually if one took into account only absenteeism, tardiness and employee turnover. Sickness absence alone costs companies approximately 2.8 million workdays each year, which works out to about \$790 per worker per year.

Presenteeism is also an issue. There's the assumption that an employee who's not absent is being productive. This is not necessarily true. Employees may experience below-normal work quality or quantity while at work. It's been estimated that presenteeism costs the U.S. companies \$250 billion per year, or approximately \$2,000 per worker per year.

Workers compensation claims also cost money. Here in California workers compensation costs in 1993 were \$9 billion a year. Ten years later in 2002 the costs had risen to \$32 billion.

In summary, industry already knows -- already makes a significant investment in human capital, most of these associated with health. A significant percentage of them, such as long-term disability, sick leave, safety initiatives and absenteeism, are well known to companies. They already know what it costs to make employees well once they've become ill. So we should be asking what does it cost not to keep

employees healthy. Adding up the costs of work stressors requires more than just integrating data and risk factors and medical claims and disability. It also means measuring things that haven't been measured in the past, such as non-traditional work stressors and lost productivity.

I just want to thank you all, and I'd like to introduce Dr. Dean Baker.

Verbal Comment 2006/02/21: Hi, I'm Dean Baker from UC Irvine. I'm going to focus my remarks on some of the specifics of research areas, but I do want to comment generally that -- I want to congratulate NIOSH for the initiatives and -- both around NORA psychosocial factors and the collaboration with APA NIOSH in raising awareness of this issue, but I also want to say I think it's a dangerous kind of collaboration because it tends to emphasize the psychosocial part of it. And as Dr. Schnall pointed out, we fundamentally see the etiology of these problems in the way work is organized in the workplace, and specifically the lack of empowerment and lack of control of workers in the workplace. This is fundamental to virtually this whole area of understanding work organization and psychosocial factors.

I wanted to emphasize some of the things that were mentioned earlier. There's a lot of research that's been done in this area that has validated the associations with cardiovascular disease and hypertension, musculoskeletal disorders and other disorders. But much more research is needed. We looked on the NIOSH web site. There's about eight projects right now that receive some funding in this area. Clearly there could be a lot more research.

We also understand that some of the trends in the workplace in terms of increasing work hours, lean production, less job security, are all issues related to work organization and psychosocial factors. And we also understand the enormous problems that have been talked about earlier today in terms of health disparities. Really there are different kind of emphases in terms of the target population that come from this.

First of all, research needs to focus on multiple sectors. This is clearly a multi-sector problem. In fact, the research is enhanced by looking at multiple sectors 'cause if you look at one workplace, or even just one job, you end up constraining the range of factors that you're studying in terms of work organization.

But also there's been relatively little research -- some recently, but relatively little research on disadvantaged minority and immigrant populations. Those special populations definitely need to be looked at in terms of these issues.

And then the other thing that hasn't been mentioned as much this morning is the focus on small businesses. Much of the research have taken place in large businesses, unionized businesses, large corporations. And clearly the vast bulk of workers in the United States are working in small businesses.

In terms of the research areas, I wanted to just briefly mention three types of research strategies. One is increased research around surveillance of these problems, and surveillance can be both surveillance of workplaces in terms of the characterization of the psychosocial and work organization stressors, as well as looking for outcomes. So for example, surveillance of hypertension in the workplace -- earlier work by Dr. Schnall and others in New York -- found substantial numbers of workers have increased ambulatory blood pressure while at work, even though in the doctor's office they may not have high blood pressure. But the high blood pressure at work was the most predictive of whether people developed subsequent heart disease and problems, and that's being missed by not doing surveillance in the workplace. But there are logistical and technical issues about how you can do that in a cost-effective manner. There are obviously issues related to how do you do surveillance in terms of assessing the workplaces in the workplace, as well.

In terms of etiologic research, although there's been a lot found, there's a lot more that need to be looked at. Many of these factors we're looking at combined exposures, host -- if you will -- risk factors the disadvantaged populations and work organization looking at a lot of outcomes. These are complex issues, which is why it's so challenging for people to sort of understand the complexity of the issues. We don't have any studies in the United States that would be like the Whitehall study in England that basically followed large populations over time so they can look at -- and they found, for example, that job strain and effort reward were independent predictor factors of heart disease and hypertension, so you need large cohort studies that can handle the complexity of this. You need to refine your models.

And you need to address the other outcomes. We've heard about musculoskeletal, but there's research about the association of work organization with burnout, with immune incompetence mostly focusing

(sic) so far at antibody changes that lead to increased infections but possibly to inflammatory cytokines and risk of cancer as well as reproductive hazards.

And then finally I want to emphasize, because this is complex and because people have trouble getting -- understanding all the mechanisms, is the important focus on intervention research. And specifically one of the things that NIOSH has supported is intervention research on integrated work site health promotion. But it's interesting, people are integrating traditional work site promotion programs and individual health promotion programs, but ignoring the fundamental synergism that the job strain literature has shown a major cause of heart disease is workplace exposures. And we also know a large focus of the health promotion independently has been on heart disease risk factors, but these have not been put together in terms of integrated programs that focus on heart disease prevention by looking at work organization.

And a key aspect of all of these things, going back to my initial point, is participatory action and research which fundamentally is an empowering form of research. So you're not both -- you're both impacting on the workplace, per se, but doing it in a way that's consistent with the paradigm that addresses the fundamental causation of -- of the work stressor problems. Thank you.

Verbal Comment 2006/02/21: Hello, my name is Pam Tau Lee and I'm with the Labor Occupational Health Program at UC Berkeley, and I'm here to speak on future research needs to support a public health approach to workplace health and safety for service sector workers. I have over 20 years of work experience with hotel room attendants, and have recently assisted two recent landmark -- I consider landmark -- room attendant health studies in Las Vegas and San Francisco.

In the United States there are over a million -- a million employees employed in the hospitality industry, and the numbers are expected to increase as business will improve. And over the past two decades guest services in particular has increased. The twin beds -- some of you may not even know that there used to be twin beds -- in hotels have been now replaced by queen and luxury mattresses; simple bedding by triple sheeting, more pillows, duvets and heavy bedspreads; bathrooms and sleeping

quarters have more supplies, amenities and equipment. And in a nutshell, the workload for room attendants has increased.

But what has been the implications for room attendant health? On the two studies that I just talked about, conducted by UCSF researcher Dr. Nicholas Krause*, it was found that indeed the workload has increased. And because of that, 66 percent of the room attendants report that they are unable to take their needed rest and recovery breaks, that the health status for room attendants range from fair to poor, that 40 percent of room attendants have high blood pressure as compared to the national average of 25, that 78 percent experience work-related pain or discomfort, but only 20 percent of these room attendants filed formal reports. Only 46 of these room attendants took time off of work for injury and illness actually got well before returning to work. Eighty-three percent take pain medications within the last four weeks of this study, and vitality and energy was rated low at 36 points for Las Vegas room attendants compared to the national score of 61 out of a real nice score of 100.

Psychosocial indicators such as effort reward, job strain and job control may be significant indicators for injury. Dr. Lester Breslow* recently reported -- published an article titled "Health Measurement in the Third Era of Health", and in this article he makes the case that health be considered as a resource for everyday life. Given that 90 percent of Americans believe that their health is excellent or good, as opposed to fair or poor, it is reasonable that further research on workers focus on sectors such as room attendants, who currently do not enjoy good health, are working in pain, lack energy to perform everyday chores.

Our experience with room attendants is similar to many low-wage workers, such as janitors and health care workers. So future research focusing on identifying more workplace hazards and effective interventions can contribute greatly towards improving health for workers in the U.S., especially the most vulnerable such as immigrant workers. High injuries (sic) of injury and illness for those sectors have implications that go far beyond lost days and productivity. Workplace injury, illness and stress interfere with normal healthy family activity and community engagement.

In a developed country such as ours, we should have the resources to prevent these conditions from occurring. I have six recommendations for further future research.

The first is comprehensive ergonomic studies that utilize the best and the latest technology to measure ergonomic strain.

Number two, long-term studies that look at health indicators such as blood pressure, diabetes, musculoskeletal injuries and other conditions among service workers, and particularly room attendants.

Third, studies to measure psychosocial conditions, especially job strain, job control and effort reward, worker compensation and return to work. Vulnerable workers such as low-wage immigrant workers are less likely to file for workers compensation, and this is further complicated by the fact that there is no light duty available. And, as you've heard today, lack of access to health care.

Two more, intervention studies that measure the effectiveness of interventions, not only for traditional health and safety injuries and illness, but also workload, work organization and psychosocial health.

And finally, before my stop button, is community-based participatory research to incorporate those who are directly impacted in the research and in the activities, and research that focuses on findings that can contribute towards identification of effective interventions. Thank you.

Verbal Comment 2006/02/21: Good morning, and thank you for the opportunity to address the community regarding the National Occupational Research Agenda. My name is Miguel Lopez and I'm a representative of the International Brotherhood of Teamsters' Port Division.

The IBT represents more than 1.4 million workers in the United States of America, Canada and Puerto Rico. Our Port Division is comprised of approximately 5,500 drivers, stevedores, tugboat crews, warehouse workers, ferry crews, employees of port authorities and workers involved with ship building and repair.

There are at least 100,000 port intermodal container drivers in the United States. A vast majority of port drivers are, quote/unquote, independent contractors and are non-union workers. Most are poorly-compensated immigrants who barely scrape together enough money to purchase a truck. Despite being relegated to the bottom of the freight-moving transportation industry, these workers play a vital role. The international supply chain and U.S. economy depends on container drivers' ability to move goods from our ports to warehouses and railheads.

