Services Employees International Union, Local 660

Categorized comment or partial comment:

Verbal Comment 2006/02/21: Good afternoon. My name is Suzanne Porcenne. I'm with SEIU Local 660 that serves Employees International Union. And we represent L.A. County workers as well as workers in special districts totaling close to 50,000 workers in L.A. County.

Our workforce includes office workers, court reporters, workers in schools, healthcare workers such as nurses, LVNs, eligibility workers in social services, blue collar workers -- custodians, housekeepers, and anyone else who delivers services for L.A. County.

As an important stakeholder in the public sector, SEIU Local 660 very much wants to work with NIOSH and looks forward to a collaborative partnership through the NORA sector research councils and other avenues. We urge NIOSH to support and conduct research that can be used to effect real policy changes, such as better ergonomic standards and an increase in staffing levels across different departments within any public sector, including county, state and federal. And also to effect changes that will reduce psychosocial stresses on workers.

For over 20 years SEIU Local 660 has had a labor/management ergonomics committee. It is one of the few committees of this type that has an operating budget that we negotiated with L.A. County

management. Our clerical bargaining unit, composed of 16,000 members, fought hard to win the creation and funding for that committee, and maintained the funding levels through a political climate that was adversarial towards workers.

We are in a bargaining year this year with L.A. County. We want to continue to make gains for county workers by negotiating better ergonomic standards, more funding for safe equipment for other bargaining units, and higher staffing levels. In order to do this we need research that will bolster these efforts. Policy makers need to see research on the correlation between the use of ergonomically correct standards and equipment, adequate staffing levels, and the reduction in injuries and less time off the job by workers, and the cost savings to employers.

I'd really like to emphasize that economic reasons for health and safety for workers is a very, very important argument that policy makers listen to. We work very closely with legislators on the state and federal levels, as well as the county levels, in SEIU, and these are the sort of issues that policy makers grapple with constantly in making decisions on funding priorities.

As was stated in the morning session, research doesn't do us much good if it does not assist us in effecting policy changes. This kind of research will be key and extremely important in educating policy makers on the local, state and federal levels to support ergonomics, staffing increases and better health and safety standards and enforcement, and the creation and increase of funding for these programs through legislation and bargaining by unions.

We hope that NIOSH will work with the stakeholders, as they've stated, including union members and staff people, to identify the priorities that make sense for the workers, as well as winnable issues that can really impact the workers' lives. If we can assist in any way in terms of resources and actual staffing to make this happen, we would like to do that. But we want to really emphasize that it's the policy changes that are really going to affect the workers' lives, so we'd like -- we'd like this research to be really geared towards that and sort of stay away from academic theory that is very useful in its own right, but would not be as useful to the workers out in the field on the front lines. Thank you.

Verbal Comment 2006/02/21: Good afternoon. My name is Pamela Vossen, and I am the senior health and safety educational representative for the union UNITE HERE at the international headquarters. I have about 20 years experience in the field of health and safety, working for unions, academic institutions and community groups as a researcher and as an educator.

I'd like to thank Linda Delp, Terri Schnorr and Cass Ben-Levi for making our participation here today possible, and to my sisters at Local 11 for their strong presence here today. It is both a pleasure and an honor to be here today while NIOSH lays out its future research agenda, while at the same time hotel workers in Los Angeles and across the United States and Canada are demanding safer jobs.

The hotel housekeepers who spoke explained only too well the price that they pay with their health as professional housekeepers working under unreasonable workloads. They may not be on assembly line, but these women constantly face speed-up every single day.

Hotel housekeepers are women who are working in constant motion, every minute of every hour of every day of every week of every year. They have all the telltale ergonomic risk factors -- heavy lifting of mattresses, repetitive bending while making beds and twisting to do so because night tables are in the way. They reach high and low to clean showers and toilets. They experience forceful loads while pushing carts lade down with linens and amenities. And so it is no surprise that when we surveyed 600 hotel housekeepers that we found 91 percent said they suffered from workplace pain; 77 percent reported that it interfered with their activities outside of work -- meaning their time at home and with

their families; 67 percent visited a doctor because of the pain; and 66 percent took pain medication. So the next time when you go to a hotel, look around at the housekeepers and realize that two out of every three of them are on pain medications.

Something is seriously wrong with the workloads. When we review OSHA logs in different cities, we see that housekeepers make up a percentage of injured workers that is greater than the percentage they comprise of the hotel workforce. So for example, if housekeepers represent 23 percent of the workforce in a particular hotel, when we look at the logs they may actually represent about 26 percent or more of the injuries. We know that about 66 to 69 percent of housekeepers do not report that -- those injuries, and so we know what we are seeing is just an underestimation of the reality.

We must remember that work is organized, and it is organized by the employer, which means that it can be organized to be safer. Also employers have a legal responsibility to provide a workplace free of known and recognized hazards. With 80 percent of U.S. jobs being in the service sector, and with record-breaking hotel occupancy rates that equal huge profits, NIOSH has an opportunity -- but I would also say an obligation -- to study workplace conditions of hotel workers, and to identify interventions that can reduce these injuries and prevent workplace-related illnesses.

From my own professional experience, I know that NIOSH can make a difference. From 1989 to 1992 I was fortunate to be funded by a NIOSH cooperative agreement at the Laborers Health and Safety Fund of North America, where I was able to do ground-breaking research on construction laborers. This time period we were able to set the ball in motion for many subsequent studies and additional funding for more studies and interventions. I'm certain that in 2006 the hotel industry is where the construction industry was over 15 years ago -- many injured workers with few studies to prove to management that the conditions must change that can change. This is what the hotel industry in particular and the service sector needs today.

We strongly recommend participatory research so the workers in the community have a role. And I'd like to leave you with a research task of your own. Next time you go to a hotel, how many pillows are on your bed? How many sheets? How many mirrors? How big are they? And know that every item in your room is one item on a 100-point checklist that workers are graded on every -- for every room that they clean. Thank you very much.

Verbal Comment 2006/02/21: Good afternoon. My name is Sonia Moseley and I'm a registered nurse and executive vice president of United Nurses Associations of California, NUHHCE, AFSCME, our American Federation of State, County and Municipal Employees. Thank you for the opportunity to provide input into the National Occupational Research Agenda. Our national union has been active with NORA -- the NORA initiative from its inception.

I want to touch on both a general area of concern as well as a specific issue with respect to the research agenda.

First, as a member of AFSCME, I want to mention that occupational safety and health for my sisters and brothers in the public sector, particularly state and local government workers, continues to be a major area that does not receive the attention it needs and deserves. State and local governments employ nearly 20 million workers. That's roughly 15 percent of the non-farm civilian workforce in this country. According to the Bureau of Labor Statistics, there were 5,703 fatal workplace injuries in 2004; 527 of these -- or those, or nine percent, involved federal, state or local government workers. Thousands more die each year from occupational disease, and hundreds of thousands suffer injuries that result in time away from work, in all too many cases permanently.

Public employees are in many ways the forgotten workers, including among the occupational health and safety research community. Despite doing some of the most hazardous work in this society, public employees were excluded when the Occupational Safety and Health Act was passed over 35 years ago. We need to examine the hazards, health effects and consequences on public employees of working without health and safety laws and enforcement. Today only 24 states have federally-approved state

OSHA programs that cover state and local government workers. And we are indeed fortunate that California is one of those states.

I'd like to focus the remainder of my remarks on an important issue to nurses and other healthcare workers, respiratory protection against airborne pathogens. Concerns about appropriate equipment and resources have risen as the world and this nation are facing the possibility of an influenza pandemic. In the past week avian influenza was reported to have spread to more counties, including Italy, Germany and other parts of western Europe. And as of February 13th the World Health Organization has reported 169 confirmed cases of avian influenza in humans, with 91 deaths.

Last November the Department of Health and Human Services released its pandemic influenza plan and recommended a surgical mask for respiratory protection. Its recommendation is based on the assumption that transmission is primarily via large droplet nuclei. However, the plan admits it does not have definitive scientific evidence to support this claim. It does not address the issue of the evaporation and breakdown of droplets into respirable-sized particles within a matter of seconds, or even fractions of seconds, after they are expelled through sneezing, coughing or even talking.

Surgical masks are not respirators. They cannot filter out droplet nuclei. They cannot achieve a tight seal against the wearer's face. They are not certified as respirators by NIOSH. The recommendation for surgical masks contradicts guidance from the Centers for Disease Control and Prevention and OSHA regarding respiratory protection for avian flu. They recommend a minimum of N95 respirators and higher levels of protection for activities that may generate aerosols.

NIOSH and others have not adequately addressed the effectiveness of disposable respirators for use against airborne pathogens. There are many questions that remain today and are applicable to other airborne pathogens, particularly a pathogen as lethal as avian flu, should it develop the ability to be transmitted between humans. Research should focus on determining the minimum level of respiratory protection needed to protect wearers from exposure to airborne viruses like avian flu where infectious

doses may be approaching one particle. We also need the research to establish the appropriate criteria for certifying the fit of half-mask respirators as part of NIOSH's certification requirements.

Verbal Comment 2006/02/21: (Unintelligible) to everybody here. My name is Margarita Ramos, I work as housekeeper for 17 years at the Century Plaza. I have three beautiful sons who depend on me (unintelligible) for belonging to hotel where we have a union (unintelligible) so that the managers of this hotel do not abuse us.

How do they abuse us? They give us extra work. They do not respect us. We work very hard as housekeepers. We have to take care of about 20 to 25 beds daily. We list to 25 to 30 mattress units on a daily basis. Just (unintelligible) it's 40 to 45 pounds (unintelligible). Sometimes we feel very pressured and we only get injured. I have two torn ligaments in my knees. Many times it is very difficult to go through my assignment of 15 rooms. As housekeepers we need to have a lighter (unintelligible) working conditions. We need to go home and take care of our children, as well.

What we would like is to work harmoniously so that our guests come back to our hotel. I would like to take the opportunity to be part of this panel to make you aware that as female workers to be around our children and our children's education. Ten years ago my husband and I decided to purchase our home, to have a car, but this means that my husband and I have to hold two jobs, each one of us and to allow -- we are happy with our three children, but we've gone through many hardships, many illnesses, because at the end of the day I have back pain and my knees hurt, as well. My children take turns to give me a massage so that I'm able to go work the next day. And that is why that I would like to take this opportunity to ask for your help so that you can help us female workers to live a harmonious life. Thank you very much.

Verbal Comment 2006/02/21: Good afternoon, I`m Mary Gene Ryan and I`m a health and safety consultant, and I work privately. But I also work with clients in the public sector and in the private sector in all the occupations that have been mentioned today. One of the things I want to concentrate on today -- or to touch base on is ergonomics, but I also wanted to touch base on a couple of other issues. As has been eloquently stated, we have laws on the books that aren`t really being followed. And our people, as has already been stated, are still getting hurt on the job. We really do need to have an action plan, and I believe NORA can -- can, as a research arm, begin to look at an over-arching action plan to address intervention and to do the research now, as you have on your initiative to actually demonstrate that interventions work.

Categorized comment or partial comment:

To go back to ergonomics, as was stated earlier by several people, we need to start at a very young age. How many in here know what neutral back posture is, who could stand up and say I`m standing in a neutral posture? Who knows what neutral arm and hand postures are? And if I`m going to make a bed, as a housekeeper, am I doing it in the most neutral posture? We need to know what those postures are and our workforce needs to know what they are and we need to learn them at a very young age. Just like we learn to brush our teeth, we need to learn to stand in a neutral posture and we need to use our hands in neutral postures.

Our technology`s advancing so fast that our children now are becoming -- are being placed, as one of the educators had mentioned, in positions of non-neutral posture when they sit in school and work on our computer systems that we now have in school. We`re not in the most ergonomic setting for that student, nor for our employees. I still find employers that do not have chairs that fit their employees. And if we can`t even get a chair to fit an individual, then how do we expect them to stay in neutral postures and know what they are?

We also need to educate our force on what good work practices are. We`ve heard today from many of our service-connected employees that they work alone, and maybe the work practice should change to a buddy system so that I do have the availability of help to do work, or that I can share my workload. If I have 15 rooms I need to clean and another person has 15 rooms, maybe we can work together and get

them done differently in a better work practice. But again, it's getting to the -- changing our focus and having a wider vision.

What I would recommend is, from an ergonomic standpoint, that we look at the hazards that -- we already know what the hazards are. We know what the risks are. But we need to classify them for each particular job task, and we need to give that information to employers and to the employees so that they can use the tools that we already have available. And we need to measure what really works because we have some guidelines that are out there, and as an individual that does ergonomic evaluations, we're not positive that everything that we are recommending really is the answer. And it's not the answer if we can't get the employee to move. And in essence, our jobs need to include movement.

Verbal Comment 2006/02/21: Good afternoon. My name is Aurelio Gomes, and for the past five years I have been an associate professor of clinical epidemiology in the Medical School of the Catholic University of Mozambique in East Africa and director of the HIV/AIDS Research Center.

My research focus is on AIDS, and with support from US-NIH I recently instituted the first rural HIV/AIDS clinic in Mozambique, in collaboration with UCLA and Pittsburgh. The clinic is located in Mangunde at a remote rural Catholic Mission. I have also worked in Beira City in Mozambique at an urban HIV/AIDS clinic developed by Sant`Egidio, a volunteer Italian lay organization which was the pioneer clinic to deliver antiretroviral drugs in central Mozambique.

Today a major topic is about scaling up HIV treatment in Africa. As this audience knows, the U.S. government allocated \$15 billion over five years to fight AIDS in developing countries under the program called PEPFAR, the President`s Emergency Plan for AIDS Relief. Such program will only be effective if health care workers -- if there are health care workers that can provide the treatment.

For those in the field, there is however a phenomenon that can jeopardize this effort, the increased care by health care workers of contracting HIV and hepatitis, as well as other infections to which they are exposed, such as tuberculosis.

The question still not answered is this: Is it ethical to ask a health worker to sacrifice his or her life to save other people's life? This is a question I got from one of the health workers in HIV clinic which was treating patients with outdated equipment, such as glass syringes.

With help from TDICT Project that you'll hear of later from Dr. Fisher, we introduced on a limited basis safer devices supplied by some manufacturers which were tested in our environment. Sadly, a lot of these devices were even known by health workers, and the few that they -- that were known certainly were not available for them. The health workers are enthusiastic and identified some issues that were culturally and environmentally relevant to them, based on their work experience and needs. This was particularly important for those working in home care. Just imagine having to provide care to someone laying on the dirty floor usually.

Policy makers often argue that cost is a limiting factor. However, anecdotal evidence shows that the costs of many of these outdated device are probably more expensive than those that are newer because they are considered custom-made. Yet they are still being ordered by government.

Today it has been recognized that providing manpower to staff these clinics has been severely hampered either by deaths due to HIV or by those deserting the health sector. To deliver proper care, and in particular antiretroviral drugs, it is critical that healthcare workers be provided with proper occupational health programs so they can remain in health sector.

We would -- I would encourage NIOSH, specifically when there is U.S. government funds available or involved, to be more intrusive and even take control of occupational health issues in international funding that targets activities that are risky to health workers in developing world through a systematic approach that includes an assessment of the actual condition and mandatory guidelines for such programs to effectively include higher health and occupational standards in their -- in their programs.

We would also encourage the medical device industry to bore attentive to the cultural values in developing countries where environmental factors can be an adverse impact on the use of devices tested only in U.S. or other developed countries. Thank you.

Verbal Comment 2006/02/21: Good afternoon. I`m -- I represent -- I`m Barbara Materna and I represent the occupational health branch in the California Department of Health Services. We`re a non-regulatory public health program that conducts research and provides services to prevent injury and illness among California workers. My written comments will provide a little more information about what our program has done, much of it with NIOSH support through the years. It also covers some of the characteristics of the California workforce that pose unique challenges to doing health and safety to serve the needs of all of our workers.

But in the interest of time, I`m going to jump right to my recommendations, which fall under two basic categories.

First, we recommend that NIOSH consider the following priorities for the next decade of NORA. First to place special attention on supporting research and other activities that will improve working conditions

for low-wage immigrant and under-served workers, which you've heard about for several hours already today, and I support all of my -- the speakers that have preceded me. These workers are found in large numbers in the services sector, as well as in other sectors that are high-hazard and significant in California, including agriculture and construction.

NIOSH should support and promote efforts that determine the most effective ways to provide health and safety information and training that is appropriate to the languages, cultures and literacy levels in our workforce in California.

NIOSH should also support efforts that develop effective interventions for preventing and reducing musculoskeletal disorders, which are a major contributor to workers comp costs and cause of lost work days and disabilities, which often in many cases go unreported and uncompensated.

NIOSH should support efforts to disseminate available information that can be used to improve working conditions such as hazard information, research findings and best practices, and particularly to reach the large numbers of small businesses and their diverse workers.

NIOSH should support efforts that involve partnerships between occupational health professionals and researchers in community-based and labor organizations that have special access to these workers and knowledge of their needs.

And finally, NIOSH should support efforts to determine how to best address health and safety within the context of other important problems and issues that these workers face. For example, language barriers, poverty, working long hours and multiple jobs, limited education, lack of access to healthcare and permanent employment, exploitation and all the other life stressors that you've heard many others speak eloquently about today.

- state public health departments

Categorized comment or partial comment:

And the other area of recommendations that we have for NIOSH are that NIOSH should enhance and expand partnerships between NIOSH and state public health departments for conducting occupational injury and illness surveillance and intervention activities, and to assist in translating materials and research findings into safer workplaces and work practices in our workplaces, in line with NIOSH's R2P, Research to Practice, initiative. Health departments are uniquely positioned to carry out these efforts. For example, we have legal right of access to workplaces to carry out public health investigations. We have statutory access to unique data sources that can be used for conducting epidemiologic analysis and case follow-up investigations. We're part of the state's public health infrastructure and have useful ties to colleagues in communicable and chronic disease control, environmental health, family health and health through services delivery. We have existing relationships with local partners, which include trade associations, unions, community-based organizations, health professional organizations and local health departments. And we have a long history of collaborating with other states and NIOSH to share information and experience and promote a growing network of state-based programs to prevent occupational injury and illness.

NIOSH support, collaboration and technical assistance has been critical to many of these state-based activities, and we have been successful in encouraging more states to expand their efforts in this important area of public health. So therefore we recommend that NIOSH increase the total amount of

funding for activities conducted by state public health departments, provide enhanced funding for projects that involve developing and implementing interventions, support proposed partnerships that allow states to work with stakeholder groups to address health and safety issues identified in participatory group processes such as the Build Safe California construction industry training effort that was funded through a NIOSH core surveillance agreement. And finally, to partner with states on efforts that involve widespread dissemination of research findings and adoption of the best health and safety practices into our state`s workplaces.

Thank you very much for the opportunity to provide input.

Verbal Comment 2006/02/21: I am -- can you hear me? I am June Fisher, an occupational health physician and former lecturer in engineering. I'm also a member of the current NORA infectious disease group. I have been involved in participatory research for -- with healthcare workers and urban bus drivers for almost 30 years. Today I will talk briefly about a user-based design in occupational health and safety giving voice to worker expertise. And I think we've heard about the need for training workers and this -- what I'll talk about will be...

But we hear a lot about user-based design, and most common we hear about it in the development of software and that -- this is typical of -- way it's being used, at the very end you'll beta* test something. That's too late. Workers need to be involved in all aspects of design development. That is including need-finding, the whole process of prototyping and going through the design and giving input to the design of really what they need, and to evaluate and select devices. In order to do this, you need to have some skills and training on both sides, the people who are bringing the technical expertise of design and the people who are bring the expertise and knowledge about their own work.

I would like to briefly discuss a NIOSH-funded project that I have been involved with for the past 16 years, which may illustrate some of these aspects. The project is a user-based collaboration of frontline healthcare workers, industrial hygienists and product designers, mostly -- the later two are mostly graduate students 'cause we were not well-funded. The frontline healthcare workers are primarily from San Francisco General Hospital, but healthcare workers from many other regions in the U.S. and Africa have been involved with the project.

The project began before devices to protect healthcare workers from exposure to blood were available, and this was a demand that our union at our -- my hospital made when they did not exist. It was not the occupational health people or the physicians at the hospital. It was the line healthcare workers were saying why don't we have safer devices, and there was stimulus for this project. And its mission is to promote the development and use of appropriate, safer medical devices to prevent such exposures.

The initial emphasis of this user-based collaboration was the training of the industrial hygienists and product design engineers to understand in depth the complexities of providing healthcare. That's critical. If you're going to design, you'd better know what you're designing for, and that doesn't happen very often. This was accomplished by observational studies, focus groups, joint brainstorming and -- most important -- intense mentoring by the frontline healthcare providers. The industrial hygienists and engineers were really nurtured, but valued, by their healthcare mentors. Thus they gained a broad understanding of the work demands and the occupational hazards in healthcare.

In our third year, at the suggestion of the product designers, a course in product design and industrial hygiene for healthcare workers was developed. The intent of the course was not to create designers, but to give to healthcare workers a language and design vision so they could understand and be directly involved in all phases of the design process. The healthcare worker -- were -- participants were most enthusiastic about the course.

Many of the participants have gone on to be key figures in the struggle for the revised OSHA bloodborne pathogen standard which mandates the use of safer devices, as well as the historic requirement that line healthcare workers participate in evaluation and selection of such devices. Many of them are active in training other healthcare workers to evaluate and select devices. These device-savvy healthcare workers also provide critical links with the medical device industry. I have no doubt that the better devices that now exist owe a

Another thing I would recommend is a specific recommendation -- we need a study on how the OSHA requirement for worker line involvement is being implemented because it's my impression -- and I have a lot of -- wide impression that it's not being implemented. Showing a worker a device you've already chosen is not worker input. We have to have real worker input.

And then totally off of the area of design, but I also think we need research on the inter-relationship of patient and healthcare worker. They are integrated, not the way it's viewed, that one has to be compromised for the other.

Thank you.

Verbal Comment 2006/02/21: Good afternoon. I`m Charles (unintelligible) Bryce, president of National Postal Mailhandlers Local 303 and also the president of the COSH group, southern California COSH. I`m here -- we represent mailhandlers who work in mail processing plants from Bakersfield to San Diego and even Las Vegas, which is a total of about 14 processing plants here in southern California.

And I wanted to speak on some things about federal workers. As you all know, we got hit with the anthrax here and that was scary. That was real -- we wish NIOSH or the COSH and anybody else could help us with that. That was a real scary moment for public workers. You know, Postal Service, we -- we can`t look in your package to see what`s in there. It`s against the law. If we do it, we lose our jobs. We would like help in that area.

But what I'm here today asking help for in the area of research is forklifts and operating mules within the Postal Service. As we drove up here today -- many of us drove up here today -- we saw the highways, we saw the streets, we -- we saw where pedestrians walk and we saw where cars go and buses go. In the Postal Service what they do, they got a mixture of all that into one, and there's a high rate of accidents. And we feel that if working with -- with you and with anybody that can research that and find out -- just basically if you'll put a plan together what's in those processing plants where workers can work, equipment operators can operate and so forth and so on, we're willing to work with you on that.

And we appreciate, you know, you coming in and thanks for hearing me.

Verbal Comment 2006/02/21: Good afternoon. I guess somebody has to go last. Right? My name is Al Perez. I'm an environmental safety and health professional. I've been in the profession for 25 years. This is my chosen profession. I started off as an industrial hygienist. I'm a graduate of a NIOSH-funded industrial hygiene program. And over the years, you know, I've had progressive responsibilities, expanding into safety engineering and environmental health and, you know, progressing up as a -- into a management position.

Most of my career has been with private industry, and I currently work for the largest commercial laundry -- or one of the largest commercial laundries in the country, and we have about 13,000 employees. Most of our employees are unionized. A lot of our employees in the production area are UNITE HERE-represented, and a lot of our drivers -- or most of our drivers are Teamsters.

I'm going to touch on a subject that's very similar to what the consultant talked about just a little earlier about those soft areas, not the technical areas but more softer areas that I feel NIOSH should -- should be focusing on.

Again, my primary job is to develop and implement injury prevention programs. And one question that kind of -- has come up over the years as a health and safety professional when I talk to my peers is -- especially those of us who work in private industry -- is we ask each other, you know, what kind of safety culture do you have at your company, and vice versa. It's just something that always comes up. And early in my career I just kind of took that for granted. If you work in a company where you have a strong safety culture, it's there. You work with it. It makes your job easier.

However, not all companies are the same. And earlier the gentleman from NIOSH showed a chart up on the wall that showed that the average injury rate in industry right now I think is five or so recordable injuries for every 100 full-time employees. Well, why is it that some companies have injury rates of one or less than one, and why is it that companies have injury rates of ten or greater than ten? I mean -- you know, the five is just the average. And if you look at it on an industry-by-industry basis, I would argue that the reason why you have companies with extremely low injury rates is because they have a strong safety culture.

And you know, what do I mean by that? There are different models with respect to safety cultures, what we call safety management systems. And there's the -- OSHA has a VPP model, and if you look at companies that are members of this prestigious VPP program, it's like -- you know, it's like getting the Nobel Prize for safety. OSHA actually recognizes companies that have stellar safety programs, and they're part of this VPP program.

And the difference is that these companies that do well have safety management programs in place. And that's an area that I'd like to recommend that OSHA really take a hard look at, and in particular I think there are three areas that I think are extremely important.

One of them is management commitment and accountability. The second is employee involvement, and the third is safety leadership.

Again, there are a lot of models out there, but what I find difficult is that you can go to reference books and you can find a lot of theoretical information about safety management systems. What I'd like to request that NIOSH do is just develop some practical solutions to improving safety management systems 'cause you can develop all of the -- the nicest-looking, well-written safety programs in the world, and if you don't have safety management systems in place at your company, they're not going to go anywhere. Without those systems in place, basically your safety program is not going to move forward. So I'd like to recommend that NIOSH come up with research and actually come up with some practical solutions and methods for developing effective management commitment programs, employee involvement programs -- 'cause you won't find -- or you rarely find a strong safety culture that doesn't involve their employees in the safety process. It just doesn't happen.

And then lastly with safety leadership, without the leadership throughout the organization, obviously I think there needs to be a focus on senior management, but everybody needs to be a safety leader in a strong safety culture. So with these three areas, how do you define these three areas, what is -- what is -- what is safety management commitment, what is employee involvement, what is safety leadership? What are the best practices, how do you achieve it? And then again, what are practical solutions to developing this strong safety culture? Thank you.

Verbal Comment 2006/02/21: Hi, I'm Linda Delp. I'm the director of the UCLA Labor Occupational Safety and Health program. We -- UCLA LOSH develops programs for a variety of workers from the public and private sectors, from the informal and the formal economy. Our goal is to improve workplace health and safety through participatory education, collaborative research and through promoting policy change.

We heard a lot today about often low-wage invisible workers in southern California. We've heard about immigrant workers, garment, restaurant, hotel, janitorial, construction industry, workers that are largely invisible to society. I want to highlight one other sector of the often invisible workforce, and that is the growing number of home care workers who provide critical personal care services to the elderly and disabled.

In L.A. County alone there are over 100,000 in-home supportive services workers, and they are predominantly middle-aged women. They're an ethnically diverse group, and about half of them are immigrant workers. And they have a really non-traditional workplace, which is the home. I'm currently

analyzing data from over 1,600 questionnaires and from six focus group discussions conducted with home care workers, a research project that we undertook with the union that represents home care workers, SEIU 434-B, to identify job stressors that are important to home care workers and what kind of support is available to them.

From the research findings so far, it's really clear that job-related stressors related to both direct care work, emotional and physical demands and to inadequate home care policies are significantly associated with workers' health and with job satisfaction. What's not completely clear are like what are all the mechanisms through which these different factors operate.

What -- I did -- I have learned quite a bit in doing this research, and I want to just highlight a few issues that have emerged based on this experience that I think are important for research. Number one is what should be the research focus, and I do believe that the occupational health needs of this workforce do warrant concerted and systematic research efforts. It's a growing workforce to serve a growing elderly population in our society. The research needs that have been highlighted in the past are lifting, back injuries, bloodborne pathogens -- though we've heard today that those still need some more research. But even more important are the job stressors associated with both direct care work and with the way the work is organized, the schedule, demands, the lack of back-up support and respite care for workers.

Secondly is the research approach, which I would say must fundamentally change, as we've heard actually throughout the day. If one of the research goals is to collect valid data that can be used as a foundation for making policy changes, which I believe it should be, then we can't use the traditional research approach -- in particular with the populations of workers that we've been talking about today, with immigrant workers, with workers that work in non-traditional workplaces.

What I believe is the only way to actually do valid research is through collaborative partnerships, so -- with -- with the groups that actually represent the workers that are most affected so that research questions can be identified, that all are appropriate to that workforce, so that the questions can be asked in a way that people understand, and so that there's a relationship of trust that's developed so that workers will respond and provide research data that -- that is accurate. This has been referred to a couple of times today as either community-based participatory research or participatory action research.

Just one quick example of how that's worked in the research that I've been doing, we actually trained a team of home care workers to interview the other home care workers in, geez, about four different languages. And I would assert that with training and adequate supervision, workers can be as good or better researchers than traditional researchers. They know how to talk to other workers. They have an element of trust with other workers that a lot of researchers don't. And they're passionately involved in wanting to conduct these projects. And a specific example is one of the Chinese worker-interviewers who was having a lot of trouble during our regular hours of making phone calls reaching other Chinese workers. And she's like the only way we can reach these workers is if we call them after they get home from their other jobs. They don't make enough money in home care. They're working in restaurants as well. They don't get home till after 11:30 at night. She said you aren't going to reach them. So we're like okay, you've had enough experience now. Take the surveys home and you can call them at 11:30 at night. She -- she came back with the highest response rate of everyone because she knew when and how to reach workers and how to talk to them. And she was very, very interested in making sure that

we got the information that -- that would -- from home care workers that would actually result in changes to improve their working conditions.

Third is that the research methods need to be diverse, and I would say that we need both quantitative and qualitative methods. You can't really understand what's going on just with survey numbers. They are important, though, to be able to document how many people are affected. But unless you have in-depth interviews or focus groups, you really can't interpret what those results are.

And then lastly, worker education has to be a critical component of research. Unless the results of the research are disseminated to the people most affected and they understand what they mean, the research is not going to result in really fundamental change to change workplace health and safety conditions, which I believe ultimately is the goal of our research. Thank you.

Verbal Comment 2006/03/06: Thank you, Tom. I'm Wayne Dellinger. Currently a Program Coordinator from Ohio State University Extensions Agricultural Safety Office. Just a little bit on my background. I've worked four years on a university research farm, three managing dairy operations, three years working as a field research technician for an OSU extension specialist and more recently, eight years employed in agricultural safety, while remaining a part-time employee on a large cash grain operation.

I chose special operations for special populations to address in this NORA town hall meeting because agriculture consists of many groups that could be considered in this category. These populations also typically operate the more dangerous equipment. Amish, youth, and what I'll call hobby farmers are three I wish to focus on for consideration in continued or future funding.

In 2004, Ohio had an estimated Amish population of over 52,000. While many of these Amish are turning to alternative employment, there is still a large number involved in agriculture. These Amish are difficult to reach and tend to use older horse drawn equipment, as well as younger and older workers than what we normally consider a typical agriculture operation. These factors create more risk for incidents, more difficulty in injury surveillance, and greater challenges in educational research and programming.

Youth involved in agriculture has been a tradition for family operations for years. In Ohio, if youth are working on their parent's farm, equipment operation may start at any age. In modern day, this is of greater concern for multiple reasons. Youth may only be permitted to operate the older equipment that may not meet current safety standards. However, if the youth are allowed to operate the newer equipment, this also creates certain risks. Today's equipment includes tractors and implements that are much larger than in the past. Some of today's tractors are also designed to operate at speeds of up to 45 miles per hour or faster. In Ohio, this creates the potential for a ten year old or younger child to operate a tractor on the road at 45 miles per hour if working for their parent.

Hobby farmers present a unique challenge. These are farmers with just a few acres or just a few animals to manage outside of an off-farm full-time job. They typically use older equipment bought at farm sales possibly without safety features or an owner's manual. Or, they may borrow a neighbor's equipment without proper training. These factors, along with an audience that is not reachable in the channels traditionally used for agricultural safety demonstrate the need for more focus, better injury surveillance, and additional educational programming.

With all of these groups and agriculture in general, roadway safety is a growing concern. Urban sprawl into rural areas, along with larger equipment sharing the same narrow roadways creates a scenario for more incidents. Even though there are fewer farmers, they are typically working on larger farms, traveling greater distances on the roads. The recent adoption of the Agricultural Safety -- American Society of Agricultural and Biological Engineer Standard 5-84, the Speed Identification Symbol, and revisions to Standards 2-79-13, Lighting and Marking of Ag. Equipment on Highways, and 2-76.6, the Slow Moving Vehicle Identification Emblem, resulted in recommended lighting and marking for high-speed tractors.

Educational programming and research should be a priority aimed at state legislators as well as producers to form laws that allow these tractors to safely operate on public roads. Continued or increased funding for all of these special populations in agriculture will assist Ohio and all states in meeting the changing needs of an ever-changing clientele. Thank you.

Verbal Comment 2006/03/06: Good morning. My name is Mary Fleming. Grady Memorial Hospital has paid me to serve as the agricultural health nurse there since July of 1991. Many years ago Daniel Webster recognized the critical nature of agriculture as a basic industry for a society. However, in

America today we see thousands who suffer disabling injuries on a daily basis; hundreds annually are killed on American farms. In addition, a myriad of diseases such as ODS, hypersensitivity pneumonitis, asthma, skin cancer, hearing loss, mental health issues and many more affect this hard working population. Dr. Kelly Dunham, Iowa State University, recognized the need for 8,000 nurses who understand the needs of agricultural health and safety, while we currently have about 200 in America today.

The Ag. Health and Safety Program at Grady has demonstrated the value of an ag. health nurse who understands both agriculture and health care. As a farmer, I've experienced the risk and learned to walk again after a fractured hip as a child. As a nurse, I have cared for thousands of farmers.

Using a case-based surveillance system, we start with identifying the cases, then carry out with investigation, individual interventions, community interventions, prevention programs and research projects. The ag. health model derives principles from public health, community health, occupational health, agriculture and research. The intersect of these circles captures the essence of an agriculture health model.

Our past success have occurred because the agricultural opinion leaders were actively engaged in setting direction as members of the Regional Ag. Safety and Health Advisory Council. They worked to create a comprehensive approaches to the problems so a new culture of safety could emerge. A singular program or research focus is not going to yield the essential changes in behavior to build this new culture.

The multi-media, multi-disciplinary tetanus campaign we conducted resulted in a 51 percent increase of adults receiving tetanus vaccinations in the first 12 months of our campaign. We also designed first-aid kits for on-farm use. In a follow-up survey, 56 percent of the responders identified this was the first time they had first-aid supplies in the most dangerous work site.

In a feasibility study funded by the Great Lakes Center, our preliminary data suggests that farmers are poised for a dramatic turnaround in their risk of cardiac disease. Perhaps the substantial shifts in mechanization, specialization, and regionalization are contributing factors. But we must remember the stress levels are climbing with the globalization of the marketplace, shifting federal policy, erratic weather patterns, land pressure from developments, and the lack of opportunity for youngsters who are interested in agriculture.

Agriculture also faces risks not seen in other occupations in the same degree, such as zoonotic diseases, lyme disease, brucellosis, and the Avian influenza that we're all concerned about will probably affect our agriculture producers first. The overlap of the home site with the worksite increases the risk not only to children, but spouses, extended family, friends, and even visitors, like the one year old who nearly drowned in a manure pit on a family farm here in Ohio.

Funding needs to cover direct reimbursement for nursing care, a balanced approach to support beginning researchers, technical experts, and experienced individuals. Funding also needs to deal with the reality of traumatic injury and death, which is our number one problem. There needs to be continued efforts to disseminate the North American guidelines for children's agriculture work. Our children continue to learn some good work ethics and responsibility on the family farms. We can provide more safety through appropriate training and experience for the family in decision making.

New collaborations are required as farmers continue to be businessman or businesswoman first, while adapting to significant changes that occur on shorter and shorter time lines. Partnerships with healthcare providers, schools of medicine and nursing, financial institutions, public agencies, like the cancer society, need to be built where they do not exist in world communities, and strengthened where they do. Rural access to broadband technology is essential for maximum productivity of the farmers and our rural healthcare providers. Geometric improvements are possible with the right combination of funding and collaborative practices where our producers help drive the programming.

Rural practitioners and care givers who treat the agricultural populations need to understand that ODS, hypersensitivity pneumonitis, viral bronchitis and occupational asthma do not require antibiotics, but the essential first step is to recognize these are agricultural exposures and make the proper diagnosis. This requires taking a complete patient history, including the list of occupations. In Ohio, 61 percent of our farmers depend on off-farm income to support their family. The interactions from multiple risks, from second occupations, combinations of chemical exposures must also be understood. Physicians and nurses in rural communities become occupational providers by default, so they must be trained.

We need a new culture of safety where Craig, a young farmer from Delaware, Ohio, will not be afraid to be pictured wearing his personal protective equipment when he's doing his daily job. Thank you.

- Ohio Bureau of Workers' Compensation Division of Safety and Hygiene

Categorized comment or partial comment:

Verbal Comment 2006/03/06: Good morning. My name is Mike Ely. I'm the safety tech for the Ohio Bureau of Workers' Compensation Division of Safety and Hygiene. I'm a certified safety professional. I'm also going to be presenting the comments of Mr. Chris Hamrick, (ph) who could not be here today. He's our ergonomic technical advisor and certified professional ergonomist.

These folks have already talked about at-risk populations, and there are two of them that I wanted to touch on briefly. And that is the aging work force. On my way here this morning there was a doctor talking on the radio that estimated in 20 years the average life expectancy in the United States will exceed 100 years of age. People are going to continuing working much longer into their life than they currently are. And statistics are showing us that the severity of injuries to the aging population is creeping up higher and higher. We need to take a look at this population before this problem gets out of hand completely.

Our interests, obviously, at the Bureau of Workers' Compensation is due to the cost of these injuries, but that doesn't exclude the human suffering that goes into it.