Port truckers' pay is mostly based on the number of round trips they complete. Therefore traffic congestion and inefficient port operations have a significant impact on their ability to earn a living by restricting the number of trips a trucker can make in a single day. They don't get paid for waiting time. They don't get paid for any time other than delivering the container.

The Teamsters have recognized for a long time the need to research and drastically improve health and safety conditions for intermodal container drivers. Port drivers unnecessarily suffer from preventable

work-related illness, injury, disability, and even death. Today I would like to bring attention to some of the most egregious dangers faced by intermodal container drivers.

Absences of lane markings, organized traffic control plans, and segregated loading areas create unsafe and crowded conditions. Port authorities benefit from such arrangements because it allows them to have flexibility in their operations. However, driver safety should not be sacrificed for the convenience of flexibility. Furthermore, operational environments that increase the risk of truck crashes and result in more crashes than necessary hurt operational efficiency.

Waiting in long lines presents numerous problems. Drivers are forced to wait without rest for hours before being released to transport a shipping container to a destination that may be several hundred miles away. As a result, hours of service rules are regularly violated. Also, truck lines often lack bathroom facilities and drinking water facilities.

Let me just add in the hours of service issue, particularly in the Los Angeles/Long Beach area since they've introduced a 24-hour clock, drivers are now exceeding those hours of service even more dangerously than before because they're only paid by the load. So therefore, in order to make more -- more work, they have to run longer hours. So let me forewarn all of you that drive any kind of vehicle on the highways of America, not only fatigue and sleeping disorders are a part of our problems now, but the hours of service that there's no enforcement on local drivers running in and out of the area are a great danger to the public, and the industry and the government are sitting on their hands in terms of this issue. This should be a very -- very important issue that's taken up by everybody, and I would just say to you all -- a little side note here -- stay away from any truck driver with a container that's driving on the highways. Put yourself one lane away from them, please. I have 35 years as a commercial driver, and I know what I'm talking about on that issue.

The length of time trucks must wait to retrieve their loads leads to hundreds of idling diesel engines emitting major air pollutants like nitrous oxide and particulate matter. This affects not only truck drivers but also citizens of adjacent communities. The health impacts from these pollutants include increased risk of cancer, premature death, asthma attacks, and work loss days. A 2003 study published by the Natural Resources Defense Committee declared port-related diesel particulates as the key pollution offender in many port cities.

At many ports drivers must remain in their trucks among stacks of containers while overhead lift cranes remove or load containers. If a container drops while above a truck, or bumps another container that is stacked, the results can be serious injury or death. While drivers sit in their trucks they have no way of knowing what is happening above them. Furthermore, truck cabs will surely crumple and the driver likely killed if a free-falling container struck it. A staging area like the ones for taxis should solve this problem.

In the past, longshore pinlock men with proper training and personal protective equipment locked and unlocked pins that hold containers onto the chassis in the area of heavy lifting equipment. Today, without training or safety equipment, container drivers are doing this work. The risk is high for them to lose fingers and hand or limb while reaching to lock or unlock chassis pins.

As a usual practice, intermodal container truck drivers clean out empty containers that have transported hazardous materials or toxic substances. In too many cases hazardous material residue remains in empty containers. Containers have no records of cleaning, and may or may not display hazmat placards indicating hazardous material was previously present. Drivers who clean empty containers lack the training and proper protective clothing and equipment to perform this type of work. Companies that own and lease containers should be required to contract with trained professionals to clean empty boxes.

A little side note, hazardous material endorsements on a commercial driver's license require an English test at the DMV, which most of the drivers who are Spanish-speakers do not understand those kind of tests, so most of the drivers do not have hazmat endorsements. Yet many companies run hazmat material without placards on containers.

The responsibility of moving chassis and containers for repairs at maintenance facilities has recently been shifted to the container drivers.

I'm going to skip on because I want to stay within the time limits. I have the rest, prepared comments. It's involving security and explosives and weapons, X-rays or gamma rays through new port terminal screening that they have at the ports. Let's see, the lack of hazmat certification, new regulations for unsafe chassis, and of course our latest campaign on overweight containers.

For those of you that don't know, the L.A./Long Beach ports handle upwards of 40 percent of the imports to our country. If you add Oakland, which is close to 20 percent, 60 percent of all import containers come through those three California ports. None of those containers are weighed as they come out of the terminals and go onto the highway. And most people who run those do not have the ability to ensure that they could safely figure out if there's -- there's a scale or weight regulation is -- is being upheld. So again, stay away from those containers.

We have a national campaign going with the Stop Highway Slaughter of truckers that roll-over on overweight containers. I'm going to put this as part of our statement, and I'm sorry I couldn't finish this. It's much too long.

Thank you for your time.

Verbal Comment 2006/02/21: Still good morning to you. My name is Norman Tuck -- not Tucker. I'm with the International Longshore and Warehouse Union, a 37-year member. Before that I worked in the shipyards in the Port of Los Angeles. It's nice to follow Miguel because Miguel and I go back some years in the same industry, in the ports, Teamsters, Longshoremen. Today we have an era where the truck drivers are not unionized. There is no ability just now to unionize them, and we all together do our best to help these workers when they're in the facilities.

I'll read a statement of the position of the ILWU, and before I do, I just spent -- with Miguel -- 13 months with past-Mayor Hahn*'s "No Net Increase" task force in the Ports of Los Angeles and Long Beach, trying to seek solutions to what we would do with ship movement, truck movement, and those pieces of equipment on the docks.

(Reading) These comments will reflect our historic and current position on this matter, as well as a synopsis on what we feel is -- needs to be done in the near, as well as the distant, future. We ask the National Institute of (sic) Occupational Safety and Health, NIOSH, give their full consideration when developing their National Occupational Research Agenda for the next ten years.

Historically longshore work on the docks consisted of many hazards, most of which have evolved over time. Years ago the work was so dangerous that it was not only common, but also an accepted fact, that longshore workers were either killed and/or maimed with alarming regularity. Work shifts that lasted 12 hours or more were common, adding to the already unsafe conditions that prevalent (sic). The work

was arduous, sweat-filled, backbreaking. There were very few safety provisions covering longshore workers. If someone was injured or even killed, they would simply be carted off and replaced with someone else to earn a day's wage, and these were the dark days.

And there used to be a time where it took -- when you had a ten-cent -- to get into a phone. That's what it took to replace a longshore worker. You're looking at someone here who, in my 37 years of working on the waterfront, I've had both my shoulders surgically repaired -- you know, the big scars -- my left -- right lower extremity crushed, five years away from the workforce, seven surgeries, plate, screws, pins. I have a plate in my hand and my finger, back injury, broken foot. I'm a mess. When I get up in the middle of the night to go to the restroom and/or when I get up in the morning to come -- place like this, I have a very difficult time moving. I worked till 3:00 o'clock this morning. I work the night shift. And we have been, for many, many years, a 24-hour port, both Long Beach and Los Angeles.

(Reading) With the advent of mechanization in the '60s it became readily apparent that the need existed for safety regulations to be instituted and implemented in the workplace and on the waterfront.

And I'll try to go on as quickly as I can and just pick up some of the highlights, and we'll submit this document.

(Reading) Over the next three decades the ILWU was successful in negotiating safety regulations with the PMA, the Pacific Maritime Association. These negotiations took place every three years.

And I'd like to point out that during contract negotiations in which I participated in 1996, in the other room we had a safety negotiation going on. There was a constant struggle and fight with the employer. Nothing has changed today that we did not see ten, 20, 30, 40, 50 years ago. It's the issue of labor/capital. Nothing much has changed. I am very pleased there are researchers today like yourselves and others who are trying to move forward in getting workers like myself and folks in the hotel industry a chance of beginning -- or be able to have a long life. I have four grandchildren and I'd like to, when I retire this August, like to have maybe 20 years to go fishing and enjoy things.

When we look at our biggest concern today, and I'll end by saying this, is the emissions from diesel ships, trucks and heavy equipment. Last night we're unloading steel. Around me is -- around me is forklift -- so you consider a small forklift. Our forklifts pick up anywhere from 15 to 30 tons at a lift. Okay? These things are spewing out diesel emissions. I'm from here to the wall from this truck, and this stuff is just falling on me. Nothing has changed, and it won't change until NIOSH and every other regulatory agency gets on the same bus and we make the federal government ante up and the state governments ante up and make it a point that we need to live longer and protect our interests.

Again, thank you very much for allowing me to come and speak. I could go on for ten or 20 minutes, but I won't. Thank you very much.

Verbal Comment 2006/02/21: Hello, thanks for having me. My name is Angelo Logan. I`m with East Yard Communities for Environmental Justice. East Yard Communities for Environmental Justice is a community-based environmental justice organization which believes in and works toward all people having the right to a safe and healthy environment where we work, live, learn and play.

Over the last five years our community has been working to reverse the negative impacts of goods movement industry, otherwise known as port-related industries. Our community in the southeast Los Angeles area is primarily a working class community of color, with a large amount of people employed in the movement of goods industry -- truck drivers, railroad workers, warehouse workers and port workers.

The Los Angeles Port complex is the largest in the nation and the third largest in the world, and continues to grow. As a port and the industry grows, so do the concerns regarding the safety and health effects associated with movement of goods through the ports and goods-movement corridors. Evidence exists that air pollutants emitted from port-related activities adversely affect people`s health and contribute significantly to regional air pollution problems. Pollution from ports and port-related industries cause an increase in regional smog, local toxic air contaminants, and the contamination of water sources. Together these increase cancer and other health risks for workers and other nearby community members.