Another population that's at risk is our immigrant population. These are the people that are coming into our country both legally and illegally working at high-risk jobs particularly in agriculture and construction. And we're seeing an excessive number of injuries involving those people. Many of them can not speak English, can not read English, yet their supervisors often are not bilingual and able to communicate effectively with them, with their rights, the knowledge they need to do their job safely, and their ability to protect themselves. We need to take a very much closer look at what we're doing with that.

Some of my comments tie in with Mr. Hammer's here, so I'm going to be going with his. Back injuries account for 40 percent of our cost. Back injuries drive workers' compensation here in Ohio, and they're driving it across the country. Research directed toward the reduction of back injuries would be extremely useful. Many of the ergonomic interventions currently eliminate or reduce lifting, but they transform the task into one that requires pushing and pulling. However, pushing and pulling creates sheer forces in the spine. Little is known about how these forces affect back injury rates. Further more, very few guidelines exist for pushing and pulling capabilities. The only guidelines out there currently are Liberty Mutual tables, which are based on 12 subjects, and are psycho-physical, not bio-mechanical. Particularly as our workforce ages this becomes more and more of an issue. Ergonomics is how were going to be protecting a lot of these workers that are put into positions where they may not be able to physically handle the job they're being assigned.

Research on the effectiveness of safety, ergonomic, and industrial hygiene interventions would also be very useful. Given the complexity, scope, and expense of such research, NIOSH is uniquely qualified to conduct these projects. The economic impact, or return on investment or cost benefit analysis of safety, ergonomic, and industrial hygiene intervention and programs will allow health and safety professionals, as well as those who direct public policy, to promote and implement sound, cost-effective safety programs and policies.

Every day we talk to employers across the state who question us about the same thing that she was bringing up earlier, what's in it for me, I'm going to spend this money, where am I going to see the return on my investment. And this is a common question that we all as safety health professionals have to answer is, how do we prove a negative, how do we prove that our efforts actually prevented something from happening? And manufacturers have this question across the board, you want me to spend money, how are you intending on me to see a return on that investment? We need to have better data out there. Not only for safety and health professionals to use, but being taught in our business schools and our management schools and in all of our business associations across the country.

The Bureau of Workers' Compensation Division of Safety and Hygiene has cooperated for years with NIOSH and we will continue to cooperate with NIOSH providing data, research, and information as much as we can to support their activities. Thank you very much.

Categorized comment or partial comment:

Verbal Comment 2006/03/06: Hi, my name is Kermit Davis. I'm from the University of Cincinnati. I'm an assistant professor there. And what I'm going to talk about is the impact of musculoskeletal disorders in the industry and two special populations.

Musculoskeletal disorders are the leading cause of lost days and disability in many industries, particularly in manufacturing. Department of Labor Statistics reports more than 500,000 individuals suffer from musculoskeletal disorders each year. Manufacturing represents about 30 percent of these. Conservative estimates for musculoskeletal disorders are estimated to be around 50 billion per year, 50 billion dollars per year. And I think there are two issues that are facing these industries that will increase these prevalence rates in the near future and these costs.

First, industry workers are becoming overweight and obese. Recent studies have indicated that more than 65 percent of the United States population has excessive weight, with about 44 million being overweight at any given time. We have recently done studies that have indicated this prevalence of overweight individuals in manufacturing facilities are actually higher, approaching 80 percent. The problem with excessive weight is that it adds additional stress on the body. Individuals not only have to perform the task, you also have to move the excessive weight, and thus increasing the stress on the bones and the body and joints.

We need to research into several aspects of overweight and obesity in the industry relating to musculoskeletal disorders. First, we need to better understand how excessive weight relates to musculoskeletal injuries. At this point we don't know clearly what that link is. Second, we need to know how to design the workplace for individuals with excessive weight, how do we compensate for these individuals in the work place. Third, we need to know how to successfully reduce the prevalence of obesity in the workplace and how that links to the other health and safety initiatives. Fourth, we need to develop intervention strategies to integrate weight loss into safety and health industries that are already occurring.

The second major issue that relates to increased musculoskeletal disorder rates in the future is the aging workforce; touched on by the previous speaker. With the shift in demographics that is expected to happen in the next decade or two, the workforce will have an increasing number of individuals that are above 55 years old. Some facilities are already seeing the average age of above 55 years old.

Since many capacities decrease with age, an older workforce may be susceptible to additional stress and ultimately musculoskeletal disorders, which leads to higher rates of lost days in this population. Some of the capacities that are known to be impacted are muscle strength and stamina, posture-balance (ph), cognitive processing, joint and tissue mobility to recovery from injury. All of these deficits can lead to longer, more serious, and more debilitating type of injuries with this population.

Thus, there are several needs for research and initiatives relating to the aging workforce. First, we need to understand the adaptations that occur for these older workers in the workplace. Given that they are exposed to the same type of stresses and strains as the younger workforce, we need to understand how we can adapt as older workers age and work longer.

Second, we need to understand the role of cumulative trauma and developing of debilitating disorders. We need to know how the previous exposures impact their longevity in the workplace.

Third, we need to understand the impact of physical workplace stresses on the older worker and how these age-related changes impact responses to these demands.

In conclusion, I think we need to make sure that the industrial sectors and what they concentrate on are focused on not only musculoskeletal disorders, but specifically how these special populations, the overweight and obese individuals, as well as the older worker, need to adapt to. That concludes my remarks. Thank you.

Verbal Comment 2006/03/06: I'm Ray Jones. I'm probably the least educated in the bunch here. I'm an old retired factory worker. But I'd like to talk about my wife, and the injury that she suffered to her back, which deals with musculoskeletal problems and such. And in this case I'm calling it, falling through the cracks.

She had a soft-tissue injury to her back, which does not show up on a CT or an X-ray, and so on and so forth. The original diagnosis was a sprain to her lower lumbar, and that diagnosis stuck. It went through a legal process and lawyers flipped through all their papers and say it's a sprain.

So in the following weeks she went through six to eight weeks of rehab, she did not heal from this, but she went back to work under severe restrictions. And being a nurse, she was told to take care of 30 or 40 patients, some of them weighing 200, 250 pounds, and she's only 100 pounds. And the supervisor decided that she wasn't performing her work as she should, so they wrote her up with intentions of dismissing her at some future date, is what we would assume.

In the next year or so she made 24 visits to the emergency room for pain medication, and this to relieve the soreness in her back so she could move. Then after this period of time then the doctors decided that she was becoming a pain addict, if she wants medication then she's becoming addicted to the pain medication, so now they cut her off from that.

But this is a workers' comp process where now the workers' comp people decide that they don't have to pay any longer. So now she is basically without assistance in paying the medical bill. Senior health insurance doesn't pay for accidents, and this was signed in as workers comp and it was an accident. So your health insurance no longer applies to you. And you try to pay a doctor cash to get some treatment and he doesn't want to do anything about it because it's workers comp, and he doesn't want to get into the mix of the workers comp.

Well, she goes to additional doctors for diagnosis as to what her problem is to submit papers into workers comp for additional evaluation. Well, some of the doctors don't speak English very well. So they transcribe their material onto a tape and they send it off to get transcribed again. Well, you can't tell the difference between should and shouldn't, or would and wouldn't, and could and couldn't; so some of the doctor's transcriptions come back with serious errors in them. They say she didn't walk with a cane, well, she did. And some of the evaluations that were done were done with her clothes on. They never put her in a gown. In fact, the doctor's office was a hole in the wall and was not an actual what you would call a practicing doctor. He had a cot in one of the rooms and he brought in a little bag of protractors to check her movement. In 15 minutes he's got a diagnosis that he sends off to the lawyer. And, again, this sticks.

So now we have gone nearly -- well, this was an accident in 1999. And our lawyer has asked the workers' comp rep for a settlement. Well, they just simply don't call back. And this has been three years. And her overall medical expenses now have come to the point that they exceed what she ever earned in her life. And she is now on Social Security Disability. Well, she has other factors too, like migraines and asthma, which helped her get the Social Security Disability. But when he represents 56 percent of the people as being at weight or below weight, and younger people -- younger people need the conditioning to handle their job. And if you're under weight you're just as bad as if you're overweight. And I thank you.

Verbal Comment 2006/03/06: I deeply appreciate your consideration here. My name is Lee Hager. I am employed by a company called Sonomax Hearing Healthcare, Incorporated. I am also here with multiple hats today to share some time with Tim Rink to discuss the National Hearing Conservation Association. People who are focused on one of the exposures issues that is critical to us.

Just a little bit of information on NHCA, just for your information, it's the only group that focuses on hazards of noise and the effects of noise on hearing on a cross-functional basis; engineers, audiologists, industrial hygienists, safety professionals, the whole nine yards. And Tim will give you more information about that.

Thirty-five years into federal regulation on noise in the workplace and what do we know? We know that about one in five people in the U.S. goes to work every day and noise levels pose a risk to their hearing. We know that about -- excuse me, I added a digit, about 25 to 28,000 people in the U.S. suffered recordable hearing loss in the year 2004. We know that work-related noise-induced hearing loss is implicit in about a third of the total hearing loss cases in the State of Michigan.

Noise continues to be a hazard, a hazard that may be well understood, but not well controlled. To give you a sense of the scope of this, about ten percent of the total illness cases reported by the Bureau of

Labor Statistics for the year 2004 were hearing loss, about ten percent for a hazard that we know, that we understand, that we know what do to about.

The reason that we're here today is that because of that group of hearing loss cases, about 85 percent were recorded from manufacturing sector. So noise continues to be a significant issue.

A couple of reasons for this, number one, we rely on personal protective equipment nearly exclusively as defense against noise in the workplace. In many cases, the first, last, and only line of defense against noise in the workplace is the hearing protector. But hearing protectors are not easily quantified as to performance. We don't know how well they work. Laboratory evaluations, even the best laboratory evaluations, do not give us a reliable estimate of how well people are protected from noise in the workplace. As a result, we wind up with poor-usage rates. People don't like to use hearing protectors in the workplace. They're communication barriers, they're comfort barriers. Significant barriers to use of this PPE that we know can be effective, but that is still resulting in significant hearing loss of the noise that's in the workforce.

There are a couple of areas of research where we would like to kind of direct the NORA efforts down stream here on a cross-sectional basis, if possible. Individual fit testing hearing protectors, much like we test respirators today, would be appropriate. There are things that we can do, and new technologies that are emerging that would permit us to determine how well individual pieces of protective equipment are working for individual people. We need to prove analysis of why people resist the use of hearing protectors. We need to find a way to quantify the comfort issues that are involved in the use of hearing protectors, so that we can get effective personal protective equipment into people's ears and prevent hearing loss.

We'd also like to talk a little bit about exposure criteria. NIOSH clearly identified and communicated to OSHA in 1998 in the criteria document that the current OSHA noise exposure criteria is insufficiently protective. NIOSH drew a line that is significantly more protective than the current law that's in place. What we need to do is find a way on a research basis to move this finding, to move this research finding into practical application. Find a way for industry to accept a more protective exposure limit than is currently in the law under OSHA. Does that mean changing the OSHA regulation? I don't know. But at some poi

More research into the indirect effects of noise, the association of hypertension with noise exposure, the relatively new association of -- potential association of acoustic neuroma with noise exposure, strong correlation between workplace noise and industrial accidents. There are many, many things that we can look at that would let us fine tune our efforts in noise to be more effective.

In addition, the combined effects of noise. The combination of noise to toxic chemical exposure. New indications that may indicate that whole-body or hand/arm vibration may sensitize an individual to hearing loss. So noise is still on the agenda, and we think it's important that NIOSH and their new NORA considerations take this into account. Thank you.

Verbal Comment 2006/03/06: Good afternoon, ladies and gentlemen. Thank you very much for your interest in safety. My name is Darrell Rubel, and I work for the Ohio Farm Bureau where I wear two hats. I'm Director of Safety Activities and also Youth Activities. I want to tell you a little bit about Ohio Farm Bureau. We're a grass-roots organization, which means that all of our ideas come from our members and from those folks who grow our food and fiber. So I have some ideas from those folks about the types of safety concerns that they have that I wanted to share with you today.

The first topic is farm rescue. What do you do when something goes wrong on the farm? One type of accidental death that we have seen happen on farms in Ohio is grain bin suffocation. Folks get caught in the grain, they get sucked down, they can't breathe. Several different things. We would be interested in having research done on the types of things that can be done to prevent such suffocation from occurring. I know that Mary Fleming back there has been working with some folks on grain safety rescue tubes that could be used. How can we get those types of tools into the hands of emergency responders, also for fire departments?

Another concern we have is providing additional training for those folks who are emergency responders when they get out to the farm. These folks are very smart and they know how to deal with medical situations. One thing that does occur though on a lot of farm accidents is there may be farm machinery involved.

Sometimes folks may not be aware with what the type of machinery that it may be, or with the different models, whether it's a different model of hay bailer, or combiner, or whatever, how to get people extracted quickly and safely from those types of things. Research about how we can spread the word

and get information out to the emergency responders on how to get folks safely extracted would be very helpful.

The second thing that I would like to mention is road safety, or as Kentucky Farm Bureau coined it, please be patient and kind, stay behind. We all have to share our roadways in the country, and our farmers need our roadways in order to get their farming done, especially during the busy times, planting season and harvest season. One of the challenges that we have as farmers in sharing the road is people that want to go around the tractors and the equipment when we're out there. Either that means crossing double-yellow lines, crossing on hills or blind curves. It leads to accidents. Also some people want to hurry around farmers. They may be trying to make a left-hand turn into a driveway, they're signaling, but people think that they're moving over a little bit to the right and allowing them to pass. That's not the case. They need the extra room to make that wide-hand turn. They'll try to go around that farmer and end up causing a collision. So research on those types of things could help.

Also as Wayne Dellinger mentioned this morning, safety concerns with tractors that can now exceed 25 miles an hour. How does that affect our folks and our fellow motorists with safety on the road?

Another program that I would like to briefly bring up to you is featuring our most valuable resources, and that is our youth. What extra kinds of safety training can we do and provide to keep our youngest workers safe, especially as they're entering those crucial first years in training and joining our workforce? I'm very pleased to announce that we have seen some wonderful cooperation from the folks at OSU Extension and from our friends at the Bureau of Workers' Compensation. This year we're having our very first Ohio Youth Safety Conference where we're bringing youth from around the state to be trained about farm safety and in the fast-food industry, the two industries that have the highest rates of incidents.

We're doing that, and I'm very proud and happy that we're doing that, but we need more. Are there additional ways that we can go out there and reach those young folks in those first crucial years? They are our most valuable resource. They're our next generation. And how can we present that safety is not just what you do, but it's who you are?

Ladies and gentlemen thank you for your time, and I appreciate it.

- National Hearing Conservation Association

Categorized comment or partial comment:

Verbal Comment 2006/03/06: Good morning. My name is Dr. Tim Rink. I am CEO of HTI, Incorporated at Worthington, Ohio, a company I founded 30 years ago to provide audiometric testing, record keeping, and recording services to clients throughout North America. Today I am representing the National Hearing Conservation Association, the NHCA. One of our prior speakers, Lee Hager, in fact, was president of the organization just a few years ago.

On behalf of the NHCA, thank you for the opportunity to comment on the Institute of Medicine Committee's review of the NIOSH Hearing Loss Research Program. In preparing these comments, it became evident that the mission of the NHCA is very much inline with the NIOSH HLR agenda. As a testimony to how important the NIOSH HLR program is to hearing loss professionals, such as NHCA, our comments are structured around the NHCA goals. Clearly the NIOSH HLR supports our mission to reduce noise and reduce hearing loss in all sectors of society.

It is a NHCA goal to provide professional development by improving the skills, practices, and services of members of the association. NIOSH has advanced in this goal by developing a research agenda which addresses questions encountered by members during their daily hearing loss prevention practices. Research findings are directly applicable and can be implemented into hearing loss prevention efforts. Some examples of the practical tools used by our members are the interactive noise, sound level meter, hearing loss simulators, frequently asked questions, and the hearing protection device contending. Publication, such as the noise and hearing loss fact sheets and hearing protection device education, free of commercial endorsements, are used in training courses with employees and employers, and they provide NHCA members with tools to facilitate the prevention of hearing loss above mere OSHA compliance.

Presentations in journal publications by NIOSH investigators continue to push our understanding of what it takes to prevent noise-induced hearing loss and provide significant content in NHCA national conferences. Conferences from 2003 through 2005 also included NIOSH presentations on impulsive noise, hearing conservation in the construction industry, hearing conservation for small businesses, hearing impaired employees, evaluation of level-dependant hearing protectors, chemical exposures, and noise-induced hearing loss, the evaluation of hearing conservation program effectiveness, and early indicators of noise-induced hearing loss. NIOSH has been strongly represented in poster presentations and a NIOSH poster earned the outstanding poster awards in both 2004 and 2005.

NIOSH employs leaders in hearing loss prevention who willingly share their knowledge and encourage professional growth and development. In 2003, Dr. John Franks was awarded the NHCA Prestigious Award, the outstanding hearing conservationist, given to an individual whose work is exemplary in the field of hearing loss prevention. In 2006, our meeting just this February of this year, we proudly honored Randy Tubbs with the Michael Beall ThreadGill Award, presented to the individual who has significantly contributed his time and effort to NHCA. In 2004, Dr. Mark Stevenson was awarded the NHCA Media Award for drawing public attention to the cause and prevention of noise-induced hearing loss.

The NHCA is greatly anticipating the formal signing to expand our alliance with OSHA to include NIOSH. The OSHA, NIOSH, NHCA alliance will be a strong foundation for us to continue our partnerships and develop tools and services. It is an NHCA goal to provide education and encourage research in noise and hearing conservation. NIOSH best practice workshops and seminars are cutting edge research, and cutting edge research is a vital part of our continuing education as we work to prevent noise-induced hearing loss.

As highlighted above, NIOSH researchers are always an integral part of our annual conference sharing their latest information and highlighting progress in the on-going efforts that we share. The upcoming conference, noise-induced hearing loss in children at work in play, which is co-sponsored by NHCA, NIOSH, and other organizations will explore and discuss the most recent theoretical and experimental

work to expand the knowledge of preventing hearing loss in children and adolescence. This innovated conference will bring together a diverse group of basic and applied researchers with expertise and hearing loss prevention.

It is a NHCA goal to stimulate the exchange of information among those involved with hearing conversation, disseminate information to professionals and others, and to provide a resource center for those inquiring about the prevention of hearing loss due to noise and other environmental concerns.

As we try to provide information and serve as a resource center regarding prevention of hearing loss, NIOSH researchers provide much of the content that is of critical value to everyone involved in hearing conservation. The NIOSH hearing protector compendium puts up-to-date information at the fingertips of researchers, product developers, hearing conservation program managers, professionals, purchasers and users. NIOSH best practice workshops focus multi-disciplinary groups toward consensus-based science and data.

Journal publications and conference presentations not only provide an insight into the excellent work of NIOSH researchers, but stimulate exchange of information among our members and beyond. The alliance is another way we can continue to exchange information and share it with those who need it to help prevent noise-induced hearing loss. The NIOSH website is an important accessible tool which has dramatically improved the dissemination of information and ability to put excellent knowledge into the hands of employers, employees and hearing loss prevention professionals; again, with a focus on practical hands-on tools. NIOSH research has helped us develop language appropriate literature, all of which helps us achieve our tangible outcomes.

It is a NHCA goal to promote the development of improved and more effective occupational hearing conservation programs. One of NIOSH's research topics is studying the effectiveness of hearing conservation programs. This topic alone has the potential to change hearing loss prevention programs by recognizing where efforts toward hearing loss prevention should be focused, addressing practical questions, like how to recognize a noise notch, assessing which test frequency should be monitored in audiometric testing programs, defining when a decrease in hearing should trigger follow up, and how best to conduct training programs are all valuable in improving hearing loss prevention efforts.

It is a NHCA goal to develop guidelines and monitor and participate in standards, regulatory and legislative activities. The NIOSH criteria document is the seminal document reflecting the best available science, and should be viewed as the blueprint for future regulatory and legislative activity. Research gives science credibility to the recommendations. Current OSHA regulations based on the best data available when the current regulation was promulgated in the late 1970's. But on-going NIOSH research in support of the 2000 MSHA regulation and other activity allow new regulation to incorporate new understandings resulting in more protective hearing conservation programs. NIOSH research points the way to better hearing loss prevention practices. I'm presenting the papers as they were given to me. I'll wrap by this, future research areas that the NHCA is hopefully going to see come under development include mechanisms of hair cell death, evaluating the most appropriate audiometric test frequencies for monitoring noise-induced hearing loss, evidence-based input for regulatory requirements, relationship between hearing protective devices, hearing loss and occupational injuries, effective applications of augmented hearing protective devices, testing needs for electronic hearing protective devices, effective methods of motivating workers to wear hearing protection, best practices in hearing prevention training, noise-induced hearing loss in musicians, effects of personal-listening devices on hearing,

hearing loss acceptability in children and methods for separating age and other contributing factors to hearing loss. Thank you.

Verbal Comment 2006/03/06: Thank you very much. My name is Custodio Muianga, assistant research at Eduardo Mondlane University, Maputo, Mozambique. And I'm a graduate student at University of Cincinnati, Department of Environmental Health. My contribution to NORA is based on my involvement in occupational environment health in southern Africa, particularly in Mozambique.

And I would focus on three main ideas. First, the use of comprehensive and holistic approach on the practice of occupational health and safety. Second, the experience to gain from big corporations versus small companies, or small businesses. Third is, there is such training problems existing on training programs.

Because of the difficulties and high burden of other problems like healthcare associated with HIV and other things. In developing countries you can't do occupational hygiene just because of occupational hygiene. So you need to focus on a qualitative and semi-qualitative approaches. These started from elsewhere in developing countries also have shown very good successes. I think that the United States also has small or very small business, which most of the time they're not covered and they would have very good input using this kind of approach. Now it's called risk management toolboxes, which will develop into the qualitative risk management.

The bigger corporations, they also work in U.S. and outside of U.S., and they interact with small companies, which are the companies that existed in developing countries. So if NORA can explore their experience starting from here and there. There is such training programs consisting on training programs between academic institutions and research institutions also who will give a double win to

NIOSH or to NORA. Because these researchers, they will be involved it, and they will see problems which they're similar. If we see the occupational health and safety problems, they are all the same, wherever you are. The only difference is the dimension of the problem and the other factors.

So what I'm saying is NORA should also focus on the use of holistic and comprehensive approach and the practice of occupational health and safety. Thank you.

Verbal Comment 2006/03/06: Thank you. I'm Scott Clark, University of Cincinnati. NIOSH has a strategic plan for the year 2004-2009. It contains three goals, and my comments will address the goal three, which is to enhance global workplace safety and health for international collaborations, and follows up the previous one, and there's three parts to that one.

The third part is to build global professional capacity to address workplace hazards through training, information sharing, and research experience. I will provide some comments which hopefully will augment the previous speakers so that the NORA 2 can include some efforts in international collaboration of meeting these goals that NIOSH has.

And we will -- I'll give an example of what our university has done in this area with the country of India. I'll do this just as an example as a possible model for other ones, there are many other ones around, but this is one that we have been involved with. And you know India is a pretty large country. It may be the largest on the earth. India and China are debating that, population-wise, and certainly the largest democracy and are very important to the U.S. in many ways.

I'll first talk about how we got involved with this. A little over ten years ago one of our alumni, Maharshi Mata (*), some of you may know, was a graduate in the early 80's. He came to one of our faculty hygiene meetings and said he was moving back to India in a few months and wanted to start the master's program there in industrial hygiene. We said well, fine, probably there are 30 other ones there, ten other ones. There are no other ones. There was no safety program, mostly shorter term, a few months. And the Factories Act recognized safety engineers, social workers actually too, occupational social workers, and physicians and nurses, but nothing in the hygiene area. So he pieced together many different groups that could help, a medical school, they have toxicology and physiology. At the university they would have the epidemiology and bio-staff and regulatory group in the nuclear

area. And also they have a NIOH, it's National Institute of Occupational Health, and their main branch is located about an hour-and-a-half from this campus.

So here just to help, we thought he would maybe get a long-term plan, first maybe have one course as an elective and then in five years admit their first student. No, he was going to begin that next year. So he stopped by with an MOU joint university in May of 1997, and these papers, you know, are kind of all good intentions, but it depends on who's behind them. But this one, I'd say, has had a lot of impact. It's been viable for ten years.

And we began by soliciting reference books and journals. For many people, probably some people in the audience were contacted. NIOSH was, ACGH, some of the military services. We have a retired department director. And Jim Ferguson, some of you know, was retiring from his practice and he gave us his core reference section. So we got those shipped over there for the first class. And we've gone -- Dr. Carol Rice and I have gone pushing every year since that time for periods up to two months. Dr. Glenn Talaska (*) went this fall also. So a lot of interaction with it. And there's a picture out in the hall showing the students getting their first certificate. They get their degree from India, but we give them a certificate of congratulations basically. And our role is to help them with it.

So this is an example. We've done similar things in Poland. It's been a benefit to them obviously, but also our students. We've had two doctoral students went there for a period of time and did some training and helped them tremendously. And they're both now university teachers in occupational health. Another student went there for a pilot project. They got best poster award in two divisions, epidemiology, another one, and it helped her get a very prestigious EIS officer position for two years and recent publications.

It's estimated that India needs 5,000 master's-level hygienists. They probably had five when we started, and one was the person who started the program. Now we've graduated about 50 people, and they're in the process of becoming certified. But obviously one program isn't enough, but it's a lot more than zero. And hopefully there will be some way to support these sorts of activities. There's also INDO U.S. working agreement that facilitates NIOSH and other groups getting involved with India signed by HHS director and CDC as the coordinator here. We've had one private on silica dust control that involved some NIOSH investigators. So that's been a positive thing.

Under the ERCs there is an item called the NORA research support, which is a pretty big item on the ERC budget now, the same size as an economic program. And this is one possible mechanism to get the nod that it could use the limited number of funds there for that. There are other countries; obviously, this was just an example from India. Thank you. We could have some extra time in this session, and one gentleman has already offered to speak. His name is down there.

Verbal Comment 2006/03/06: My name is Carol Rice. I'm on the staff at the University of Cincinnati. And I want to talk with you, now having heard the morning presentations I know that I'm know that I'm preaching to the choir about worker training.

Under sections 21 of the Occupational Safety and Health Act it states that NIOSH shall provide for the establishment and supervision of programs for the education and training of employers and employees in the recognition, avoidance, and prevention of unsafe and unhealthful working conditions.

These are very specific phrases in the matter. Phrases that characterize outcome of training and education, recognition, avoidance and prevention. This comprehensive description to NIOSH extends the responsibility well beyond the creation and dissemination of information. Information understood and retained is essential to any increase in knowledge. And that is the foundation for activities that leads to recognition, avoidance, and prevention.

However, knowledge alone can not provide the vital skills, ability, and attitudes to fully recognize the hazards or to design and implement successfully actions and programs to avoid and prevent unsafe and unhealthful conditions. In the current climate of smaller regulations and even smaller enforcement it's increasingly incumbent on employees to take improvement of safety and health into their own hands. Increasingly, a union or active joint labor management committee that might provide effective health and safety training resources are absent, and they've never been there in small business. NIOSH can, and is, in fact, mandated to address this need. Certainly the crafters of section 21 intended that the change would be successful, a result that can only emerge from research and then research to practice.

Currently the need is enormous. In dimensions, personally, I believe that it exceeds that of improving science literacy, which the President has addressed as a national priority. And the easy approach of providing information is fundamentally a failed system, as illustrated by the situation, at least those of us with gray hair, approach routinely of the struggle when given written information on directions to operate a wide variety of electronic devices, and you need somebody who is about ten who can help you get through the system.

While the task is light, it has to be recognized that the benefits are also huge. Workers participating in training design through research in one sector and targeted to increase knowledge, skills, and abilities and to develop attitudes to support continued diligence and improvement have been documented to be able to make substantial changes. For example, antidotes of, we now use cameras in confined spaces. Cameras go in, people remain out. We have not had an ammonia release in our facility for many years. Because of the skills my team members had, we were able to isolate and abate the ammonia leak efficiently and effectively, and were able to keep anyone from getting hurt. That's the true measure of effective public safety training.

We also have reports that training has changed our work behavior. Training has been extended to recognizing hazards outside of work. The true transfer of knowledge and information to recognizing the effect, the potential for hazards in the home.

Economists can and truly must, as many have said here today, put dollar figures on these examples in order to sell them to the constituency. They're essential to documenting value to both employers and insurance companies. But to the workers and the families of workers that benefit from this research to application, the training dollar is really not relevant. They're much more guided by the expectation that each day their family members will return home from work with no diminution of health. Most importantly, these benefits of avoided exposure are meaningful on an individual level, and that is clearly the foremost priority, the individual level, for occupational safety and health.

So I would suggest that NIOSH begin in developing a research agenda for effective worker health and safety training by updating and supplementing the NIOSH review by Cohen and Colligan (*), identify targets for improvement, such as design and the design of research to identify why and where current approaches have failed, to conduct research and to identify effective methods. I believe NIOSH has a unique opportunity with a redevelopment of NIOSH to put workers at the forefront. Thank you.

Verbal Comment 2006/03/06: Good morning. I would like to thank the academy for bestowing this honor upon me today. Moving on, my name is Chris Speelman. I happen to be a certified hazardous material manager employed by Sheakley UniService, Inc. in its Cincinnati office. For those of you who aren't familiar with Sheakley, it is a provider -- basically a provider of workers' compensation services to public and private employers in the State of Ohio.

In my position as a safety control I'm expected to work with employers in all types of industries in an effort to help them reduce the injuries and illnesses experienced by their employees. Even though I do work with a range of industries, there is one constant that I typically encounter, nearly all the companies I work with are small businesses; companies that employ 100 people or less. It is these small businesses that I am here to speak with you today.

NIOSH appears to recognize the importance of small businesses to the national economy. In researching my comments for today, I performed a quick search at the NIOSH website by entering the word small business into the search line. This search pulled up the Small Business Assistance and Outreach page, one lonely paragraph of text. This text told me that 98 percent of all businesses in the United States employ less than 100 people, and 87 percent of all those businesses employ fewer than 20 people.

In the publication identifying high-risk small business industries, I am told that more than half of the U.S. workforce is employed by these same small businesses. This document also suggests that, at least in some industries, the occupational injury and illness rates are typically much higher in small businesses,

especially when compared to the larger businesses. In some cases it can be up to ten times the fatality rate in small businesses compared to the larger businesses.

More over, this same search also revealed that there are only two NIOSH publications that deal specifically with health and safety in small business establishments. For specific health and safety implementation assistance I was routed to the OSHA small business website.

Just to pose a quick question. If these small businesses are so important to America and they typically have much higher injury and fatality rates, then why have we only two small business-specific documents on NIOSH's website? Now, granted, I realize that NIOSH is a research-based organization. Its purpose is not to help with small business compliance. However, the beneficial research conducted by NIOSH effects all businesses across all industries.

Unfortunately, based on my personal experiences with small employers here in Ohio, it seems that small business, especially small manufacturers, are unable to obtain the same benefit as larger employers from these technological advances. This is due to several reasons. Perhaps most noticeably, the lack of financial resources available for health and safety technologies. Again, -- excuse me, additionally, the men and women who run these businesses are often ignorant as to what health and safety information and assistance may be available to them. I am here today to urge NORA to address these last two points.

First, NORA should examine ways to disseminate information to those people who run America's small businesses in order to close this information gap. If these people understand what resources are available to them, then they are more likely to take the steps necessary to protect those whom they employ.

Secondly, while the advancement of worker protection is dependant upon the discovery of cutting-edge evaluation and control technologies, the price of these technologies is generally cost prohibitive for small employers. As a result, more than half of America's workers are often protected, if they're protected at all, by sub-standard technologies. I encourage NIOSH, through NORA, to conduct research towards making both new and existing technologies affordable for implementation by small business.

In closing, it's been my experience that most small business owners have the desire to do the right thing when it comes to protecting the workers. However, they are often limited by not knowing what resources are available to them, or they are unable to afford the technologies that are available. I encourage NIOSH to address these two issues in an effort to fully protect all employees, not just those fortunate enough to work for large corporations. Thank you for your time.

Note: Verbal testimony provided to NORA Town Hall meeting in Piqua, OH 2006/03/06.

Verbal Comment 2006/03/06: Well, I am Susan Kotowski. I'm a PhD candidate in Occupational Ergonomics and Safety in the Department of Environmental Health at the University of Cincinnati. I wanted to talk about the economics of injury, which has only been briefly touched on today, although it's been acknowledged a number of times as an important subject.

Of the research that has been done, they're really now just starting to understand the impact of injuries and musculoskeletal disorders on the companies' bottom line. For example, we know that the annual cost of musculoskeletal disorders exceed those of cancer and only trail those of cardiovascular disease and acute injuries. Current estimates for the direct costs only of musculoskeletal disorders are about 50 billion dollars yearly. However, these are only real crude estimates.

To date, most of the costs have tended to focus on only the direct costs associated with the injuries. Direct costs consist of medical treatment, workers' compensation, and rehabilitation. However, estimates of indirect costs are much more difficult, and often more times controversial to obtain, although they comprise a large portion of the cost associated with the injury. Indirect costs include costs associated with an injury, such as lost productivity, overtime, hiring and training of assistant workers, absenteeism, presenteeism, accident investigation, any product damage, and possibly increased insurance premiums. It is estimated that for every dollar of direct cost there are typically two to five dollars in indirect costs. However, so little is known about indirect costs and this might be a drastic underestimation of these costs.

Recent trends have indicated that there's a yearly significant increase in the direct and indirect costs associated with injuries, and this cost is growing every year. For example, in 1985 the total cost associated with injuries was 158 billion dollars. In 1988 the cost increased to 180 billion dollars, or a 14 percent increase. In 2002 the cost increased to 240 billion, or a 33 percent increase.

Another wellness issue to consider, although not an injury, is obesity. Obese and overweight individuals now comprise 65 percent of the population, or nearly 45 million people. Obesity attributed medical expenditures in the U.S. were estimated to be 75 billion dollars in 2003, over half of the cost financed by Medicare or Medicaid. Others have estimated these costs associated with excessive weight to be between two and eight percent of total health care expenditures in the U.S.

We are really just beginning to scratch the surface of understanding the costs of injuries, musculoskeletal disorders, and obesity. A major research void exists in the thorough documentation of costs associated, or including both direct and indirect cost for the duration of the injury.

There's also a need to document the interaction between one injury and a secondary injury and the costs associated with the co-morbidity. It's also crucial to distinguish between what fraction of the cost is associated with the initial injury and a subsequent injury.

There's also a need to document how other health issues, such as obesity, affect the risk of developing an injury or musculoskeletal disorder. This is very much lacking, although very critical.

In addition, there's a need to document the costs associated with other factors, such as impact of quality of life, impact on family life, the impact of pain, as well as functional abilities.

Finally, more research is also needed in the area of cost reduction and the benefits of intervention to reduce injuries. Understanding the impact of wellness programs, weight-loss programs, ergonomic interventions, and other safety and health-related programs on the cost of injuries and the companies' bottom line is critical. Thank you.

Verbal Comment 2006/03/06: Morning. My name is Jim Wirth, and I'm the Safety Manger for GatesMcDonald in Columbus, Ohio. Although we're competitive of Chris, we're going to talk on some similar ideas this morning. I'm here to speak on behalf of NFIB Ohio, National Federation of Independent Business. NFIB Ohio is the state's largest small business advocacy organization with 600,000 members nationally, 36,000 members in Ohio, dedicated exclusively to representing the interests of independent business owners.

Our membership spans the spectrum of the business community ranging from sole proprietorships to substantial independently held enterprises. The typical NFIB member employs fewer than ten workers and grosses less than \$450,000 in annual sales. In aggregate, our organization's members employ near 440,000 Ohio workers. I and my team work closely with NFIB members across the state to assist them in providing a safe and productive work place. NFIB members are owners of businesses in all the sectors that you saw shown on the screen this morning. If you look in the Yellow Pages, they do it.

We're currently involved in a study with NIOSH encompassing nearly 300 NFIB Ohio members to develop more effective safety training materials for small business. It's been quite a journey. I looked at some of my earlier e-mails and it's been about five years. But you know how it goes with getting the funding and getting all the people together. But it's been a real pleasure. These participants received these materials consisting of sample safety training modules, and are using them to keep their employees safe.

We went to a whole process of working with the NIOSH folks, people coming out and attending our seminars and being focused with us. NIOSH will collect information on what worked, what didn't, and what business owners would like to see.

Additionally, the Ohio Bureau of Workers' Compensation Division of Safety and Hygiene is a partner in this study as well. And they'll be able to take the information collected and developed by NIOSH in this study and create training materials and classes to educate all of our employers. We're also currently participating in a national alliance with OSHA, and we have a state alliance as well.

I'm here today to comment on the opportunity of continuing this research, albeit on a slightly different tact. Many small independent business owners involved in the day-to-day operations of the business find it difficult to fully understand safety requirements and how they pertain to their operations.

We believe that by breaking down the requirements and highlighting the points of the program of process, along with examples of good practices, they will then be able to understand how it relates to what they do and why they must implement these safe-work practices in order to provide a safe workplace.

Since we are involved in the current study to find the best ways to educate employees, we feel as equally important to develop the method or methods of providing small business owners the safety or other regulatory information in a form they can easily understand and that is directly related to the rules and safe-work practices that they're required to implement.

Too often I meet employers who truly want to provide a safe workplace, but they're not able to understand the highly technical nature of the safety regulations. We feel it would be very helpful to provide some type of best practice, basic inclination, or even a sample program of process for the small business owner so they are able to decipher the rule or regulation, understand how it applies to them, and how to train their employees. For instance, this best practice or sample program would illustrate how a program would be implemented and suggestions on how to train employees. The hazard communication standard, for example. Material safety data sheets best practices give examples of how they are kept and shared. Labeling seems simple, but what kind of label should be used and what must it say? Training must be done so employees understand the hazards, but form should it take and what should it include?

As a safety professional, I'm keenly aware that some employers simply take safety programs and processes, add their own names, and call it their program. I do not feel that that should keep us from trying to develop more user-friendly processes to meet safety regulations and standards for those employers who the majority, I believe, truly want to implement these rules in an effective manner.

Finally, one last issue of concern is NIOSH's recommendation that OSHA take action to deal with silica exposure in the workplace, despite the continued doubt or trend silica-related deaths nationwide. If it weren't enough, then scientific studies are showing that the risks of harm from silica exposure are much less than originally thought. Three separate panels of the SBA have concluded that the recommended policy actions would place crippling demands on America's smallest businesses. NFIB recommends that NIOSH reconsider its prioritization to abatement of crystalline silica exposure in the workplace.

NFIB appreciates this opportunity to address this panel, and remains committed to continual partnership and participation to promote safe work places. We also really appreciate the good work that NIOSH does. And it's been an enjoyable five years, and look forward to more. Thank you.

Verbal Comment 2006/03/06: Hi, I'm Ronald Klein. I'm the Medical Director of (inaudible) Workers Care, which provides occupational medical services throughout the Dayton area at various sites. I do not have a script to talk. Obviously, I couldn't keep my mouth shut.

I've heard lots of good material here. We've skipped around the ergonomics and the low-back issue. And I'm surprised at how many -- I thought I would see many more of my medical providers here who are working in day-to-day providing ongoing frontline services. I'm a little dismayed that we're not here, and I'm going to apologize for it, because we should be.

One of my concerns is, obviously, we've touched on some of the low-back issues that obviously comprises probably the single largest percentage of patients that we see, and it is a very difficult group to deal with. There is currently not really good research of how we are dealing with these low back and their ongoing treatment. One of the things that we have instituted is what we call a back decompression device. And, unfortunately, it is not reimbursed. There is no particular code for it.

While retrospective studies would indicate that you have 85 to 86 percent success rate in reducing herniated or ruptured disks successfully without surgery, there is no prospective studies being done. And I think that we would like to see NIOSH and OSHA get involved in funding some of that research to try and see if we can't do a better job at treating low-back issues.

The only other thing that I wanted to bring up is carpal tunnel syndrome. That has been an ongoing problem here in the United States. It is -- the United States and Canada are the only two holdout countries still recognizing carpal tunnel as being work related. There is no evidence that this is a work-

related problem, statistically, at any population that you look at. And I wish we'd come out with a statement of paper that finally calls it what it is, so we can clarify that to our providers that are having to deal with it on a daily basis, as this continues to be a very muddle ground. That's all I have to say.

Verbal Comment 2006/03/06: Good morning. My name is Farhang Akbar with the Medical University of Ohio. And, again, I couldn't keep my mouth shut. I didn't have anything for presentation, but I thought I would make a couple of comments from my own personal experience.

In fact, we have employers, we have workers, and then we have other bodies, like government and industrial hygienists and all of that. What we are trying all to do is eventually control the exposure. Unfortunately, our recognition, our applications of hazards, or monitoring, they are going very well. Everything is electronics. We can cut various spawn amounts of pollutions and so on. But, unfortunately, when it comes to control we are so weak. I'm talking about the (inaudible) expense, I'm not talking about (inaudible).

I'm a researcher. I spend my time hands-on. I tell my students that I collect dirt and notes. This is what we do. One of the things that is very, very popular now a days is using in lieu of very good control methods is personal protective devices. And I have very, very long experience personally with PPEs. And we have published two papers. And in both of them you will be very, very surprised that people don't like PPE. And either they don't understand that why, or we do ignore it.

In my experience that conducted a research in about five, 600 people, 50-something people, they didn't like the respirator. Still, we insist that people use respirators. The same with hearing protectors. They don't like it. They don't like the collar, they don't like the size, they don't like how they're made, they don't like the way they're designed on the face. They're all issues. And we do not have any research. As I said, the only research we have, very, very short, and in a short time, was a couple of things that we published.

And I'm going to ask we put in our agenda a more elaborate, a more intensive way of looking at personal protective devices. Not walk there as an industrial hygienists or health and safety professional and throw a hearing protector or something in front of the worker and say, go and use it. Why I'm saying that is because I see them all over the factories, shops. They're not using them, they're not cleaning them, they're not maintaining them well. There is no way to check in and out. So that's a major problem. That's number one.

Number two comments I wanted to make, again, comes from my personal experience. Last year I tried numerous employers and unions to let me do a simple pilot research in this state. I couldn't. They didn't let me to do that. And I'm sharing that until we do -- if you're not providing the research, and Leggs is one of the employers for us, if you're not going to cooperate with us and let us do our work, how are we going to do the research?

So my second suggestion is, we put in NORA how we approach employers. It's not a matter of educating them to do health and safety, like educate them and let us do research. And then don't have any good communication on that either. I probably share this through frustration, as the first presenter said here with you, and ask for help.

And thank you very much for the opportunity to let me speak.

Verbal Comment 2006/03/06: I want to actually comment on what Chris mentioned, the small business. Now, we have been kidded about the small businesses from our industry collaborators. Now, my question -- I had a particular question which amplified on the previous speaker, and that's targeting NIOSH and targeting our friends from industry and partnerships and so on.

Now, when we go and approach a small business to conduct research, it would help them out -- there are very few companies that are very proactive and come forward that speak with us. However, based on our limited experience, the grand majority are kind of reactive. So my question to people like this and others, what would you do to overcome those obstacles, particularly one who approves them with research. I'm not going to call it research we're going to call it smart solutions. Because whenever you talk to people they say, oh, these people are in high ivory towers. Well, we are engineers. We have learned to do things on the shop floor. So how do we overcome the obstacles whenever you go and talk to those small manufactures, which is like 80 percent of the U.S. manufacturing, or maybe even more into the future, especially when we get into nanomanufacturing. The major player will not be the P and G, GE, it's going to be predominately this one manufacturer. So that's what we'd like to know. We'd like to know how can we help these people, how to break the ice and get to them. Thank you.

Verbal Comment 2006/03/06: My name is John Hochstrasser. I'm a graduate at the University of Cincinnati, PhD, and I also graduated from their Engineering Department with a degree in -- Master's degree in Civil and Environmental Engineering. I've been practicing in industrial hygiene for well over 30 years now. And in 1993 I ran into a situation where I had two employees in the workplace that had obstructive airway -- lower airway disease, obstructive lower airway disease. Over four-and-a-half years of pursuing it, we pretty well discovered what we thought was the cause.

And, of course, you can always get rid of an occupational disease if you engineer it out of your workplace, but you seldom find out what the causative agent it or the interactions are. It was gone.

And around the year 2000, 2001 popcorn workers came up with the disease. It's one of those things that just doesn't go away. One of the problems we found, we thought that there was an implication of viruses or bacteria and pre-infection of employees from those diseases. And as infectious diseases spread globally, I think what we're going to see, and we may already be seeing it, but not finding it for some reasons I'll mention, is diseases that predispose employees from a viral disease or influenza and go into the workplace and the levels to which the ACGHTLVs, or the OSHA PELs state are insufficient to protect those workers that are predisposed.

Now, one of the problems that we have today is there is no one in the workplace to recognize the disease. Unless you're doing a respirator program with a very good pulmonary function program associated with it you may not find the disease. And you won't find it unless you're monitoring by the year, every year doing pulmonary function tests.

So I believe as we go through these research possibilities, one of the things you need to look for and keep an open mind to is the possibility of natural occurring diseases. If you go to the CDC website you'll find a publication called -- let's see -- infectious diseases, emerging infectious diseases. The publication started in the late 1980's as a quarterly publication, and now it's every month, 200 pages long every month. And I think as globally we expand in the workplace we're going to see these diseases start to spread, and it's bound to have an effect in the workplace. And one of the reasons we don't find as much today is because we don't have occupational physicians and occupational nurses actually working in the workplace to find these diseases and head them off. So that's my comments.

Verbal Comment 2006/03/06: My name is Dr. Judy Jarrell, and I'm at the University of Cincinnati, Director of Continuing Medical Education and Director of Continuing Education in our Education and Research Center for NIOSH. I just wanted to come and say a couple of comments, and reiterate what Dr. Carol Rice was speaking about earlier.

As an educator, as a trainer, I run into frustration a lot. I do a lot safety training, a lot of health and safety hygiene training. And the thing that's come up in my research and the thing that comes up repeatedly in our training is that, okay, we understand. So there's not a problem with getting our workers to master the material that we're teaching them. And, yes, we feel it's beneficial. So they're maybe not widely motivated, but they're motivated to change behaviors on the job. The problem comes in when they get back to the job. And, as you know, training is of little utility unless it changes behavior on the job, and safety.

So my concern is that we get some more funding, some more support for doing the after-the-training type of research that we need to do into what can we do best on the job to be sure that behaviors are changed and that there is a culture of safety that is built within our companies, especially when the bottom line means so much to them and they see safety as detrimental to them. Thank you.

Verbal Comment 2006/03/06: I'm Jay Jones, and contrary to what it says on your agenda, I'm not representing the University of Missouri-Rolla. I'm not sure how that got on there; maybe because I'm an alumni at that university and have an alumni e-mail address. I think they must have pulled it off the e-mail address. Anyway, I'm a self-employed industrial hygiene consultant, also an adjunct faculty member at the University of Cincinnati, Industrial Hygiene. The comments I've got to make really go across -- really relate to some of the stuff this morning about small business.

First, I guess I will offer a little bit of defense of some of the NIOSH work. There is quite a bit of work that NIOSH has done in small business. A lot of it you have to find under individual industries. And so the main point of the comment this morning that they weren't finding stuff I think is true. It is there though, a lot of stuff, but it's not very easily identified. And that kind of relates to my concern about this.

I think small business is an important topic for almost all of these sectors, certainly it is in manufacturing and across the board. But I'm afraid that if there isn't specifically mentioned in the charter for these groups that small business stuff needs to be the emphasis since 40 percent of the workers are smaller businesses. But it ends up and gets forgotten, especially down the road as we progress on with these.

Also, I think the other thing, if it isn't specifically spelled out that small business issues need to be taken care of, that as universities begin to -- or other people apply for research money, unless something's in there that talks about small business, it becomes much more difficult for them to put in projects that relate to small business.

And I think, concerned with that, one of the big areas that needs to be looked at is the delivery; how do you get information to small businesses. I think they're -- also, in each of these sectors we need to be cognizant as we're developing strategies, that the same things that work in the big companies may not work in the small companies.

So those are two issues that I think are important to keep in mind to cross these, but also I think there really needs to be something spelled out fairly specifically about small business in there. Thank you.

Verbal Comment 2006/03/06: I'm Tim McDaniel, and I'm the Environmental and Safety Manager at the International Truck and Engine over in Springfield, Ohio; manufacturer of medium-duty trucks. And a few of areas that we've been seeing our area of interest that we think are worthy of considering for research might include the relationship between illness injuries and the fitness of employees, as our company's been getting more and more involved into wellness programs and in fitness programs.

We think we're seeing some -- maybe some benefit there, but would like to see some research to confirm that. Right now at our location we have about 280 people going through a fitness program that includes diet and exercise and things like that. We're just into it right now about six weeks into the program. But longer term we think things like this should have an impact, particularly in the area of ergonomic-type issues out in the plant, but would like to see some research in that area.

So we're wondering -- or questions that we would have are, are better fit employees less likely to have straining injuries or carpal tunnel or other repetitive motion-type injuries, associated things. What effect does pre-conditioning have on preventing injuries and such?

The second area of interest, and one that our company did a little bit of work in a couple of years ago was in the area of medications. And they worked a little bit with one of the pharmaceutical companies and looked allergies, and seeing if there was -- based on an employee survey, to see if there was any relationship between employees that were taking allergy medications and whether they were reporting injuries, and there seemed to be a little bit of a correlation there. The people who were taking allergy medications tended to have a higher incidence of reporting injuries according to this survey. So I think that could be an area of interest. And not necessarily just limiting it to allergy medications, but it could be other over-the-counter medications or prescription medications that are commonly out there. But are those things that are causing employees to come to work that shouldn't be at work, or are they things that are some how distracting employees if it's injuries, or if it's -- again, more ergonomic-type things. Are they things that are causing them to be more prone to building up stress in their joints or their muscles or just -- I think there could be a variety of things you could look at there for questions.

Best practices in returning injured employees to work, or particularly those with repetitive motions and strains. In our union environment, the employee -- the way the process works is you try to get the employee back to their particular jobs. The same one that they were complaining of having problems with is the job that they're going to move right back into. So what are some best practices to try and deal with that sort of environment?

And the last one is, just as we see more and more business trying to move away from the traditional five days a week, eight-hour workdays, what are some of the implications of that? Our company has looked -- has a couple of operations in other states that work four days a week, ten hours a day. I know other companies have other modifications of the 40-hour work schedule, but just trying to understand how that -- again, ergonomics being one of the areas, how it might impact that.

Also, the similar facts on respiratory issues and just tiredness towards the end of the day. Does there tend to be more injuries if you extend the days and things like that?

So that's all I have. Thank you.

Verbal Comment 2006/03/06: Good afternoon. My name is Dr. Diane Mundt. I'm an epidemiologist based in Amherst, Massachusetts office by ENVIRON International. We're an environmental and health consultancy. Now, I'm not representing a particular company today, but I'm here to speak in support of a research agenda for occupational health and safety in nanotechnology, that some have called the next industrial revolution.

We've recently worked with some companies that are looking for guidance and best practices in nanotechnology. And we looked to NIOSH, which has provided an important lead in providing access to the limited research findings that are available, as Mary mentioned, through their website, as well as through conferences and meetings in occupational health and safety. They've also been active in supporting research in occupational health and safety, but more is needed.

The population at risk is currently somewhat different from what you would consider a traditional occupational work environment. That is, it's primarily consisting of those in university labs, start-ups, RNDs and small RND sectors in small and large businesses. This will change over time as research and development moves from the development stages to the large-scale manufacturing. It includes those

who are using nanomaterials and what they're doing, as well as those who are actually manufacturing nanomaterials.

Risks and diseases associated with nanotechnology are currently unknown, and efforts are needed to develop surveillance tools, as well as to define what is needed for monitoring. Nanomaterials are highly diverse, and exposures are not low characterized. Additional research is needed in how and what to monitor, as well as how to interpret the findings of that monitoring, including whether, in fact, the monitoring results indicate that some risk is apparent for the health of those working in the industry.

Associated with understanding the exposures is the need for continuing research on fast and effective engineering control strategies and PPE for those who are in real world settings using and developing nanotechnology. NIOSH will need to find creative ways to encourage participation in research by the small and large companies, as well as the research labs, which currently represent the frontline of occupationally exposed workers. This is all particularly challenging where a proprietary nature of the work may in fact be a disincentive for participation.

Nanotechnology research will require intra-disciplinary expertise, including health scientists and engineers, individuals who are generally not seeking collaborative research agendas. We would encourage any nanotechnology research agenda to be industry relevant. That is, involving exposures and materials and methods that are, in fact, currently in use for those doing nanotechnology.

Finally, we would encourage NIOSH to advise and update any planned research agenda, as we can only begin to imagine what new challenges to occupational health the next ten years of nanotechnology will bring. Thank you.

Verbal Comment 2006/03/06: Good afternoon. I'm Gordon Reeve. I'm the Manager of Epidemiology at Ford Motor Company in Dearborn, Michigan. And what I'd like to do first is congratulate NIOSH on the process of continuing their work with NORA, and also offering our strong support for the process.

I'd also like to say that we're very pleased with how NORA 2 is being organized. As a charter member of the NORA 1 group in traumatic injury research, we had certain problems in looking at just traumatic injuries because as we went along it was not only people that had traumatic injuries in the manufacturing sector, there's people that have traumatic injuries in 7-11 stores, people have traumatic injuries in taxicabs, and people who had traumatic injuries while working as lumber jacks. And so you try to put that diverse group of people together to try to develop a unified agenda for research, it was next to impossible.

But we managed to do that with first stepping away from the fatalities and getting to the injuries, because if you said, what industry has the greatest fatalities, then it skewed everything in one direction, but then you said which industry has the greatest number of people injured and the greatest amount of disability, it pushed you in a much different direction. So I think we still need to do that.

But the step that you've taken forward now as looking at these things in terms of manufacturing sectors and other segments of industry alleviate a lot of these problems. It also lets you cover acute injuries, ergonomic issues, and cost of injuries across each of these manufacturing sectors and other things that you're looking at.

I would, however, with the manufacturing sector suggest that we probably start off with a manufacturing sector split into two parts. One part would be the labor-intensive manufacturing. And I would haphazardly guess that even though Ford is very labor intensive, we're also very cost intensive for equipment in engineering, which is very different than running a chemical plant or a chemical manufacturing facility like a Dow Chemical or an Amoco BP you've set up where the cost of the equipment is very expensive but you might have acres and acres and acres of equipment, but only 50 to

80 people running the whole thing. Again, very different sets of issues, but I would suggest that we start off with those separately and then try to merge them as we go along.

So with that background, the things that we've learned from having all of this data to look at is that, one, we need to do a much better job on incident investigations in terms of coding them, in terms of underlying cause or root cause, and the safety terminology, instead of looking at the immediate cause.

The other thing would be we need to do a much better process of assigning a risk score so we can prioritize them. No matter how good of a year Ford has, we will never have enough money to tackle every injury problem that comes along and just say fix them all. And even if you could fix them all, you have to fix something first and something second and something third.

So what we are looking at, and we have a model running this in our operations in Australia, where we look at the frequency of the injury, the clinical severity of the injuries, and that targets you on getting a number. And, actually, our managers in those plants, they say, well, you know, I know we've got a problem, we had X number of people hurt and I've got this and this to do, show me the number and if the number is above a certain score, there's no question they fix it. And we're trying to pull that into the U.S. operations and also the European operations. So we don't have the argument, well, gee, it was only this guy, it was only that guy, and it only happens once in a while. It puts severity and frequency into a whole issue of risk.

The final one is looking at some quantitative effort to look at the cost of injury interventions and the effectiveness of those interventions. We have a lot of cost information about work comp, days away and those types of things, but we have very little cost about the impact, the economic impact to the

cause to the worker that doesn't get reimbursed from any recognizable source other than that worker's own pocket. We also wanted to make sure we could look at the intervention in terms of the injuries before the intervention, after the invention, and look at the cost savings.

So those are the three things that we would like to make sure that we can push into the agenda based on our experience of having a lot of information and data. And it's not just for a large company like Ford, it could be for small companies and down to the small business of the workplace. Thank you very much.

Brush Wellman, Incorporated

Categorized comment or partial comment:

Verbal Comment 2006/03/06: I'm David Deubner, Medical Director for Brush Wellman, Incorporated. Brush Wellman is headquartered in Cleveland, Ohio, its largest manufacturing facility is just outside of Toledo. Brush Wellman is the largest world-wide supplier of beryllium materials.

So what's beryllium? Beryllium is a light-weight grade metal. It and its alloys and compounds are used in a variety of important products. From medical lasers and X-ray machines to telecommunication satellites, to building fire sprinkler systems, as we have here, to bushings and bearings in commercial and military aircraft.

The reason I'm here today is to report on and thank NIOSH for the research on which we have collaborated for the past eight years. This collaboration is a model for government industry interaction to further the health and safety of workers in the manufacturing sector.

In 1997, with the backing of company management, I wrote to NIOSH requesting help in better understanding how beryllium could affect health so we could improve protection of workers engaged in the manufacture of beryllium materials and products. We received a very enthusiastic response from NIOSH. In 1998, we signed a formal agreement to work together. With NIOSH we have conducted intensive studies in seven of our manufacturing facilities. The outcome of this has been the

development of the enhanced beryllium safety model, which we have implemented in our facilities. With NIOSH, we are in the final stage of preparing for scientific publication a report that documents the effectiveness of our enhanced safety plan. Our workers are healthier thanks to the efforts of NIOSH.

In addition to converting research to practice in our own facilities, we are currently beginning a process with NIOSH in a project of how to best communicate this enhanced safety model throughout the downstream beryllium manufacturing industries.

We are also working together to better understand the broader implications of some of the lessons learned with beryllium. As an aside, I have personally consulted to portions of the diisocyanate chemical industry and the cobalt industry on how the NIOSH industry collaboration can be mutually beneficial.

NIOSH and Brush Wellman are collaborating -- just beginning collaboration on the case study of the business case for improved industrial safety. We are exploring the potential applications of some of the technical aspects of beryllium safety to emerging technologies, such as you just heard, nanotechnology, as well as other occupational hazards that involve either very low levels of exposure or allergic mechanisms of disease causation.

The NIOSH/Brush Wellman work-together has required mutual respect for the missions and the practical realities of the respective institutions, as well as the continuous support of management in both Brush Wellman and NIOSH. It has also required ongoing work on both sides to identify potential misunderstandings and to surface and resolve potentially divisive issues.

One of the greatest benefits to Brush Wellman has been the enthusiastic support of workers for the NIOSH relationship and the research. Brush Wellman workers have developed improved trust in the company's commitment to their safety as a result of receiving the company's openness and inviting NIOSH into its plants, and as a result of the consistent communications of research results and safety coming directly from both parties to them. We hold an annual conference in Morgantown to which we bring a group of production and maintenance workers and supervisors. And these workers have also taken great pride in showing to NIOSH at this conference their dedicated work in implementing a variety of the aspects of the enhanced beryllium safety plan.

In conclusion, both objectively and subjectively, the NIOSH relationship has been a win for Brush Wellman, for which we are thankful. Thank you.

Verbal Comment 2006/03/06: Good afternoon. I'm Manuel Gomez, the Director of Recommendations and Outreach for the Chemical Safety and Hazard Investigation Board. And before I tell you what I'm here to talk about on behalf of the Board, I wanted to tell you a little bit of a story.

We have at our office a chemical incident reporting system because we investigate chemical accidents, and I carry with me the name on everybody's existence, one of these little gadgets. So I looked at sometime around noon this morning, and it turned out that two workers were killed in a Texas incident in a hazardous material treatment facility. And 15 were injured, some of them apparently seriously, in an electronics manufacturing facility, I think a semi-conductor one, somewhere in California.

I don't have the details, but I'm saying that at the out set to put in perspective what I am going to try to share with NIOSH today. In any case, the Chemical Safety Board, the CSB for short, is an independent federal agency that investigates chemical accidents in fixed facilities. We're modeled after the National Transportation Safety Board, but we've been around for about a decade only.

We look at root causes, as the gentleman from the Ford Motor Company pointed out, and try to look at not only equipment failures, but also inadequacies in safety management systems, in regulations, industry standards, volunteering and internal industry standards, in any case, anything that might be the root cause of an accident.

Our investigations result in recommendations that may go to regulatory agencies or even research agencies. We, in fact, have one to NIOSH from an earlier investigation. They can go to the plants themselves, to corporations, through labor unions, to extend their develop organizations in short to any number of different institutions.

I can cite two examples from the region in the event that there are still some of our guests here from this area in Ohio. In 2003 we investigated an incident of nitric oxide explosion in Miami Township, which is not far from here. Fortunately, there was only one injured worker there. Fortunately in the context of what I said earlier, but, of course, not certainly fortunately for him. But there was also damage to several nearby homes.

The second one that I can mention, which is somewhat related to the area, is that we have a 2005 urgent safety recommendation to BP out of a Texas city incident in which 15 people died in March of last year. That recommendation is to conduct a very major study about safety culture in the entire company. And one of the facilities which they will be looking at, or perhaps has already looked at in a panel that was formed as a result of our recommendation, is a facility near here in Toledo, Ohio, one of their refineries.

I brought with me, by the way, and I have outside copies of some of the paperwork reiterating or talking about what I'm saying, a FAQ sheet about the CSB, and two CDs that have, one of them has all of our investigations, the reports, and the other one has several short videos that we've begun to create to do outreach with regard to the lessons that we draw from our investigations.

We're led by a Presidential-appointed board, and I'm here on their behalf. Our Chair, Carolyn Merit (*), considers of NORA, and I'm actually quoting, it's a defining frame work for the nation's occupational safety and health research goals in the past decade. And so we're very happy as the CSB to be here, and we're pleased to collaborate with NIOSH in their efforts to revamp the NORA agenda.

They recently -- the Board recently voted -- unanimously voted for a statement suggesting that NIOSH incorporate into NORA research in the future topics that focus on chemical process safety and the prevention of accidental releases of chemical substances through explosions, fires, and similar incidents. We think that NIOSH can accomplish this by a combination of in-house and extramural research, and by being a catalyst for such research and partnerships with other stakeholders, which hopes to speak at this manufacturing sector.

But I should point out that we could probably just as well have gone to a cross-sectional meeting if it had occurred because many of the incidents that we investigate, in fact, many chemical incidents occur not only in the manufacturing sector, either the producers of chemicals or the users of chemicals, but they occur in practically every one of the other sectors that you saw on the slide.

Research in this area of chemical process safety we think will address very serious hazards that effect large numbers of workers. The available data don't permit us to make really good estimates, but at least in 1992 when OSHA promulgated their process safety management standard they estimated the population at risk was approximately three million workers.

I think it's probably safe to say that certainly the population at risk remains at least at that level, but I would dare say much higher because the process safety management standard for which those were made encompasses only a limited number of substances after they go past a certain threshold, amounts of the substances present in the workplace. But chemicals exist in many quantities and they're processed in many, many different ways that are not necessarily covered by the PSM standard. So the estimate of three million effected workers by the risk of catastrophic chemical incidents is probably very conservative.

Not only that, but I think that we can -- we would probably all agree that the growing concern with chemical security, which is a related but closely, closely related topic, it's very, very much, very much touches on the question of chemical process safety. Because to make chemical manufacturing use transportation and handling safer, inherently safer, it's also to make it less susceptible to criminal intentional activity, such as terrorism.

We also think that research in the chemical process safety area can bring important benefits in other areas of health and safety. Because management systems and I would dare say that many of us here have been hearing that word a great deal, play a central role in the prevention of catastrophic incidents, as they do in any health and safety programs and practices. In fact, the use of management systems across a safety introduces principals and procedures into the workplace that can improve health and safety far beyond just the prevention of incidents, chemical incidents, or chemical release incidents.

The requirements of the OSHA PSM standard, in fact, one could argue, were the forerunner of ideas that are now contained in the more recent and more comprehensive management system approaches that we see in ANSI Z-10, the National Voluntary Consensus National Standard for Occupational Health and Safety Management Systems in the vital guideline on the same topic, and in the commercially available technical specifications called 18,000. It's got a long name, but I probably won't -- can't even remember it.

For example, OSHA PSM requirements require, and that's of course for that narrow, relatively narrow group of substances and therefore companies that are covered by that standard, but it required the systematic collection of safety and health information about the chemicals, processes, and equipment, as well as process hazard analysis of that information. It requires a lot of other things, but I'm giving that as an example. These two steps in PSM are called process safety information, PSI, and process hazard analysis is called PHA.

Well, if you leave the jargon aside -- in fact, if you take the word process out, you're really talking about the more traditional approach, risk-assessment approach, which applies to all health and safety; what have we got here, how hazardous is it, what is the size of the risk, and then you go on to what do I do about it and how do I prioritize it. That's what management systems do.

So I would argue that this kind of proactive management systems approach, which is inherent PSM, in the process safety arena it's applicable to prevention of chronic health and safety -- health hazards and safety hazards and other kinds. NORA has not explicitly included work on this area of process safety in the past. And, in fact, researching this area has been relatively scarce. And as a result, there are many gaps in knowledge that that kind of research could address.

In our statement we list a few as examples. We're not trying to point them out in any particular order of priority. But to give you a feel,

We need to better understand the possible safety impacts of a large contractor workforce in the chemical industry, and especially the petrochemical industry where we think that the percentage of contractors runs to 15 to 20 percent, a very large proportion who are not working directly for the employers. We need to learn how to better and more objectively define what people call these days safety culture, perhaps by combining the ways we're trying to measure the effectiveness of occupational health and safety management systems.

It would be useful to develop and implement methods. Guess what? To reach small and medium-size businesses, although I won't belabor that one; I think we hit on it real hard before during in this event. But particularly learn how to get -- learn better ways of getting the lessons out to them. We're all tried, but none of us know how to do it very well at all. So we've got a lot of learning there, and I think research could help a great deal.

And, finally, we need to improve the data that are now available to measure trends in accidental chemical releases and their impacts. You know, there's a phrase out in the business world that says if you can't measure it, you can't manage it. And we can't and don't measure very well lots of things in health and safety, but certainly one of them is how many accidental chemical releases we have.

So to conclude, I guess I may have run out of time already, but I think we're flexible, and to reiterate, the CSB believes that NIOSH is in a unique position to stimulate research in the area of process safety and that this research can have beneficial ripple effects in areas that are much broader.

And as the new NORA takes shape we also would like to emphasize that the CSB is very willing to support, participate, collaborate, whether it's with the research council on the cross-sector, research council in what ever way is possible to help better define what the most important areas of research should be, to prioritize them, whether they are the ones that I've listed or others that we have identified.

And on behalf of the CSB I thank you for the opportunity to speak to you. Thank you.

Categorized comment or partial comment:

Verbal Comment 2006/03/06: Good afternoon. My name is John Morawetz. I'm speaking today on behalf of the International Chemical Workers Union Council of the United Food and Commercial Workers Union. I currently work for the chemical workers, both as the Director of a national HAZMAT training program for a consortium of seven unions and as the (inaudible) Director of Health and Safety.

First, NIOSH has a proud history of service to America's workforce. From health hazard evaluations, industry-wide studies, (inaudible) technology, to hazard alerts, library services, respirator approvals and NIOSH pocket guide to name a few areas. NIOSH is the primary national research organization to protect workers. For chemical industry, for peoples of companies both large and small, NIOSH is an important source of assistance in what is all too often a difficult situation. (Inaudible) health and safety activists, there is no other place for them to turn to for all of these services and follow-up.

NIOSH provides essential services, and although not all activities results in a scientific article, they are invaluable. We have often called NIOSH and you have rapidly responded both walking us through technical subjects and meeting our needs.

NIOSH conducts research in a tripartite format, which involves both management and labor at each stage. Workers all too often perceive themselves as, at best, subjects and, at worst, guinea pigs for research. Worker and union involvement helps to minimize this, produce better and more useful research, and is a practice to be consistently implemented in all research efforts.

Second, occupational health and safety research is not done for its own sake. It's done to identify areas to intervene, to lower exposures, to help assist in injury rates, to give workers and their employers information to ask the right questions and to get answers that will improve people's working lives. All NORA projects, therefore, should include evaluation on how the research is utilized.

[Editor's note: The third item is presented below, so all the "Comments on the NORA Process" could be grouped together for efficiency.]

Fourth, we all need to review the overall NORA process and accomplishments to date and what are realistic short and long-term goals. NIOSH has continued to openly discuss what they're accomplishments were at the first decade, what was learned, and what questions remain in these priority areas. I've tried to find current information on the NORA website; however, it does not look like some of these web pages are being updated regularly.

[Editor's note: The fifth item is presented below, so all the "Comments on the NORA Process" could be grouped together for efficiency.]

Sixth, the use of significant NIOSH resources in recent natural disasters clearly will delay or reduce most other efforts. Although we firmly support securing all additional funding, the political reality might be that NIOSH will have to use existing resources. Rather than trying to accomplish everything with finite resources, NIOSH must have a plan to adjust its normal agenda when responding to another anthrax incident, hurricane, or public health disaster.

Seventh, we have serious concerns on the possibility of contracting out NIOSH's workforce. We do not believe that this is in the best interest of either quality research, NIOSH's workforce, many whom are members of the American Federation of Government Employees, NIOSH as an Institution, the companies and workers who are NIOSH stakeholders, or our national interests. Chasing the allusive rhetorical goal of cheaper work all too usually only serves the lucky contractor and few else.

Eighth, and related, is the need to preserve and strengthen your highly qualified and dedicated workforce. While there are many excellent professionals outside of NIOSH, many of whom are here today, a strategic view should balance the contracting out of research projects with the need to preserve your internal professional resources. Specific priorities will change, but ensuring your strong professional staff and Institution is crucial. From the national perspective, NIOSH adds a valuable public health approach. NIOSH needs to remain institutionally separate within the nation's public health structure to ensure continuing and appropriate emphasis upon protecting our workforce.

A recent example of NIOSH's contribution was a collection of anthrax exposure data when a musician was infected in New York City. The rapid use of antibiotics to his friends and fellow musicians, one might say fellow workers, is a protective measure that we learned after the failure to take these steps for Washington, D.C. postal workers in 2001. Tragically, occupational health research all too often reaches conclusions at the expense of the health of workers as in the -- I'm repeating myself, in the death of postal workers in 2001.

NIOSH and its NORA agenda is a vital institution in investigating and disseminating information to decrease this national burden. Thank you for your time.

Third, NIOSH should continue their efforts to investigate hazards, such as nanotechnology, mixed exposures, and special populations. Industries, hazards, and demographics change, and NIOSH must have the necessary resources on hand to launch investigations. Some may be industry specific, while others will cut across various sectors. Similar to the original NORA priority research areas, and will therefore be an issue, I presume, for the cross-sector research council.

Verbal Comment 2006/03/06: Good afternoon. My name is Chris Henderson. I've been in the food business for 17 years in the safety and health systems. I actually graduated from the Rocky Mountain Research Center. And I'm actually here today representing the Poultry Industry Safety and Health Committee. That is a committee whose member companies employ 250,000 workers in the United States. But based on my experience in the food and pharmaceutical business, I can tell you that the concerns that that committee asked me to bring to you are concerns that the entire food industry share, and I have no idea what they employ.

I actually on the agenda I put down for two subjects. The first one is impact of cold on musculoskeletal illnesses. I will not address that, because we're fortunate that a local employer in the area is able to attend, Mr. Kevin Reed, and he's going to address you following me, and he's going to talk on that. But I am going to talk a little bit about chloramine exposures and the concern that is in our industry. And, actually, we had a safety committee meeting in February and we were discussing the subjects that we voted on to bring to this meeting, and I was shocked that this was such an issue within our industry, having been in the industry for 17 years. I've only had two experiences, both of these in my personal work were just in the past few years with chloramines.

So I need to give you some quick background to let you understand how insidious these are in the food business. We use chlorinated water a lot in the food business. Usually it's to rinse equipment at the end of the day, but it can be used during the processing also. For example, returns on conveyers or a conveyer loop going back on the bottom. If it's bringing a product on that conveyer, it will be rinsed

with a spray of chlorinated water. When chlorine in water, a solution is combined with ammonia it produces a gas, a various gas of chloramines. These are very obnoxious or irritating to employees. We have no means to monitor chloramine in the workplace at this point.

My first experience was I got a call from a plant that employees were extremely upset and complaining and complaining month after month about the irritating chlorine. But yet the safety health people at the plant were monitoring the chlorine levels, and there was no significant exposure taking place. I hated to do this because it was in the middle of the night that I had to go out there to the plant and I took my meters to verify and sure enough the level of chlorine in the air was quite acceptable. But yet you could look at the workers and all of them had bloodshot eyes. So either they were having a real good time and I didn't know about it, or something was going on. There was a very faint smell of chlorine. And this was my first exposure. It took me about a month to figure out what was happening there. And this is usually the way it is with chloramine exposures.

I took did a little research coming down here today. It just so happens there is a local facility, a food company in this area, that has had a suspect of chloramine exposure in which six workers were sent to the hospital just a couple of weeks ago. Now OSHA and EPA are trying to determine how those chloramines formed, and they have a couple potential solutions or a couple of reasons that they're investigating.

But really we don't have any idea what kind of exposure is out there, how many workers are having these problems. I think it is being missed. As an example, at our meeting we were having this discussion and I asked for a raise of hands of all the members there with our committee, how many have had a suspect chloramine issue. About half of those raised their arms, which shocked me. I thought there would be two or three. Which then makes me wonder if maybe the other half that didn't raise their arms probably have also had issues, they just don't know it.

And what we would need from NIOSH is some sort of estimate about what exposures are occurring in the workplace, what their causes are, and most importantly, what can we do about it. Particularly, there would need to be some effort put into how can we monitor it and determine when we have an exposure. I think that's all I have. Any questions?

Verbal Comment 2006/03/06: Good afternoon. My name is Kevin Reed. I'm the Safety Manager for Cooper Farms Processing in Saint Henry, Ohio. I'm here as part of the Poultry Industry Worker Safety and Health Committee. My subject is the impact of cold work environments on musculoskeletal injury rates.

Although cold environment is generally accepted as contributing to musculoskeletal injuries within the meat industry, the significance has not been described. Anecdotally, highly repetitive work in warm environments, such as hatcheries and evisceration departments, does not result in the level of symptoms that are reported in refrigerated environments.

For example, at one federal OSHA program location the incident rate for the evisceration department where the average room temperature is 50 to 52 degrees and meat temperature is over 100, the incident rate was 4.1. Yet, at the same location in the de-boning department where the average temperature is 44 to 47 degrees and meat temperature is 45, the incident rate was 7.3 to 8.5.

Epidemiological studies could provide some quantification of the impact of cold on repetitive work. This would benefit both industry management and regulatory concerns in accessing efforts in ergonomics. A more formal understanding of this relationship, if it proves to be significant, could also lead to industry-wide changes in work practices. And that's it. Thank you.

Verbal Comment 2006/03/06: Good afternoon. My name is George Shaw. I'm with NK Parts. We are a Honda supplier in Sidney, Ohio. We provide logistic and manufacturing for Honda facilities.

Two issues that I would like to address for NIOSH and NORA agenda. First of all, ergonomic modeling. That is our primary concern at NK Parts is improving the ergonomic risk factors in our job processes for both the warehousing and the manufacturing. Currently we have seven models that we have been using; the NIOSH lifting equation, the University of Michigan 3DSSP, the rapid upper limb assessment in job streaming. These all provided useful information in modeling and assessing risk to form a (inaudible). However, each of those has some significant limitations. First of all in terms of (inaudible) that it covers. The shoulder (inaudible) aren't addressed in any of these models, some of them address the back, some of them address the upper extremities. We've had some significant cost associated with the shoulder.

Also, secondly, this does not address the aging workforce. In none of these models is the age range of the associates doing the job in a variable that is input into this model. So we feel this is also a shortcoming that can be addressed during ergonomic modeling over the next decade.