To alleviate the severe impacts of air pollution it is important to invest in new technologies and make people aware of strategies to reduce or eliminate these pollutants -- our pollutant sources. It is crucial to promote studies on the -- on the occupational and environmental health effects of exposure to diesel and other air contaminants facing both workers and those who live in surrounding communities.

To do so, partnerships between researchers, community organizations and labor are critical. Partnerships with the affected groups will enhance the likelihood that research findings are reported back to the members of those affected groups, and will facilitate the participation of those groups in policy change to reduce air emissions.

We encourage the National Institute for Occupational Safety and Health to fund research that is developed and implemented by partnerships between researchers, community and labor organizations, to fund the dissemination of research findings to the people most affected, and to organizations representing them. In this way workplace, regulatory and legislative policy changes will occur, improving the health of workers and other community members. Thank you.

Categorized comment or partial comment:

Verbal Comment 2006/02/21: Good morning. My name is Jesse Marquez. I'm executive director of the Coalition for a Safe Environment. We are also an environmental justice community organization. We are headquartered and based in Wilmington. Wilmington is a community in the Port of Los Angeles, and we are the Los Angeles Harbor.

I live four blocks from the Port of L.A., about 15 blocks from the Port of Long Beach, about seven blocks from ConocoPhillips oil refinery, about ten blocks from Valero oil refinery, about 15 blocks from Shell oil refinery, about 12 blocks from the Alameda Corridor, about ten blocks from the Watson rail yard, and about 22 blocks from BP ARCO oil refinery.

The Port of L.A. is the number one stationary source of air pollution in southern California -- not the harbor, not L.A., not the south coast (unintelligible), but southern California. The Port of Long Beach is the second largest source of air pollution in southern California. And the oil refineries in my community are the third largest source of air pollution.

My point being is that not only are workers on the docks being impacted, but those workers' families and of those communities that border these industrial sites are also impacted by air pollution. We also have to recognize we're not talking about just air pollution. Air pollution pollutes water. It pollutes the oceans, our rivers, our lakes, our tidelands or wetlands. It falls on our houses and our cars and our yards, our parks and our schools. So it impacts all of us.

What I have learned over the past five years, so you know, is that five years ago I was not an environmental activist. My IQ in terms of all the environmental issues that I was facing was zero. But in four and a half years I can now read a 500, 600-page environmental impact report that was put out by a government agency who hired expert consultants, and I'll rip that document apart page by page, paragraph by paragraph, and line by line. I have read over 40 of these documents now, all by a government agency -- either a city, a port or whoever. And not a single one ever complied with the law. That's what I discovered. They are a lie. They misrepresent the facts. And they even leave out the facts. Not one have I ever read complied with CEQUA. Not one has ever complied with NEPA, the federal standard. That's what I have learned.

Right now there are no laws in the state of California that state that the port, or any refinery, must -- in five years, ten years, 15 years or 20 years -- reduce their pollution by 99 percent, 90 percent, 80 percent, 70 percent, 50 percent, 30 percent. There is no law today. There will be no law tomorrow. There will be no law five or ten years from now.

So what does that mean? Air pollution and environmental pollution will get worse. Workers will continue to get worse in their health. And all the neighboring communities will also face an increase in health problems. That's what we are facing.

How can NIOSH help us? We need you. But we need you to be doing the right things. We need you to be able to help us in the right ways. And here are some of those ways how you can help us.

First of all, we must be made aware of what dangers we are being exposed to. The south coast air quality (unintelligible) district released a study back in March of 2000 called the MATES II, which was their multiple toxins inventory. None of us in Wilmington, San Pedro or west Long Beach, or in the Harbor, were even aware of this study. And what did that study state? That Wilmington, San Pedro and west Long Beach were at the highest risk of cancer due to diesel fuel emissions. So that means all residents, all children, all senior citizens and all workers. We weren't even aware of the study. So it does no good for me and my community and to my three brothers that are longshoremen, to my niece and nephew that are longshoremen, to my cousin that's a longshoreman, and other union workers when we don't even know the information that's out there. So we need to know that information. We need to be partners in research studies.

I was called three weeks ago by an ARB worker at Sacramento saying they were going to do a little health study. We were told that we could possibly work together. I asked him to send me the survey that they were going to do. I got the survey e-mailed to me and the first thing I said was oh, my God, another amateur. This person had absolutely no survey background, no public health research background. And I e-mailed him back saying would you mind if I sent you some recommendations on your questions? And I literally re-wrote half of all the questions and gave him ten more questions to add to that survey to make it a worthwhile survey. And I volunteered to provide some of our people to help do the survey.

So there are community organizations like ours and others out there that'll work with you in defining what needs to be done and how to write and how to ask the right questions and how to make it a very successful survey and study so that that information will be useful for us, because we need that information and we need you to support us. Thank you.

Verbal Comment 2006/02/21: Good morning. My name`s Marianne Brown, and as a former director of the UCLA Labor Occupational Safety and Health, or LOSH, program, it`s really a pleasure to participate again in the NIOSH NORA priority-setting town hall meetings for -- as we go into the second decade of NORA`s existence.

In the time allotted this morning I will focus on the transportation and warehousing sector that is connected with the ports. This includes dock workers, railroad workers and truck drivers. Regionally this is a very important health and safety focus right now, as the previous speakers have attested to, because these two ports, the Los Angeles -- in Los Angeles County, the Los Angeles/San Pedro Port and the Long Beach Port, make up the largest seaport complex in the United States. Together now, depending on which resource you turn to, some call it the third largest port complex in the world, others say the fifth largest, but anyway, it`s extremely immense and it`s growing daily. The Los Angeles/San Pedro Port last year supported an estimated 259,000 jobs and \$8.4 billion in wages and taxes. Longshore workers at the ports, and other workers who transport cargo containers from the ports to their destinations, are exposed to air pollution in the form of particulates from diesel engines and other sources, which are associated with premature death, cancer, heart disease, asthma and other

respiratory illnesses. I have the references for those studies that are attached to my -- what I am submitting.

And now is a pivotal time for NIOSH to sponsor research which examines particularly two aspects of port and goods movement workers' health. One is health effects research and the other is intervention research.

With respect to health effects research, there's further need for studies on the health effects of air contaminants such as diesel fumes from ships and yard equipment on dock workers. There already is the research on railroad workers and truck workers.

With respect to intervention research, there is a need for a new kind, a new initiative for research in NIOSH, and that is on what types of policy changes are most effective in reaching and reducing worker exposures. As part of this there's a need for research on how research findings are used to effect policies aimed at reducing air contamination.

This is an important time for this research because these two Los Angeles County ports are the gateway for 40 percent of all goods imported into the United States today. That means that southern California workers are on the front line of exposures as they handle millions of cargo containers destined for other localities around the U.S. In fact, in today's Los Angeles Times, as many days in the last couple of months, there are articles related to the ports, and the title today is "Railroads Back on Track." After years of retrenchment, railroads across North America are reporting record profits and rolling forward with massive expansion projects of the kind that haven't been seen in decades. The change is most evident along the route from the Ports of Los Angeles and Long Beach to Chicago, the nation's busiest freight corridor for intermodal shipping traffic, the large steel cargo containers and truck trailers that can move by ship, rail or truck.

As the Mayor of Los Angeles said recently when describing this dilemma, we are at a very unique moment, a moment in which we can simultaneously deliver faster freight and cleaner air. It's a pivotal time because the ports and goods movement industry expand-- while they're expanding, there's a growing political will to set policy that will reduce the inevitable air pollution that will come with this expansion. The mayors in Los Angeles and Long Beach, and the Harbor Commissioners for both ports, are committed to greening the ports. In December both Commissions issued, for the first time in the history here, a joint memorandum of agreement to coordinate the greening effects. And just a few weeks ago the union which represents the west coast dock and warehouse workers, the International Longshore and Warehouse Union, AFL/CIO, a union with a strong history of safety advocacy, issued a call for stronger state, federal and international standards requiring cleaner technologies for polluting ships. And last year the California Air Resources Board approved regulations requiring ocean-going vessels and cargo-handling equipment to use cleaner-burning, low-sulfur fuels. At the beginning of this year the Governor of California proposed port and highway expansion projects which some public health advocates have criticized due to what they believe is a lack of appropriate protections in place to reduce air pollution from diesel-powered ships, trucks and trains.

Last year the California Air Resources Board concluded that air pollution generated by the state's cargo industry would result in 750 premature deaths in 2005, and generate tens of billions of dollars in related healthcare costs over the next 15 years.

In conclusion I would like to again stress the two areas that are in need of research are more health effects research, more research on the health effects of worker exposures to air contaminants in the port, trucking and rail material transport industries; and that these -- this kind of research should be conducted by university-based researchers in collaboration with labor groups, similar to the well established NIEHS-funded university/community research partnership grants program.

And with respect to intervention research, a new initiative by NIOSH could utilize public health professionals, economists -- as was mentioned earlier by Ms. Schreiber -- and other social scientists to study the impact of goods movement green policy changes on worker exposures to air contaminants. Let me emphasize again that as part of this initiative there's a need for studies on how research findings are used to effect policies aimed at reducing air contamination.

So I want to thank you for the opportunity to provide this testimony.

Verbal Comment 2006/02/21: Good morning. My name is Elisa Brown. I don't think I'm related to the previous speaker, but that would be okay.