Second of all tying into that is cost analysis. After we've identified the jobs and we've prioritized for the next fiscal year, we have to do a cost-benefit analysis to justify the cost of the improvements we want to make. And currently we can do a good job of assessing the direct cost; looking at the workers comp history of these injuries, both of that we have had in our plants and through industry averages. However, we do not have a good handle on indirect costs, things like overtime, lost production, supervisor time, retraining. And so a good method in measuring indirect costs will help justify some of the projects that we want to do in the upcoming. And that's all I have. Thank you.

Verbal Comment 2006/03/06: Good afternoon. My name is Ralph Froehlich. I'm a certified industrial hygienist and consultant with Helix Environmental in Dayton, Ohio. I'd just like to recommend three areas of additional consideration for the National Occupational Research Agenda.

First, and I think the most important, is additional research on the interactions between chemical air contaminants. You've heard about chloramines being a concern, that's the interaction between two chemical contaminants and the reaction products. But there are additional reactions that can occur inside of people to multiple chemical exposure venues. And while we've done a pretty good job of identifying direct chemical health effects for about 700 air contaminants, we've done a very poor job in looking for interactions and the health effects of multiple chemical exposures, and I think that it is time for that to be a major focus of the national agenda.

The second issue that I think requires a lot of work in the manufacturing sector is the health effects associated with increasing use of promenaded [sic] [brominated] organic materials that are used as drop-in substitutes for chloric-chlorinated insolvents.

There has been some evidence of reproductive health effects associated with these promenaded [sic] [brominated] compounds. And because of those rather dire health consequences, I think a lot more research needs to be included in the national agenda; just looking at the direct health effects of those promenaded [sic] [brominated] compounds, especially the reproductive health effects.

Categorized comment or partial comment:

Finally, indoor air quality remains a concern in all sectors of the economy, and we are poorly equipped to define acceptable indoor air quality at this time. So that is a significant research need in my opinion. We also need to define the levels of biological and surface -- air and surface contaminants in indoor air quality complaint situations so that standards can be developed against which measurements can be compared, both for problem and non-problem indoor environment.

Finally, I strongly recommend that the research be directed to define the best practices for indoor air quality communication and involvement. Often times we've been involved in indoor air quality complaint situations where we can't identify or even postulate any indoor contaminant being present that we haven't sampled for. Yet, the occupants still have significant concerns about indoor air quality. Either we haven't looked hard enough, or, more likely, we're having a horrible time communicating our results to the occupants in indoor air quality complaint situations. I see this as a major research need for the next ten year period.

Thank you.

Verbal Comment 2006/03/06: Thank you very much. I want to add to something that the previous presenter was talking about combining effects of chemicals together. But I would like to add combined effects of chemical and physical agents, particularly noise and heat stress and ultraviolet radiation. And, unfortunately, even though we don't have any standards, OSHA doesn't have any direct standards for UV and all of its physical agents.

I wonder if we can put that in our agenda to do more research on, say, UV radiation exposure by itself, and with the chemical. For instance, we know with tar and so on create cancer. What other chemicals? You don't know that. The same thing with heated stress. Heated stress is something that is just completely forgotten by us. Even we don't understand this. You have some recommendation from ACGIA. And any chemical exposure, or any physical exposure, heated stress is one of the contributing factors.

So there are some of the things that they could probably put in the agenda for the next ten years to work on is physical agents and non-ionizing radiation. Thank you very much.

The division of topics by industry may dilute the importance of noise as a leading hazard. Noise is one of the last real industrial hygiene issues. People in many sectors are still losing hearing every day, particularly in construction, which needs more research and best practices development.

Health and Safety Issues for Workers with Developmental Disabilities

Robin Dewey, MPH, Labor Occupational Health Program, University of California, Berkeley

Approximately 4.5 million individuals in the United States have developmental disabilities. Developmental disabilities are severe, life-long disabilities attributable to mental and/or physical impairments which result in substantial limitations in three or more areas of major life activities such as self care, language, learning, mobility, self direction, economic self-sufficiency, and capacity for independent living. Examples of developmental disabilities include mental retardation, autism, Down Syndrome, cerebral palsy, traumatic brain injury, and epilepsy.

An estimated 30 percent of working-age adults with developmental disabilities are employed. The federal government has targeted the increased employment of persons with disabilities as a national priority. Recent legislation, such as the 1997 amendments to the Individuals with Disabilities Education

Act (IDEA), the Workforce Investment Act of 1998, and the Ticket to Work and Work Incentives Improvement Act of 1999, as well as President Bush's New Freedom Initiative of 2001, indicate that promoting the employment of people with disabilities has become an even greater area of focus.

Workers with developmental disabilities are employed in both facility-based settings ("sheltered workshops") and in integrated employment settings (competitive and supported employment). In 1999, NIOSH published recommendations for protecting the health and safety of workers employed in sheltered workshops. This year, NIOSH funded the Labor Occupational Health Program (LOHP) to further examine this issue and conduct an assessment of the needs and resources currently available to address occupational safety and health issues of workers with developmental disabilities, particularly in integrated employment settings. This study has involved conducting a comprehensive literature review, creating a database of agencies and organizations that could potentially be partners in the effort to promote the safety and health of individuals with developmental disabilities on the job, and interviewing key informants about these issues.

Preliminary results of the current NIOSH study indicate that workers with disabilities are often employed in hazardous workplaces (including food service sanitation, janitorial and building services, retail and clerical support) and frequently bring unique risk factors to the job. Many adults are also exploring opening their own businesses. For example, a recent newspaper article reported about two individuals with mental retardation who own a salvage company in Ohio where they handle forklifts and disassemble telecommunications equipment to extract metals for resale.

Very few agencies and organizations serving this population appear to be addressing the issue of workplace health and safety or have knowledge or resources to help them prepare their constituents for safe employment. In many cases the topic seems to come as a surprise as an area of concern but after discussion, staff agree that more attention, support and resources are needed. Additionally, anecdotal reports to the National Young Worker Safety Resource Center, staffed by LOHP and its partner, the Education Development Center, Inc., indicate that the groups most interested in delivering health and safety education to their participants and most enthusiastic about the Center's basic curriculum, Youth@ Work: Talking Safety, are typically those who transition youth with disabilities from school to work. Over and over we have heard from these practitioners that they are thrilled to have a curriculum that specifically includes learning activities that are adapted for individuals with cognitive and learning disabilities.

The topic of health and safety issues for workers with developmental disabilities should be a priority of the National Occupational Research Agenda. Recommendations for future research and other activities include:

1. Provide for more extensive research into the health and safety issues facing workers with developmental disabilities in integrated employment settings.
2. Research best practices among employers of workers with developmental disabilities to identify examples of accommodations, training programs, and support systems.
3. Evaluate the National Young Worker Safety Resource Center's Youth @ Work: Talking Safety curricula for young workers specifically for its effectiveness in teaching youth with cognitive disabilities basic occupational safety and health skills.

4. Sponsor a partnership of key staff from federal agencies and national organizations as well as researchers in the field to plan future activities that promote workplace health and safety among individuals with disabilities and the groups serving them.

Verbal Comment 2006/02/17: Thank you, Wayne. Yes, I am John Lundell, and I'm the Deputy Director of the University of Iowa Injury Prevention Research Center. I'm also a co-principal investigator on the NIOSH funded Iowa FACE program. I'm here today to speak on the huge public health toll caused by occupational injuries and why their prevention should be a priority area on NIOSH's research agenda.

Every day, 16 workers in the United States are killed on the job by traumatic injuries. More than 5,700 workers were killed in 2004, and here in Iowa 89 workers were killed by injuries that year. And of course, the number of workers with nonfatal injuries are many times greater than the numbers who are killed.

Let me begin by describing the NIOSH FACE program, and how it is improving the health and safety of America's workers. The NIOSH Fatality Assessment and Control Evaluation Program is a research program designed to identify and study fatal occupational injuries.

The goal of the FACE Program is to prevent occupational fatalities across the nation by identifying and investigating work situations at high risk for injury, and then formulating and disseminating prevention strategies to those who can intervene in the workplace.

The FACE Program has both a NIOSH in-house component, as well as state-based programs such as the one here in Iowa. Currently, there are 14 other state-based FACE programs, besides the one here.

Since 1995, the University of Iowa has operated the Iowa FACE Program under a subcontract with the Iowa Department of Public Health in Des Moines. The Iowa FACE Program is organized around three specific goals; to conduct comprehensive occupational fatality surveillance, to conduct rigorous investigations of priority cases, and formulating and widely disseminating prevention strategies.

The FACE team here at the University of Iowa is comprised of a wide variety of disciplines, including an occupational physician, an industrial hygienist, an agricultural engineer, a product safety engineer, and an injury control specialist.

At the health department we work quite closely with the Director of Forensic Operations in the Office of the State Medical Examiner. This multi-disciplinary approach enhances the ability of the Iowa FACE Program to undertake highly technical investigation of specific cases.

Through a wide variety of notification mechanisms, including first responders and law enforcement, news media, and colleagues, our goal is to identify every worker killed on the job. We then follow up each of these incidents by contacting public safety officials and others, to collect baseline information.

From this surveillance system, we develop a comprehensive profile of fatal occupational injuries in our state. Over the past five years the victims were 97 percent male, 27 percent were over 60 years of age, and 40 percent were involved in agriculture. Further analysis indicates that agricultural-related fatalities tend to be over represented in both the youngest and oldest age groups.

Over the past five years, two-thirds of the fatal occupational injury victims in Iowa were under the age of 18 who had been killed working in agriculture. Similarly, during the same period over 80 percent of the victims over age 70 were working in agriculture.

Using priorities established by NIOSH for state programs we then select specific incidents to conduct in depth on-scene investigations in order to analyze the circumstances of the fatal injury. More importantly, we develop recommendations aimed at preventing similar events from occurring in the workplace. Since the year 2000 we have conducted 53 in depth investigations.

The final phase of Iowa's Program is the broad dissemination of these preventive strategies. Our Program truly believes in the NIOSH research to practice initiative. We have taken our FACE Program on the road, making numerous presentations at symposiums and professional meetings, as well as published an impressive list of related articles in the peer-reviewed literature.

But what makes the Iowa FACE Program unique and we believe effective is our emphasis on publishing in the trade literature. During the past several years we have published FACE investigations in trade journals such as Wallace's Farmer, Professional Safety, American Towman, Arbor Age, World of Welding, Waste News, and Successful Farming. I was just going to show some slides showing these publications.

We have found the trade publications very receptive to printing our FACE investigations, and believe that this mechanism places the preventive recommendations in the hands of the most important readers, the managers and the workers in the industry described in the report.

These magazines are frequently found in waiting areas, lunch rooms, and break areas where employees have time to peruse them. Similarly, agricultural-related publications such as Wallace's Farmer or Successful Farming are read by most Iowa farmers and their families.

It is human nature to be interested in reading about workers in similar situations who have been killed on the job. We strongly believe these FACE related articles with preventive messages have the potential

to influence worker behavior. In addition, we make ample use of media releases, when appropriate, and maintain an informative website to disseminate our prevention message.

In closing, I urge you to include occupational injury surveillance and specifically the FACE program in your NORA recommendations. Thank you for this opportunity to speak before you today.

And now I'll just take a minute to run through some of the fabulous publications that we're proud to have authorship in. American Towman; we've published an article about -- We've actually published twice in this magazine related to fatalities related to the towing industry. There is one of them (indicating), that was a double fatality that occurred up on Boone, Iowa. Arbor Age; we've also published twice in there. This was an article about a cherry picker that collapsed. It was old and should not have still been in use. World of Welding; published twice in there. This was an article about -- I believe he was welding on a barrel that exploded. Wallace's Farmer; published a number of times in there. This was a very well-received article, very sad and tragic. These all have tragic stories about a farm wife that was killed by a grain wagon.

And Professional Safety; we won an award on this particular investigation that had to do with a crane that was assembling a water tower that collapsed and killed a worker. And wonderful World of Waste News; we published about a garbage truck operator who was killed.

That's just a sampling of what we believe is the effective way to reach the workers who need to hear this message from the FACE Program. Thank you.

Note: Verbal testimony provided to NORA Town Hall meeting in Iowa City, IA, 2006/02/17.

Verbal Comment 2006/02/17: Thank you, Wayne. I'm actually here representing Dr. Corinne Peek-Asa, who prepared some remarks on workplace violence and then was unable to come and deliver them. So I agreed to come and deliver them for her.

Violence in the workplace has been recognized as an important occupational and public health issue only within the last 25 years. In these past 25 years, we have estimated the scope of the problem, we have identified violent hazards in different industries, and we have described factors that place some employees at greater risk over others.

In this same period over 20,000 workers have been homicide victims, and an estimated 25 million have been victims of violence at work. We have not yet done enough. The work to reduce violence in the workplace has just begun and the most important steps are yet to be taken. Research that identifies the most effective and comprehensive strategies to reduce violence needs to be conducted. Evaluation studies need to use rigorous methodologies with sufficient power to detect program and outcome effects.

We need to understand and motivate employers to take on the issue of workplace violence prevention, and to provide employees with the information and tools to make good decisions.

We need to move beyond associating basic typologies of workplace violence with specific industries, and identify the components of comprehensive approaches that can address all types of violence. We need to identify how the workplace fits into the larger social agenda of safety and security.

Acquiring this knowledge will require resources, partnerships, and collaboration. NORA 2 will work to remediate the most important occupational hazards and fill gaps in the occupational health programs.

Addressing the safety of workers who work in a climate of fear and risk for violence should be one of the most prominent roles included in this effort.

That's the end of her remarks. You might be asking yourself why faculty at the University of Iowa are so interested in workplace violence. Fifteen years ago this coming November, a disgruntled graduate student bought a handgun and went on a shooting spree and shot and killed three faculty members, shot and killed a fellow graduate student, killed a vice president of the university, and shot and rendered quadriplegic, a young secretary.

These events had a tremendous effect on all of us who live and work on this campus, and led to our beginning to explore the issue of workplace violence. Together with our colleagues from NIOSH and other stakeholders, we convened a national symposium on workplace violence, which resulted in a report on workplace violence and the things that needed to be done to address workplace violence. That report was quite successful. Senator Tom Harkin was particularly touched by it because he was touched by the events that happened on this campus, and he led an effort in congress to get the special allocation of funds to NIOSH to nourish researching workplace violence.

We think that the research in the field has now gotten to the point where we have interventions that can be tried out in the field and evaluated. And we think that's the most important next step to be taken, and we hope that there will be room in NORA 2 to include that material. Thank you.

Verbal Comment 2006/02/17: Good morning. I have a presentation, but I have no keyboard. I'd like to talk to you today about building ventilation; workplace respiratory system.

We've all appreciated the need for ventilation. This wonderful 16th century wood carving depicts a workplace described by Pliny the Elder in ancient Rome. The two workers in the center of the picture wave a linen cloth to move clean air to and contaminated air away from a digger. This ventilation delayed the development of workplace disease, although most of the people who dug in ancient Rome died of workplace disease.

Modern ventilation, we've come a long way. Modern ventilation systems are everywhere. I see supply air grills in this room. I see intakes to move contaminated air away from us. They provide us with clean air and they remove contaminants; nothing has changed there.

We have gotten a little bit more adept at installing these systems, and they help our respiratory system prevent occupational illness.

However, if we look at the life cycle of a ventilation system, it's quite strange. We install them, they get up above the ceiling, and we never look at them again until there's a complaint or there's an occurrence of a disease, or some other threat such as Anthrax in senate office buildings.

Immediately after installation the burden of occupational illness switches -- gradually switches from the ventilation system back to our own respiratory system; so new research is needed. This is a quote from Mel First in 1984. He said that the industrial hygiene profession is still living off of Delvals' 1930 and Silverman's 1942 doctoral thesis for its entire body of ventilation theory. We desperately need a new infusion of science and engineering.

Well, my Ph.D. work at North Carolina was on ventilation ducts and particle transport. I was shocked at the dearth of literature that exists in our journals and any research that's funded at a national level. My work was funded by Ford Motor Company. It won an award for the best dissertation in the School of Public Health at the University of North Carolina. Since arriving at the University of Iowa, I've tried to submit grants for national support, but found it very difficult to have things funded on this type of research. I get comments such as it's not significant. It's too practical. So I've moved to hot topics, such as exposure assessment of nano particles and the health effects of diesel exhausts. These are important problems too, and I'm really excited about working on them. However, I think it's a shame that we don't have some national support for these things that are also very important.

So basically my message is pretty simple, and I suppose that my message fits under the category of identifying failures in the system. I suggest that the next NORA should add ventilation systems by name as cross-cutting issues in all sectors, and I think that the new NORA should add language to heighten the significance of work in this important area.

I believe that these changes would provide national support for researchers like myself, who seek to keep our building respiratory system brunting (*) the burden of occupational illness. Thank you.

Note: Verbal testimony provided to NORA Town Hall meeting in Iowa City, IA 2006/02/17.

Verbal Comment 2006/02/17: Good morning, my name's Bill Heitbrink. I'm an Associate Professor in the Industrial Hygiene Program here at the University of Iowa. But before I came here in 2001, I didn't really work as an industrial hygienist I worked as an engineer working in occupational safety and health for NIOSH.

One thing I wanted to talk about that I think NIOSH should support both internally and externally is the ability of occupational safety and health researchers to work with equipment manufacturers, so that we have control measures for various occupational injuries and illnesses built into the equipment.

My latest experience has been working on cabin filtration systems. These systems cut across agriculture and surface mining. In agriculture, we've got issues of high dust exposures during combining, pesticide application. In surface mining, the issue is silicosis, a very dangerous respiratory disease.

I think NIOSH needs to fund this work, both internally and externally. It offers several major advantages to the workers. One, think about a combine or cabin filtration on the surface mining vehicle. If we've designed the thing right the worker gets into the cab and he's protected. He may not even -- Worker acceptance may not be an issue because the control is so inherent to the design of the product that the worker may not even be totally aware that he's being protected. He does not have to put on a respirator. That -- as I will discuss later -- has several advantages and disadvantages.

Basically, when we fund research in this area it needs to go into health product development, but it also needs to help develop engineering standards for product specifications. This can involve some very implied research that answers questions that need to be answered, so that you can develop adequate testing procedures that are needed to make sure that the control measures actually work.

The occupational safety and health community, I believe, can assist manufacturers in a couple of ways. One, we can perform in situ evaluations of control measure performance, both to answer the question, does the control measure initially work and a more important question when you think about the length of time that agricultural equipment will be in the field, does this equipment continue to work over the long term?

As Wayne had pointed out in some of his research in Iowa we have tractors that are functioning for 40 years. So, does the ROPS really work for 40 years? Does the cabin filtration system work for 40 years?

As we all know if we own automobiles -- when was the last time you were able to run a car for three or four years without maintaining it and not getting into trouble? Clearly, there are many practical issues that need to be addressed.

In doing this research I think manufacturers may end up being good partners, but we also have to understand many of the practical issues that manufacturers face. In dealing with a consensus standard on cabin filtration systems that was eventually withdrawn, product liability was an issue. The manufacturers could only control the equipment until it leaves the factory floor and is sold to the end user. And then the practical issue is how long will this equipment work? How do we integrate the use of this equipment into a comprehensive safety and health program? What sort of steps do we need to take to make sure that this equipment continues to provide useful hazard control over the entire life of the product?

All of these are issues which need to be addressed and unless we address them, ultimately, the implementation of control measures will fail because they will initially work, and then later on as Tom found it on ventilation systems, they will ultimately fail.

So with that, I rest my case. And hopefully Mr. Job, who's retired actually from AGCO, can talk about details pertaining to the cabin filtration system standard.

Verbal Comment 2006/02/17: Thank you for providing me with this opportunity. I'm speaking on behalf of Dr. Terry Stentz from the University of Nebraska at Lincoln. He is a human factors engineer on the faculty there, and does research on meat packing-related injury in particular he's interested in lacerations and cumulative trauma. And he is funded by NIOSH to do work on lacerations in this setting together with collaborators at Harvard. And he cannot be here today, so he kindly provided me with some slides and invited me to give this presentation.

This is a great example, I think, and I'm familiar with this environment. I'm interested in occupational health in general, not only respiratory problems, but I think this is a wonderful example of how NIOSH resources have provided funds to look at a very important problem.

The people who work in meatpacking have a 3.5 times greater risk of traumatic acute injury than do people who work in other sectors. Lacerations are very, very common despite extensive use of personal protective equipment.

The plant I'm going to talk about, or the plants -- there's actually three of them in this region have state-of-the-art safety programs, state-of-the-art safety equipment in place, and there's a big problem with that in spite of this.

This is a pork processing facility (indicating), one of three. There's one in Nebraska, Iowa, and one in Illinois. They graciously have been welcoming to investigators who want to help them improve their safety programs, and this has been a very fruitful relationship.

The Fogus Plant has 1,200 employees. They run five to six days a week, two shifts of kill and process, and they clean the plant in the night shift. They process up to 9,000 hogs per day.

One of the huge challenges in this area is working with people who do not speak English as a first language. At this particular plant, anywhere from nine to twelve languages are spoken as a first language by these individuals. The main one is Spanish, but there are a number of other ones.

This plant does have established safety and ergonomics programs. And in spite of that for lots of reasons, there's a very, very high worker turnover. This makes it very challenging to have effective safety programs and to keep the plant functioning optimally.

There's a lot of issues, one of them is many different types of cutting tools are used, both powered and non-powered. This is just one example of this kind of work environment (indicating).

These people are working on a cold side of the plant. It's really quite cold there. The temperature's in the high 30's; so people's hands tend to become stiff and that just makes it that much more likely for them to become injured.

Dr. Stentz and colleagues conducted a retrospective descriptive analysis of laceration injuries for nine plant years, and they used this analysis to underpin a major research grant proposal. Also, the results resulted in a publication, which came out last year. And I'm happy to say that grant proposal has recently been funded.

They used OSHA 200-log injuries. First reported the accident/injury forms, and then the plant production operations information, and worked very closely with the plant safety officer. And they analyzed demographic information about worker populations, in addition to the information that was available from the log itself, and did calculations looking at person hours by plant, department, year of incident, et cetera. They found that the first report of injury was not always entirely complete. There were some of the issues. No PPE use documented -- they did not -- the people who filled out the forms did not always indicate how much time had elapsed from the beginning of the work shift to when the injury occurred, and the description of the work activity at the time of injury was incomplete.

Understandable when you see how busy these plants are, how busy the nurses are, but it makes it difficult to reconstruct what happened and how this can be avoided.

They had a large number of cases, the majority were men. That may be in part because of the division of jobs in a meatpacking plant. The kill side of the plant is usually where men work, and that is where the majority of the injuries occurred.

The majority were lacerations and there were however a variety of other injuries reported. And again, missing data was a huge issue. A number of the people -- if you look at the bottom line -- actually a fair percentage of people who got hurt were on the job for less than one week. So that's where the worker turnover becomes a big issue.

The laceration cases were a substantial portion of the OSHA 200-log cases, so that was definitely an important problem for them to address. And that was true for all the plants, even though they differed slightly in their approach to the slaughter and processing aspect.

The rate has fallen since 1998 in their analysis, but it's still considerable. As I said, it varies quite a bit. Plants Two and Three are not kill plants. Plant One, is one where the entire range of activities occurs in reference to pork processing.

So possible risk factors for these injuries, PPE use, time of day, people get tired and they did notice -- I didn't have time to present but, more injuries in a certain time of day. Experience, were people current on being trained appropriately or had they been transferred to a new department because someone didn't come to work that day, also things like the wrap-up speed. The lines have gotten faster and faster over the years and for some people it's just too fast for them to work safely. Were there enough rest periods? These people have a 15-minute rest period in the morning and the afternoon and a half hour for lunch, which isn't really a whole lot if you're doing fairly physical work.

They looked at day of the week, and then production bottlenecks, new equipment and product-line problems, et cetera, being factors; and then finally training issues and language barriers.

So again, this is a great example of the research that NIOSH is funding and I hope that it's possible to continue doing this work, extending it to other aspects of problems related to the occupational environment in the meatpacking industry. Thank you.

Verbal Comment 2006/02/17: I perform research in the area of agriculture in Iowa, particularly the health and safety of Iowa's farming population. My primary research activity in this area is through the Agricultural Health Study, a prospective cohort study of 90,000 Americans, composed of farmers, spouses of farmers, and commercial pesticide applicators from the states of North Carolina and Iowa.

Over 58,000 of the studies' participants come from Iowa. The activities of farmers in Iowa are broadly representative, especially of the Midwestern United States. Common exposures experienced by this population include pesticides and fertilizers, fuels and oils, engine exhausts, zoonotic microbes, organic solvents, paints, grain dust, welding fumes.

Health outcomes associated with farming include injuries, Parkinson's disease, and other neurologic conditions, musculoskeletal diseases, reproductive and developmental outcomes, immunologic effects and autoimmune diseases, respiratory diseases and cancers; particularly lymph, stomach, brain, prostate, connective tissues, skin, leukemia, lymphoma, and multiple myeloma.

These common exposures and diseases experienced by the agricultural sector are not unique to them. The urban population of the United States shares them also, and stands to benefit from the research knowledge gained from the agricultural sector.

Many of the diseases I previously spoke of are classified as chronic diseases. For these chronic diseases we still have poor understanding of their relation to the common exposures experienced by the farming population. I request that NIOSH continue to include in its National Occupational Research Agenda the pursuit of an improved understanding of mechanisms relating exposure to health outcomes in the farming occupation. Two particular challenges are exposure assessment and genetic susceptibility. Regarding exposure assessment, how can we better measure or quantify the common exposures experienced by this population?

A good example here is pesticide exposure. This improved assessment is particularly needed when research needs to account for the long latent period associated with the chronic diseases experienced by farmers. Second, what is the role of genetic susceptibility factors? In particular, how do they increase risks of the chronic diseases experienced by farmers?

Thank you.

Verbal Comment 2006/02/17: Thank you. Well, my name's Chuck Jennisen and I'm a pediatric emergency medicine physician and a faculty member of the University of Iowa College of Medicine in the Department of Emergency Medicine. And I've always had a great interest in agricultural-related injuries and in health problems, having grown up on a dairy farm in central Minnesota, and seeing a lot of the injury-related problems that occur in agriculture, in the emergency department.

And I received a number of e-mails about this town meeting occurring and I felt it was really important for me to come and say a few comments about what I thought was important as far as research in the future for occupational safety and health and particularly about agriculture.

I think everyone probably realizes that agricultural-related injuries is -- Well, agriculture is one of the most dangerous occupations. And because of this, of course, it is important for us to continue to fund research in decreasing agricultural-related injuries and health-related problems.

And I would like to talk a little bit more about how it's very important to keep in mind the youth that work on farms, and the research to identify why they have problems, and have injuries on the farm, and

how we can take the research that we do know and put it into practice and get it out to families who are working on the farm.

One of the big problems that we run in agriculture, agricultural-related research is that we have a difficult -- really identifying the number of injuries and even maybe worse the health kind of problems that people suffer being on a farm.

Most farms are not regulated by federal rules, and we have a hard time getting -- You know, where a lot of occupations may have to report those injuries they suffer while working a lot of those are really hidden from people who are doing agricultural research and we don't know exactly the numbers that we're dealing with.

And because of that it makes it difficult to see what kind of changes our research and our interventions and education is really making out there. And so certainly I think one of the things we need to continue to fund related to research is the surveillance, so that we can see what kind of changes in agriculture we have made through our research and interventions.

In addition to that, we have identified a number of things that could make a big change on the farm, and again, this research to practice; additional research in looking at what it would take for farmers to adopt interventions that we know work.

So providing money in that area -- And for example, we know retrofitting rollover protective structures work for decreasing tractor-related injuries and deaths. What do we need to do to get farmers to put those on their tractors to decrease those injuries? What kind of incentives have to be made to do that?

Obviously, some of that may be additional funds, funding needed to help that take place, but certainly identifying those things that would make farmers make those changes that we know already would work if they were practiced.

And in addition to that, I think a very important area that some people here at the University have worked on is really, since again most farms don't fall into these federal regulations, what -- Can we identify farms that are safer and have implemented strategies to decrease work-related injuries in health practice? And can we take a list of standards that actually if farmers would implement on their farm would make them safer and have less health-related problems? If we can prove that and put research to prove that then maybe they can be adopted, we can set up programs to have farms certified as being a safe and healthy farm, and maybe decreasing insurance premiums, and proving to get insurance companies to accept that and have a decreased rate so that people would have incentive to do so. And I think a safe certified farm is kind of a model and has potential to do that. But research -- there's other places that have worked on this as well. I think that's a very important area of research to get research to practice.

And finally, I'd like to just mention again about the importance, I think, of pediatrics and children on the farm. Often we don't think of children as, you know -- perhaps teenagers over 16 are working on other fields, but in agriculture there's children that are basically a part of that factory and are everywhere in that situation and can be injured. And even though some of them are not actually working, I think we still need to think about efforts to make that a safe place because it is affecting the workers on the farm, the farmers themselves.

Efforts in research are looking at daycare options or kind of innovative ways to deal with children on the farm and preventing them from getting injured, helping implement developmentally appropriate tasks

for children on the farm. We have a lot of guidelines that have been developed, but how can we get that out to farmers and have them implement those?

And additionally, one of the things that I have been seeing so much in my practice is ATV injuries. I think it's no surprise to many people that the escalation of all-terrain vehicle-related deaths and injuries is just escalating exponentially. And it is, I think, important for -- These vehicles are used for agricultural-related things on the farm, also recreation. But they are a very dangerous item that we need to put more research in because it is becoming unfortunately a terrible epidemic of injuries and deaths related to this vehicle. Thank you very much.

Verbal Comment 2006/02/17: Hi, I'm Ashleigh Haus, a youth delegate from Farm Safety 4 Just Kids. I represent Farm Safety 4 Just Kids as a member of their youth network serving the United States and Canada. We attend meetings, promote local farm safety efforts, and serve to increase peer-to-peer education.

I am here today to talk to you about keeping childhood farm safety a top priority. Without support from educational programs like Farm Safety 4 Just Kids many youth like me wouldn't know about the dangers of falling grain, how fast the power take-off shaft can turn, or about storing chemicals in a safe place.

I grew up in the city and represent a large majority of rural Americans who are making the move to live on small acreages. I wasn't aware of the dangers such as ATVs or four-wheelers, horses, or small equipment. By becoming involved in Farm Safety 4 Just Kids, I have been given the tools to teach other youth, like me, about the dangers.

Farm Safety 4 Just Kids believes that youth can make an impact in spreading the word of injury prevention. Each year, Farm Safety 4 Just Kids selects youth representatives to represent them at various functions. This year, I represent Iowa; while we have other representatives from Michigan, Arkansas, and Pennsylvania.

Here are some of the events that we have been participating in. Waco Phillips of Nebraska and I both were on RFDTV program called Living the Country Life. Waco talked about ATV safety, and I spoke about horse safety. The segments aired all across the country.

Waco was awarded a \$5,000 scholarship and a \$5,000 community grant from the 2005 Do Something Brick Award for his work on an ATV safety demonstration. This award was presented to him by Former President Clinton. Waco was also on the cover of High Plains Journal for his farm safety work.

Wayne Lenderman (*) participated with Marilyn Adams and Dave Schwartz in a one-hour call-in show on RFDTV. Thousands of viewers tuned in or called in questions about farm safety. Wayne was poised, professional, and up to speed on many farm safety issues.

Nicole Shannendorf (*) of Michigan and Waco Phillips helped give presentations to FFA Members and their advisors at the national FFA convention about ATV safety. Nicole also was well received when she presented at Michigan State University. She stepped in when Marilyn couldn't attend due to prior commitments.

Waco and Nicole represented farm youth when they traveled to the National Organization of Youth Safety Meetings in Washington, D.C. All four current Farm Safety 4 Just Kids youth representatives have helped plan, organize, and present at Farm Safety 4 Just Kids regional chapter conferences.

Each of these examples shows that youth can and are on the forefront of making a difference in farm safety and health. And these examples do not include the countless hours that youth from everywhere devote when they perform puppet shows for younger kids, review material to make sure that it fits the youth audience, conduct sessions at Farm Safety day camps and other farm safety and health programs.

As you begin looking at ways to allocate funding please keep agriculture a viable industry by supporting initiatives that impact children and youth. Together we can keep rural children safe and healthy.

Verbal Comment 2006/02/17: Hello, it's nice to follow Dr. Jennisen. My name is Shari Burgus. I am education director at Farm Safety 4 Just Kids. We're located about 135 miles west of here, and we hope that you've all heard of our organization.

We deal with a lot of the issues that Dr. Jennisen was talking about. We try to educate in ways to provide a safe environment for all that live and work there, primarily with kids, but we work with kids and adults.

I've been with Farm Safety 4 Just Kids for a little over 14 years, and I've seen a lot of changes in agriculture throughout those years. Children are the future of our agriculture in the United States. Their health and well-being need to be preserved to ensure agriculture's next caregivers, protectors, and influential leaders remain safe and healthy.

While children are young it is an adult's responsibility to protect them. That means that we need to do everything in our power to eliminate the hazards through engineering modifications, reinforcing established safety and health regulations, and education of family members about safe ways to stay safe within that rural environment.

Education and community outreach are Farm Safety 4 Just Kids' area of expertise in farm injury prevention. After nearly 20 years of nonprofit experience, we are still looking for new ways to reach children and their families with life-saving information and programs.

Nearly 140 volunteer chapters conduct farm safety and health information every year on a continual basis. And each year we reach over one million kids, families, and their parents.

North American farms are changing. With these cultural changes comes the need to modify programs and resources to meet specific needs. That's where we fit in. Increases in small hobby farmers, large corporate producers, and migrant workers are all examples, and that all affects what we do as nonprofit people. Recent education efforts at Farm Safety 4 Just Kids include a comic book on pesticide exposure for Spanish speaking audiences, and a magnetic display for Amish issues.

Funding is needed to make sure that these programs are designed, delivered, and evaluated to reach the unique audiences through appropriate channels. We rely on research institutions like the University of Iowa, the University of Kentucky, and everywhere else to help us develop and evaluate programs, strengthen those programs that are making a difference, and altering the ones that are making a positive impact on knowledge, attitudes, and behaviors.

A couple of examples that come to mind that we've been working on recently are types of cooperation where we reach people on all-terrain vehicles, just as Dr. Jennisen was talking about. Another example is where we're reaching people with rural health issues.

ATVs have become popular in rural communities. The number of injuries attributed to ATVs, especially among the youth, are staggering. To identify how youth are using ATVs and to create programs to address these behaviors, Farm Safety 4 Just Kids has recently worked with the Great Plains Center for Agricultural Health, where we surveyed 600 FFA attendees at the recent national convention down in Louisville.

A rural health education packet was also developed by Farm Safety 4 Just Kids recently, and it's being evaluated by ASH-NET. This allows us to take a critical look at programs that teach youth about preventing health-related problems in the future. Our role within the research-to-practice model includes the practice end of the spectrum, and we try to do that through working with other organizations that are on the research end of the spectrum.

In order to provide quality community programs, research is needed to work in tandem with programs like ours that are implementation in nature. We believe at Farm Safety 4 Just Kids that children's health and safety issues need to be a prominent importance when determining the direction for future NORA and NIOSH initiatives.

Safety and health practices start at a young age. Children crawl before they walk and walk before they run. In the same sense, they need to learn how to use a lawn mower to mow the grass before they start using larger and more powerful equipment.

I urge you on behalf of Farm Safety 4 Just Kids and all youth on the farm to please place high priority on our youngest farmers. Thank you.

Verbal Comment 2006/02/17: Thank you, Nancy. As Nancy mentioned, I'm on faculty at the University of Iowa here and I have some presentation points that I have also written. And I think the written version is probably better than the spoken version. I usually write much better than I speak. And these are not -- These comments are not being coordinated with the University of Iowa, so I think you can consider them being just my own.

I'd like to approach this issue, again, from the agricultural sector point of view. And I would not in this presentation like to present any specific research areas that are important, but rather just address some of the structure and organization within NIOSH and how the decisions are made and how in my opinion those processes could be made more effective, so that they serve the agricultural sector better.

And so here are my five points. First, add agricultural industry representation into critical NIOSH decision making processes, including preparation of grant announcements, scientific review panels, and agency grant decisions.

The purpose of the NIOSH agricultural program is to produce information that can help farmers to stay safe and reduce injuries. And I think it is important to have input from the agriculture sector in the decision making. And if we don't have that, it is very hard to get buy-in afterwards, after the fact.

And I think it would be a great asset for NIOSH to have agricultural representation from groups that represent the agricultural workers and the industry. And that would really help guide the research so that it really serves the industry as good as it can.

Secondly, the agricultural expertise within NIOSH should be strengthened. We used to get a lot of collaboration, actually with NIOSH people we used to get site visits and we used to have people come and discuss on a very practical level how the programs are going and what should be done. And I thought that was a very good idea, but it seems like lately bureaucracy has taken over and that process has not been as effective as it used to be. And I think it would be very good for NIOSH to utilize the

expertise of those people who know the agriculture program already, and I think NIOSH should hire more people who actually have real agriculture background and who can discuss with USDA Farm Bureau, agriculture industry commodity groups at the level where they are, and be very effective in exchanging ideas and seeking input and cooperation.

Third point, there needs to be more transparency in the NIOSH agriculture program; especially the intramural program seems to be something that we don't really know much about and we have not been able to collaborate -- It may be our fault, as well, but I think there needs to be a better connection between the intramural and extramural programs. And I think at our end we have felt that the extramural program has perhaps decreased in funding levels. And we would like to, I guess, have good transparency so that we know where the funds that are appropriated for agriculture research, where those funds are used. And I think particularly that applies to the NIOSH intramural programs.

Categorized comment or partial comment:

Fourth point, I think we should do more research that affects larger numbers of people. We tend to do small studies with small samples, effecting only small numbers of farmers. If you go today and do a survey on American farmers and you ask them what they know about NIOSH or research that has been funded by NIOSH, the result may not be as good as we would like it to be. And I think we should find ways how to develop prevention models that are actually affecting greater numbers of farmers. And those kinds of things can be, for instance, occupational health service models with financial incentives, which have been very effective in, for instance, my home country about 40 percent of farmers are members of an occupational health service system.

Also, I think the new information technologies and education needs to be utilized more because that's about the only way you can really reach over two million farms on a frequent basis all the time.