I am an advanced practice nurse in mental health. I'm speaking on behalf of the American Nurses Association. I wish to thank NIOSH for the opportunity to give input into the research agenda, and also for the privilege of listening to the wisdom and recommendations made by the previous speakers today.

I'm going to cover six particular issues in relation to nursing and healthcare workers.

Safe patient handling, according to the Bureau of Labor Statistics, in a recent study nurses had over 8,000 reported work-related musculoskeletal disorders which resulted in an average of seven days away from work. This was the ninth-highest rated profession in this category of injuries. Research to prevent back and other musculoskeletal disorders needs to promote appropriate education and training in the use of assistive equipment and patient-handling devices, and in no-lift programs. Research needs to be done on reshaping federal and state ergonomic policies that would highlight ways to do safe patient handling, add techniques that would benefit patients and the nursing workforce, and in line with some of my previous speakers, to disseminate those results, not to keep it to themselves.

Worker fatigue, research shows that overtime and extended work shifts for nurses is associated with increasing risk of smoking, alcohol use, risk for back and neck injuries, vehicular accidents, and increased exposure to biological hazards. A recent Institute of Medicine study states that effects of fatigue include slowed reaction time, lapses of attention to detail, errors of omission, problems with problem-solving, reduced motivation and decreased energy successful to complete their work. More research is needed to evaluate overtime and extended work shifts and their relationship to productivity, quality and safety provided in hospitals, and the incidence of workplace accidents, injuries and stress-related illnesses among nurses and healthcare workers, and to look at the impact on the general health status of healthcare workers. Research needs to be done on reshaping federal and state policy that will limit the ability of employers to mandate overtime.

Bloodborne pathogens, exposure to these -- there are still many needle-sticks and sharps injuries, many more than should be occurring in light of the fact that we now have safe devices. What I'm finding is that what many of the institutions do is keep their old ones until they run out, even though they have ordered the new ones in, and so we need to do more work in looking at that. Research is needed on the human factors and work practices of nurses related to safe handling of sharp devices and compliance with policies to protect them from exposure. Further research is also needed on facility-wide policies to promote worker compliance with practices. And research should develop safety-engineered devices that are improved as needed.

Verbal Comment 2006/02/21: I`m Cindy Burt. I work at UCLA and I have some areas that I wanted to mention that were a little different than this morning. One area that I have seen problems cropping up across all the sectors that were talked about is the impact of care provision for mothers working in a lot of different industries. We`ve done work in the past in looking at the lifting injuries, manual materials handling which -- with mothers, but we`ve not really looked very much at the impact of the stress levels of having child care responsibilities on mothers working in jobs that require a lot of repetitive activity, like data entry and those kinds of things. And I`m seeing enormous amount of injuries in that area, and that would be a good area for future research.

To that same area -- I work with children as well, and I would really like to see is to do some studies to see how effective we'd be working with children at younger ages and teaching them basic ergonomic concepts so that they grow up knowing these things and not having to learn them when they enter the workforce.

A lot of people talked about workers and workers needing more assistance, needing more training, needing better-designed facilities. We are trying to work here with our designers and our architects, and the people who develop the environments where people work need to have a lot more training. We need to do research in finding out whether they know what they're doing and whether they really incorporate ergonomics -- concepts into the work that they do.

One last thing I'd like to mention is we -- we do a lot of training here at UCLA with our workers, and a lot of times it comes to nought because the supervisors are the missing link in terms of reinforcing concepts, understanding concepts, understanding how to manage people, how to deal with workers comp injury without making the worker feel like that he's a criminal. We have a real problem with people using our system, using it effectively and using it without fear.

Thanks.

California EMS Authority

Categorized comment or partial comment:

Verbal Comment 2006/02/21: Good afternoon. Good afternoon, I`m Cesar Aristeiguieta. I`m the director of the California EMS Authority. For those of you who may not know the lingo, EMS stands for Emergency Medical Services, and that`s the area of healthcare that encompasses everything before you get to the hospital, so the paramedics, the EMTs, private ambulance companies, fire departments and the like.

I`m here speaking on behalf of the National Association of EMS Officials at the request of the President, Bob Bass. I was appointed to my position back in August by Governor Schwarzenegger, and since that time I`ve had a significant concern for both patient safety as well as worker safety in our field. The two items that I`m going to be speaking of that I believe that require a significant amount of research in this area is the area of worker safety in and about an ambulance, as well as the issue of -- of personal protective equipment for those workers. And let me run you through a couple of scenarios.

Riding in an ambulance can be a hazardous environment, both for the person being transported as well as for the workers that are in it. This applies to both helicopter or an aircraft type ambulance as well as to the ground ambulance, and we`ve seen countless headlines over the past five years or so indicating what a problem this can be. Let me give you some examples.

Within ambulances there's poor restraint mechanisms. As you know, a patient lies flat in -- in a cot in an ambulance, but the ambulance is traveling in the same direction as the patient is lying, which means that if you get into a wreck, a front-end collision on the ambulance, the patient's body will continue traveling forward. Although some restraint systems have been designed to try to restrain the patient in that position, they're not being utilized and many of these restraint systems have not been tested in real crash situations.

In addition to the patient safety, the worker in the back of the ambulance is also at high risk in many cases. You can imagine a paramedic doing CPR in the back of an ambulance, starting an IV, trying to intubate a patient -- meaning putting a tube down their throat so they can breathe for them. All of these are unrestrained conditions, all of them critical situations which also mean that that ambulance is traveling with red lights and siren at excessive rates of speed and usually through traffic lights and the like. These are very hazardous situations for that occupant in the back of the ambulance, and if an accident occurs they're going to be propelled into the forward compartment of the ambulance, causing severe injuries.

As some research that has been done in the area also demonstrates, the helmets that the firefighters wear that operate ambulances are not effective at protecting the head in a motor vehicle collision, so significant research has to go into this area.

Weather plays a very important role in traffic safety, as well as helicopter safety operations, and the role of weather and optimal flying and driving conditions needs to be researched further.

Mechanical failures, whether it's to an aircraft or to an ambulance traveling 60 miles an hour on the freeway that blows a tire can significantly affect the performance of the ambulance and put the occupants at risk.

The back of an ambulance, as you can imagine, has a certain amount of shelves and equipment that is prepared to deliver care to a patient. In the event of a motor vehicle accident, all that equipment becomes projectiles that are pushed forward into the occupants of that ambulance.

Finally, ambulance technicians or EMTs and paramedics are continually being exposed to hazardous environments around them. With the fear of terrorist attack, we worry about chemical, biological, radiological or nuclear type of weapons, as well as the typical spills that may happen on the I-5 freeway where a paraquat truck overturns and now the paramedics are exposed to the chemical which can have just as severe reactions as a terrorist attack, but obviously on a smaller scale.

With all this in mind, we'd certainly like to propose that more research be done into the construction, design, safety features of ambulances. This is a largely unregulated area at this time, and largely because there is no research that shows what the best practices might be and how to better protect the occupants of the vehicle.

In addition to that, California has been the first state in the union to develop some basic standards for personal protective equipment for paramedics and EMTs, and we would like to provide that information to NIOSH and assist them in developing nationwide standards that perhaps can influence where the -- this particular business is headed to.

The last thing I would like to say is that this is not just a firefighter type of hazard. In California 73 percent of the fleet of ambulances in the state are run by private ambulance companies. So just because firefighters have breathing apparatuses and helmets and turnout coats doesn't mean that the

vast majority of the personnel that are responding to emergencies are protected, and we certainly need to look in the private sector also. Thank you very much.

Verbal Comment 2006/02/21: Hello, my name is Catherine Porter and I work for California Committee on Occupational Safety and Health, or Cal-COSH. Cal-COSH is a non-profit organization that advocates for safety and health within the low-wage worker community. We are a California State Bar-funded legal services support center, which means that we provide information, advocacy, technical assistance to legal aid organizations on occupational safety and health issues to those legal services programs in the state of California.

There are 77 legal services programs in California, and those programs represent, assist and advocate for low income and immigrant workers and non-workers. They provide assistance on a broad range of legal issues. Approximately 1.4 million Californians work at or near minimum wage, and the majority of those are full-time workers. In California the minimum wage is \$6.75, which over a year -- if you do the math, working 40 hours a week -- brings in a grand total of \$14,000.40. So you can see that there are a lot of workers that legal services programs assist. And unfortunately there are a lot of workers work at poverty or below level.

Legal services programs generally have financial eligibility requirements at one to two times the poverty level, and so again, this is what I was saying about their constituency is a very low income to poverty level clientele, including workers who are working full-time. The low-wage workers in California served at legal aid centers come from a wide range of industries including garment, janitorial, domestic, bakery, child care, restaurant, hotel, dry cleaning, construction and retail and carwash. And you heard some testimony or input about some of those industries including household domestic or hotel workers.

Wage and hour issues take predominance at legal services programs, such as unpaid wages, non-payment of overtime or minimum wage, mis-classification of employees as independent contractors, failure to provide meal or rest breaks -- and that's just to name a few. And these in turn can impact greatly worker health and safety.

Many low-wage workers are exposed to a range of safety and health hazards including chemical hazards, violence in the workplace and economics issues. And yet many of those occupations or subsets of occupations are either inadequately protected or not protected at all by occupational and safety health laws or by workers compensation in the state of California.

Today I'd like to focus on what I'm referring to as four cleaning occupations in the state of California, and they are, again, a predominantly low-wage workforce, and that includes janitors, maids -- either working at hotels or working at private homes, dry cleaning workers and carwash workers. And these workers, not even counting the carwash workers because I couldn't find any statistics in regard to them, number approximately 332,000 in California. And that's one-quarter of the low-wage workers in California. And whoever is from Los Angeles, you probably are aware that -- of how many car washes there are in Los Angeles, and similarly in the urban areas of the Bay area, probably down in San Diego. So that's a huge sector of population also.

Some of the work conditions that those sectors are exposed to include -- for instance, with janitors -- chemical exposures from cleaning and waxing products, from dust; ergonomic issues such as bending, stretching, stooping and kneeling; and they're often working at night and working alone.

Maids and housekeeping cleaners, including those at hospitals and lodgings and at private residences, similarly have chemical exposures, ergonomic issues, insufficient protective equipment. Their wages are usually from the mid-\$7.50 to \$10.50, averaging about \$9.47. And the wages of janitors are pretty comparable, maybe slightly higher, especially if they're part of a union.

Oh, 30 seconds -- carwash workers and dry cleaner workers are also exposed to a wide range of chemicals and ergonomic issues. So obviously I didn't time this before I came here today and I should have.

So the research areas that we are asking for are in areas to bolster policy -- policy goals, which include improving wage and hour laws to -- by there -- therefore improving health and safety on the job, and to also impact and improve policy around setting workplace chemical exposure levels.

So -- just 15 seconds more. So we'd like research to be done on the chemicals to which these workers are exposed, the health effects of those chemicals, the real costs of those exposures due to chronic illness including lost wages, education and rehabilitation, hospitalization and other medical costs. And also the same sort of research and compilation of information in regard to other health and safety hazards.

We`d also like information on how violation of workplace wage and hour laws impacts health and safety and -- well, thank you.

Verbal Comment 2006/02/21: My name is Denise Peters and I'm with Mr. Clean Maintenance Systems, and I didn't actually plan to speak today. But I would like to say that I agree with most of the things that you just said. Those are all issues that we have with our janitors, as well.

It is a tough situation to be in, employing janitors, because they are in a low-wage position and they are spread out. They don't usually all work together in one place -- at least not in our circumstance -- and it's very difficult many times to be able to communicate well with them on the issues of health and safety. So I think, as a corporation, while we're trying to really promote health and safety in our workplace, we are finding that there are issues that we're struggling with in workers taking personal responsibility for their own health and safety, and that is an area that we would certainly like to see some research done in.

Additional issues that we see that definitely affect health and safety in our workplace are the underground economy and the competition with that, how it limits our dollars to be able to help our employees or our workers. Because of the underground economy we have pressure with being able to compete and get enough dollars to include a healthcare package for our people, which is something that we'd like to be able to do. However, if that's something that we could look at as far as research, how can -- improving that situation, how that can improve workers' general healthcare and safety would be a real good thing for us. Thank you.

Verbal Comment 2006/02/21: Good afternoon. I want to thank NIOSH for inviting me back. I was one of those 500 correspondents that they used in 1996, and I have four basic recommendations that I want to bring to NIOSH on the education sector. I am the director of health and safety for the American Federation of Teachers.

Before I make those four recommendations, I just want to preface my remarks with a few observations. Interestingly enough, NIOSH has been in more schools in this country than any other federal agency. They have responded to requests for HHEs and I'm very -- very, you know, heartened that NIOSH chose to go in and look at primarily indoor air quality issues in schools.

The second observation I want to make is that a school is children's workplace, and you know, believe it or not, children do not have any statutory right to a health and safety school given by anybody -- locally, federally or anything. And I would really like to see NIOSH be given a broadened mandate so that when they do go into schools they can look at the impact of conditions on children, as well.

And last but not least, I want to really say that schools are very complex industries. They're more than teachers. I really -- I think people generally just think that teachers are a synonym for schools, but there are all kinds of work -- workers there, all kinds of activities. And schools are becoming the most densely populated institution, aside from maybe prisons and jails, in our society. And in case you didn't know it, the schools are undergoing a historic growth that's not supposed to plateau until 2009, and maybe beyond. They're extremely crowded, and I don't know if any of you have kids -- anybody have kids in schools? You've been in the hallways when they're changing classes or in the cafeteria? The noise is incredible.

Anyway, here are my four recommendations.

First of all, I think that education needs to be considered its own sector. It's somewhat like how NIOSH and health and safety people looked at healthcare back in the '70s. They sort of made all these

assumptions about hospitals and healthcare facilities being safe. And lo and behold, they began to understand that`s not the case. We don`t really have any data or any surveillance that`s useful.

BLS has very incomplete data on the education sector, so we need a way of doing surveillance for this sector that's meaningful. A lot of work-related conditions never get reported -- like voice disorders, bladder infections, asthma -- which is really on the rise among many workers.

Categorized comment or partial comment:

Number two -- maybe in -- by 2016 we'll have them as their own subsector. Anyway, we really need partnerships. NIOSH is such a tiny force for good in doing research in health and safety, but they aren't the big money-bags. And if we're looking at education, we need to really recruit a lot of partners, like insurance companies for instance, who are paying for the healthcare of these people for work-related illnesses. We need people like, for instance, infectious disease people to come and partner with NIOSH. NIOSH can really, for instance, characterize exposures better than any other agency, probably, in the -- in the federal government. And infectious disease people don't know this, but they really do need NIOSH to tell them about how these agents are transmitted in the workplace.

Number three, we need partnerships -- oh, excuse me, we need intervention and demonstration projects. And again I'll look at the whole communicable disease issue as an example. We know from some little titillating research that many pathogens like rhinoviruses can be found in ventilation systems. We don't have a clue what the ventilation rate should be in a very highly dense population like a school to really protect everybody, the students and the staff. So we need the building scientists working with NIOSH and everybody else and doing this.

And then fourth, I would say that we need to have some policy research that shows how effective regulatory and other policies are at really protecting people. It really surprises me that we have not looked at the hero* law and other laws to see if they have been effective at protecting workers -- also OSHA regulations.

One last thing is that I will be submitting a review article which will give me -- give NIOSH my entire laundry list of all the hazards found in the education sector, and I look forward to working with the agency. Our organization will be happy to cooperate in any way we can to help NIOSH pursue research in education.

Verbal Comment 2006/02/21: Good afternoon, everybody. My name is Rosa Balan. I work at the Westin layers (sic). I've been working there for 30 years. I work at night. I am a housekeeper there. I also take care of other duties, as well. I pick up the linen. I pick up the trash of ten floors. Not only that, I clean meeting rooms, 31 of them. After that I go to the offices, pick up the trash there. Once I'm done, I clean the housekeeping department. But now I am disabled.

The work there is very hard. The beds and mattresses are very, very heavy. Mattresses are about 35 to 40 pounds in weight. I have to lift them with one hand at times.

Right now I'm in a very difficult situation. I'm waiting to be -- to have four surgeries. The money I'm being compensated with is not enough for anything. It's only enough for rent.

I got injured on June 17th trying to lift a 75 to 80-pound bag. On July 4th I had a miscarriage. That was a big hope of mine, to have my baby. I lost him. I lost my job. I am not working right now. I don't have money, I don't have anything to offer my children. It is very difficult as a parent when -- when your children come to you and ask you to take them somewhere, and not be able to provide them with that.

I'm on very heavy, strong medication. I'm on morphine, pain killers, very strong pain killers. We are not safe at work. Sometimes we don't have enough cleaning products. We use dishwashing products. Most of the female workers at my workplace are ill. They are injured or disabled, but they're unable to speak up because they are afraid to lose their jobs.

Thank you. We are here because we need your help, and we want your help. We need your support. Thank you very much.

Verbal Comment 2006/02/21: Good afternoon. I'm Shane Que Hee, professor of environmental health sciences in the UCLA School of Public Health. I'm also a member of the UCLA Center for Occupational and Environmental Health. I'm also a member of the NIOSH Education and Research Center of Southern California. I also served a term on the NIOSH Board of Scientific Counselors from 2001 to 2004. On behalf of the Southern California ERC, we thank NIOSH for their past and present support in training industrial and environmental hygienists so as to achieve health and safety in the workplace.

We graduate about five to six masters -- professional masters -- professionals per year, plus a doctorate about every three years. We like to think of ourselves as a leader in the industrial and environmental hygiene profession nationwide, and also here in southern California, hence our contribution to the current NIOSH town hall.

Most of our students come from southern California, but we also do needs assessments so that we can know how to serve southern California better. Many of our graduates also stay in southern California. We want to be part of any solution to problems in our southern California community, and not be part of a problem. This is another reason for why we are here.

We know that NIOSH funding and support is an essential part to the existence of the ERC. We want the U.S. government to continue supporting NIOSH's efforts to produce leaders in the industrial and environmental hygiene community. I would like to see NIOSH's efforts to be expanded even more than current in southern California.

Why is such a NIOSH presence needed in southern California?

Well, there are over 15 million people here, with many diverse industries and workplaces, an ideal laboratory for research and training. There are many hazards -- chemical, physical, psychosocial, ergonomic and biological -- that need research and monitoring. There are many diverse communities

that require specialized help. There are many sweatshop conditions where health and safety are secondary, and even tertiary. We, as an ERC, have only scratched the surface of these problems.

In fact, NIOSH should really think of establishing a research center here to complement that in Spokane, which is the only NIOSH center west of the Mississippi. Such a center could then make more systematic investigations of health and safety in California than currently done by us, who are all dependent on research grants which are becoming increasingly hard to come by. Our ERC would benefit also by the proximity of such a center.