I guess my next point and last point is that we should support research that helps develop standards or technical innovations or some solid ideas that we know are effective. And I think we should judge new projects, incentives or initiatives from the prevention point of view.

There's already a lot of preventive information. If you go on NASD you will find over 4,000 documents that describe in great detail what farmers should do to prevent exposure or to reduce their hazard. And

if we propose a project that doesn't create anything new, that we don't already know about prevention, then what good is that research?

But we know that new standards, for instance, the ROB standard is about, maybe, one of the most effective tools in the agriculture health and safety sector that has really made a difference in increase of use of roll-over protective structures on tractors. And we may need some new other standards. We may need a standard in organic dust exposure levels. We may need other new standards that could be something that can really be a yardstick and move the field forward.

And I guess finally, just whenever we're doing studies, we should really look at the existing prevention information, especially at NASD and judge whether our new projects are really creating something new and some new value that moves the prevention forward.

Thank you.

Verbal Comment 2006/02/17: Good morning. My name is Wane Baker with Michael's Engineering and I am very pleased to take part in today's session. I don't have prepared comments, and I thank those of you who are onsite for your careful preparation of the PowerPoint materials. My segment -- my participation today is going to represent something of a departure because I'd like to speak to the issue of indoor environments, and specifically the concept of the damp buildings and the impact that it has on -- for the impact that it has on our nation's workforce, that is non-industrial, non-agricultural represents about 70 percent of our nation's workforce of approximately 90 million Americans working in indoor environments that again, are non-industrial, non-agricultural.

I recognize and appreciate that the indoor work environments represent just one of -- as I understand it -- 21 priority areas for the occupational research agenda. But nevertheless, I feel very strongly as part of my professional practice over the last 25 years that some additional emphasis and effort must be placed on looking toward the impact of damp buildings and the health of our children in schools, office workers, folks perhaps like myself that spend some time behind a desk, as well as many of you in attendance today.

The research from Scandinavia, Europe, and Canada clearly shows a significant impact in relationship between damp buildings and hazardous health effects. And many of you may be familiar with the various studies, but frankly the mechanisms behind the adverse health effects associated with exposures to damp buildings remains a mystery and remains unclear.

When I registered to take part in today's meeting my topic was identified as adverse health effects of damp buildings and the role of microbial amplification. I'm a certified industrial hygienist, a licensed professional engineer and my associate -- a lot of my associates here are master-level microbiologists.

It's what we do every day, we help people figure out why they're feeling poorly in their work-a-day world. And it's more than just a matter of the sniffles or a runny nose. There appears to be a series of rather profound, adverse human health threats associated with time spent in damp indoor environments.

And I'd simply like to encourage in these few precious minutes today, NIOSH to consider additional huddling and research associated with trying to figure out what this mechanism is. The Institute of Medicine, in their recent report on damp indoor spaces, made it clear that we simply don't know yet. We recognize that there is an association between damp buildings, but we simply don't know what the mechanism is. And again, this is an issue which affects an enormous number of people in the United States. And that's about all I have for you today. I appreciate the opportunity to address this group. And thank you, I'll certainly stay tuned and listen throughout the day.

labor unions

Categorized comment or partial comment:

Verbal Comment 2006/02/17: Thank you. As Nancy indicated I'm the director of the University of Iowa Labor Center. The Labor Center was established in 1951 to serve Iowa's organized workforce. We teach non-credit courses to trade union members each year, reaching between 2,000 and 3,000 trade unions a year.

The classes we teach vary greatly, but relate to practical industrial relations, labor history, communication and leadership economics, safety and health, train the trainer, and other related areas. And of course, worker safety and health education is one of our primary missions at the labor center, and we've been teaching programs in those areas for many years.

I would like to first emphasize what I think is critical in NIOSH's research program, and that is the importance of working with labor unions in your research activities. And I say that really for two reasons, or rather two main contributions that labor unions can make and that is knowledge and voice.

Knowledge. As workers on the job site, union workers are intimately familiar with the occupational hazards of their fields. And because of this first-hand knowledge they are often key to finding solutions to overcoming those problems. Unions also bring an important institutional knowledge in perspective to health and safety research. Unions are uniquely able to collect and analyze the experiences of workers across industries, and because of this are often able to identify hazards in terms of their severity and frequency that may be less obvious to researchers who may depend on reported data or other indirect sources of information.

And of course, knowledge without voice is useless and unions provide workers with a voice that can be heard, unlike their non-union counterparts who routinely face employer retribution for reporting injuries and safety and health hazards. Union workers are in a much better position to defend themselves against such employer retribution and to speak out and honestly when they are confronted with occupational hazards.

Unions also organize that voice through local health and safety committees and through their international union health and safety departments. Also through basic workplace democratic processes, unions are able to prioritize their health and safety concerns, thus helping to focus researchers attention to the most important and immediate needs of workers.

The union voice is present in health and safety education and training programs conducted by local, state, regional, national and even international union organizations and institutions. Through these educational programs and other organizational activities, unions are in a unique position to disseminate research findings to workers across entire industries. No other group is in a better position to educate workers in health and safety issues than our labor unions.

And I wanted to add a few other comments that relate to issues that are reoccurring themes that come up in the classes that I teach from workers in Iowa. These are more specific. Number one is line speed, which continues to be a problem for workers in this state and I believe across the country. Increasingly, there's pressure to do more with less and this is having an effect on worker injury rates.

Second, I wanted to mention a related topic and that is staffing levels and work organization. Again, doing more with less is a reoccurring theme that I hear across all the groups that I deal with in the labor movement and should be researched in detail.

Ergonomics continues to be an issue for workers. I think it's particularly challenging for unions today because of the rollback of the ergonomic standards. Ten years ago it was common for unions to negotiate comprehensive ergonomics programs. I can't think of one that's been negotiated in this state since the rollback of the ergonomics standard; that's just very difficult to achieve success at the bargaining table.

Fourth, employer policies that discourage the reporting of injuries and in particular behavior-based safety programs. I believe that there is a prevalence of those policies that result in a serious and wide-spread under reporting of occupational related injuries and illnesses. While I believe the problem exists in almost all occupational groups, I think it is particularly true for recent immigrant workers, low-paid workers, and also workers in the construction industry.

Research focusing on the relationship between such programs and policies to injury rates and occupational hazards, I think, would be particularly beneficial and relevant today.

Fifth, I think the role of enforcement or rather lack of enforcement in eliminating worker exposure to occupational hazards is a problem. Iowa, for example, has 21 OSHA inspectors responsible for covering 90,000 workplaces. And it's essentially impossible for them to cover that many workplaces in Iowa. And what I'm hearing from unionized workers and non-union workers is that OSHA is simply unable to provide the enforcement that is needed to have a serious impact on health and safety in the workplace, and this problem needs to be studied.

Certification and recertification systems for skilled workers, particularly in the building and construction trades is important, as well as gas, electric, and communication utilities. Many states do not require certification or recertification for junior-level workers. And the question is whether this has an effect on the health and safety of those workers, as I believe it does.

And lastly, let me just say I think there's general support in the labor movement, at least this is my impression, for the industry or sector-specific research programs that NIOSH is moving towards. I believe that that is the most useful form of research for the labor movement.

And I will conclude my comments there unless there are questions. Thank you.

Verbal Comment 2006/02/17: Thank you, Nancy. I'd like to take this opportunity to make a comment on my colleagues' and my understanding of the NIOSH acquisition process. Director Howard and Dr. Soderholm, it is an honor being able to participate in this forum. I am the director of the Jolt Vibration Seating Lab in the ergonomics section of the Iowa Spine Research Center. In addition, I am a licensed professional engineer and a certified professional ergonomist. I'm a faculty member at the University of Iowa and have been working in occupational safety and health for 33 years.

I participate in standards development related to human exposure to vibration. I have received funding from NIOSH and other agencies and I've been involved in creating significant practical solutions. I will participate in the first American conference on Human Vibration, to be held in Morgantown this June, where I understand Director Howard will be the keynote speaker.

For many years I have worked with talented and thoughtful people who understand effective approaches and research directions needed to address work-related musculoskeletal disorders. These same people have also been frustrated by and have cautioned me to be careful about a particular aspect of the NIOSH acquisition process. That is, if anyone advises NIOSH to support a particular area he or she is barred from applying for funds in that area.

I suspect one reason for this has to do, at a minimum, with the appearance of a conflict of interest. Occupational health issues are preventable. Is there anything that can be done that would allow those with practical insight into occupational health and safety to advise NIOSH?

It is a common perception that one is barred from participating in the process after giving such advice. This is a generic problem that compromises the efficiency of NIOSH. Knowledgeable people are not participating because they are unable to participate. The Department of Defense seems to have exemptions with similar issues, how do they do it?

It would be extremely beneficial to the occupational safety and health of the people of the United States to grant an exemption in this area in the name of prevention. With ever increasing healthcare costs, a stitch in time would indeed save nine. Thank you for considering this question.

Verbal Comment 2006/02/17: Thank you, Nancy. It's a pleasure to be here. Dr. Soderholm, thank you very much for making this happen here. I have about three major things I want to say, and the first is in a process like this let's make sure that we build on the past. There's been a lot of people that have put a lot of effort into designing [sic, defining] what the problems are. And it's one of the things that started way back in the early or late 1980's was this conference called Agriculture at Risk, which led to the first Surgeon General's conference in 50 years, which was Agriculture and Safety Conference, which was held

in 1991. There's a lot of good information there. [Editor's note: Proceedings can be found at <http://www.cdc.gov/niosh/docs/92-105/>]

And then follow up to that, there was a conference that was put on by the Agricultural Health and Safety Network in 1999 called Using the Past and Present to Map the Future Actions. And it included a lot of information that had gone on in the past and tried to funnel that into the future. So my message is to use that information and build on that past and into the future. [Editor's note: The conference website and a summary report can be found at <http://www.uic.edu/sph/glakes/agsafety2001/> and <http://www.cdc.gov/nasd/docs/d001701-d001800/d001786/d001786.pdf>, respectively]

One of my assignments for that particular conference, which was Using the Past and Present to Map the Future Actions, was to review the success and the failures of the 86 recommendations that was in this particular report. Those 86 recommendations are broken down into about four or five different areas that included policy recommendations, education, occupational health and service delivery, and research.

And one of the -- In our analysis of that, of those 86 recommendations, the research actually came out probably one of the best areas in terms of percentages of or percentage of increase or progress in that area. We estimated it somewhere in the neighborhood of about 54 to 57 percent of the goals in that area were achieved.

Categorized comment or partial comment:

However, one of the big deficiencies -- and this is my major message today -- is in the area of occupational health and services delivery. It relates to some of the comments that Dr. Rautiainen had mentioned in his item number four up there on the board. So we do have failures in the occupational health and safety services delivery.

There are some innovative programs scattered across the country that have been facilitated by NIOSH, particularly the certified safe farm that Dr. Rautiainen had mentioned. There is a new organization that is developing within the region -- or at least within Iowa so far and hopefully to the region, it's called the AgriSafe Network. But broadly speaking, there is relatively little delivery of occupational health services to the agricultural community, and that's what I wanted to focus on.

And I wanted to then mention some of the specific recommendations that came out of this report that are still rather in need of development. Development of a phased system to provide comprehensive occupational health and safety services to the agricultural communities involving federal, state, local, and private partners. And that's a large category that needs to have -- And I think there's really research applications here. There's a whole -- as you know -- in terms of health services delivery, it's a large research area in many places in the country. And I think this can be applied specifically to agricultural occupational health and safety services.

Funding of projects with concerted efforts towards development of occupational health and safety services is something that was a recommendation that still needs to be considered. Incorporation of costs sharing arrangements with farmers, farm groups, insurance companies, and local hospitals in communities assuming some of the responsibilities. An establishment of linkages with services such as community access hospitals, a whole new notion of new hospitals that have specific funding where they can charge what it costs. And there, I think, is a growing opportunity there to help to ensure that there are some occupational health services put within that context.

So that's my main message, is to consider that because it is a bottleneck. There's a lot of good research that's being done, but unless we can get it into the health services delivery community the access to that research and the translation of that research doesn't happen very effectively.

Many of us who are involved in this area do so because of personal experiences. And having grown up and raised on a farm, having been on the wrong end of a serious injury to my father who received a permanent disability from that injury and had very poor, or no actually occupational health and safety services to help him through that period and to remove the hazards. That really has stuck with me because I generally don't see much of an improvement since that time, 40-some years ago.

So it is an area, a bottleneck, and certainly an area that I would promote to really help get the research out to translation, where it's really needed.

Thank you.

Verbal Comment 2006/02/17: I'd like to thank NIOSH and the Great Plains Center for making this town hall meeting possible. I drove 220 miles today to get here, and I hope that tells you how important I think that this process is. I have really three main points to make.

The first is to build on what Dr. Donham and Dr. Rautiainen introduced, and that is research that gets the word out to large groups of people. My work with AgriWellness, which is a nonprofit corporation, is in seven states, Iowa, Wisconsin, Minnesota, North and South Dakota, Nebraska, and Kansas. Our work is to build behavior health supports for the agricultural population.

In each of our states we have a farm helpline, which is used annually by more than 35,000 farm people in terms of number of callers. We have trained staff who operate these hotlines 24/7, every day of the year. We also have trained agricultural professionals who deliver behavior health services; mental health, and substance abuse counseling, primarily.

Our work involves training the staff who operate or provide these services in what we call agricultural behavioral health. We can reach lots of people, but the funding in anything that has to do with rural has taken a substantial hit during the past year-and-a-half or so and in some ways longer than that. So we need help from NIOSH showing that this kind of a support network can do some good.

The suicide rate for the agricultural population is twice that of the non-agricultural population and even higher for males. Depression is rampant as a stress-related illness in the agricultural population. And not only does stress impact the injury rate, but it also impacts the psychological vulnerability rate. So that's my first point.

Second comment, and it's kind of related to this point that Kelley and Risto made and it is that put greater portion of NIOSH funds into grassroots research, if it all possible. Because it's at the grassroots level where agricultural injuries and their prevention start, both for physical and psychological injuries.

National Rural Behavioral Health Workgroup

Categorized comment or partial comment:

A third point I'd like to make is to invite NIOSH to consider joining the National Rural Behavior Health Workgroup. This workgroup has formed within the past year to bring together all of the federal agencies that have something to do with rural mental health and substance abuse issues in rural areas. With agriculture necessarily being almost entirely rural, we think it important that NIOSH be at this table.

The organizations that are at it already are the Substance Abuse and Mental Health Services Administration, the National Institute of Mental Health, the Bureau of Primary Healthcare, Indian Health Service, USDA, Center for Mental Health Services. We think that NIOSH needs to be at this table to help set the agenda. The last meeting was held on January 23 and 24, not only were all those federal agencies there, but so were chief representatives of the National Rural Health Association, the National Association for Rural Mental Health, WICHE, the Western Interstate Commission on Higher Education, and AgriWellness, and several other groups. So we think it's important if NIOSH can find a way to dialogue with that, and I'm going to provide you with some information about that particular workgroup, as well as an e-mail that I addressed to Dr. Max Lum, but I think you'll read it.

So that takes care of my comments unless there's a question or two that I might be able to respond to.

DR. SPRINCE: Could you tell us the name of the workgroup again?

DR. ROSMANN: The workgroup is called the National Rural Behavioral Health Workgroup, and it's an agenda setting workgroup that has been formed primarily because rural needs a voice that is unified at the federal level.

Thank you very much.

Verbal Comment 2006/02/17: Good morning, I'm Todd Wyatt. I'm an associate professor at the University of Nebraska Medical Center. I would like to address lung disease as my topic.

Lung disease is the number three cause of death behind cancer and heart disease. But unlike cancer, deaths due to lung disease are increasing each year.

The interest that we have is that NIOSH continue its funding related to basic laboratory research in airways diseases. Particularly, I'd like to make the pitch that increased funding be appropriated for combination injury studies centered around tobacco and alcohol exposure. And as you can see these are very important causes of death in our society today.

The major disease problem that we're facing is chronic obstructive pulmonary disease. It's the fourth leading cause of death right now. A lot of Americans are affected by it. You may not be aware of the fact that alcohol -- there is a component of alcohol consumption that contributes to the development of COPD.

The majority of people with COPD are cigarette smokers or previous cigarette smokers, but a significant amount of COPD is caused by occupational exposures. And this is where NIOSH comes in in its

commitment to researching that. COPD is very complex and poorly understood and therefore our treatment modalities are very inadequate. Yet, in the study of COPD it consists of an intersection between chronic bronchitis, emphysema, and asthma.

The hallmarks of this injury after the inhalation of substances, toxins, organic dusts, consist of the elevated tissue inflammation in the lungs, a decrease in our innate ability to clear the things that we've inhaled, as well as a decrease in the repair processes that remodel and restore the lungs to its normal functioning. Basic research in these areas need to be continued and need to be expanded.

That innate protection that I'm talking about, what I'll focus on, at the level of the cilia lining the airways participates in a mechanical mucociliary transport system that keeps us healthy from things that we inhale. A lot of people refer to this as the mucociliary escalator of the ciliated cells that function in coordinated action in the airways to clear inhaled particles out of the airways and into the GI tract where those particles can be processed and destroyed.

The upper airways as well as the lower airways -- this orchestrated ciliary beating is essential to move substances into the esophagus where we swallow them and then they can be processed. And this innate ciliary beating and mucociliary transport apparatus is essential as our first line of defense about anything we might inhale in the workplace.

So we're hypothesizing in addition to the exposure of dust that can impact proper clearance in the maintenance of lung health that co-exposures of cigarette smoke and alcohol that haven't been previously studied in combination with these concepts be addressed as workers in every occupation are consuming alcohol and smoking cigarettes.

You may have been aware that the vast majority of alcohol abusers are cigarette smokers and studies have reinforced that. But, what you might not be aware of is that anywhere between a third and a half of all cigarette smokers have problems with alcohol consumption, as well. So the two exposures go hand in hand and basic research needs to be addressing that, and I think NIOSH is a good vehicle for that.

In addition, preclinical animal models need to be continued to be supported and developed for co-exposure studies. Lots of studies have been supported for cigarette smoke exposure in small animals, such as the one pictured here (indicating), as well as lung function and exposure studies that can deliver alcohol and other organic and dusts and particles to the airways. But, the combination of these exposures has not been addressed and not been reported in the literature.

So to summarize, COPD is a growing and very significant disease that has been addressed by basic science and laboratory research through NIOSH funding and I believe should continue to be a priority. Our basic innate protection against inhaled particles, I believe, is a very important thing that we should be investing research dollars in because this is addressing how we can maintain -- If we can understand proper innate protection of mechanical production then this will lead to understanding how we can prevent disease as opposed to just treating symptoms of a chronic disease once it's developed.

I feel that animal models are extremely important in developing this, and public policy is always impacted by individuals who like to limit the use of animals in research. And I would like to see that not be public policy, but rather the importance of animal models for preclinical disease studies be an important feature of funding and continued funding.

And then my own particular emphasis would be I would stress that we look at the context of multiple sources of injury, like cigarette smoke and alcohol, and how they combine to affect the lung health in the workplace. So thank you.

Categorized comment or partial comment:

As Dr. Sprince mentioned, I have a role in the Iowa FACE Program and the Great Plains Center for Agricultural Health. I'm also a board member of Farm Safety 4 Just Kids and president-elect of the National Institute for Farm Safety, the professional organization for people in our field.

Part of yesterday I had the rather sobering task of plotting on the four-state map the roughly 120 farm and agricultural deaths in 2005. Depending on how you count and who you count that's one-sixth the national total. For Region 7 there were 30 tractor-overturn deaths in '03, 23 in '04, and 19 in '05; is that progress or just different numbers?

The ATV, if not already so, is becoming the agent most frequently involved in deaths and injuries in our nation surpassing tractors. Nationally 600 to 700 deaths in agriculture/forestry/fishing, which now includes logging, it didn't two years ago and before. The number 600 to 700, if you use the National Safety Council method of death-to-injury ratio calculations, which in the past has indicated 120,000 to 150,000 disabling injuries; that is where you can't return to work the next day. But if you use that same ratio process one might conclude 15,000 to 25,000 disabling injuries in our four-state region.

Eighty-five percent, historically, of the National Safety Council, the BLS numbers for census of fatal occupational injury deaths, 85 percent have historically been associated with the production agricultural; crops, life stock, and agricultural services portion of agriculture. Our farm and agricultural injury monitoring system, which is essentially a press-clipping service captures 120 deaths, 110 nonfatal injuries of a serious nature each year. And some of these same deaths, of course, make it into the FACE catch basin, since I capture both of them. And much later, many but not all end up as part of the CFOY

count (*), especially those which -- Well, it excludes the course, those which do not meet their selection criteria.

Fatalities alone, and if you add them together with nonfatal injuries, present the same picture; tractors, self-propelled equipment, other machines top the list of agents. However, the life stock maulings, grain suffocation's, manure pit tragedies can't be ignored. Within the machinery category, overturns, run-overs, crushes, and crashes with motor vehicles predominate.

I would hesitate not but a moment to say there are too many that occurred to those who are too young, too many that occurred to those who are too old, and most of them that occurred to people in between.

Second, incentives are incomparably powerful motivators. To the extent we can effectively incentivize that which will improve safety and health we need to do so. Incentivizing the system, measuring the results, continuously feeding back to improve and doing it over lead to my third and final comment. And that is that I encourage NIOSH and appreciate their support for the infrastructure because without it we won't find the incentives and we won't measure the progress that's needed to improve the safety and health of the people engaged in agricultural activity.

Thank you.

Verbal Comment 2006/02/17: Good afternoon, this is Richard Job.

I am currently the chair of the ASABE, which is the American Society of Agricultural and Biological Engineers. My comments this morning are we know that a properly designed cab using the application of toxic materials in agricultural can provide protection superior to a respirator. We need research on the need to define when the level of protection of these cabs falls to levels below the limits. If you look the basic operations involving the process of agricultural, tilling the soil, preparing the seed beds, application of fertilizers, pesticides, and herbicides -- (inaudible). The questions that we have are how well are the operators of the equipment protected in the cab with equipment that we have today.

In industry, we think we've done an excellent job, but there is no research to verify that. There is also no research to verify how long these cabs are effective. Earlier this week, I was at the ASABE Technology Conference in Louisville. And the question was asked how well do our cabs protect the operator? (inaudible). Another question that was asked was how well do our cabs protect the operators of lawn care equipment when they are doing lawn care or lawn maintenance work? (Inaudible).

The one thing that we have no way of identifying today is the protection provided by the cab (inaudible). So essentially in our cabs and the standards today (inaudible). We would like to see sensor technology that will identify when the level of protection provided in an environmental cab has been compromised and maintenance must be performed. We need a simpler, reliable, refutable, and cost-effective test so that when maintenance has been performed we can verify that the protection level offered by the cab (inaudible).

When you have answered these questions in applied technology, we could have confidence that we can provide the operator to (inaudible). Thank you.

Verbal Comment 2006/02/17: My name is Terry Meek. I am the executive director of Proteus, Inc. We are a nonprofit organization that works with migrant seasonal farm workers, as well as other immigrants that come to Iowa to work in agribusiness and other professions.

We conduct every year sessions for migrant seasonal farm workers on workplace safety and pesticide training. And the thing I think that's become quite evident to us is that many employers do not give adequate time to providing education on these very important subjects in a manner that will really help their workers.

Many of the employers use videos, which allow -- Which do not allow for any conversation or question answering for individuals that do not speak English well. And this sometimes clouds the issue with overall safety procedures, as well as working with pesticides in the field. And we have found many workers who have many questions to ask and without there being some type of bilingual interchange between the trainers and the workers it becomes very difficult for them to pick up the kinds of information that they need to protect themselves while they're working.

If there could be a way that would deduce more employers to do a better job in this area, I think that we could eliminate many accidents or things that happen in the field or in the workplace that we have problems with now that OSHA and ETA have to deal with.

Those are my main comments, and I'm very thankful that you were able to include me right now.

Verbal Comment 2006/02/17: Thank you, Dr. Sprince. As she said my name is Kimberly Gordon. While I'm literally wearing my hard hat representing our Heartland Center, I'm speaking today with my NSN graduate student hat on and as an occupational health nurse.

America's workers are aging, many with co-morbid conditions and preventable chronic illnesses. As occupational health nurses, we deal with worker's lifestyles and that link to their ability to be at work every day in our work on a daily basis.

Work sites are large, they're small, they're diverse with many special populations of workers. Many Americans work eight to twelve or more hours a day, some six to seven days a week in jobs that cover

all the sectors that were discussed here this morning. With all of the other family, personal, and commitments that workers have, a healthy lifestyle is often forgotten. Let alone, finding the time to exercise for 30 minutes a day, as the Healthy People 2010 Program recommends. Employers in the Midwest and Federal Region 7 vary in the type and the amount of health promotion activities and programs offered to workers. Large employers may have resources to provide such services, but it is the small employers that make up the majority of work sites in this region. If there are budget cuts, it is often these extra services that are eliminated.

The question from occupational health nurses is what is the effect of lifestyle, physical conditioning, and overall health of workers on their productivity, the injury rates that we see, the severity of work-related injuries, and their ability to return to work following an injury?

Research to show health promotion and health-related program effectiveness, reduction of work-related injury and illnesses because of such programs can only benefit employers, workers, and us as a nation with a more productive work force. I suggest the overall health and physical conditioning of workers in all sectors be considered as a priority in NORA 2.

Research findings could help motivate employers to take a broader health expectation for what we want in workers, and could help workers accept the challenge of living a more healthy lifestyle. Thus, NORA 2 could help all of us have more productive and effective workers. Thank you.

those delivering services to agricultural health professionals and farmers

Categorized comment or partial comment:

Verbal Comment 2006/02/17: Thank you. I feel fortunate to be able to participate in this session, especially because I'm far away. And for those of you that are not aware, the AgriSafe Network is a nonprofit membership organization that consists of health professionals who have been trained in the field of agriculture health and safety, and they receive that training there at the University of Iowa through I-CASH. So we have a strong link to the University of Iowa and a strong history. And it's actually a wonderful example of a program that went from our research phase to something that translated in the community.

We have 20 clinics now in the State of Iowa that are based in hospitals, health departments, rural health clinics. And again, they're run by health professionals who have received core training there at the University of Iowa in the field of Ag. Health and have gone back to their organizations and started applying services.

The network is a membership organization representing those health professionals. We provide resources for them in training and technical assistance to make sure they can do the job.

We're also very excited because we launched a new initiative to expand that particular model in other states because we are a national organization and you can't be national unless you have presence in other states. And so we are going to -- by the end of 2006 we're expected to have new AgriSafe clinics developed in at least ten other states. We've joined an initiative with the National Rural Health Association to make that happen.

And we're very, very excited by the response to our recent (inaudible) promotion program where we have people throughout the country who are excited to go to core training there at University of Iowa and excited to think about developing AgriSafe clinics.

I just give you that background because it's important to understand that we have health professionals out there that even felt (inaudible) of rural communities that we're serving farmers and yet they don't feel they have the resources and the information and the training, and technical assistance to serve those health needs. And so it's really important when we think about research agendas and their translation that we make a connection between what the universities can offer the trained health professionals and what organizations such as AgriSafe Network can deliver in disseminating that important information.

So I would encourage you to think about how to design research initiatives that have a strong dissemination component, that have organizations, non-profit organizations that are really providing the outreach actively involved, very familiar with other funding sources. We get some funding from the (inaudible) Health Policy, whose federal agency is very interested in the field of agricultural health.

They fund -- They don't fund universities, mostly they fund organizations that are out delivering services. And I think we need to think about some collaboration between those who deliver and those who do the research. And I know that we've just begun, but perhaps NIOSH needs to think about career programs that are specifically geared for research institutions that require collaboration with those out in the field, and then grant programs where those who are out in the field require collaboration with research institutions because we want to make sure that the research that's being done reaches the farming community. And I can say that both I-CASH and the Great Plains Center have been actively involved with doing that. And I think what's happened in Iowa is a wonderful model for other states to follow. And as we expand to other states, we are going to actively be looking to other universities to partner with us in delivering services to health professionals and farmers. Thank you.

Verbal Comment 2006/02/17: This is Marty Limmex and I'm a safety consultant for an Iowa-based utility.

(Inaudible) With the vehicles, NIOSH has done a lot of research. A more recent report was with regards to how to (inaudible) delivery trucks. (inaudible)identifying the hazards of these trucks that are problems that the employees face, the slips, trips, the strains, the potential strains, diesel emissions, noise levels, et cetera. But, they never really developed a standard.

I guess I'd like to speak for all construction vehicles and service vehicles. This is an ongoing battle with safety consultants. We are constantly faced with trying to reduce slips and trips getting on and off the vehicles and in back of the service part of the vehicle. There's really no standards in place for, like, in the building construction trade, every step that you go up to in a building is typically between 15 and 17 inches. There's no standard for vehicles for getting on and off.

So everything that we do has to be custom done, which adds -- It's tough to get our customers' employers to do -- to get the vehicle ergonomically equipped.

The other item with the vehicles is diesel emissions, just wanted to push an effort to put forth and encourage the use of Iowa-based fuels, (inaudible) potential hazards that we see with diesel emissions.

We constantly struggle with the placement of the exhausts. There's no set standard out there, once again, but we go to manufacturers to get the vehicles built and it's always something special we have to pay extra for it.

And the third item is noise levels within vehicles. There's always been a standard for quite sometime where noise levels an operator in a cab can have so that his cab is totally closed and the vehicles open up where you have constant readings over maybe two to three decibels over an average for operators of vehicles going down the road.

So that was a concern of mine and there's a lot of research that we can use out there on vehicles, construction and service vehicles, but there's just not a lot to help us out with -- just go back and maybe preventing less trips and strain coming on and off vehicles. On the ergonomics side, our diesel emissions and our noise levels.

The second item I just talked was from the standard that's going to be forthcoming here from OSHA and NIOSH has done a lot of research on that. (Inaudible) That's all I have. Thank you.

Verbal Comment 2006/02/17: Thank you. I'm Ken Culp. I'm director of the graduate program in the Occupational Health Nursing Core at the Heartland Center. And I just wanted to make some antidotal comments about the supplemental NORA funding that the centers receive.

Like many nursing faculty entering the field of occupational health, many of us have had established careers in other specialty clinical areas, and mine was in aging. And in fact at the time that I became director of the Center, I had R-01 funding from the National Institute of Aging, as well as R-15 funding from National Institute for Nursing Research.

And I've really found this supplemental funding that the centers receive and the flexibility as it currently exists very, very helpful in facilitating my career and actually I think improving the graduate education of occupational health nurses.

Categorized comment or partial comment:

In the three years that I've been able to get some of this supplemental funding I've been able to pursue work in studying problems of older workers. And we recently did a survey, for instance, in three counties here in rural Iowa. Very basic questions about what is the participation rate of older workers in the workforce? And I guess I've had an ongoing interest in older workers.

And I find it really -- I think a phenomena that I don't know if NORA and NIOSH is going to continue to place emphasis on older workers. We have an aging workforce and when we move to this sector classification system I feel like I don't know how important it really is. Does it all fall under special populations or what?

So I do hope -- You know, I'm not the type of researcher that does some of the things that NIOSH funds; the industrial hygiene, you know, chemical toxicities. I'm the type of researcher that's going to be looking at older workers in the workforce, whether there's increased injuries in older workers. We recently undertook with that NORA supplement another study here in Iowa in a meatpacking plant looking at injury rates in older workers and particularly minority workers as well.

So I would just advocate that we continue these supplemental funds to the ERCs, and allow the center directors the flexibility to allocate those funds to the individuals that need it. I think it works really effectively in its current state. Thank you.

Verbal Comment 2006/02/17: Hi, I'm Joe Brenson from facilities management here at the University of Iowa. And I had not prepared anything, had not intended to speak, but there's two things that I think are very important for NIOSH to understand.

Number one, supporting what Mr. Culp just said, I think the aging workforce is critical. We've done some looks at our workforce in facilities management. We have places where our average worker -- this is maintenance workers, custodial staff and those folks are 53 years old.

This is a big issue for us. There are a lot of injuries for that. We have not a good injury rate here and now we're really starting to look at those things. So any work that you're doing on aging workforce is tremendous.

Also, to support that, the other thing I want you to think about is the sector. I think is a great idea of the sectors. It looks very good. The one sector that I'm not hearing anything about is service, and we are a service organization in facilities management and we have that aging workforce.

Remember in the '80's we told our kids, get your educations. Go get those good jobs. Well, guess what? For once the kids listened. They're out there getting the good jobs and they're doing well.

But as manufacturing and all the other areas start to diminish jobs, those jobs are being created in service. And who's getting those jobs? The older folks from the manufacturing, and ag., and the other businesses are now our employees in the service sector.

They're older, they're moving into service, and we need to figure out ways -- Ergonomics seem to be a huge issue for us and we need to figure out ways that those folks can have good, safe careers and be productive workers for a long time and not be hurt.

So again I'm supporting what Mr. Culp said, and hopefully you'll look at the service sector because that's where I think a lot of those older folks are. Thank you.

Verbal Comment 2006/02/17: My name is Bob Aherin. I'm a professor in the Agricultural Biological Engineering Department at the University of Illinois. I worked in the research and education fields of agricultural safety and health for a little over 30 years -- I don't want to say well over 30 years; and just a few comments. I commend NIOSH for its continued support in research and academic activities, development in the agricultural safety and health area. Our industry has some significant problems to the efforts that were made in the '90's and the early 2000's by NIOSH. We have certainly been able to understand many of the problems better and have developed concepts and interventions will have more of a lasting impact on our industry and have had lasting impact.

However, there are some issues that concern me a bit, and I encourage NIOSH to take a look at these. When we look at data that's been presented on morbidity/mortality data a lot of it's been analyzed, developed, or collected by NIOSH researchers and other institutions, all of them sponsored by NIOSH, as well as the National Safety Council's Department of Labor.

The greatest problem that faces our industry, based on the data that we currently have -- currently we need better data in the illness and disease area, but by far the biggest morbidity/mortality problem is traumatic injuries. Yet, when I pursue or review the research projects that are involved with some of these, both in health and traumatic injury side of things and supported to the centers and other sources, particularly by NIOSH, it appears to be -- while I don't have hard data -- it appears to be that

somewhere in the neighborhood of 67 percent of the research projects are focused in illness/disease issues.

And part of that might be the nature of the people who are applying, whether these centers are funded, and these are certainly areas -- the disease/illness areas are needed. There's a lot of issues that are in need of being evaluated and understood better. Yet, I feel that we are not really addressing as strongly as we should the traumatic injury problems in agriculture. And I would encourage NIOSH to review, you know, where is the funding going? I have a hard time putting all that data together, I'd like to do that to see if there's an imbalance here to some degree. And if there is, as I perceive there is, I would encourage that there are -- we need a greater effort to fund traumatic injury type of research problems.

We have a number of needs in this area and you are addressing several of the critical ones, particularly the tractor overturn issues that are going on and have been going on. And this is certainly very important work, but when we look at traumatic injuries there are other issues with general machinery, there's problems with (inaudible) equipment structures. We need better designs for structures. We have a real problem with (inaudible) that have appropriate fall-out systems, particularly in grain bins and silos. The musculoskeletal injuries are very significant in all our workforces. The dairy industry and the (inaudible) industry, and we need to continue that work and enhance the work in those areas to prevent the high percentage of back injuries that are occurring and other musculoskeletal type of injuries I think are also -- We are going to work with you to continue your enhanced work in that area. We need to take advantage and think also of the new technologies and enhance those (inaudible), particularly in the areas of sensory technologies that have potential -- and the research that I read on this is that and the people I work with here and other locations I've talked to there's great potential to help us do a better job of automating our equipment.

Even so our older equipment can be adapted to better prevent injuries in the first place and to take the place of a (inaudible), where it cannot use (inaudible) both in our equipment, as well as other industries.

And final comment, when we talked about special populations, and some of the previous speakers already discussed this here and also the other hearings you had, but I also concur that one of the areas we have not looked at very closely -- we did a lot of work on child safety issues and some special populations such as migrants and Amish workers and so forth, but we do need to take a closer look at the older workforce. Because we need to draw better guidelines, appropriate tasks, grain workers need to be aware of risks and how to minimize those risks.

We learned mortality/morbidity injury rates to worker's over 55 or close to all the studies I reviewed had a more significant experience as far as incident rates in this area. There is research being done and that we need to look at these issues.

And a final comment is that it is very important at the beginning that you continue your efforts in research to practice because our industry's not as heavily regulated as other industries. That's an issue we need to look at closer and the appropriateness of that to try to change some of the culture to some degree and I think it's happening to some degree. But we need to try to incorporate in the social structures of agriculture the adoptions of the way the state practices interventions that we write out our research hoping that the industries serve the production agriculture in the farming industry itself.

I thank you for your time and appreciate making some comments.

Verbal Comment 2006/02/17: Yeah, thanks Wayne. My name is Tom Cook. I'm on the faculty here in occupational and environmental health and physical therapy and international studies. I just have two areas that I think NIOSH needs to look at or continue to look at.

The first of those is the international involvement of NIOSH. I've been fortunate enough for the last -- well, ten years now, since 1996, to be involved with the Fogarty International Center and the International Training Program in Occupational and Environmental Health. During that time we've been able to bring over 60 physicians and health professionals from central eastern European countries, West Africa, and South African here to the University to participate in our programs and to connect with our faculty and our faculty mentors.

They've done a number of things. They've enriched our curriculum so that we now have students who interact with people who understand different social systems, different health systems and so on. So it certainly enriches our students, but I think it also keeps us in tune with this whole globalization thing.

And I think of research priorities for the next ten years -- We're all overwhelmed with what's happening in terms of globalization and outsourcing, and other things. Clearly in the next ten years our occupational health and safety issues are going to be more and more entangled with the world's occupational health and safety issues. I think there's a lot that can be learned by comparing and contrasting other countries and other things that are going on. I give you a couple quick examples just from our program, which is one of 16 programs that NIOSH helps fund.

We've done a couple of studies; ergonomics in Slovakia. And again, the different healthcare system, a different social system, different economic system, and but yet the musculoskeletal injuries to construction workers are fairly identical, except for hand and wrist, and upper back. So that's an example of -- We're still trying to figure this out, but that's an example of, you know, by sort of these natural experiments by the way things are done differently in different countries, we can learn something about how we do things and how we might do things better or how they might do things better.