I welcome and encourage NIOSH to be less focused on locations east of the Mississippi for their specialist research centers, and to address community health and safety problems as a major focus in the National Occupational Research Agenda.

With regard to the latter, the 8-sector approach has one problem. There needs to be an integrated approach to all simultaneously rather than a piecemeal approach at the current NIOSH centers and ERCs. The best way to tackle these research sectors is to base centers and ERCs in areas where all sectors are present and where the interactions amongst the various sectors can be investigated since the whole is often greater than the parts.

Southern California has all of these sectors, and Los Angeles or its environs would make a wonderful base and center for a NORA multi- and inter-sector research center. Thank you.

Verbal Comment 2006/02/21: Good afternoon. My name is Bill Meyer. I've been in (unintelligible) Piping Trades, Plumbers and Steamfitters Local 393 for the last 25 years. Also I've served as a authorized OSHA instructor for Cal and Fed OSHA at our pipe trades training center in San Jose, and at this point I'm about closing out my first year in office as a business manager of the Plumbers and Steamfitters Local.

In the 25 years I've been in the trade I've been routinely subjected to unregulated exposures of regulated hazardous substances, items such as silica dust, which a fellow brother brought up earlier this morning, noting that when he went in after having lung damage, he was unaware -- at least the doctors told him they were unaware of the hazards of silica dust. Yet in my possession at home from 1935 I have a video done by the U.S. Department of Labor -- in fact, Ms. Perkins, who the Department of Labor building is named after, is in this videotape. And it was very profound, having worked in the field for 25 years and then all of a sudden becoming aware of these 71-year-old issues as we speak to date. And just myself out in the field working a year ago battling these issues, working at a brand new hospital facility in Santa Clara, California, we are breathing silica dust like a vacuum should be sucking it in. However, sadly it's our lungs instead of a HEPA filter.

Weld fumes, PVC glues and primers -- I'm up in silicon valley so we're dealing with intel, HPs, we're dealing all the semi-conductor facilities, on top of the hazards we encounter in that environment, as well as biotech facilities. But all it really takes is a concrete building to generate these hazards. And it was extremely profound when I realized that crystalline silica dust is listed as the same degree of hazard as asbestos (unintelligible) International Agency for Research on Cancer.

As a (unintelligible) instructor of both federal and Cal-OSHA training courses, I have become thoroughly aware of the laws and regulations governing workplace health hazard exposures, as well as the medical studies which reveal that we're losing an estimated 28 human lives each and every day in California just to totally preventable disease. We lose over 60,000 per year in the U.S. from occupational disease. And having become aware of California Labor Code, as well as Cal-OSHA regulations in my period of time teaching, as well as being subjected to them on a daily basis out in the field, I did move at one point to have Cal-OSHA enforce some laws for me, only to have received a very thoroughly unproductive response, including words such as "do nothing, blow the guy off." The reason I bring that up to you was not because I want any kind of profound response from that, but we are dealing with a systemic problem per my observations of being in the field for 25 years, also teaching on the subject matter.

On first, second and third blush, how do you do this job correctly? I mean how do you actually ask employers to do this job in a proper manner where it's going to cost dollars? And per NORA's own graph on the web site, you have the -- indicating the \$171 billion burden that's estimated to be on our society a year from injury and illness, and of course they compare that on this graph with the monetary burden of AIDS, Alzheimer's and circulatory disease whereby the graph equates to the cost of injury and illness on American workforce is five times greater than AIDS, more costly than heart disease and equal to the cost of all cancer on our society.

And with that, what I ask and what I would hope that we can do in the research mode is not only do the wonderful job we're doing to research the hazards, but to try to come up with the means and a mechanism that we can actually allow our enforcement communities to move forward and do this job where, per my observations, we're spending ten times more to do this job incorrectly rather than correctly. So what I do, once again -- in our -- in our environment in Santa Clara County we have adopted many ordinances dealing with biotech and semi-conductor, and one of them was how to pipe the arsine* and phosphine, all these hazardous gases that we used to just put together in the '80s with compression fittings, pretty much a mechanical fitting. We moved over to welded systems, double-contained systems. We've really raised the bar in that area. However, I can tell you the one spot that we need serious assistance with is how to enforce and how to implement the regulations and laws 'cause in my eight years of teaching I've learned most all the laws and regulations are already on the books. It's just we have this severe disconnect, especially when it comes down to the chronic, long-term disabling diseases. Thank you very much.

Verbal Comment 2006/02/21: Hi, good afternoon. My name is Maribel Barrenechea. I'm going to try to speak in English. If I find I can't, I'm going to request the interpreter help.

I'm a housekeeper from the Westin Bonaventure in downtown Los Angeles. I'm a single mother. I have two daughters. And I was being worker for nine years in there and the thing I can tell you right now is about a problem we have is a national problem we have and this problem is through the union for hotel and restaurants or hotels, and this (unintelligible) it was already implemented in Las Vegas and in other cities and these programs are some -- they put -- they measured out their population of the housekeeper and they -- they know how this operation went there. They are working with (unintelligible) to be -- when they are resting, when they are working and how effect -- and their help and their -- with their family in general. And that program is to help us to how to avoid injuries in work, and these problems -- it was (unintelligible) I talk to you it's international -- it's national. It was in Toronto, Hawaii and Las Vegas and other cities, and we were working -- like we did our program where we put a big (unintelligible), and a lot of ladies, they -- they put a sticker where otherwise they hurt, and a lot of ladies -- we notice a lot of ladies that are already hurt and they don't report because they're afraid to -- to lost their job, and that's the (unintelligible). And we notice a lot of ladies, they don't take their breaks -- their breaks, even their lunch sometimes. They (unintelligible) go to clock in and clock out, but they don't take their lunch. We're trying to -- to tell them why it's so important to take their lunch and their breaks. And I know a lot of ladies, they are hurt and like they're still working, and they're afraid of how -- to tell the managers or supervisor they're already hurt because when I talked to

some of them they say, you know, because I don't have another income. If I (unintelligible) I don't have enough money to -- to pay my necessary -- something I need for my kids or myself.

I'm sorry, I'm a little bit nervous in here. And where I notice in -- for -- for these people or the owners of the hotel and restaurant like are really -- they don't -- they don't like to know when other people that are hurt, and they have a lot of pressure on -- the coworkers, they have a lot of pressure to do their job. Like example, we have eight hour to do our shift, you know, but we have our 30 minutes -- our lunch and like ten minutes in the morning for a break and ten minutes in the afternoon, and totally we have like seven hours to do our work. It's like 14 to 15 rooms. In total we have like 15 to 20 minutes to do a room. And like if you notice, everyone in here, we have our beds at home, you know, and how -- how long would take to do a bed, you know. And like we have to do -- like some of the ladies, they have to do more than 20 beds, like 30 beds, you know, and they have -- be rushed because 20 to 15 minutes to do a room is like it's not enough time. And we have -- like -- like they call to them -- checklist, and we have like 100 points in there, and like every point -- like if they found a hair in the bathtub, like they take away five points, so you know, it's a lot of pressure for that. And I know a lot of ladies like they can -- they can finish their work because really they have a lot of -- lot of pressure for other coworkers, and I don't think like that's fair to the other coworkers to be working like that when they're -- they're really hurt and -- sorry, I'm very nervous, but I hope they understand what I want to talk to you. Okay.

Verbal Comment 2006/02/21: Hi, good afternoon. I'm Jessica Barcellona, health and safety project coordinator with SEIU, United Healthcare Workers West and the Joint Employer Education Fund. SEIU, United Healthcare Workers West, represents 135,000 healthcare workers throughout the state of California. We're part of the Service Employees International Union, which represents 1.8 million healthcare workers, building service workers and public sector workers nationally.

I'm grateful for the opportunity to speak today and thank NIOSH for planning these town hall meetings throughout the country. Overall, healthcare workers suffer a higher absolute number of injuries and illnesses than workers in any other industry sector. This sector has been growing larger every year, increasing the chances for more workers to be injured.

The rates for injuries in nursing homes are substantially higher than those in hospitals. Other healthcare workers, such as home care, social assistance and mental health, venture into the community to provide care, increasing their risk for injury and illness. Many workers in the healthcare industry are considered vulnerable workers as they are women, people of color, immigrants. They work in entry level positions, are non-English-speaking or suffer from illiteracy.

NIOSH must be commended for its work on recognizing and addressing hazards facing healthcare workers. More attention has been paid to health and safety issues such as latex allergies, needle stick injuries and hazardous drugs due to NIOSH's research and alerts. However, there are still many occupational health hazards facing healthcare workers which need more consideration from NIOSH. These hazards include controlling glutaraldehyde and other carcinogenic chemical exposures, reducing anesthetic gas exposures, implementing workplace violence controls in healthcare and mental health settings, repetitive strain injuries and musculoskeletal disorders, and the impact of short-staffing on healthcare workers.

Unfortunately I do not have the time to elaborate on all of these issues, so I'll focus on the last two I just mentioned.

Repetitive strain injuries are perhaps the biggest unaddressed hazard facing healthcare workers. Neck, back and shoulder injuries are among -- among healthcare workers are most commonly caused by the dangerous practice of manual patient lifting and transferring. On average, nurses are getting older, while patients are getting heavier, and this is a recipe for disaster.

About 12 percent of nurses who have left the profession report the main reason they've left being they have suffered one or more of these preventable repetitive stress injuries. While at least one NIOSH-funded study has focused on the use of mechanical lifting and transfer devices, the need for more research is clear.

In addition, a large number of healthcare workers who do not provide patient care also suffer from work-related musculoskeletal disorders. Hospital and nursing home employees in the dietary, housekeeping and clerical departments, or home care workers who cook and clean for their client in their homes, are required to push heavy carts, work in awkward positions, or sit for long periods of time. And workers who do patient care are also expected to complete other tasks such as maintain charts or distribute medication. The emergence of mobile work stations have created a new potential for ergonomic injuries in healthcare.

The other issue that is most important when we talk with our healthcare workers, members of our union, they identify short-staffing and stress as a high priority in health and safety. Short-staffing has become the norm within most healthcare institutions. Many healthcare workers are feeling the stress and strain that comes along with it. Due to short-staffing, stress and fatigue increase, therefore raising the potential for injury and illness for workers. Also the quality of patient care may suffer as a result of healthcare worker stress and strain.

Stress may manifest itself in psychological symptoms which can be hard to diagnose as work-related. Also many stress-related physical symptoms -- such as headaches, gastrointestinal problems, sore muscles, high blood pressure -- are often attributed to personal health problems as opposed to work-related stress.

We urge NIOSH to focus more research on short-staffing, stress and other related psychosocial issues, as well as ergonomic hazards in the healthcare industry. Thank you.

Verbal Comment 2006/02/21: Hello, my name is Richard Gorham. I used to be a state employee but I retired early to go to work for United Professionals. Some of our members include psychologists, social workers, dieticians, individual program coordinators, recreation therapists, physical and occupational therapists, audiologists, chaplains, rehab counselors, pharmacists and licensing program analysts.

The basic problem with the state of California is understaffing. All occupations are covering at least one-third of a vacant position. This adds stress to everyone. The psychiatric technicians, level of care, they're an endangered species. The state's way of addressing that is to hire a PT assistant. This is a certified nurses's assistant. It's like ten weeks of training. And they also have student assistants.

Who picks up the slack from all this work? The psychiatric technician. That's the person that actually delivers the level of care work.

Hiring process, if they are advertising, takes up to six months to hire someone. They have to do a background check which includes a credit report and a physical. And by the time they are called, they either starve to death or have found another job, and you're back to square one trying to hire them.

They had a program in the '90s, it was called Salary Savings. It was -- upper and middle-management were getting a salary bonus for every salary that they saved, every position that they kept open. I cannot find from anybody -- I don't get a straight answer when I ask is that in effect now. It has every earmark of that.

They also ha-- we also suffer from contracting out psychologists, social workers, pharmacists, rehab counselors. We've been in negotiations with the State of California and they've agreed to stop, but they don't seem to be complying.

We are underpaid. Our basic salary is augmented by a recruitment and retention bonus, which is not included in our peers' retirement. Psychiatric technicians that -- it's not even an A.S. degree -- make more than the individual program coordinators, dieticians and recreational therapists. They -- everyone in our union has at least one, if not multiple degrees.

Overtime, we're salary so we get no overtime. I worked ten hour days four days a week. Just because there was so much work, I was required to come in from one to four days every month just to try to keep up with the workload. My case load stayed the same, but the work just -- it's phenomenal. It costs me \$6 in gas just to go back and work -- forth to work, so -- and I'm not earning any money while I'm doing that.

We have some outside influences. The federal, state licensing, Department of Justice and the courts, they keep raising the bar. More rights for the clients, more activities, more services, even though they're aware that they cannot deliver these services. This creates a neglectful atmosphere.

Borderline hostile work environment, ever-increasing workload, pressure to keep up, unresponsive management and their inability to change direction. Injuries have skyrocketed, both for the clients and staff, both from workplace violence. We represent people that work in department of corrections, developmental centers and mental health facilities. Every single one of those is understaffed.

I've got a pharmacist at Etascadero. He just was involved in an altercation. He ended up with three broken ribs. But we also have communicable diseases, methicillin-resistant staphylococci and vancomycin-resistant enterococci. These are two very bad pathogens. The treatment for that is -- is treating them with two different top of the line antibiotics, and they're not always successful. We also have people that have hepatitis.

My recommendations, bring outside influences back into reality. Keep positions filled by speeding up hiring and provide incentives for hiring. And our highest priority for the upcoming negotiations would be increased pay, to that of the private sector, and include recruitment and retention in the base pay. Thank you.

Verbal Comment 2006/02/21: Good afternoon. My name is Sheryl Moore and I represent the City of Los Angeles, as well as Cal-COSH. I am a -- on the advisory board. For the City of Los Angeles we're talking about over 5,000 clerical and support services members, which includes your 911 operators, a lot of your support staff when -- which you go to the counter and wish to get information from.

In the City of Los Angeles over a year ago we -- AFSCME Local 3090 put on the table for the City of Los Angeles to -- to sit down and look at injuries within our workers. Those injuries has skyrocketed as far as workers comp claims in the City of Los Angeles, so we took it upon ourselves to put some language down and then we started a program, with the assistance of UCLA, in order to look at injuries within the City of Los Angeles. Now what I found astonishing was the fact that we had surveys done -- each time we did a class or an awareness class, we had surveys done. Now I'm going to just throw these numbers out at you. Out of -- based of 741 surveys, because we have a female-dominated class, we had over 594 women who responded to the survey and only 146 males. What I thought was -- and then the average age is 43, so you're talking about an aging workforce in the City of Los Angeles.

We heard a lot about what's going on in the private sector. Well, there is just as many injuries going on in the public sector, if not more. And the thing about it is, these people are not reporting these injuries simply because they have a mechanism to do it but they won't do it. And you know why? There is a fear factor in the public sector, just like it is in the private sector.

Just to throw out a couple of numbers, 69 percent or 80 percent of the people that work in the City of Los Angeles uses -- uses a computer, and 80 percent of them are injured on the job. Yes, if you get

injured you're supposed to fill out a form. You have to wait 90 days in order for it to be approved. But people are working hurt in the City of Los Angeles.

One of the things that I also found astonishing was there's a lot of neck -- we asked them if -- if they're experiencing discomfort with their neck within the last 70 -- seven days; 63 percent out of the 741 said yes, they are experiencing the basic neck, shoulders, upper back pain. Large numbers of people are experiencing pain, but they are not reporting it. Not reporting it.

One of the things that I found just -- just -- just threw me off the loop through these -- the survey was 70 perc-- 70 peop-- 70 percent people answered "no" to missing works -- missing work at their job. They will come to work hurt. Only 22 percent said they missed working days and not come to work. Now that -- that's -- that's ridiculous. Why are people coming to work hurt?

Another thing is 73 percent said no, they don't file workers comp claims. Well, there's no incentive to file a workers comp claim. Why should you? Because if you do, it's not going to do any good, in the first place. You still have to work on that job and complete that task before anybody will even take a look at you, and that's including the City's doctor, as well as your own.

The other thing that I found quite astonishing was -- and you would think the City of Los Angeles with its bureaucracy would -- would promote good health and safety among its workers simply because they depend on workers in order to make a difference in the City of Los Angeles. Well, 74 percent said no, they don't receive any ergonomic training in the City. If UCLA, City of Los Angeles as well has asked me, didn't put on the table and say hey, you need to do something about the workers that's coming on in here, they wouldn't have done anything.

What I found that the research needs to be done, and I'm just asking, is education. There should not be any fear factor with anyone reporting their injuries. Also on-the-job training, ongoing training that includes peer health advisors, people within the establishment get additional training in order to help one another, because I'll go to a coworker before I'll go to management. The psychosocial behavior that's -- and that's reducing the fear of on-job -- reducing the fear of on-job injuries, so that way these injuries can be reported. And then also looking at follow-up. We need follow-up. You need management as well as City workers in order to look at the bigger picture. What is it going to take for us to reduce these injuries as a group, you see, and not just put it all on the workers. These are some of the areas that I feel that is -- that needs to be researched more often and in place. We are trying to do it, but it's going to take a lot more help and also cooperation on all ends. Thank you for your time.

Verbal Comment 2006/02/21: My name is Fred Drennan. I'm a safety consultant and I've consulted for large corporations such as Exxon, 3M and to small mom-and-pop organizations around the United States. And I've -- also have been the task force leader for the American Society of Safety Engineers for the last year and a half. We have 30,000 members across the United States and our initiative is to help NIOSH with the steps to a healthier U.S. workforce. And some of the issues that the previous speaker presented is that while these problems that we have is the health of the worker, the aging worker, and how are we going to be melding safety and health issues because they really are one and the same picture. And so that's been my -- my focus for the last year and a half, speaking with John Howard and Greg Wagner and also Paul Scholte* in New Orleans just before the hurricane hit. And so -- but my presentation today is to really to talk to you about my position as a safety consultant and the other speakers here that are responsible to implement safety programs and to promote safety within their organizations, and that's the perspective I want to give you today.

And the first one is is that NIOSH, from my perspective, has been focused on what I call the hard sciences -- respiratory protection, the chemical exposure, dermatitis, things like that. I want to -- I'd like to see NIOSH focus on what I call the soft sciences. And for the last 20 years in the field of safety one of the dominant management systems has been what we call behavior-based safety. And that philosophy says that 96 percent of all accidents in the workplace are caused by workers' unsafe acts. And so this -- this program is being promoted by other consultants such as myself and these programs cost millions of dollars and a lot of the major corporations across the United States have had less than stellar results from these. And so it's almost a consumer protection program is how do we -- companies -- individuals, the people like myself that are there to help small employers and large employers to implement and

promote safety for their help, for their workers, and also that behavior-based safety has taken a new twist and it's called people-based safety. And there's no real research to say are these really valid, and so the unsuspecting buyer out there is kind of in a vulnerable position.