PCBs, again, in Easter Slovakia, there's sort of natural experiment, there's a place there where workers and people have been exposed to inordinately high -- some of the world's concentrations of those chemicals. We can't go out and do that experiment and just say what are the health effects of PCBs in the workplace in this country? But we have a natural experiment by studying the health of those people.

And similarly pesticide use in Gambia and West Africa. Dr. Sanders and others have been involved -- and Kelley have been involved with some of our students from there and there's just a lot to be learned about, again, pesticide use, toxicity, fertilizer, and other things. So I think over the next ten years NIOSH will need to be more and more in tune with what's happening in other parts of the world because the world is shrinking, like it or not.

Categorized comment or partial comment:

The second area that I would like to encourage NIOSH to be involved in is information and communications technology, and that's probably, you know, looks like a natural for me since I've been pushing all the buttons and doing this stuff. But I really think that, again, it would be wise of NIOSH to take advantage of the ever-changing technology for communicating ideas and information.

We just heard, you know, our previous speaker talk about research to practice and certainly NIOSH has been active in that area, but I think we can do a whole lot more. I think we need to understand from a social marketing point of view, where do people get their information? Where do they get the messages to change their behaviors?

We really live in a sound bite, bumper sticker society and we need sound bites and bumper stickers that send NIOSH messages, you know, and health and safety messages. And I don't think we understand how to most effectively deliver that information. For example, we know farmers get most of their information from the radio when they're out in the field driving their combines and tractors.

So I think we would do well to do things like the FACE Project is doing; publish in, you know, Waste Management Magazine and places that things that are laying around in the break room of the service workers that we talked about earlier.

And then I think we could use the communications and information technology like we're doing now, in terms of sort of spanning time and space and involving people who don't come to scientific meetings and don't read scientific journals or maybe don't go to the NIOSH website. Maybe we need to go to them.

I think the idea that if you build it, they will come might work for baseball in Dyersville or Field of Dreams, but it doesn't work necessarily -- We can't be satisfied that we build the world's greatest website with all the information in the world. Many times the people who need it most are the least

likely to come to those places. And I think we need to beat them over the head, if you will, with the information that they need to hear.

So I think those two, international involvement and information technology will be very important in the next ten years. Thanks.

Verbal Comment 2006/02/17: So I basically have two broad questions. One question is, I think that there needs to be a greater effort in a concern about tinnitus. There's lot of interest and noise-induced hearing loss at times, but it seems like there's very few research activities funded. It's hard to find information on the web page and in fact in many situations tinnitus can be much more debilitating than hearing loss. And I don't think that's widely appreciated, and it think deserves more careful attention.

So my second -- Should I just go ahead?

DR. SANDERSON: Sure. Sure.

MR. TYLER: My second question is, there have been standards for noise-induced hearing loss, and recommended limitations of noise exposure for decades. And it's my impression that workers are still getting noise-induced hearing loss and tinnitus from the exposure. And I wondered if people appreciate why that's the case, and if they do, if there's a chance of changing the standards.

I think there's lots of evidence to suggest impulsive noise is much more damaging than continuous noise; that's one major reason. And I think a second major reason is that there are lots of workers that work more than 40 hours a week. And the standards in fact are based -- The noise exposure limits are based on research done many years ago where workers were exposed to 40-hour work weeks.

And I think that those two factors in themselves have probably been major factors. There are many others, but I think that many people would largely argue that the attempts to prevent noise-induced hearing loss and tinnitus in workers based on the current guidelines for noise exposure have frankly failed. Thank you.

Verbal Comment 2006/03/20: Thank you. I really appreciate this opportunity to speak with you today. I work at the nonprofit Education Development Center where I co-direct the National Young Worker Safety Resource Center, which is funded by OSHA to increase the state capacity to provide occupational safety and health training to high school students. And prior to that in collaboration with the Massachusetts Department of Public Health, I worked on several NIOSH funded projects. One, to work with community groups looking for ways that they could increase the safety and health of teen workers, and then another NIOSH project to work with state agencies to help them look for ideas for resources and activities that would better protect young workers.

So I'd like to speak today about the need for NIOSH to maintain a focus on the safety of young workers. Although I think teen safety can be considered within specific industry sectors, it's important that it remain an important cross-cutting issue.

Teen workers are a unique population and deserve special attention from NIOSH. Between 200,000 and 300,000 14 to 17 year olds seek emergency department treatment every year for injuries they suffered at work. And teen workers have a higher rate of injury than adult workers, despite the fact that they're

protected by child labor laws from working in the most dangerous occupations. And then tragically between 60 to 70 young people are killed on the job every year.

So having worked on this issue for over a decade it's clear that a lot of progress has been made, especially in our knowledge about the types and locations of injuries, about potential prevention strategies. And much of the credit for this project is really due to NIOSH for having conducted and sponsored research in this area. Nevertheless, it's also clear that a lot of progress needs to be made. So I'd like to suggest three general areas in which research is needed.

The first is the unique risk factors associated with adolescent growth and development. Some collaboration with experts in adolescent health and injury prevention, research should be conducted on the roles that size, strength, bone maturation, motor coordination, sleep needs, judgment, and cognitive ability play in work injuries. Particularly concerned are the large numbers of back injuries suffered among teen workers, and this can result in long-term disability.

And also, NIOSH should complete the initiative it began in 2002 where they were doing research to recommend updates to the child labor laws by determining which tasks that are being done by teens that are prohibited by teens should continue to be prohibited and which needed to be added to the prohibited list.

The second main area of research that's needed is in training and health communication. Professionals in the field of substance abuse, injury prevention, health promotion for adolescence have made great strides in understanding how to best frame and deliver messages to teens and to those responsible for their health and safety.

This research may or may not translate to the field of occupational safety. So research is needed to answer questions such as what education and training methods are most effective with youth. What strategies are being used now, especially by employers? What information to parents, healthcare providers, educators, and employers need to know about young worker safety and what's the best way to deliver that information to those groups?

The last general area of research that's needed is an intervention effectiveness. It's important to examine whether the kinds of prevention strategies being used in other disciplines are relevant to occupational health and safety. And programs that are already being implemented and those that are suggested in documents such as the Institutes of Medicines' Protecting Youth at Work report, need to be piloted and evaluated. Some of these interventions include teaching safety as part of job readiness programs, passing and enforcing stronger child labor laws, awarding safety certificates for youth who have received training, implementing worksite safety programs tailored to youth workers, and delivering occupational safety training to teachers and job placement professionals.

NIOSH has been a leader in fostering research to protect young workers. It's essential that its emphasis on industry-sector research not diminish its focus on the vulnerable population of teen workers who need our protection today and our help in preparing them to become adult workers of tomorrow. Thank you.

Verbal Comment 2006/03/20: Thank you, Dr. Wegman, and thank you for taking me out of turn. I'm here today to talk about non-friable asbestos. And the Massachusetts Division of Occupational Safety respectfully suggests that the NIOSH research agenda include an examination of asbestos hazards associated with commonly conducted renovation and demolition activities that disrupt non-friable asbestos-containing materials.

Assuming the asbestos exposure hazards are demonstrated by the studies, we'd further recommend that NIOSH develop model-safe work practices that can be broadly applied to control exposures in a manner that is both effective and economically feasible.

Since the publication of landmark studies on asbestos exposure in human illness over 25 years ago, the federal government and virtually all state governments have instituted regulations aimed at limiting asbestos exposure for workers and the general public. Because friable asbestos materials pose a high

risk of exposure due to their tendency to release fibers when crumbled, most regulations were initially focused on them.

Friable asbestos, of course, is commonly found in pipe coverings, boiler coverings, and spray-on insulation. In recent years, however, the use of more sophisticated analytical techniques has demonstrated the presence of asbestos in a wide array of so-called non-friable materials where the asbestos fibers are more or less encased in a hardened non-asbestos matrix. These materials include floor tile, joint compound, mastics, and window glazing compounds, just to name a few.

It's been widely assumed that the tendency of these non-friable materials to release asbestos fibers is low as compared to friable materials. Nevertheless, the requirements of state and federal asbestos regulations are increasingly being extended to work operations involving these non-friable materials. In many cases, particularly those involving renovation and demolition work, the asbestos content of non-friable materials is never tested and the work proceeds with a total absence of any asbestos controls. Such a scenario routinely occurs during painting operations, when window glazing compound, for instance, is disturbed during sash painting and during interior renovation and demolition work.

In other cases, non-friable materials are found to contain asbestos in advance of the work taking place and the owner or contractor is required to utilize an asbestos contractor to perform very expensive, but questionably cost-effective abatement. Because of these anomalous situations, there's a need for research on asbestos exposure potential occasioned by renovation and demolition work involving these non-friable asbestos materials, and where risk has demonstrated the development of model work practices, which will adequately control these risks.

DOS suggests that NIOSH focus on one or two of these materials, such as joint compound or window glazing. The current don't ask/don't tell approach toward the treatment of these materials is not acceptable, both from a public health and from a public polity perspective.

Here in Massachusetts, over 138,000 workers are employed in the construction industry. Nationwide, this figure is over 6.9 million. These workers and many workers in other industries who conduct renovation work in structures where non-friable asbestos materials are present are potentially impacted by this issue. Property owners are also impacted if they own structures that potentially contain non-friable materials as well.

We feel this issue has broad implications, both in terms of cost containment and worker safety. We surmise that appropriately scaled controls for renovation and demolition work that disrupts non-friable asbestos-containing materials lie somewhere between the existing framework established for friable materials and the complete absence of controls found on most projects.

The basis of our recommendation is that the measurement of the actual asbestos hazards involved with this work should form a foundation for the consideration of appropriate controls for the protection of workers, the public, and the environment. Thank you.

Verbal Comment 2006/03/20: We're going to do two small group activities in my five minutes. Thank you. My name is Nancy Lessin. I'm health and safety coordinator for the Massachusetts ALF-CIO, and a proud member of the Steel Workers' Union.

I've worked in the field of health and safety for over 25 years. I've served on NACOSH, and I served for five years on the NIOSH NORA team on organization of work. I've worked with workers in unions in all sectors of the economy, both private and public sector, nationally and internationally.

Fifteen or 20 years ago when I asked workers and union representatives what's happening in your workplaces that's causing workers to be injured, made ill, or stressed on their jobs. The list they created included many traditional health and safety hazards.

In the last decade, the responses to this question have changed. The answers invariably begin with downsizing, under staffing, mandatory overtime, push for production, job combinations, multitasking, speed up, work overload. It doesn't matter the industry and it doesn't matter whether it's public or private sector.

Workplaces have been undergoing massive changes in the way in which work is organized, often made possible by innovations and information and communications technologies. New forms of work organization are being introduced with very little attention to their potential to hurt workers. However, we do know that these forms of work restructuring can increase workers' risk of injury, illness, stress, and death.

Work's being restructured by management to achieve the goals of standardization of work, which in turn is used by management to increase their control over the work. And in many workplaces undergoing changes, worker knowledge about the production and service process is gathered through employee involvement and management then leans out and standardizes the process. This has resulted in job loss for some, while increasing the workload and work pace for others.

And I turn your attention to the first activity, which is called basic principles of continuous improvement. This is from a multi-national corporation. And you look at the job that's being documented here, the left hand isn't doing very much, the right hand is doing all the work.

If you turn the page over, you'll see the new improved job where the left hand and the right hand are working equally hard. This multi-national corporation says it's an ergonomic improvement because workload impact is spread across more body muscles instead of being isolated to only the right arm and hand.

The first way of doing the job is a recipe for repetitive-strain injury. And the right hand, the second way, is a recipe for bilateral carpal tunnel syndrome or something like that.

Workers are experiencing increased injury, illness, and stress from downsizing, mandatory overtime, 12-hour shifts, increased workload, and increased work pace. And to hide this increase, employers are implementing blame-the-worker behavior-based safety approaches that discourage workers from reporting injuries, illnesses, and hazards. These programs and priority in policies and practices blame workers who have or report injuries for committing unsafe acts and engaging in unsafe behaviors. They include safety incentive programs that provide prizes to workers who don't report injury discipline policies that provide discipline or threat of discipline to those who do report. Programs that focus on OSHA recordables and lost work days as key measures and milestones in attaining a safe workplace and full-blown behavioral observation programs that focus away from hazardous conditions and blame workers for being inattentive or working carelessly when they suffer injuries.

We've tracked the rise of behavior-based safety programs and linked them with the increase in employers' work restructuring efforts. These blame-the-worker schemes are hazards in and of themselves. When workers are discouraged from reporting their injuries, not only do they risk not getting the care they need, but the hazards causing those injuries don't get identified and addressed. It's hard enough to fix the problems we know about, it's impossible to fix the problems we don't.

I want to call your attention to the second small group activity. It's an accident report form from another multi-national corporation. The injury in this case was a bee sting. The question on the form says what did the effected employee do or not do that contributed to the accident? Why do you feel their actions contributed to the accident? The response on the form is the employee should have been aware that a bee had landed on his shirt and taken the appropriate steps to remove the bee without being stung. There is no injury or illness that a worker can have at a workplace like this that is not their fault.

The letter I received from NIOSH about this meeting stated the meeting is a key part of a national effort to keep working people, business, and the U.S. economy strong and vital in the next decade by reducing worker injuries and illnesses. Right now the perception is that workplaces are getting safer, except perhaps for nonunion mines, and that workplace injury and illness rates are down. Employers are working hard to create that perception as they discourage the reporting of work-related injuries and illnesses.

If NIOSH truly wants to meet the goal of reducing worker injuries and illnesses there will need to be concerted effort on the part of NIOSH, OSHA, and the Bureau of Labor Statistics to cut through the fairytale figures that too many employers are passing off as their OSHA recordables and find ways to understand and document what is really going on regarding injury and illness experience in this nation's workplace. Thank you very much.

Verbal Comment 2006/03/20: Thank you. Working conditions in the U.S. have changed greatly over the past several decades, as Nancy's been detailing. More people work in the service sectors and fewer in unionized manufacturing settings. Precarious employment is a more common experience in the U.S. workforce than it was in the early decades of NIOSH's history. The U.S. now has more immigrant workers who often work under hazardous conditions for low wages and may be politically and legally insecure.

Work has changed and so our understanding of health and safety risks and prevention programs are probably out of date and not sufficient to address the needs of many U.S. workers.

NIOSH needs to support and promote new and creative research designs and approaches that will help us to discover the occupational health and safety conditions and issues that have resulted from these changes in the U.S. economy.

I have a background in work environment policy, using qualitative and case study research approaches, worker health and safety training programs, and have been the PI for the past five years of a study of health disparities among healthcare workers that was funded by NIOSH. Early in that study, we learned that employers are fearful of employees knowing enough about health and safety issues to complain.

We also learned that workers were mistrustful that we were working in collusion with employers. Employees didn't have the time to participate in the research because they either had to work multiple jobs or were juggling shared work/family schedules with their spouses so that the kids were taken care of, the chores were done, and both parents got to work on time. The many single parents in these facilities had to manage all of that on their own.

Despite these challenges, our research has succeeded largely because of the integration of multiple qualitative and quantitative research designs; epidemiology, ergonomic exposure assessments, and political economic case studies. We also incorporated participatory research approaches midway through the study, successfully overcoming some of the barriers we were facing. In addition, we have had an interdisciplinary team that's broadened our scope and perspectives about the research. We've been conducting case study research to understand the context of health and safety in these settings. We interviewed managers, conducted focus groups with workers, examined years of employee newsletters, reviewed media reports about each facility. We've learned that through case study research we have a better sense of the questions that we need to ask in all our data collection efforts.

If research is to be put into practice then data collected must be valid and reliable. Increasingly we are going to need to use community-based participatory research approaches to attain good data. A more varied set of approaches and designs are needed to learn what hazards are presented in new work arrangements and how to prevent the risks, exposures, and the associated adverse health outcomes.

If we want our research to help advance the prevention of morbidity and mortality then our research has to start with the people who can make that happen; workers, unions, employers, and communities, and not simply give the results to them when we are done. That takes time and NIOSH will need to provide resources that support such relationship building.

When it comes to learning about the conditions of low-wage and precarious work, and work in the so-called informal sector, we would rarely be able to conduct studies with the permission of employers. Study of the health and safety of minority and immigrant workers in these settings must carefully aim to protect them from jeopardizing their livelihoods.

These conditions are going to require new approaches. Hester Lipskum (*) and her colleagues wonderful study of poultry workers in North Carolina is an example of how excellent work can be done without gaining access to the workplace. Of course, neither researchers nor workers have the immediate ability to improve working conditions, but working together just might make us stronger than working apart.

Lastly, for bringing research to practice, NIOSH has supported intervention research. But I would like to suggest a different model. We could call this new strategies research. The idea would be to promote work environment improvements through research that doesn't just address one issue or set of issues,

but develops the capacity of workers, communities, and employers to make continual workplace health and safety improvements.

Using community-based participatory approaches, the changes can be informed by the knowledge and experience of local actors. Their involvement at all stages of the research will establish a foundation for not just an intervention, but for the ability to learn about improving the work environment in ways that can be sustained over time and through whatever market and technology changes affect the production process.

NIOSH should look to the National Institute of Environmental Health Sciences success with funding community outreach and education programs as core components of research projects. Workplaces are different from community settings, but to put research into practice it's going to require education and training, and change networks will help sustain local action.

The economy has changed, work is changing, and work environments are changing. NIOSH is needed to promote new research approaches for the prevention of workplace injuries, illnesses, and deaths. Thank you.

Liberty Mutual Agency Markets

Categorized comment or partial comment:

Verbal Comment 2006/03/20: Good morning. The mission of Liberty Mutual Agency Markets is the same as our parent group, which is to help people live safer more secure lives. We do that by providing insurance services to small and medium-sized enterprises.

We have approximately 125 consultants and industrial hygienists, the majority of which our customers have between ten and 50 employees. We're making around 25,000 visits a year to those customers.

The U.S. Small Business Administration estimates that 95 percent of all new businesses are small businesses. They may not end up that way, they certainly start that way. So we would request that NIOSH and NORA focus on occupational injuries and illnesses for small and medium-sized enterprises.

Certainly, we would also want to continue the focus on occupational injuries versus illness. Illness is important, but injuries are what we see in our market as the major problem.

Also research partnering. We have partnered with our industry association, the PCI, Property Casualty Insurers, as well as OSHA to provide small business training for safety and health. We welcome partnerships on the research end as well. Thank you very much.

Verbal Comment 2006/03/20: My name is Chuck Levenstein. I'm a professor emeritus here at the University of Massachusetts Lowell, but I am also the co-chair now of the MTA Health and Safety Committee. And unfortunately Cathy Boudreau, who's the head of the MTA was not able to be here, but she asked if I would present testimony for her.

So the Massachusetts Teachers Association represents 93,000 workers in Massachusetts, including faculty and staff in K-12 schools, as well as higher education. We are the largest union in the Commonwealth, and we are affiliated with the National Education Association.

Surveillance. We have joined with a coalition of public employees unions in this state to petition the legislature for public employees OSHA, in order to ensure that the most basic protection that is guaranteed to employees in the private sector also apply to our members. Perhaps most important is that the absence of federal OSHA surveillance and reporting requirements; there is no systematic collection of data on the occupational injuries and illnesses of teachers. Our members have been exposed to hazardous work environments and building materials, including asbestos, but there's scant data available to inform policy and prevention.

Second, indoor air quality. We are supporting separate state legislation concerning indoor air quality in public buildings because we have innumerable complaints from our members, as well as data collected by the State Department of Public Health about mold and other air contaminants that threaten the respiratory health of teachers, staff, and students.

We understand the current OSHA standards do not deal adequately with such indoor air issues. We are deeply concerned about the health of children who spend their days in contaminated schools, as well as the large number of staff who report one form or another of respiratory illness. We would welcome research that examined the relationship between respiratory health of teachers and the variety of indoor air contaminants in schools.

Third, construction and renovation hazards. At a recent meeting, the MTA Environmental Health and Safety Committee heard complaints from members about the difficulties of working in the midst of deteriorating physical plant renovation projects and new building construction. Noise and unidentified dusts were the principle hazards mentioned. We are concerned about these conditions which may pose serious threats to the health of educational personnel, but are considered mere nuisances by public officials. Investigation of such circumstances is warranted and would be very, very helpful.

Job stress and violence. Teachers report that job stress and violence in the schools are problems that warrant attention. In particular, we would like to know if there are identifiable health effects of the level of stress that teachers experience, and we would like to know about the efficacy of interventions to reduce stress and violence.

These are issues that addressed by occupational health researchers concerned with the healthcare industry; there has been inadequate attention to the education sector.

Infectious disease. We know that the Centers for Disease Control recently recommended flu vaccination for children under seven years of age. As the New York Times commented in an editorial, it is important to make available vaccination for school-age children in order to protect them, their teachers, and the community.

A recent pilot study of faculty and school personnel by the Mass. Department of Public Health suggests that a third of these staff suffer from respiratory disease. A larger study of school-age children in Massachusetts suggests that about 25 percent have asthma, not in infectious disease, but one which could be exacerbated by a flu epidemic.

We need NIOSH research to examine the school environment as a promoter, if not the sole cause of illness. And we need studies to establish effective intervention to prevent the spread of disease among staff and children.

Categorized comment or partial comment:

School siting. We are concerned that localities are induced for economic reasons to site new schools on or near wetlands and landfills, which may then pose a variety of hazards for children and teachers. We believe that the mold problem in many schools, even new ones, is related to this unfortunate siting.

It would be desirable to study the long term health effects of schools sited on contaminated property, particularly those on or near landfills that leak. Some of the schools on landfills have monitoring systems, but we have no information on how frequently they are calibrated or otherwise monitored, or how often the bells go off. It would be useful to have studies of the health effects of such environmental conditions since they have profound effects on children, as well as teachers and other school personnel.

And finally, the economics of health and safety. We believe that many of the occupational health problems experienced by teachers are the result of inadequate and inequitable funding of public schools. Maintenance of buildings and staffing levels are serious issues. Low-bid requirements for maintenance, renovation, and school construction are a threat to safety and health of teachers and children.

There is virtually no research on the cost effectiveness of interventions to protect school health and safety. NIOSH's previous interest in social and economic dimensions of health and safety could well be applied to the investigation of problems in the education sector.

Thank you.

Verbal Comment 2006/03/20: Good morning. I'm Noreen Hogan. I'm a Registered Nurse. I'm here representing the Massachusetts Nurses Association. The Mass Nurses Association represents over 22,000 nurses in the State of Massachusetts. We've also taken the leadership in looking at the issue of workplace violence. I am also on the Task Force for Workplace Violence and Abuse Prevention, and we have -- I'll talk a little more, I guess, as I go on about some of the things that we have done.

The issue that I want to address today is preventing and reporting workplace violence in healthcare settings. As we all know, violence has increased everywhere in our world, and healthcare facilities previously known as caring places and once considered immune from this are now frequently the site of violence. In fact, violence in healthcare settings continues to rise.

The violence often is assault on the healthcare personnel, nurses in particular. Some of the Bureau of Labor Statistics show that nurses are being assaulted and hurt and victims of violence at a much higher rate than other healthcare professionals and at a much higher rate than workers in other industries.

From studies we know that there are multiple risk factors for this rise in the violence in healthcare settings. This includes the low nurse staffing levels, inadequate security in hospitals, unrestricted access to most hospital areas, and lack of staff training in recognizing and managing potentially violent situations.

And we believe on our task force, the Mass Nurses Association in total believes that workplace violence is not getting addressed because nurses and other healthcare providers fear being blamed and retaliated against, and this is much of the feedback we get from our members of why assaults and other violent acts aren't being reported.

In fact, what happens in many settings, in many agencies, that the victim is the one that is blamed for the action and for the violence and is often retaliated against and they often end up leaving; either are forced to leave or leave because they feel that things are just so uncomfortable in the setting. Another reason for not getting reported and getting addressed is inadequate reporting systems and a lack of effective response and aftercare programs.

One of the things that the Mass Nurses Association Task Force has come out with is a position statement where we recommend that all healthcare employees implement a workplace violence prevention program that's consistent with OSHA guidelines for preventing workplace violence to healthcare and social service workers.

We also really felt strongly and have come out strongly in our position paper that each facility should develop a defined plan for the agency's response to any incident of violence, including the right and protection to call the police and file criminal charges against assailants.

Part of the work we do on our task force in the Mass Nurses Association is a big piece of education. The position paper is just part of it. We've also come out with guidelines on how individual nurses can respond if they're assaulted in the workplace. We have addressed -- We've had speakers come to our conventions the last couple of years. We have also presented several day-long and sometimes half-day workshops on prevention and response to workplace violence. So again, as I said, we've taken the leadership in the State of Massachusetts.

What we would like NIOSH to look at for us is to research the effect of improved reporting systems because we feel one of the big, big issues, again, is the under-reporting that there's a much higher percentage of assaults that are occurring that never get reported. We'd like help in developing appropriate reporting tools and best practice formats so that the information can be readily utilized and replicated in healthcare facilities and agencies across the country.

This information will be useful in helping to change the culture of the healthcare industry to embrace worker safety with the same commitment as they do patient safety. Thank you for this opportunity to share my concerns and those of the Mass Nurses Association.

Verbal Comment 2006/03/20: I'm going to talk about environmental occupational asthma. Asthma is a serious chronic disease, which is a critical public health issue in the United States. Morbidity and mortality linked with asthma has markedly increased. Adult new-onset asthma that is work related has risen to between five and 29 percent of the workforce.

Mandatory reporting of occupational asthma became a requirement in Massachusetts on March 1st, 1992. This reporting requirement does not provide a complete account because it is known that many cases are not reported.

Cases are identified using doctor's reports of workers they have treated. Hospital discharge data are also used by identifying those workers with asthma and participating on workmen's compensation.

The Massachusetts program distributes research information gathered for the SENSOR program. This surveillance system gathers information for healthcare providers about specific occupational diseases in the state.

One of the diseases of interest in this system is occupational asthma. In 1988, Massachusetts, New Jersey, and Michigan received funding to establish this surveillance system, and in 1992 California also received funding.

The concept of this model is that occupational asthma is a preventable disease and disability, or untimely death serves as a signal that prevention efforts have failed and others could be at risk. With surveillance data, work-related exposures are identified and marked for intervention.

All four states describe a rise in reported cases of occupational asthma and new agents are being discovered. Workers' compensation could be obtained if pre-existing condition was exacerbated by workplace exposure.

Occupational asthma is caused by exposure to substances in the workplace. Many substances found in the healthcare industry fall in this category, and they are pharmaceuticals, animal dander, proteins, enzymes, and other low and high molecular weight molecules.

Over ten percent of the workforce is employed in the healthcare industry, which has been growing steadily since the 1990's. Most of the reported cases are new-onset asthma due to exposure to hazardous chemicals. A large percentage of occupational asthma occurs after exposure to sensitizing agents.

Another form of work-related asthma is reactive airways dysfunction syndrome, or RADS, which occurs after a single exposure to high levels of an irritating vapor, fume, or smoke. Symptoms develop minutes to hours after exposure, and they can persist for more than a year. Clinical manifestations of this condition are obstructive symptoms and airway hyperactivity.

The onset of RADS can be usually specifically timed and dated. These symptoms usually are evident after a dramatic event, such as an accident, such as a spill involving a vapor, gas, high level of smoke or dust exposure. This is why the worker is able to identify the substance by where exposed to and exactly when the exposure took place.

Causes of workplace or occupational asthma in the healthcare industry are triggered by many toxic chemicals; environmental cleansing agents contain bleach and/or ammonia. If these are accidentally mixed together they produce chloramine gas. The fumes from this mixture cause tearing, rhino rhea, cough, dyspnea, and it can also be deadly.

Cleaning agents contain chemicals that are known sensitizers and respiratory irritants. Disinfectants such as chloramines, chlorhexidine, formaldehyde, are known allergens and these products have safer alternatives and are available and are in use today.

This information will be helpful in helping to change the culture of the healthcare industry to embrace worker safety with the same commitment as they do patient safety. Thank you.

Verbal Comment 2006/03/20: Hello. Thank you for the opportunity to address the meeting and to see all of my colleagues out there. It's nice to see you all here. I'm at the University of Massachusetts Department of Work Environment here in Lowell. I was trained at an ERC. I'm in a training grant center now, and have been doing research in occupational health and safety for many years.

I'd written a bunch more extensive comments that I'm going to submit, so I'm just hoping to highlight a few things. And I want to focus on what was highlighted as one of the new Es, evaluation, by Max Lum in his introduction.

My first point in the topic of evaluation is to point out or to remind people that the TOSCA inventory contains about 80,000 chemicals currently, and of those about 2,800 are considered high-production volume chemicals. EPA has done a survey of those high-production chemicals and found that only 43 percent of them have toxicity information on them and only seven percent of them have any OSHA standards.

So I guess my first point is that I think that these -- at least these high production volume chemicals should be a focus for examination of human health effects. They're in use out in industry and we know very little about the human health effects of these chemicals. So epidemiologic studies and so on, I feel, are a high priority for this group of chemicals.

My second point is that over the past several years there seems to have been a move away from exposure surveillance and quantitative assessment and towards this concept called controlled banding. And although on the face of it, I think, controlled banding is a useful tool in the public health arsenal of prevention. I also want to point out that there's been very little work done to validate this approach across a range of industries, and jobs, and tasks. And so I would strongly encourage NIOSH to put some effort into an extensive validation of the controlled banding approach before it is -- before encouraging its wholesale acceptance.

And I guess the last area that I'd like to comment on is the role that NIOSH has played in the development of exposure assessment methods. I personally have come to depend on the basic research that NIOSH does in analytical chemistry and aerosol science, clinical lab science and toxicology. Over the years, they have been the backbone of my research that I have used and applied; the applied research that I do.

And so I feel that it's vitally important that NIOSH continue to focus its resources in the area of exposure assessment, and some of the topics that I would like to see them focus on are the development of new analytical and exposure assessment methods to identify and characterize exposures to those chemicals that are currently in commerce, and especially those chemicals that are in new products and processes such as nanotechnology, as well as helping us identify some of the hazardous components of some of the older technologies like metal-working fluids.

A focus on methods development should also include a collaboration between toxicologists and analytical chemists, and together, hopefully, they can identify classes of compounds with similar biological activity. And then the analytical chemists can work to develop methods to measure these classes of compounds, rather than having to develop methods for each individual compound, separately. A good example of this kind of development might be looking at isocyanates and measuring the active NCO group in isocyanates, rather than developing methods to measure each individual isocyanate separately. This kind of an approach to classes of chemicals would also help in validating the controlled banding idea, which focuses on the concept of risk groups for chemicals.

Also, I'd like to see development of new direct reading or portable and expedient measurement methods that could be used in the field. There are lots of situations where field personnel could use these instruments for a quick assessment to determine the level of control needed. And so I would like to see NIOSH focus on exposure assessment, the basic sciences, in the future.

Thank you.

Verbal Comment 2006/03/20: Thank you. Good morning, everybody. My name is Marlene Freeley and I'm an occupational health nurse practitioner, and I have worked in the healthcare industry for 20 years. Healthcare has been faced with increased costs, but more importantly the loss of knowledgeable technically-expert experienced nurses due to work-related injuries. Back injuries are the most common problem associated with nurses' injuries due to the type of work we do; the manual patient handling. And going forward, we expect to see that this trend will increase because we have issues with an aging workforce, but we also have issues where there's more obese patients in the hospital than ever before, and there's more dependent patients in the hospital with multi-system problems. And what this does is it puts more physical work on the nurse who's doing the care.

Let me give you a quick picture. If you were a construction worker and you were told by your boss to go and move a 200-pound block of cement, you would say certainly, and you would get your forklift and you would go and you would move that block of cement.

If you are a nurse and you are told to go move a 200-pound patient, you would say certainly, and you would go into that room and try to move or reposition that patient by yourself or maybe with the help of another nurse, and that's the reality for nursing.

Job tasks that are associated with musculoskeletal injuries, mostly back injuries, are lifting, transferring, and repositioning patients; tasks that nurses do, not once a shift, but constantly every hour throughout their shift. The magnitude of this problem is absolutely huge. We have about eight million healthcare

workers and we make up less than ten percent of the workforce, but nurses lead most other occupations in terms of injury rates.

And as other industries have tried to figure out ways to decrease their injuries, in the healthcare industry we've struggled with increasing injury rates. Between 1980 and 1990 there was a 40-percent increase in injury rates among nursing personnel. Right now, the rate for a nurse in a hospital -- the rate of injury is 9.8 per 100 FTE, which makes nursing the fourth highest injury rate for all occupations. So the magnitude of injuries in nursing is well substantiated, both from research in this country as well as international research.

The healthcare industry hasn't been sitting around, not trying to address this problem. First of all, there's been body-mechanic training that we focus on. And body-mechanic training has actually had its founding in people living vertically from the floor to the waist level. But as you know, nurses don't -- hopefully, we're not lifting a lot of people from the floor, we tend to lift horizontally. And so the body-mechanic training that we force on nurses has absolutely no application to nursing; it doesn't work, it cannot be applied to nursing.

And yet we make nurses feel guilty when they have a back injury, and we say did you use proper body mechanics? We also have had in some places nurses are told to wear back belts, which again we know is not effective at all. So traditional methods the healthcare industry has used; absolutely not effective at all.

But, what's really exciting for me is that there are some new technology that's emerging, some safe patient handling technology that looks really hopeful. And this new technology goes from the high-tech stuff, which are like ceiling lifts and portable patient lifts to low tech stuff, such as friction-reducing sheets. And we know from studies that are just coming out that this technology reduces the amount of work that nurses have to do. Studies are showing that this new safe patient handling technology decreases costs between 20 and 80 percent. And now we're also finding that it increases patient satisfaction because they have more dignity, being moved up in bed instead of being hoisted. And we're seeing better patient outcomes because instead of getting out of bed maybe once a day, nurses are able to get patients out of bed four or five times a day, which again leads to better outcomes.

So we need help. We need research to be done to study this new safe patient handling technology. We need to see what the cost benefit is so we can convince administrators that this is the way to go. We want to measure the health outcomes of patients who are being transferred by this safe patient handling technology and also the satisfaction in healthcare workers. Thank you.

Verbal Comment 2006/03/20: Thank you. I appreciate this opportunity to bring the concern of the nurses and the Massachusetts Nurses Association. We're talking here about nurses' exposure to hazardous drugs.

The use of hazardous drugs as identified in the NIOSH publication "Alert: Preventing Occupational Exposure to Hazardous Antineoplastic and Other Hazardous Drugs in Healthcare Settings" is extensive. Today, many drugs have multiple uses, and while they may be recognized as antineoplastic agents, thus hazardous in a chemotherapy unit, they are not recognized as such in other settings.

Immuno-suppressive drugs, gonadotropins, estrogens, estrogen agonists and antagonists, and antiviral's are all classified as drugs considered hazardous according to NIOSH.

New drugs come to the market almost daily with little or no recognition of the damage that can be done to the health and well being of nurses and others who work with these drugs on a daily basis. Since the healthcare industry is still recognized as the fastest growing industrial segment in this country, millions of workers have the potential for exposure and disease in the future.

The NIOSH publication classified many of these drugs in use today as actual or suspected cancer causing agents, others as contributing to adverse reproductive events, such as infertility and miscarriages. Many other drugs are known to have properties that cause or exacerbate asthma.

As nurses we could count off on our fingers the number of our friends and colleagues who have had cancers and who have had adverse reproductive events. Today, I know at the MNA we have three -- nurses in three hospitals who are concerned about clusters, either of breast cancer or brain cancer. And we really have no way to research or to look for research to find causative agents.

While the extent of the adverse health effects of many drugs are recognized and have been known for years, in some cases the extent to which nurses are informed of the hazards is not well understood. As nurses, we learn the intended action of drugs on patients and diseases. We also learn to recognize adverse effects of drugs as they're administered to the patients and how to respond in the event of an adverse reaction to protect the patient from harm.

Historically, nurses have not been taught about the potential effect of these drugs on themselves or their coworkers. Nurses are seldom trained to select and utilize appropriate personal protective equipment other than gloves or to carry out appropriate disposal or spill clean-up methods. Protective equipment that is utilized is often for the protection of the patient.

While nurses in specialty practice or with advanced education may have been provided with this information, the majority of nurses at the bedside, in outpatient clinics, in home care, or office settings have not had this opportunity to learn why and how to protect themselves.

OSHA requires that chemical hazard communication is the employers' responsibility, and there are very specific requirements for that training. Drugs and pharmaceuticals are exempted from hazard communication training, only if the drug is administered in a pill form. Once the pill is crushed or the drug is administered through a vein as a liquid or inhaled as a mist, the drug falls under the requirement of the OSHA Hazard Communication Standard. This standard also requires the employer to identify and provide engineering controls and appropriate personal protective equipment.

Also poorly understood is the type of protective equipment that is appropriate for protection against exposures, both to nurses and other workers. It would be valuable to have research that identifies nurses' knowledge related to the hazards of the drugs that they use and the personal protective measures that are necessary.

It would also be valuable to have research related to hazard communication programs that are in use in hospitals today that provide training related to preventing exposure to hazardous drugs. We would like to see examples of hazard recognition, selection of personal protective equipment, engineering controls, recognition of exposures; that is spills, releases, contact with patients' blood or waste materials, post-exposure reporting, and follow-up protocols and medical surveillance.

This information then could be transferred into fact sheets and information bulletins that are so useful in educating nurses and other healthcare workers, including doctors and hospital managers, and administrators. This information will be useful in helping to change the culture of the healthcare industry to embrace worker safety with the same commitment as they do patient safety. Thank you very much.

Verbal Comment 2006/03/20: Thank you for this opportunity to address this group today. I have had a number of years now in occupational safety and health, and have the privilege of engaging in NIOSH funded research, including under the NIOSH NORA umbrella for a project we call the Sustainable Hospitals Project, and now a project on blood exposure and sharp injuries among home healthcare workers. And this latter project we're very excited about because it's located both here at the University of Massachusetts Lowell, together with our collaborators at the Massachusetts Department of Public Health, and we work with both labor partners through the Massachusetts Nurses Association, the SEIU Local 2020, and a number of private home healthcare agencies. So it's really a partnership that we're quite excited about.