The second one is this -- this is our trade journal for the American Society of Safety Engineers and the lead article here is the ANSI Z-10. It's a safety management assistant, so this is going to be the benchmark for the next several years, and ANSI is American National Standards Institute, and it was only done by a group of 80 individuals such as myself and they got together and they called best practices, so this is going to be the new standard. But there is no real research that says is the ANSI standard really the gold standard, if you want to perceive it that way.

And then the next issue that is gaining more popularity is organizational culture. What are the cultures that we have in these different organizations that promote safety or hinder safety and the City of Los Angeles obviously has got a dysfunctional safety culture there.

So it goes from there to my last statement that I would like to see and I think is the most profound that I would like to see NIOSH do research on is how do we sell safety to management. How do we sell safety to business owners. You know, in the 28 years I've been doing this, my first issue has always been an easy way to make a living is sell compliance. Well, once the compliance issues are taken care of and the management and business owners start focusing on other areas and they take their eye off the ball that safety and things start going back down again until they start accelerating and getting (unintelligible) back hey, we've got a compliance problem.

The second issue, especially in the last couple of years in California, is the workers comp cost, including the -- self-insured has been very, very expensive in California so that's been my second biggest sell. So what I would like to see NIOSH do is focus on how do we sell management safety that's beyond compliance and workers comp issue. We need to show business owners and business executives that it improves efficiency, improves productivity, it improves morale, it improves all of these other issues than making businesses better places to work for, and the only way that's going to be done is if NIOSH comes and looks at -- and does some really broad-stroke demographic research of executives to find out how can we do a better job so people like myself and the lady here speaking for the City of Los Angeles, we have some real concrete data that we can present these things -- and the union speaker here was talking about that. So I think that that's what I would like to see NIOSH focus on is the soft science, the sociology of safety, and that's my degree. I'm a sociologist and I hope that's the direction they take. Thank you.

Commission on Health and Safety and Workers Compensation of the State of California

Categorized comment or partial comment:

Verbal Comment 2006/02/21: Good afternoon. My name is Irina Nemirovsky and I`m actually part of the Commission on Health and Safety and Workers Compensation of the State of California. My remarks are also on behalf of executive officer Christine Baker, who unfortunately apologizes and was not able to be here today.

First of all I would really like to thank NIOSH and UCLA for the opportunity really to be here today and to provide some of our key research issues for the workers compensation and occupational health and safety community in California. But before I begin, I`m not sure how many of you really know about the Commission or what its role is, and I`d like to just give you a brief introduction on what we do and what our mandate is in the state of California.

The Commission was created by the 1993 legislative reforms of the California workers compensation system. The eight members of the Commission are appointed by the Governor and the legislature to represent employers and labor. And the mission of the Commission is really far-reaching. It was formed to monitor the health and safety and workers comp programs in California, and the Commission is charged with recommending legislative and/or administrative modifications to improve system operations. It`s mandated to conduct a continuing examination of systems in California and to evaluate those programs in other states.

Many of the Commission's studies and research findings have been incorporated into the workers compensation recent reforms of A.B. 749, A.B. 227, S.B. 228 and more recently in S.B. 899, which was signed in 2004.

We believe that considerable progress has been made in improving workplace health and safety, as some of the recent injury and illness statistics demonstrate that there've been considerable declines in the past decades of injury and illness incidence rates and has -- there has been a huge decrease in incidence rates really for all industries.

But much of the progress that has been made improving workplace health and safety has largely been based on support and knowledge generated by occupational safety and health research. However, resources for occupational safety and health research are limited, and the toll on costs of injuries are still high. There's still about 700,000 non-fatal occupational injuries and illnesses in California annually, and an additional 416 deaths from injuries on the job. Thousands are permanently disabled as a result of workplace injuries. The workers comp costs, as some panelists have mentioned, for work-related injuries are really high. They're over \$20 billion annually in administrative expenses, medical and indemnity costs.

Our -- CHSWC's -- some of the CHSWC's key research priorities which we would like to address here today and really recommend for NIOSH to take a look at include -- we really feel that there's a need for ongoing monitoring and independent evaluation of the workers comp system. It's critical to assess system performance and determine whether the goals of the reforms are being realized. More research needs to be done in evaluating the medical outcomes, quality and access of the recent reforms. Yes, workers comp reforms have been put in place to control some of the above-mentioned costs and make improvements in the workers comp system, but their impact still needs to be evaluated, and the impact especially on the quality of care and access. That work still needs to be done.

We would like to recommend that more research be done on integrating -- on the integration of non-occupational and occupational healthcare and what the impact of that is on improving continuity of care, quality of care and reducing workers comp costs.

The implications of the aging workforce on occupational health and safety and workers compensation needs to be studied. Incorporation of health promotion into existing occupational health and safety programs, that's a priority. There needs to be more information about workers compensation system available in several languages in addition to English and Spanish -- other languages such as Chinese, Vietnamese, Tagalog, Cantonese and Korean. There needs to be actually more information disseminated into these languages as well.

Lastly, it would be great if we can determine the feasibility of establishing a northern and southern California resource centers for employers and injured workers that would maximize successful return to work after a workplace injury and reduce workers compensation costs.

I would lastly like to emphasize that all of the Commission studies have been done with input from stakeholders. We believe that strengthening and broadening partnerships with partners is of great value in leveraging limited resources, obtaining important feedback and helping to implement and evaluate programs. Partnership with stakeholders are key to improving the workers compensation and health and safety systems in California, and we look forward to partnering with NIOSH and other

organizations on helping to improve workers comp and health and safety systems in California. Thank you.

Human Factors and Ergonomics Society

Categorized comment or partial comment:

Verbal Comment 2006/02/21: Good afternoon. My name is Lynn Strother and I am the executive director of the Human Factors and Ergonomics Society. We're located in Santa Monica, California -- right here down the road -- and I represent about 4,500 scientists and practitioners internationally in the area of human factors and ergonomics. And our mission is to advance the science and practice of human factors and ergonomics, and today my remarks are focusing primarily on some concerns within the research community regarding NORA's sector-based approach.

NORA was originally established in 1996 to consider the occupational and safety and health needs of industry and how to define a research agenda that would be meaningful for society. The idea was to bring together researchers, practitioners, academics, industry representatives and so forth to determine where weaknesses were in the research agenda and where future research focus should be encouraged. We applaud this inter-disciplinary and multi-dimensional focus to addressing this important public health issue.

Given the production of NORA I, we think that the research agenda positively influenced the field of occupational health and served as a useful guide for policy makers and researchers to help focus their efforts.

The original NORA effort was effective and appeared to encourage research in needed directions. Research that would have had greatest impact across industry sectors was encouraged, and often focused upon fundamental illness and injury causality issues. This work reinforced traditional research values that encouraged the advancement of the science that would underpin the basic principles underlying health causality issues.

The new NORA effort appears to have significantly changed its approach from the focus on the injury/illness-based research to an industry sector approach that would encourage industry to identify the areas of research that are most -- of importance to them, to industry. Given the fact that the

occupational health recording system has changed dramatically over the years, our fear is that public funds will not be appropriately directed to the real occupational health issues facing society, but they will only be directed to the issues that are permitted by whatever the surveillance system is designed to identify.

An example of this concern can be found in musculoskeletal disorders. It is well known that musculoskeletal disorders represent the primary reason for missed work in industry overall. However, recent changes to the recording system have eliminated the MSD category from the surveillance forms. Thus this system would permit the country's most widespread health issue to be under-appreciated in this sector-based approach since it would most likely be buried in a generic accounting system.

Although musculoskeletal issues are to be addressed via the cross-cutting sector category in the new NORA plan, it is difficult to understand how addressing musculoskeletal disorders as a cross-cutting topic can facilitate a better understanding of the causal pathways that are needed in order to bring about truly effective solutions.

We live in a rapidly-changing world from an occupational perspective. The fundamental manner in which work is accomplished has changed, along with out-sourcing, in-sourcing, globalization and large corporations increasingly being responsible for worker health across a multitude of industrial sector definitions. The sector-based approach to occupational safety and health research represents an effort to encourage immediate applied research efforts and, we fear, to minimize basic research efforts. Although applied research can be useful and of immediate assistance, any effective research portfolio requires a balance between basic and applied research.

Applied research can be optimal and useful in the long term only if it builds upon a strong scientific foundation that has been well-reasoned and builds upon a systematic approach to understanding the causal relationships underlying an occupation-related injury or illness. Our concern is that research defined and based upon industry sector will not lead to meaningful research that is consistent with the long-established process of scientific inquiry. This sector-based approach will encourage superficial research that may not necessarily address the most important occupational health issues, and instead may result in industry control practices that address symptoms of occupational health problems instead of their root causes.

An additional concern involves the body of research that was initiated under Phase I of NORA. As stated earlier, scientific inquiry is a progressive process that often takes decades to come into fruition. Many of the efforts that were funded under the research topic-based NORA initiative over the past ten years will only lead to useful solutions if they are followed by research efforts that can build upon these initial steps.

I have a little bit more. I have been told to stop. I'll make sure that my comments get into the record, and I just want to offer the assistance and partnership of the Human Factors and Ergonomics Society, its members and technical groups in this effort. Thank you very much for your attention.

Note: Verbal testimony provided to NORA Town Hall meeting in Los Angeles, 2006/02/21.