Many of the colleagues have already spoken about issues related to healthcare. And so what I would like to do is focus on a cross-sector strategy, a cross-cutting issue and apply it to two of the NORA sectors.

The cross-cutting strategy is one that we've been working on here at the University of Massachusetts Lowell in many capacities, which is to develop and apply methods to substitute or eliminate hazards through the identification and design of safer and healthier products, materials, and work practices.

At University of Mass. Lowell, we're calling this Alternatives Assessment and Design, or Redesign. And the alternative being to finding alternatives to conventional materials, products, and all the associated work processes and practices that go with them.

I'd like to talk about applying these to the healthcare sector and also to the sector of manufacturing, in particular the manufacturing of nanotechnologies. It's been a top priority of the occupational hygiene hierarchy of controls that we should substitute or eliminate hazards. But really, more of the focus over the past decade has been controlling hazards through engineering controls, administrative controls, and we hope as a last resort but often not, personal protective equipment.

Yet, many products, materials, and their associated processes are introduced into the workplace and then eventually communities, without any input from occupational health and safety researchers or professionals. That is, materials and products are produced as a given. Occupational health researchers, workers, community members are not assumed to have any role in saying what those products should look like and how they should be made.

But, thanks to decades of important research in occupational safety and health, including much of it funded by NIOSH, we actually now know a great deal about many substances of their hazards of exposures. And I think it's time that we begin to develop methods to reduce those exposures or eliminate them, in addition to measuring and controlling those hazards. And I know that's been a focus of our field, but I'm proposing that we try to actually become involved in the design and redesign of processes and materials, and even products.

And applied to the healthcare sector, that might look like something we engaged in in the Sustainable Hospitals Project to have occupational health and safety researchers, along with clinicians and administrators in hospitals identify hazardous products like needles and getting safe needle devices, as in new drug delivery systems, and seeing if we could identify alternatives to those and if those alternatives did not exist actually suggesting ways to redesign them.

And one of the things that we became involved in is actually starting to work with manufacturers around their product design, especially when hospitals and other clinics decided that their purchasing power was enough to get them to influence how they might actually design their products in a healthier and safer way.

I just wanted to touch on this issue related to nanotechnologies because we're getting a whole new, very widely dispersed technology introduced here. And I think that occupational safety and health researchers and professionals could be on the design teams for these new products, not just waiting for them to come off the line and then the rest of the world saying well, how are you going to make these safe for us once they've already been produced?

We should ask do we need to take these hazards as a given or can we design them? This approach, I think, is cross-cutting and can be applied to other areas, especially these two sectors. And I think that it can help to expand the scope of occupational health and safety research and also the role of professionals in their practice. And I hope that we can grow our field in addition to deepening the research in the field.

In addition, I think that it's a way that we could lead to innovation. Occupational safety and health can be innovative in addition to measuring and controlling. Thank you.

Verbal Comment 2006/03/20: My name's Chris Pontus, I'm from Mass Nurses Association. My topic and title of comments are mandatory overtime, safe patient handling devices, workplace violence and the relationship to administrative policies and procedure. And my last question is is there a need for best practice model in each of these arenas?

My basic premise is that in the proper environment many accidents and injuries can be prevented. I will briefly discuss the issues and concerns of each category, and then suggest that each healthcare facility have policies, procedures, and most importantly the key personnel in place to work towards prevention and decreasing the amount of these injuries.

In the current healthcare system, health and safety professionals need to be empowered to create environments for healthcare personnel to deliver patient-care services. It has been my experience through various healthcare systems that there is a lack of consistent practices in place to ensure safe working conditions.

A disconnect exists from the health and safety policies in place to the actual implementation of getting the needed or anticipated result. When it comes to the health and safety of the worker, there are pockets or voids of misunderstanding and department through most healthcare organizations. I find that some departments have a sense of what health and safety provisions are necessary and other

departments do not. For example, some medical centers are not even equipped with the appropriate equipment or knowledge base to implement a basic safety action plan.

A recent actual example is an ICU nurse attends a seminar. She was interested in obtaining safe patient handling equipment and training for her unit. When she returned to work she was unable to communicate the lessons learned during the seminar. Her workload interfered with transferring the critical information to her associates. Consequently, the proper safe patient handling equipment was never acquired.

On the frontline is the lack of support from the immediate supervisor and director of nursing due to a misunderstanding or lack of understanding the problem when the nurse attempts to bring a solution to one of the nation's leading causes of injury in healthcare. This lack of response from the working infrastructure to provide a pathway for a dialogue to be initiated and reach someone within that facility who could and should understand the need to respond is an issue often not provided.

We as occupational health nurses know that repeated and overuse of the body without rest periods and/or the use of ergonomic equipment to help with certain tasks can lead to a breakdown of the body for many workers. Recent studies indicate that those working in jobs with overtime schedules experience a 61 percent higher injury rate in comparison to those working the same positions without overtime. Individuals working 12 hours per day are associated with an increase injury rate of 37 percent. Those working 60 hours per week experienced an increased injury rate of 23 percent.

Substantial efforts should be made to create an in-house pool of nurses employed part-time that understand they could be on call for a certain day of the week. There are many practical solutions that could be implemented before the use of mandatory overtime. Mandatory overtime should be a last choice of action.

Strategies to prevent workplace injuries should consider changes in scheduling, practices, job redesign, health protection programs for people working in jobs involving overtime or extended hours.

Last, the incidents of physical violence is increasing in America. Healthcare providers are exposed to violent incidents due to neighborhoods that city hospitals are often located in, the population served, such as mental health or forensics, meaning violent patients, a family member sometimes upset or out of control, an operational environment that is open to the public at all times.

We at MNA believe that there are procedures that can be taken to prevent violent incidents and proactive measures that can be implemented when an incident occurs that can lessen traumatic effects. We also believe that the incidents of workplace violence is under reported. Additionally, there are cultural and organizational acceptances of inappropriate behaviors that contribute towards violent incidents.

The researchable issues of the sectors just spoken to are healthcare facilities that have established effective workplace prevention policies procedures need to be identified. Is there a best practice model in healthcare that we can follow? And that there is a breakdown of organizational communication interfering with health and safety issues and is perpetuating preventable occupational injuries in most facilities. Thank you.

Categorized comment or partial comment:

Verbal Comment 2006/03/20: Hello. Thank you for the opportunity to speak here today. I have about 26 years of experience in nuclear power plant biotechnology healthcare and academia. But relevant to my proposal today I am a member of the Pandemic Flu Project Team of the American Industrial Hygiene Association, and I'm the Infection Control Team Leader of the AAHA newly created Healthcare Working Group. I'm representing the Massachusetts Nurses Association today.

During the 2002 SARS outbreak there were 8,450 reported cases in 33 countries on five continents. The eventual death rate was 9.6 percent; 774 people, worldwide. The elderly rate was over 40 percent. It was also noted that in Toronto, 42 percent of the cases were healthcare workers; in Vietnam, 57 percent.

It's assumed that most of these were nosocomial or transferred within the hospital; work acquired. They were infected at work, and it's also a concern that the nurse to doctor ratio was ten to three, SARS death rate.

After the SARS outbreak, several shortcomings became evident in the healthcare incident response. These included the inability to identify and contain agents, inadequate worker protection and surveillance, misunderstanding of transmission. It was also determined that after the fact workers had

inadequate understanding of personal protective equipment and there was a shortage of isolation equipment.

Information about the disease was unavailable or poorly integrated, and there were few monitoring capabilities to survey the agent in the environment or the workplace. Other hospital management and industrial hygiene shortcomings included the failure to track patient contact history, the failure to track visitor contacts, and an overall lack of preparedness and an inability to prevent the spread of the disease.

Much of the system failures mentioned here were due to a general lack of consensus in infection control in healthcare. In the past, infection control emphasis has been on patient care. Infection control professionals tend to emphasize medical and administrative controls and are not thoroughly aware of industrial hygiene rubrics. Industrial hygiene and safety professionals have to deal with rapidly changing conditions for which the risks, the transmissions, the viability, and other issues are not well understood.

Lastly, there remains a general attitude that healthcare workers should continue to accept workplace risks that would be unacceptable in other industries. As an example, in a recent document published by the World Health Organization they showed this overwhelming acceptance of risk in healthcare workers by issuing the following statement with regards to when a respirator may be warranted instead of a surgical mask, quote, serological surveys in close contacts of patients, communities where clusters of cases have occurred, or high risk populations, such as healthcare workers, will provide early alerts to changes in the behavior of the virus, unquote. With the future outbreak potential still looming, and the last I checked the World Health Organization has us in a Pandemic Alert Three, meaning human infections with a new subtype but no human to human spread are at most rare instances of spread to a close contact. If this virus mutates in such a way that the disease can be transmissible from human to human like SARS did a serious pandemic could become a reality, unquote. So that's the WHO.

So to summarize, the needs for increased industrial hygiene research in infection control are evident. The following topics should be prioritized. Determination of acceptable environmental levels for various agents, the development of air/surface monitoring capabilities and other evaluation techniques, better abilities for industrial hygienists to describe how agents may move through or exist in the environment to expose workers, better ways for the medical community and industrial hygiene to communicate about diseases. And then, just naturally, development of better engineering controls, ventilation filtration disinfection, isolation, administrative controls, the needs for clear and concise programs and procedures, policies planning, techniques for tracking worker exposures and monitoring materials in the environment, job rotation access control, and when to administer prophylactics.

And lastly, but not least, going back to the respiratory protection issue is clear and concise directions for personal protective equipment. Thank you.

Verbal Comment 2006/03/20: Hello. I'm going to speak today about hazardous drug exposure in the healthcare environment. I'm a registered nurse with more than 30 years of direct-care provider experience in major Boston teaching facilities, and I'm a member of the MNA, and in the Congress on Health and Safety. I'm here on their behalf today, as well as UMASS Lowell, where I am a student in the work environment policy program and also research assistant in the PHASE healthcare study, which is Promoting Healthy and Safe Employment in Healthcare. I'm also an injured worker.

Currently, more than 5.5 million healthcare workers may handle hazardous drugs like chemotherapeutic agents, antibiotics, antivirals, hormones, bio-engineered drugs, and other miscellaneous drugs. Serious health effects have been reported in healthcare workers exposed to these hazardous agents, and Evie actually went through those effects.

Hospital staff, particularly nursing and pharmacy personnel may be exposed to hazardous drugs by breathing them, ingesting them, or having skin contact with these agents while preparing, which

includes counting the pills, crushing them, breaking tablets, administering and/or disposing of the hazardous agents, the equipment that's used to administered them, and linens patients may come in contact with, or the patient's body fluids or feces.

The healthcare industry has been recognized as one of the fastest growing segments in the economy. In the future, more and more workers will have the potential for work-related exposure to the myriad of hazardous drugs found in the complex healthcare environment.

A 2004 NIOSH conference was entitled Alert on Reducing Occupational Exposures to Hazardous Drugs in Healthcare, Converting Theory to Practice. Unfortunately, while we have made strides in recognizing these hazardous exposures and the potential health effects facing healthcare workers, we have not gone far enough. Converting theory to practice, even in large teaching facilities, has not been consistently accomplished.

We would like NIOSH to focus on prevention by conducting research in facilities that have successfully designed, implemented, and are practicing comprehensive hazardous drug exposures prevention programs or aspects of programs, which reach workers in all potential exposure areas.

Information on the types, frequency, and circumstances of exposure to hazardous drugs among healthcare workers will assist in prevention efforts and also help occupational health professionals monitor exposure and resulting health effects, detect emerging problems related to hazardous drug exposure, for instance, the occupational health and safety implications of nanotechnology in hazardous drug administration, and monitor prevention program impact.

We have made progress in identifying and focusing on a wide variety of exposures found in the healthcare environment since the last NORA agenda was set. I am very proud to have been part of that last NORA meeting. This invaluable work should not only continue, but be expanded.

Additional focus should be placed on research and education that will provide support to the healthcare workforce directly, particularly for direct-care providers who are most at risk. Aspects of the work environment that serve as barriers to training and the ability to carry out what has been learned, like staffing, are also integral to effective preventive efforts. These barriers should be researched and solutions supported by the occupational health community, as well as hospital administrators.

We would like to have this research translated into fact sheets and best practice formats so the information can be readily replicated and utilized in healthcare facilities and agencies across the country. This information will be useful in helping to change the culture of the healthcare industry to embrace worker safety.

Thank you for this opportunity to share my concerns and those of the MNA and the UMass Lowell community.

Verbal Comment 2006/03/20: Good morning, my name is Elizabeth O'Conner and I'm here on behalf of the Massachusetts Nurses Association. And I am the last nurse to speak to you this morning, but certainly not the least. I also am a member of the Congress on Health and Safety at our Mass Nurses Association, as is Kathy as she mentioned, and also Chris and Tom.

I am speaking to you today on the topic and the title of my comments is preventing needle-stick and sharps injuries. I'm a registered nurse and have been providing bedside care for 29 years now at a major teaching hospital in Boston. I'm also a member of the Needlestick Advisory Board of the Massachusetts Department of Public Health.

I appreciate this opportunity to bring forward to you the concern of continued exposure of nurses and other healthcare workers, including doctors, to blood and body fluid through needle-stick and sharps injuries. This blood and body fluid can transmit HIV, Hepatitis B, Hepatitis C Virus, as well as viruses that cause West Nile Fever. Many of these injuries occur because healthcare facilities and agencies purchase and provide workers, unknowingly in some cases, with unsafe devices, although there are safer alternatives on the market that may have not been researched by the facilities.

The healthcare industry continues to be recognized as the fastest growing segment in the U.S. economy. And for this reason, more and more workers will have the potential for exposure in the future. A few years ago, OSHA estimated close to one million needle-stick injuries in this country occur each year. We quote the number as an estimate since it is recognized that probably 50 percent of these injuries go underreported, yearly.

The hospital I work in had a proactive approach to preventing needle-stick and sharps injuries. Prior to the changes in the OSHA Blood Borne Pathogens standard and the Massachusetts legislation which followed that requires reporting of needle-stick injuries and sharps injuries by healthcare agencies and facilities to the Department of Public Health. Before those -- Prior to these changes, a committee was formed at my hospital and monthly meetings were held to discuss the needs to research and test engineered safety devices that would be appropriate for specific departments in our facility.

These meetings included hospital management and were attended by representatives from nursing, pharmacy, surgery, radiology, anesthesia, and medicine. As safety devices appeared on the market they began to be utilized. Problems were identified with certain products, and alternatives were selected.

I feel that my hospital has been ahead of the curve in working to prevent needle-stick and sharps injuries. As a member of the Needlestick Advisory Board at the Department of Public Health, I realize that not all nurses, such as myself and other workers are as protected and not all facilities and agencies are as proactive. Injuries continue because of a lack of commitment to assure that only engineered safety needles and other sharps are provided for their workers. I have learned that unsafe devices are still available due to several factors.

The first factor is backdoor purchasing, a term that describes how specific departments can order equipment outside of the regular purchasing channels. This allows them to bypass the system that would only purchase safety devices and lets them order whatever they choose, or whatever they have been used to using. That was the case at my facility in certain instances.

The second factor is procedural kits that include unsafe needles and/or sharps. These kits contain all the supplies and equipment in one sterile package to accomplish a medical procedure. The suppliers who fill these kits are not held to the same requirement as that of the employer in relation to protecting workers from exposure. Thus, unsafe devices often costing less and in great supply from the manufacturers are placed in the kits, posing a hazard to the workers using these kits unless the safer alternatives are chosen and they are instructed to do so from their facilities.

And thirdly, purchasing contracts. A hospital or agency may be included in a purchasing agreement with a supplier to allow lower costs for bulk purchasing of medical equipment and supplies. And I must be speaking very slowly.

Just to summarize, those three factors are a major reason why we feel that there needs to be further research in this area so that we could develop fact sheets, as has been stated earlier this morning, and best practice formats to provide information to other healthcare providers in this country so that they will not be injured. And the information would be useful in helping to change the culture of the healthcare industry, as also was mentioned earlier today. Thank you very much for allowing me to speak at this time.

Verbal Comment 2006/03/20: Good morning. I'm research faculty here in the Department of Work Environment at the University of Massachusetts Lowell, which means that 100 percent of my time is spent on occupational health and safety research, most of it funded by NIOSH.

I was trained in occupational health and safety research at Hunter College and here in the Department of Work Environment, and most of that training was also supported by NIOSH.

I'm currently the principle investigator on a NIOSH-K or career development grant to investigate methods for evaluating nail salon hazards and health effects. And this work was motivated in part by interest in the apparent need for new ways of reaching immigrant workers, non-English speaking workers, and workers in very small businesses, all of which have generally been underserved by research money in the past.

And there is good reasons for this lack of attention to these working populations. These workers are hard to reach, there are cultural and linguistic barriers between them and university researchers, and often times they are alienated from mainstream institutions, be that universities or unions, or professional associations, or government.

So I've worked hard over the past few years to form relationships with and to collaborate with my research partners in the Vietnamese community from which nail salon workers generally come. And this

focus was inspired in part by NORA's focus on special populations, and I've gotten a lot of guidance from that committee on my approaches.

Together with the Vietnamese -- my partners in the Vietnamese community, we've conducted community-based occupational health and safety survey and designed a unique culturally and linguistically appropriate outreach tool; the Nail Salon Health and Safety Calendar.

I'm now co-investigator on a research application to continue our department's work with Hispanic construction workers. This proposed project links many of the current -- the existing NORA's goals, especially the targeting of at-risk special populations and the prevention of falls; a leading cause of death for construction workers.

We believe that in order to be successful we have to work closely with the entire affected community, including more than the contractors and the workers, but also their families, local government, and even the religious community.

I urge NIOSH to recognize the challenges and the rewards of such research/community links and to support through the next NORA research with special populations and the methods required to work with them; qualitative inquiry, community-based participatory research, and time. Thank you.

Note: Verbal testimony provided to NORA Town Hall meeting in Lowell, MA, 2006/03/20.

Verbal Comment 2006/03/20: I'm Pam Quinlan. I'm a senior occupational health nurse for Tyco Electronics M/A-COM division, here in Lowell. I'm here to talk about repetitive-motion injuries as they relate to our worker population.

I manage the workers' compensation for M/A-COM facilities across the country and also the disability. What we are seeing is an injury that has probably been focused on quite a bit already. I'm sure lots of research has been done. We did have an ergonomic standard provided, but I don't think it was ever put in place. And, we really need more guidance in this area.

We're finding that workers, not only who are doing the manufacturing -- We have FABS across the country. We have workers who are doing project management working at computers for eight hours a day. We have people who are in the IT programs, SAP programs, entering data for eight hours a day. And what we need is more guidance to teach them about ergonomics, and also guide us in the rest periods; how many breaks they should take, what the exercises should be.

We've taught all this, we know. We've done the ergonomic evaluations. We have a very good safety record. Our environmental health and safety committee is very active. We're proactive in educating our employees to set up their work stations so they do work in neutral positions.

We know the value of administrative controls, engineering controls, and changing jobs.

But in this economic environment, we can't really change jobs because if a person cannot do their job chances are they won't have one. And especially now in the electronics field, much of our business is being transferred to China and other countries, actually where we also have many plants.

So I'm asking that NIOSH go back to this diagnosis, it's an old injury, you know, repetitive-motion injury has had a lot of work done, but I don't want to keep it on the back burner. I'd like to see it come to the front burner again and have a lot of research done on it, as to how we can prevent these injuries.

Because I not only manage the claims in dollars, and half of the dollars spent on all our claims are spent on repetitive-motion injuries. I also manage the case; the individual's healthcare from the time that they report the injury until they either return to work full-duty or are totally disabled. Yes, some of our people are totally disabled across the country, whether it's California, Virginia, Maryland, here in Massachusetts, we have plants all over this country and it is causing a disability, even today.

So thank you very much. And I would just like to say that I'm on the Board of Directors for the Greater Boston Association of Occupational Health Nurses. So I am an employee advocate, and that's what I'm here for today. Thank you.

Verbal Comment 2006/03/20: Thank you. I'm a certified professional agronomist [sic], and I am also a registered occupational therapist licensed in the State of Connecticut. I've worked in ergonomics for the last 15 years for a large property casualty insurer in Connecticut in the loss control department. My role is to be a resource to our field staff and also to work directly with our insured on various aspects of ergonomics. Prior to that, I worked for many years in the healthcare industry as an occupational therapist.

I'd like to address three topics briefly.

The first, I'd like to support the trend toward addressing occupational safety and health by industry group. This approach is inline with trends in the business community, including the insurance industry, where aggressive efforts are currently underway to produce industry-specific insurance products and associated occupational safety and health programs and products, such as ergonomics and occupational safety and health programs and materials, including training programs. Such a coordinated approach would promote greater effectiveness in employee-based occupational safety and health programs and practices.

Secondly, focused outcome-oriented research on the advocacy and cost effectiveness of ergonomic interventions would help those of us who work directly with employers in the field on various aspects of occupational safety and health, and would also help safety directors and risk managers in those companies who face the challenge of developing effective safety and health programs, selling those programs to senior management, and implementing those programs effectively.

The employers that I work with want to know -- They want to hear about practical solutions to ergonomic exposures. They want to know what those solutions will cost and what the return on investment will be. They're asking for training programs and materials, and in particular, time-efficient training programs; the time available for training in the workplace is just shrinking rapidly.

They want to know more about how effective training programs -- Excuse me. They want to know more about how effective those training programs are and what the most effective training approaches will be.

As a previous speaker stated, back injuries continue to be a major exposure in the workplace and certainly a major challenge in the healthcare industry. Material handling continues to be a challenge in other industries, as well. Recently, for example, I've received many requests from the retail industry. Employers want to address issues associated with loading and unloading trucks, stacking shelves, delivering products to customers down narrow flights of stairs and in and out of various buildings.

In the spirit of the NORA research-to-practice agenda, can we identify and utilize those, who like me are in the position to pass research and best practices onto employers effectively?

And lastly, the other issue I briefly want to address is older workers. Employers attempting to implement ergonomic programs are recognizing the aging of their employee populations. They want to know what they need to do, what they can do, to support the health and productivity of their workers. What's different with the older worker? What works with the older worker?

Thank you.

Verbal Comment 2006/03/20: Good morning. I'm Laura Punnett on the faculty of the Department of Work Environment at UMass Lowell. Musculoskeletal disorders of the back, upper, and lower extremities represent a continuing major source of morbidity in all sectors of the U.S. economy; we've just been hearing about some of that. It's very important that NIOSH not permit political events, such as the overturning of the OSHA rule to push musculoskeletal disorders off of the research agenda. We should also note that recent changes in the BLS record-keeping rules eliminated the repetitive trauma

category of illness. And NIOSH also has a special responsibility to make sure that this -- the resulting artifact in reporting is not confused with a true decrease in the magnitude of these problems.

Unlike diseases that are eventually fatal or acute injuries that can be witnessed by others, medical surveillance of musculoskeletal disorders relies primarily upon monitoring the behaviors of individuals, such as when they seek medical attention or tell their employers about their problems. These behaviors, of course, are influenced by circumstances both within and outside the workplace. For example, if I don't believe that my employer will or can take steps to help me recover, then I'll be unlikely to report the problem.

Anecdotally, the availability of support systems and appropriate employer responses varies by socioeconomic status and possibly also by gender, and race or ethnicity. NIOSH should support more research to examine the magnitude of reasons for and distribution of under reporting, as well as the extent of work-related morbidity that remains obscured in the general population for the same reasons.

There's substantial epidemiologic evidence demonstrating the musculoskeletal effects of exposure to physical stressors at work. Recently with WHO researchers we estimated that over one third of back pain globally is explained by occupational demands. Of course, still there are gaps in knowledge. Musculoskeletal research could better inform preventive efforts if we had more longitudinal studies generating data on the natural history and the latency of effect for different exposure profiles, including combinations of physical and psychosocial exposures.

There's been little examination of how occupational experience might affect disease risks or progression even after leaving work. We need outcomes research to examine the long term impact on health, as well as on employment and economic status, especially the vicious cycle of worse outcomes in low-status workers who are injured.

We also need more laboratory studies on patho-mechanisms that are relevant to the forms of mechanical load that occur occupationally. Such research can inform the development of more etiologically relevant exposure indicators and of better diagnostic instruments. The available examination techniques do not adequately serve for many of the symptoms and syndromes that are commonly reported in workplace settings.

The challenge of analyzing non-routinized jobs has become more pressing as fewer people than ever work on traditional manufacturing assembly lines. Certified nursing assistant, hotel room cleaner, bus driver, legal secretary, construction laborer; these are only a few examples of jobs that are repetitive in their fundamental motion patterns, but are not routinized to the extent that they can be described completely by observation of only a few minutes of work time.

As ergonomic exposure assessment becomes more time consuming and more labor intensive, the trade-off between the precision of direct measurement and the need to describe exposure variability over time also becomes more challenging to optimize.

Ergonomic exposure methods are almost as numerous as ergonomists. Worker self-report, investigator observation, direct measurement; they each have utility, but the lack of standardized exposure metrics severely limits our ability to compile findings across studies. While the epidemiologic literature has consistently implicated a common set of physical exposures, the magnitude of specific exposure outcome associations often vary substantially. Besides differences in operational definitions of exposure, variation in quantitative findings may also result from differences in case definitions,

exposure-dependent latency periods, correlations among risk factors or the ranges of exposure available for analysis.

Similar to the important role that NIOSH has played with respect to standardization of chemical exposure assessment methods, NIOSH could play a similar role here with regard to ergonomic exposures. And it's badly needed in order to facilitate the meta-analytic tasks such as quantifying exposure/response relationships and defining permissible exposure levels.

There have been some highly counter-productive arguments in recent years about how to partition musculoskeletal disorder risks between physical and psychosocial exposures. It's important to appreciate that many of these job features have common upstream determinants rooted in the way that work is organized. More studies should utilize multi-level analysis to identify those work organization features that explain variability in both physical and psychosocial conditions.

And finally, I would urge that there be more research on the role that occupation plays in socioeconomic disparities in health. NIOSH could enter more fully into the mainstream public health conversation by stimulating and supporting more research that examines the way in which worse working conditions among lower status workers form part of the mechanism of socioeconomic disparities in health. Thank you.

Verbal Comment 2006/03/20: Thank you for the opportunity to speak. My name is John Eagan. I'm an employee of NStar Gas and Electric. I am a member of the Local U, WUA-369 Joint Safety Committee. I represent the overhead line workers at NStar.

My reason for being here today is I am the blue-collar worker that you hear about. I have 36 years of experience in line work. I on a daily basis rubber-glove 8,000 volts, which means I put on a pair of 20,000 volt gloves and go up and put my hands on the conductor.

I work with many individuals that have a tremendous need for training in this field. Unfortunately, as Nancy Lessin got your attention earlier today explaining the fairytale that is in the work environment today of training and lack of training. The company that I work for has a tremendous amount of paper that shows training, but the actual field training is very lacking.

I can give you an example of what the younger workforce, those with less experience than myself, must deal with on a daily basis. They are exposed to the similar risks that I am. It's a very unforgiving commodity. You do not get a second opportunity if you make a mistake in the work that I do.

What happens, unfortunately, is individuals are sent out into the field under my guidance as an example, and I'm instructed to give them what they need. It's a very difficult task to monitor that and to do what needs to be done.

What I'm requesting and what I would love to see is some kind of monitoring research so that some agency outside of the individual utilities is responsible for what goes on. These companies, not just the one that I work for, have the ability to hide many, many statistics. As has been mentioned earlier, those

individuals that are injured do not come forward with injuries, even though there is a mechanism and a method to do such, they're afraid.

Also, I will tell you some of the circumstances that I've worked under recently, and this is just a brief example. There was a storm on Cape Cod on December 9th; it was termed a wintercane or a bombogenesis. On December 9th, I reported to work at 7:30 a.m. I was instructed to work for the day in a storm. From that point, we were instructed to drive to Cape Cod. Under the direction of the state police, they closed Route 495 to allow us to assemble and continue to the Cape. Then continued to work all night, all day Saturday, and was given rest at 11:00 p.m. Saturday night. Without doing the math, I'm sure you people understand how long a time period that is. Under that time frame, we were rubber-gloving 8,000 volts, alive. Now continue that whole process to the point that I returned to my home on Tuesday afternoon. I was there Friday, Saturday, Sunday, Monday, and most of the day Tuesday. Now, would you like to be facing me coming down the road if I've worked under those conditions when I'm driving a huge bucket truck on the major highways of this state? I don't think so, but that's what's going on every day.

So on the premise that we could get training that would allow others to be in a great spot because we're going to be doing this regardless of what happens, because of downsizing, because of economic issues with power companies now, deregulation, the DTE demanding reliability, we're going to be doing this. I request training and monitoring of that training which allows other individuals to be at the top of their game so when I'm not then they can take their own ownership of what they're doing. Thank you.

Verbal Comment 2006/03/20: Thank you. My name is Raphael Moure-Araso. I am the chair of the Department of Work Environment of the School of Health and Environment of the University of Massachusetts Lowell. And I would like to give my remarks about NIOSH research to understand and prevent hazards arising from emerging technologies.

NIOSH has been committed to understanding and preventing hazards arising from emerging technologies for very many years. For example, ergonomics issues on BDTs in the '70's, indoor air contamination in the '80's, and impacts of new drug manufacturing on the skin and respiratory systems in the '90's. In 1996, NIOSH through NORA recognized emergency [sic] technology as one of the 21 priority research topics for the next decade.

The first nine years of NORA have demonstrated the importance of strategic research partnerships in providing safe and healthy workplaces. NORA now seeks to build on past successes while preparing for new challenges in designing research to address the 20th-century workplace. Framework to integrate

emerging technologies research in each of the nine proposed sectors will provide guideposts for research directions and to develop partnerships in support of those pursuits.

The sectors that you heard from early this morning -- I recall mining, constructions, manufacturing, retail, transportation services, healthcare, and an additional one that is cross-sector research. I am aiming to that cross-sector research perhaps, but also to all the different sectors that definitely have emerging technologies.

The original approach to emerging technologies was the creation of a team that anticipated the elimination of occupational hazards associated with new technologies. NIOSH convened a multi-disciplinary team and applied consensus and (inaudible) assessments techniques to identify research gaps. The challenge was to apply knowledge to emerging occupational hazards before they become ingrained in workplace technology. The vision was of a proactive design of emerging technologies that incorporated principles to eliminate hazards rather than just controlling them.

The team met from 1997 to 2002 and it identified four areas of research and development to address perspective emerging technologies. I will discuss three of those four areas, modify my own analysis -- As a matter of fact I don't pretend to represent the team; I have this opportunity to tell you my piece of it. And I'm going to propose that this consideration of research be applied to the nine sectors of future NIOSH/NORA research work.

The first area is to identify and prioritize emerging technologies by sectors. The need to identify and prioritize the emerging technologies that must deserve attention with regard to their potential positive or negative consequence of occupational health in these nine sectors was considered during the deliberations of the team. The suggestion was a two-tier approach to fill this identification and surveillance gap. The first tier will use existing sources of information to identify relevant emerging technologies, and the second tier will prioritize which applications of these technologies could potentially harm or benefit occupational health.

We discussed the specific needs of research, like to determine the minimum data needed to identify technologies and their hazards. We also need to periodically evaluate the emerging technology literature, specifically the NIOSH Health Hazard Evaluations Database for potential reported effects on workers health.

We also talk about the need to conduct prospective analysis, specifically promoting the use of alternative analysis that will apply prospectively a framework for the search of optimal technology. And then, analyzing each alternative of emerging technologies by interactive risk assessment.

The third sector was apply the concept of inherently safety processes. We believe that the design of emerging technologies and their deployment is needed that will resort in safer workplaces. This new approach of inheriting safer process, considered (inaudible) and processes that are inherently safer for the workers. We make specific recommendation of where to look at the published literature in inherently safer process to apply in the development of new technologies.

Finally, it is important that we create an integrated process for adopting beneficial emerging technologies and avoiding potential safety and health problems with these technologies in all sectors. This process needs to integrate identification, and knowledge, and design of emerging technologies. It must also encourage collaboration between safety and health professionals and technology developers in all the sector areas identified by NORA. Thank you.

Verbal Comment 2006/03/20: Good morning. My name is Steve Schrag, and I work for the Service Employees International Union in our HAZMAT training program. I want to thank NORA for the opportunity to give my input on the proposed research for the next ten years.

Since 1985, I've worked for SCIU and I've either facilitated or conducted workshops for over 20,000 workers in a variety of workplaces: hospitals, nursing homes, homecare workers, Department of Transportation both on the road and in their facilities, and for building maintenance workers. What I see is a lot of holes in training programs that most employers put together. I see workers who get a HAZCOM training that's 15 minutes, and it's a video, and go back to work.

What I see as operations-level training, or what's called operations-level training where people get little time to actually use the equipment they're supposed to use, whether it's confined space or whether it's decontaminating a patient. I see lots of situations where workers are asked to sign a sign-in sheet before the class that says yes, I understood everything I learned in the class; a little bit presumptuous. And what I see is for most of those programs there's little impact on what happens to workers in terms of protecting themselves.

So I think that what NORA should look at is a couple of questions. One is what is the quality of training that is currently provided to workers, to fulfill OSHA mandates? Second is is the length of that training adequate for workers to assimilate the information that's provided? And third is the frequency of the training sufficient to ensure up-to-date information and skill development using necessary safety equipment and protocols?

OSHA mandates dozens of kinds of training in their various standards. Some of them are compliance standards where they just have to check it off that they did the training. Some of them are performance

standards where they actually measure what workers know. I find that the use of lecture and PowerPoint and now online training and use of experts dominates many of these programs that employers do in order to fulfill their compliance requirements.

What I've seen in the training that we've done is that participatory small groups and the use of peer educators offer the opportunity for greater performance success and that is people actually leave the workshop learning something.

Other participatory methods such as using hands-on activities, such as donning and actually doffing personal protective equipment, handling and practicing with specialized safety equipment can increase the retention of information provided and increase their understanding.

If you wanted to learn how to ride a bike, you wouldn't listen to an expert to teach you how to do it, you wouldn't watch a video on how to ride a bike, you wouldn't go on an online program to learn how to ride a bike, you'd get on the bike. You'd probably learn it from your older brother or sister or somebody else who's a bike rider. So if we want people to learn, and that's the goal of these mandates, that's the way it needs to play out.

And when we look at other people who take care of the health and safety of others, like requirements for professionals, they spend years learning a body of information. Why do some employers think that an hour or two is enough for workers?

Emergency medical technician paramedics go to school for at least two years of training, epidemiologist's, four years, industrial hygienists, four years, physicians, eight years. To understand the information in occupational health and safety sufficiently, there needs to be enough time allocated so that students can absorb the information and be able to apply it to real-world situations.

It is common for many employers to use the new employee orientation as their basic health and safety training. Unfortunately, a new employee may not have a lot of practical questions on workplace hazards unless they already worked in that industry. So that's not the place for people to get the training.

Other kinds of programs require annual performance appraisals; people who get their performance appraisals in terms of their work, corporations in terms of their finances, professionals in terms of continuing education training. If other training and measuring tools are conducted annually, why can't all OSHA mandated training have the same requirements?

Knowledge is the first step to help protect workers from occupational hazards. Without adequate knowledge, there is no motivation to change the behaviors of the working conditions.

However, knowledge alone will not help reduce exposure to occupational hazards. Workers need to understand the information provided. Understanding comes from a combination of absorbing the information and practicing using it in a combination with their own practical work experience and hands-on activities.

There needs to be a greater emphasis on determining the effectiveness of current training practices in order to assess how effective OSHA mandated training is working to help reduce injuries and illnesses on the job.

OSHA can issue standards, NIOSH can do terrific research. However, if workers don't understand what needs to be done, then little will change on the worksite. Too many workers are needlessly exposed to hazards every day, and every day that another worker gets sick or ill, we have failed.

I hope we stop failing in the future and NORA's research will help in that cause. Thank you.

Verbal Comment 2006/03/20: My name is Chris Witkowski and I'm director of the Air Safety Health and Security Department for the Association of Flight Attendants Labor Union. We represent 46,000 flight attendants at 22 airlines, which is about 40 percent of the flight attendants in the United States. Don't forget that about a billion U.S. based passengers shared this workplace last year, alone; that's one person getting on one individual flight leg throughout 2005. I'm here today to raise awareness at NIOSH on three points. First, flight attendants have inadequate safety and health protections on the job, making them an at-risk population. Second, flight attendants sustain a significant burden of occupational illness and injury. And third, flight attendants are sorely understudied populations.

These three points serve to justify AFA's request to fund some specific and inexpensive air quality-related research that we described in detail at the December 1st NORA meeting in College Park, Maryland. I don't want to waste my time going over again what we presented then, but I want to take the time to put them and the urgency with which they need to be addressed in context.

For my first point, flight attendants are particularly at-risk population because no agency has bothered to issue and enforce necessary safety and health regulations for them. Crew members were stripped of their OSHA protections almost 31 years ago with no opportunity to submit comments, no fanfare, no

opportunity to engage in discussion about this, just a simple federal registered notice by the Federal Aviation Administration in which they announced that they had exclusive responsibility for regulating the safety of civil aircraft in operation. And they went on to say that you can't take apart the occupational safety and health issues from the aviation safety issues so they have to remain together under the FAA. So they made the announcement, but they did not exercise that jurisdiction. So they didn't issue the occupational safety and health protections in '75, and they haven't done so since.

Twenty-five years later, OSHA and FAA signed a memorandum of understanding, committing the agencies to jointly address the safety and health hazards in the aircraft cabin. Unfortunately, all that the MOU has amounted to is that the agencies are inviting airlines to participate in voluntary safety health programs, effectively giving the air lines the message that we'd like you to please issue some protections, but if it's too burdensome or costly, then don't worry about it. Well, according to the Bureau of Labor statistics on occupational illness and injury data, the airlines have not worried.

This takes me to my second point, that flight attendants sustain a significant burden of occupational illness and injury. You might wonder how that can be so, after all how dangerous can it be to tell people to buckle their seatbelts and serve sodas and pretzels?

A survey of our AFA safety and health representatives reveals that injuries related to turbulence, poorly designed and maintained carts and galleys, handling or being struck by heavy carry-on baggage, opening and shutting doors on turbo-prop aircraft, falling on icy walkways and galley floors, and getting cuts and burns from oven racks and coffee pots, and in addition, getting their arms crushed by food service elevators from the lower deck to the main deck of wide-body aircraft continue.

Flight attendants report poor air quality, aggressive and violent passengers, hearing loss, cold cabins, poor sanitation, malfunctioning equipment, and rigorous flight schedules with short ground times. They are concerned about radiation exposure at altitude and contact with blood, which is a common occurrence, by the way. They report that they routinely work when sick because they fear losing their shift or losing their jobs altogether. Our analysis of the Bureau of Labor statistics data from '98 to 2002 identified non-fatal recordable injury and illness rate for flight attendants were at least twice as high as the rates for construction workers, and up to four times as high if you consider that flight attendants only work 20 hours per week. Also, the flight attendant data were three to four times as high as the rates recorded for all private industry, and double that again for hour by hour comparison.

For my last point about flight attendants being understudied, it must be said that last round of NORA research did dedicate significant time and money to testing data collection methods for flight attendant cohort studies, and we acknowledge the NIOSH work on contaminant monitoring under normal conditions. However, we since learned that NIOSH has apparently cut funding for their intramural program on aviation health. So we're concerned that the advances in data collection methodology will be left sitting on the shelf.

We have also been told that NIOSH has never solicited research specifically for this industry in their extramural requests for applications, despite the many health and safety threats to cabin crew and passengers. So in closing, I want to remind NIOSH about the 115,000 U.S. based flight attendants who need research to address specific hazards in their workplace, and we thank NIOSH for providing these forums to identify at-risk populations, and our members are ready to assist to make any research that's proposed a reality. Thank you.

Verbal Comment 2006/03/20: Good morning, everyone. My name is Angela San Philipo. I've been the president of the Gloucester Fishermen's Wife Association for the last 29 years. I'm here today to speak to you about the hazards and the health issues of the commercial fishermen of Massachusetts, New England, and our nation. In the past, I've also served as a U.S. Coastguard on Commercial Fishing Vessel Safety Advisory Board. I am the Founder of the Massachusetts Fishermen Health Plan. And I'm also -- I worked with Tufts University in translating medical booklets for the Italian population.

Yes, the commercial fishermen in Massachusetts, especially, and around the country, they are immigrants. The Massachusetts Gloucester primarily is Italian-speaking; in New Bedford they are Portuguese-speaking. This is an industry that today has been decreased very much because of fishing regulations and it posed many, many health hazards, not only physically, but also mentally to the fishermen themselves and their families, as well. In the last 20 years since fishing regulations have taken place, we've lost many people, but once the Coast Guard report is filled out, it's put on a shelf.

And the next thing is we're going to see enormous tragedy in the fishing industry. And this is why I'm here today because I really would encourage NIOSH to allow some funds to do some good research.

Fishing days have been cut to 52 days a year, and on May 1st they will be cut to 25 days a year. There is not much income to keep our boats safe.

Fishermen don't have insurance. If you own a boat and you're the captain the insurance company will not insure you. So if you have a medical problem resulting from an accident in your boat, if you have personal insurance you can be treated, if you don't, you will just receive the minimum benefit that you can get from a free-care hospital. And once this injury takes place nobody traces them and nobody knows what happens to them. This is why I repeat again, we need some serious research funding to see what happens to these people.

I want to give you two examples that just happened in the last four months in the fishing industry of Gloucester. On November 26th, my husband was fishing in his 47-foot boat alone, as he has done for the last three years, because the fishing regulation he cannot employ other fishermen to help him. On a 47-foot boat, normally would be three people on that boat, but he's fished alone.

It was a beautiful day when he saw smoking coming out from his galley. He was smart. He grabbed his survival suit, went to the stern of the boat, put his suit on and then tried to go forward to see what happened. As he did that, fire hit his face and he turned and realized that there was nothing that he could do but just to jump in the water if he wanted to survive.

Little did he know that a survival suit, at the cost of \$700, is not fireproof. Nobody knew that until then. He jumped in the water and 20 minutes later another fisherman picked him up. And it was after we looked at the survival suit, we saw that the back of his suit was burned. And thank God, not to the degree the water would've got in because if water were to get in he would've never survived. And there's nothing anybody can do about getting the manufacturers to make them fireproof, but the fishermen's wife will make sure that happens.

But another incident -- Another incident happened about two weeks ago. A 36-year-old young fisherman -- and we don't have many of those because young people are not getting into fishing because fishing regulation doesn't give them a future. They were fishing on a day where they should not have been fishing because the weather conditions were not that great. But you know there are so many days and at the end of this month, if they don't use those days, they lose them, and they have families and they have boats to keep up.

Something came untangled from this wings the boats have so they're stable in the ocean. This thing hit him in the stomach, and he weighs 300 pounds. He was knocked unconscious, airlifted by the Coast Guard, and brought to the hospital, operated, and most of his intestines were removed. That boat doesn't have insurance because he's an owner. Their bill is getting paid by his personal insurance that we created back ten years ago through the Massachusetts Fishermen Health Plan.

These are the stories that you don't read in the newspapers or read in magazines. What will happen to this young fisherman? Nobody knows. There is no support groups. They tell you to go to psychiatrists; they don't know nothing about fishing.

So these are the things that we need, and I really urge NIOSH that they will work with us so we can study these people who little by little by federal regulations are being wiped out. Remember, we always going to eat fish and we always going to need good and brave fishermen. Thank you.

Verbal Comment 2006/03/20: Hi. My name is Karen Hopcia, and I'm a nurse and a doctoral student at the Harvard School of Public Health. My current research projects include injuries to nurses. Today, I would like to raise awareness of the special circumstances surrounding the work of nurses.

There are several points I would like to make.

First, despite numerous articles examining nurses' work in organization health, or the impact of workload on patient outcomes, there are few studies that examine the association between nurses' work and their health. Second, nurses sustain significant occupational illnesses and injuries, and this may increase as the mean age of nurses' increases. Third, there are inadequate studies on nurses, despite the large number of practicing nurses in this country. These points justify a looking at increased expenditures on nurses' working conditions.

As mentioned, studies involving nurses usually revolve around how nurses impact the organization or patient outcome, such as medical errors. But there are few studies on how nurses' work impact their health. Today's nurses face increased demands in the hospital environment. There is more intensity and a faster pace at work, as the rate of patient turnover continues to increase and patient acuity rises. There are also organizational changes that have increased the demands on nurses. These include

enhanced monitoring and surveillance at work, increased sensitivity to reimbursement issues, evidence-based medicine, and an emphasis on improving patient safety.

Furthermore, individual care has become more complex with sicker patients, increased technology, increased skill requirements at the bedside, and more multitasking. This change in work creates not only more physical demands, but psychological demands for the nurse.

My second point is related to nursing injuries and the increasing age of the workforce. Nursing work is hazardous. Nurses work 24 hours a day, seven days a week. Overall, nursing injury rates are substantial with a particularly high rate of sustained back injuries, third only to construction and transportation workers.

However, our knowledge of nurses' injuries is derived from BLS statistics that are reported per annum across industrial settings and occupations, but exclude organizational data such as staffing, the impact of shift work, and the variability of work in a given setting or in changing settings. It is therefore impossible to understand how the contribution of the organization of work and stress in nurses impacts occupational illnesses and injuries.

Additionally, nurses are aging. The average age of a nurse is between 44 and 47, depending on the state where they work. This increase in average age will continue if fewer nurses enter the field due to poor working conditions, the abundance of attractive alternative careers, and general wage suppression relative to the cost of living and inflation. Also, the continued shortage of qualified nurses in an aging population requiring increasing medical care will only continue to exacerbate these issues surrounding nurses' working conditions. Yet, there is almost no data on how the aging nurse workforce responds to injuries, how injuries affect their health, and whether they continue to work or exit the workforce.

Finally, the demands in today's work environment are significant and more stressful than ever for the more than 2.9 million nurses in the U.S. However, the relationship between stress, work, and health in nursing is seldom examined. Most studies segregate physical exposures sustained by work from the psychological exposures at work. Studies to date have focused on nurses' health without examining exposures, on work exposures or work-related outcomes without full appreciation of stress or the organization factors.

When researchers try to examine the relationship between nurses' stress, their work, and their health, these studies are limited by small sample sizes, varying definitions of stress, or limitations in cross-sectional designs. Furthermore, measuring physical and psychological demands of the job does not take into consideration the interaction of total workload experienced by the nurse or any outside demands experienced in the home.

In closing, aims of future research on nurses should include the exploration of the work of nurses, their stress and health outcomes, how reorganization impacts the health of nurses, how aging is impacting the nursing workforce, and the relationship between healthy nurses and the productivity of the healthcare system.

I would like to thank NIOSH for providing these forums to discuss this important issue. Thank you.

Verbal Comment 2006/03/20: Just a slight correction, I am Richard Rabin, but I'm here as a board member of Massachusetts Coalition for Occupational Safety and Health. What I want to talk about is research that's needed regarding immigrants and other low-wage minority workers.

Immigrants are in -- you name the high-hazard industry, and they're probably in it. Construction, services such as hotels, restaurants, beauty salons, healthcare; the list goes on and on. In the lead registries around the nation, Hispanics are found to be in disproportionate numbers in Massachusetts, in Texas, New Jersey, California, of course. And in the Boston area, in the last several years, Brazilians, Brazilian house painters have increased in tremendous numbers of getting very high blood-lead levels. And nationwide, Hispanics who are foreign born have roughly a third higher fatality rate than does the rest of the workforce. So we have the problem. Now, what kinds of research questions do we have? Well, one is in specific industries, why is it that immigrants have these higher rates? Do they have more hazardous jobs within the industry than other people do? Do they lack training? Do they lack

environmental controls? Are there language barriers? Fear of retaliation? Do they simply not know where to turn?

So what kinds of programs? We want to see research that tells us what kinds of programs and policies can help solve the problem. A more effective OSHA? Do we need bilingual inspectors, training, emphasis programs, local emphasis programs by OSHA where there are large numbers of immigrants in high-hazard industries? And English classes. Can there be programs directed specifically -- much more resources directed at training programs for English so that workers have literacy in hazards and understand what the health hazards and controls need to be? And these could be offered both by employers, because a number of employers have their own training programs in English, and community groups.

And lastly, to what extent are immigrants denied benefits, such as workers' compensation? Why are they excluded? Is it simply that they lack the knowledge? Is it that they have a fear of retaliation? Or simply the inability -- even when they know what their rights are -- the inability to navigate the bureaucracy of workers' compensation?

And again, barriers, programs. What kinds of programs can address these barriers? Thanks.

Categorized comment or partial comment:

Verbal Comment 2006/03/20: `I'm just going to give a little context to put my remarks in, and also I'll do that before I have five recommendations. My name is Davida Andelman. I'm the director of community health at the Bowdoin Street Health Center in Dorchester, which is a section of Boston. I've been at the Bowdoin Street Health Center for almost 15 years and have been interested in occupational health and safety issues for over 25. I'm also a member and co-chair of the Occupational Health Surveillance Advisory Committee at the Mass DPH.

The Bowdoin Street Health Center is a community health center licensed by Beth Israel Deaconess Medical Center. The health center has played an important role in the delivery of medical care and public health programs in Dorchester since 1972. In addition to primary care, public health, and other services, the health center for almost 15 years has had an interest in ensuring that our patients, who are primarily members of immigrant and communities of color, have access to occupational medicine services.

The health center has 7,500 patients. There are approximately 40,000 patient visits per year. Our patient population is composed of 40 percent Cape Verde, 35 percent African-American and Caribbean Islander, 15 percent Latino, and five percent Vietnamese, and five percent Caucasian.

For fourteen years, the Bowdoin Street Health Center had on staff a primary care physician, who had a sub-specialty interest in occupational medicine. While this physician is no longer at Bowdoin Street Health Center, our current medical director maintains a commitment to ensuring our patients receive appropriate occupational medicine services.

However, as a community health center, this commitment can be a challenge. In Boston alone there are 27 community health centers. Most have very little understanding of occupational health and medical issues. This is important to note since community health centers serve mostly lower-income and communities of color.

A few years ago, the Bowdoin Street Health Center was a part of a project carried out by Mass DPH Occupational Health Surveillance Program. This project was funded by NIOSH to prove the hypothesis that work-related injuries and illnesses are common and disproportionately affect racial and ethnic minorities and lower-income workers.

Understanding the occupational health experiences of low-income and minority immigrant workers will inform prevention, intervention, and policy strategies to protect the health of working people. One hundred and eighty-two Bowdoin Street Health Center patients participated in the anonymous survey. Bowdoin Street Health Center was one of five community health centers involved in this project.

While there's not enough time to go into the results of the survey, here are some of the results, along with the experience of having been in charge. And here with my five recommendations is some of the experiences and some of the recommendations I have as a result of my involvement in occupational health.

One, immigrant workers do not obtain access to occupational medicine services as easily as other workers. Perhaps this might explain the severity of their injuries and illness by the time they have presented to an occupational medicine provider. This was a frequent occurrence at Bowdoin Street Health Center.

Two, there are disparities between immigrant workers and others when looking at awareness of OSHA and workers' compensation. There needs to be further analysis throughout the United States as to how information about both of these programs is presented to immigrant workers. Issues associated with language and literacy are barriers to people getting access to this information and how to use the programs.

Three, safety training at work is less likely to happen in workplaces where there are immigrant workers, and what safety training there is is conducted often in English or in a language not understood by the immigrant worker. An example of this is training given in Spanish where there are Cape Verde and Creole-speaking workers.

Four, family medical leave. The intent of this law is not to undermine the workers' compensation system. However, in far too many instances this is exactly what has happened.

When workers are not informed or do not have an understanding about this benefit they are taken advantage of and employers are successful in minimizing their workplace injury and illness experience. There needs to be a nationwide analysis on how FMLA is used when the situation involves work-related injuries and illnesses.

What happens when an injured worker -- What happens to an injured worker who has maximized his or her FMLA benefits and then has a family member who becomes seriously ill and the worker needs to spend time with that family member?

Five, health insurance. Finally, there are also far too many instances of employers not informing the state workers' compensation departments of workplace injuries and illnesses, and then telling the injured worker to use their own health insurance or to have the bill sent directly to the employer.

This also has the effect of undermining the system. Immigrant workers who are not informed and do not understand the system are most vulnerable. This practice has huge implications should the worker become injured or re-injured again. I hope NORA will take these recommendations under consideration. Thank you very much.

Verbal Comment 2006/03/20: Hi. Good afternoon. My name is Elisa Garibaldi. I work as outreach worker at Lowell Community Health Center in the COBWEB Project. The COBWEB Project means Collaboration for Better Work Environment for Brazilians, and I'm a health educator. I am also physician by training in Brazil. I'm going to talk a little bit about Lowell, Lowell Community Health Center, and culture competency.

Today, Lowell has one of the largest Brazilian immigrant communities in Massachusetts. The 2000 United States Census Bureau data counted that the population of Lowell as 105,000 people making it the fourth largest city in Massachusetts. Residents in the city come from many parts of the world, including Southeast Asia, the Caribbean, South and Central America, and many countries in Africa.

While census data from 2000 does not reflect or clearly categorize the growing Brazilian population in the city, we do have some information that gives a sense of the numbers of Brazilians here in Lowell. Of the 11,000 students in the Lowell Public School -- I'm talking about pre-k to eighth grades population -- five percent identified themselves as Brazilians. There is only one high school here in Lowell with a population of 3,700 students; seven percent of these students identify themselves as Portuguese speakers with the vast majority of Brazilians.

Indication of the economic impact of the Brazilians in the community includes Brazilian stores through Lowell and other business, like hair dressers, computer stores, and restaurants. Brazilians, as well as other immigrants, clearly contribute to the new workforce and the economy in the Merrimack Valley and the rest of Massachusetts.

Based on the history of immigration in Lowell, we know that before this new wave of immigration Lowell welcomed other newcomers, including the Irish, Polish, Greek, and Canadians. The community has responded to the needs of new populations in many ways, as well as being enriched by the contributions of these new neighbors.

The Lowell Community Health Center is an agency that's recognized the needs and assets within the community. Created 35 years ago, our mission is to provide caring, quality, and culturally-appropriate health services to the people of Greater Lowell, regardless of their financial status. We are devoted to enhancing the health of our community and to empowering each individual to maximize their overall wellbeing.

As with any community health center, we work to identify and then eliminate access barriers. As an example, language and culture can be a barrier for some seeking healthcare. Lowell Community Health Center works to remove this type of obstacle by recruiting a staff reflective of the community we serve. Over 50 percent of our staff at Lowell Community Health Center is bilingual/bicultural with many speaking three or four languages.

Lowell Community Health Center works with community agencies, including the Brazilian Immigrant Center, Massachusetts Alliance of Portuguese Speakers, the Cambodian Mutual Assistance Association, and the African Assistance Center to help us to build a better relationship with our patients, increasing and improving our skills to meet their needs and strengthen our relationship, thus creating credibility and trust.

In 2002 and 2003, Lowell Community Health Center noticed an increase of the number of Brazilian patients. These new patients came not just looking for primary medical care and place to refill medicines, they also came to ask questions about their lives and guidance in dealing with the different way of life and culture in United States. Their concerns included navigating the healthcare system for their children, as well as questions about symptoms and illness that may relate to their new work environment.

Prior to that, UMASS Lowell had been working with the Lowell Community Health Center in projects with new immigrants to the city. Eduardo Siqueira approached us with the idea of a partnership between academics, community health providers, health and safety based organizations, and community. This led to the birth of the Collaboration for Better Work Environment for Brazilians, the COBWEB Project, with focus on the Brazilian immigrant workers funded by the National Institute of Environmental Health Sciences.

Lowell Community Health Center's previous experience and expertise in ethical and respectful community-based research was clearly an asset to this potential partnership. Our approach to the community research is collaborative. When seeking information, our methods include the development of advisory boards comprised of stakeholders to inform any program development.

COBWEB staff at Lowell Community Health Center is often to see Brazilians concerned about or affected by hazards in the work environment. As important first step in the outreach work necessary to inform people of the resources within the Lowell Community Health Center and COBWEB Project. When more investigation of hazardous workplace is necessary, this mediation may be helpful or if it's needed for legal assistance, we refer to the Brazilian Immigrant Center.

In summary, our staff became a bridge between Brazilians and providers at Lowell Community Health Center helping us to offer our services in a better way. The COBWEB provides a light in the tunnel for those immigrants who may be overwhelmed and sometimes blinded by the difficulties and complexities in their new lives in the United States. Without the support of agencies such as NIOSH and NIEHS, the fundamental work that combines community research with services that assist communities, our work would not be possible. Thank you.

Verbal Comment 2006/03/20: Good afternoon. My name is Tom Oiumet, and I'm a certified industrial hygienist and certified safety professional employed by Yale University, and as an independent consultant. And although I work for an ivory tower, I really come from the trenches underneath that tower. I'm a practicing safety and health professional.

And I'd like to bring to NIOSH's attention today two areas of research, which if supported could bear, I think, significant fruit for the industrial hygiene profession and worker safety.

The first involves the application of Video Exposure Monitoring or VEM. This is a technique that was pioneered by NIOSH and others in the mid to late 1980's. The technique involves a simultaneous display of a worker's activity with real-time exposure monitoring data. It's an extremely useful technique for pinpointing the workers' activities that lead to exposures and the sources of those exposures. And as an industrial hygienist, I always feel that I understand exposure, but whenever I've used that technique, I've proved myself wrong. Armed with this information, very effective exposure controls can be devised.

The second very important use of this technique is as a training tool. The video and exposure overlay can be used in real-time in the workplace to demonstrate to workers and management the impact certain activities and controls have on worker exposure. I have found this to be an excellent way to change worker behavior and attain the resources from management necessary to implement effective exposure controls.

Despite its potential usefulness to the occupational health and safety profession, adoption of Video Exposure Monitoring has been very slow due to its high costs and the high technical hurdles that must

be overcome to get non-standardized equipment to function together. The costs and technical hurdles have made Video Exposure Monitoring inaccessible to most industrial hygiene practitioners and has failed to live up to its potential as an exposure assessment tool.

However, recent advantages in two technologies that support video exposure assessment monitoring, real-time sensor technology and digital videography are now making this technique less expensive, the equipment less bulky and wireless, and the data collected more compound or agent specific; all of which will further increase its potential value as an industrial hygiene tool.

I'd now like to identify two critical needs that would encourage its use and dissemination of this technique in the industrial hygiene profession. The first, software needs to be developed that can integrate the video signal with several channels of data in real-time on a laptop so that it can be shown and replayed to workers and management in the workplace, as well as studied later in detail. This software must be available to the industrial hygiene community at reasonable cost.

Two, suppliers of real-time sensors and instruments must be encouraged to produce equipment with consistent data output so that their equipment can be easily integrated with the Video Exposure Monitoring system. A committee of interested parties should be established to recommend a standard for sensor or instrument output and integration. The community must also discourage a current trend by some real-time instrument manufacturers to produce sensors that only output proprietary digital signals that can not be integrated into Video Exposure Monitoring systems.

The VEM could be packaged so that the software and existing video and sensor technology were plug-and-play. It would provide the industrial hygiene profession a powerful new tool to assess and control worker exposures to a wide variety of agents, particularly those for which agent-specific sensors are being developed. It would also be an effective worker/management training tool.

Categorized comment or partial comment:

In my few remaining moments, I'd also like to make a pitch for NIOSH to begin exploring how new training and communication technologies can be integrated with the existing approaches and used more effectively to train and communicate hazards to workers. I, like many of the speakers this morning, am finding the traditional training methods are not adequate. That training is often not sufficiently assimilated by workers to be useful when it is needed, often months after the training is provided. However, traditional classroom or hands-on training, coupled with web-based tools and resources often referred to after forming support systems, an additional just-in-time e-learning can provide a worker the knowledge needed to perform a complex task or an infrequently performed hazardous task safely.

However, no research has been conducted how to effectively integrate traditional training, just-in-time training, and performance support systems. As jobs and the hazards faced by workers get more complex and change quickly, new methods of training, coupled with performance support systems must be utilized in the workplace, and we do not know how to apply them today.

Also, the use and effectiveness of multimedia, audio, video, animation, graphics, and even virtual worlds, and training and communication should also be researched and new uses explored. These tools appear to make information more readily understood and assimilated by workers, but today we don't know how to apply them.

Thank you very much.

Verbal Comment 2006/03/20: Thank you. Good afternoon. I'm going to talk to you about occupational health surveillance. I am currently the chief of health statistics and data management for New Hampshire DHHS, Division of Public Health Services. I'm also adjunct professor in the Master of Public Health Program at the University of New Hampshire. Prior to taking the position with the state, I worked as a research consultant in the occupational and environmental health sciences, collaborating with such entities as UMASS Lowell, Rutgers University, New Hampshire COSH, and others on EPA and NIOSH funded research projects.

In my capacity as the head of health statistics for the state, and mind you I've only been there for six-and-a-half months so far, I have learned about the importance of administrative public health data in forming occupational health surveillance. Health surveillance data are needed to determine the magnitude of work-related injuries and illnesses, identify workers at greatest risk, and establish prevention priorities. States must be able to measure baseline health of their populations and changes that take place over time.

Occupational health surveillance systems would allow for this assessment and monitoring of overall health, and would lead to comprehensive policy development, service planning, and program evaluation. Successful interventions to reduce the burden of occupational injury and disease in any state have to start with good occupational health surveillance.

The current nationwide system for surveillance of occupational illnesses and non-fatal occupational injuries has substantial gaps. Many of the public health reporting systems are fragmented, having no

consistent or standard system for collecting, analyzing, or interpreting data. Many do not have data compatible systems or systematic methods for coding or linking data sets, and many do not even capture occupational information.

Increased funding for the national occupational health surveillance research agenda will help NIOSH reach its goals to identify these gaps and deficiencies and reduce fragmentation among current surveillance programs. It will also provide states and the nation as a whole with the ability to streamline resources, to identify and target high-risk industries, occupations, and worker populations for outreach and intervention, and to measure progress in preventing work-related diseases and injuries.

According to the first reports of injury to New Hampshire's Department of Labor, in fiscal year 2005, businesses reported over 47,000 work-related injuries and disease, involving 3,700 lost-time cases, and 1,200 permanent-impairment cases, which along total over \$12 million.

New Hampshire's workers' compensation data is unique in that the law requires employers to report all work-related injuries and illnesses, regardless of whether or not lost time was involved. Employers understand that reporting in this system has no bearing on acceptance or denial of a workers' compensation claim. As a result, there appears to be fairly complete capture within the occupational injury reporting system, and even some over-reporting as employers err on the side of reporting questionable cases. This is quite different from most other states, where reporting is required only for lost-time cases, or where the employer believes that the condition is definitely work-related.

Prior studies using New Hampshire DOL workers' compensation data demonstrated that older workers had significantly more pre-injury co-morbidities and had more severe injuries, requiring more medical care and surgery and chronic medications. Priority groups of older workers include those who are forced into early retirement by their work-related injury and older workers with significant pre-existing health problems. These subgroups are at particularly high risk for adverse post-injury consequences, and should be the focus of further studies using the New Hampshire Department of Labor database.

In addition to workers' compensation data, New Hampshire has several administrative data sets that can be used for occupational health surveillance. These include hospital inpatient and discharge data, death data, insurance claims data, cancer data, and behavioral risk factor survey data. Under CDC bioterrorism funding, we are piloting a project to collect live emergency department data from our hospitals on certain syndromes that could be linked to acts of terrorism.

All of these data sets of information that can tell us so much about work-related injuries and illnesses; however, there is no systematic method of collecting this data for occupational surveillance purposes. We need better coding, additional fields to discern occupation, employer name, injury at work, and we need better ways to link databases to match exposure data with health outcomes.

New Hampshire has a high incidence of high-occupational blood-lead levels. We don't really know why. Is it better surveillance? Is it low numbers? Is it a record-keeping artifact? Is it immigration of out of state workers with high blood-lead levels that get picked up at work in New Hampshire?

Asthma is also increasing in our state. Studies indicate that at least ten percent of new asthma cases are occupational asthmas. However, SENSOR data tell us these numbers are very low. There's a disconnect that needs to be explained.

In New Hampshire, we're equally constrained under the tightening budget belts of both our federal and state governments. Without NIOSH funding, however, the Division of Public Health Services in New

Hampshire is unable to allocate any resources to hire dedicated personnel to do occupational health data collection and analysis. Our public health community relies on surveillance information to set research and prevention priorities.

Building capacity to design local occupational safety and health interventions and increasing their quality and effectiveness is an intentional product of an improved surveillance system. Research to enhance surveillance will identify occupational safety and health hazards particularly to New Hampshire, assisting in prioritizing the numerous hazards and issues needing to be addressed and provide key targeting demographics in the design and execution of local interventions and programs.

Finally, an improved and integrated occupational health surveillance system will provide information to policy makers who need to understand the magnitude of occupational injury and illness and their costs. The interrelationship of causal factors inside and outside the workplace, and the necessary data to build outcome measures for progress towards state and national goals. Thank you very much.

Verbal Comment 2006/03/20: Good afternoon. I'm going to be talking about negative impacts on worker health of environmental workplace practices. An emerging issue today is the growing risk that environmental decision and practices in the workplace can result in negative impacts on worker health and safety. In a number of cases, in a major manufacturing plant in Massachusetts, in an auto-assembly plant in the automotive repair industry, attempts to reduce or eliminate ozone-depleting chemicals have resulted new hazards for workers.

In one plant, CFCs were replaced by flammable chemicals resulting in fire hazards that did not previously exist. In another case, the CFC was replaced by a substance that caused severe dermatitis and did not work well in the process. In both of these cases workers, through their established health and safety committee structure, raised the concern and pushed to have it resolved. In the second case I mentioned, a solution was found using steam as a cleaning agent. This eliminated a toxic chemical and improved both the work and the ambient environments. Workers, industrial hygienists, environmental managers, and process engineers worked together to develop this new solution.

In the State of California, automotive repair shops were urged by a state agency to replace methylene chloride, an ozone depletory, with hexane for brake and engine cleaning resulting in debilitating

peripheral neuropathy for many workers. In chemical plants in New Jersey, similar instances were reported by workers and managers of unforeseen occupational health impacts resulting from environmentally motivated chemical substitutions.

In many cases, elimination of a chemical that is an environmental hazard may improve working conditions; the elimination of hexavalent chromium from a process, for example. But there is also a distinct risk of creating new or worse occupational hazards, including ergonomic hazards when health and safety issues are ignored and occupational health professionals and the workers closest to the operation are not included in the decision making.

Military and other government specifications may also be developed for environmental purposes without regard for the work environment. Such specifications affect large numbers of workplaces and workers. The Air Force, for example, provides a list of acceptable substitutes for high VOC products, even though some of these substitutes are toxic or flammable, creating new workplace hazards.

Green construction is a growing trend with the laudable goal of creating safer more environmentally friendly and more comfortable buildings. However, many of the new materials are untested or are not examined from a worker health perspective. New types of flooring materials that are promoted as natural may contain significant concentrations of formaldehyde, for example, creating risks for the construction workers. What happens when bamboo or new composite materials are cut, drilled, or sanded? What is the occupational impact?

In research I conducted independently and with others, workers were often the first to recognize or to suffer the effects of these new hazards. In one plant, an active joint-labor management health and safety committee has been expanded to include environmental issues, as well as a means of preventing unintended effects of environmental decisions.

It is unknown how widespread this problem of risk-shifting from the environment to the worker is because little research has been done. This is a new important area that needs to be explored in a number of ways. NORA needs to recognize the cross impacts of chemical substitution on the work and ambient environments. Research is needed to document the prevalence of this problem, as well as uncovering best practices in the area.

Intervention or other research is needed to explore decision-making structures that may prevent cross-over hazards, as well as developing systems which may enhance the wellbeing of workers and the ambient environments simultaneously.

A methodology for determining appropriate chemical substitutions and/or process change that take into account both occupational and environmental health concerns is needed. Thank you very much.

Note: Verbal testimony provided to NORA Town Hall meeting in Lowell, MA, 2006/03/20.

Verbal Comment 2006/03/20: Good afternoon. I would like to thank NORA for letting me address the issue of health and safety and literacy. The morning sessions and some of the earlier ones prior to myself have spoken about the issue of health and safety training. I've been a trainer for two years and a health educator for three years. So I have seen first-experience what happens when you do training.

It's not enough to provide training in the language that the workers speak. I've come with my presentation, my big old folder, PowerPoint slides, translated, ready to do in Spanish or in English to find out 30 minutes later that the workers can't read, which means I have to switch my whole training session appropriately for the workers.

We've seen everybody asking for training, but we also have to make sure that the training that is provided to the workers takes into account the literacy level. I'll just give you statistics. According to -- This is the old statistics, but the 1992 National Adult Literacy Survey showed that 40 to 44 million people of the 191 million adults in the United States could not read, could not understand written material that require very basic proficiency in reading. They could not read the instructions on a medication bottle, household cleaning solution, or directions on a map.

As some of you are trainers, you've seen what material safety data sheets look like. Those sheets require at least 15 to 17 years of education, which is a college degree. The hazard communications standard was a great move to allow workers to understand what they were being exposed to at work. The problem is is that hazard training can be anything from a material safety data sheet, a fact sheet of best practices guide, ten-hour OSHA training or one hour, and as somebody has explained, it can be part of your employer orientation training.

So people have to understand that it takes more than just training in the language in a short time. You need to make sure that the workers understand what you're trying to provide in the training for them.

So as I said, my experience -- I believe that more research is needed in the areas of how health and safety literacy affects illness and injuries, the effects of literacy in the workplace in regards to health and safety training, and effective training strategies for workers. What are the best practices? What training? How should training be conducted, so workers can understand and stay safe? Thank you.

Verbal Comment 2006/03/20: Good afternoon, and thank you for the opportunity to speak this afternoon.

I am a practicing safety manager. I've worked in a large number of industries; heavy industry, construction, and transportation. And I'm here informally today to represent contractors and highway construction workers to advocate for further research into highway work-zone safety, specifically because this is an area that has been well researched over the years.

The specific area of emphasis is short-term highway work-zone activity; resurfacing, temporary repair, guardrail repair, activities where workers are exposed in very short-term durations to the work zone that they're operating in.

This is a unique problem. In addition to contractor activities and work-zone activities, and worker activities, it also very much depends on public transportation policy that sets the contractual guidelines that contractors and these workers will work under. And it also is very much related to the behavior of the public as they pass through these work zones, which is essential to a significant number of safety issues that occur in these work zones.

Short-term presence work-zone activity is very important to focus on. Unlike a lot of heavy highway construction activity where there are engineered barriers and a lot of work goes into isolate passing traffic from the presence of those workers, in short-term work-zone activities, typically, the workforce is isolated from passing traffic only by temporary cones that are very easy for vehicles to come through.

Increasingly, this work is scheduled at night to provide a minimum inconvenience to the public that are passing traffic. This creates a significant number of problems in terms of the pressure of working at night, the increased hazards of working in darkness, and the increased speed that is typically encountered by traffic passing at night. And again, there's a very strong interrelationship between the public behavior as they pass through these work zones.

On paper and within the literature, this is a well-researched problem. NIOSH has done some great work in terms of the 2001 Building Safer Work Zone Studies, and there were extensive standards that are available, including the Federal Highway Administration's Manual of Uniform Traffic Control Devices.

However, there's a significant gap between that documented knowledge and the implementation of that knowledge when you're trying to occupy a roadway. And the research work that exists needs to work on the implementation of that theory, of that documented knowledge.

Specifically, needs include practical methods of risk assessment before deployment on a roadway. Typically, there's a contracting document that will indicate from a construction perspective what type of work is supposed to happen and when and maybe set out a work schedule. But there remains to this day -- it's very difficult for an industrial safety manager, construction safety manager to assess the hazards that are presented by a particular roadway. The hazards that I speak of are accident frequency, the average speed of traffic, local hazards that may be unique to that particular roadway in terms of its configuration and its type of use.

There needs to be increased research into practical and effective methods that calm and control traffic, which is a huge problem. So many of these issues related to injuries to workers, collisions that occur from vehicles passing through work zones, and collisions that occur from vehicles and construction equipment as they mingle trying to get in and out of work zones is related to the speed of traffic. And there needs to be much better research and practical methods to calm and control traffic.

I know for the construction activity, which we're about to engage on in the upcoming season in the state of Massachusetts, by our own radar assessments, we're about to enter roadways where we know that the 85th speed percentile of traffic is frequently ten or 15 miles an hour above the posted speed limit. And we're just a few short weeks from having to put workers into this environment to try and restrict the roadway that's available.

We know in one unique example -- it's anecdotal, it's not scientific. In one unique example last year, in response to collisions of vehicles entering our work zone, we had speed observations by state police officers. In a single day of cars moving, there were more than 100 observations in a single shift of cars moving more than 80 miles an hour in speed within the controlled work-zone area.

The problem only gets worse the further you pave the road. Once the damaged roadway that people are used to driving very slowly on -- as you pave the road and your work zone is now at the end of ten miles of pristine, immaculate, high-speed capable roadway, the situation gets worse as the progress goes on.

There needs to be much greater research in the management of safety, the practical application of it in terms of risk communication and safety management techniques that work, in terms of how you communicate risks and how you control risks presented by the public, specific contracting policies, which very definitely affect the safety of workers on the road, the management of safety work that contractors employ and the safe work training and preservation training to workers and police agencies that control the traffic. Thank you.

Verbal Comment 2006/03/20: Good afternoon. My name is Dina Dickinson. I am originally from northern Italy. I don't know how to do this, sorry. When I was in my early 20's, I fell in love with an American boy and follow him here to Boston. For the last 18 years, I am being a single parent. I raise five kids on my own by working as a room attendant at the Logan Airport Hilton Hotel.

By working very hard, I was able to keep my family together and give my children a chance to better themselves. I am very proud of my family; all five of my kids went to college. One of my sons is in the Army Reserve and he was recently called for active duty.

I have been a room attendant for 18 years, and I am proud of my profession. Our hotel is successful because we don't just clean rooms; we take care of our guests. Hotel management, no respect housekeeping work.

My job has always been very physical, active job, but the workload has gotten heavier and heavier. Twin beds have been replaced by queen and king luxury mattress, simple bedding by triple-sheeting, more pillows, duvet, and heavy bedspread. Bathroom and sleeping quarter have more supplies, amenities, and equipment.

Also the company expects a higher cleaning standard than they did years ago. This means that me and my sisters in housekeeping have been working with injuries and more and more pain in our bodies from the work.

Last year, my hotel introduced a new bed, which greatly increased our workload and strained our body to the limit. I saw a lot of my coworkers getting hurt because of the bed. The new bed has bigger, heavier linens, and much, much heavier mattress and mattress pad. We put three sheets on now, instead of two, and we now stuff up to eight pillows per room.

Because we have only about 20 minutes to clean the room, make the bed, and scrub the bathroom, we have to work faster than ever. Most of my coworkers are working with pain, and almost all of us take some sort of pain medication every day. This is not just the situation at my hotel. I have talked to attendants who work at the Sheraton and Westin, and all the major hotel chains. What I'm describing is what room attendants face everywhere, no matter what hotel company.

I'm fortunate that I have a union at my hotel. We have ability to fight against and limit the hotel push to increase work at the expense of our health and safety. After the 16-month long fight, we were able to get Hilton Corporation to reduce the number of rooms that we are required to clean in a shift at our hotel. The concession that we won from the Hilton is a step in the right direction, but is not enough. We are just one hotel.

Ninety percent of hotel workers in this country don't have union. For most room attendants that means a hard choice. Do the work and ruin your body, health, and often your family life, or lose your job; that is a problem. It's a big problem. Thank you very much.

Verbal Comment 2006/03/20: My name is Tish Davis, and I'm Elise's boss. For over 20 years, with help from NIOSH in much support, I have directed the Occupational Health Surveillance Program at the Massachusetts Department of Public Health. And, you've heard about our program from Elise, and as you might predict I'm here today to underscore the importance of surveillance. And frankly, surveillance is historically or typically placed second fiddle to ideologic [sic, etiologic] research in any kind of research or academic environment, and I've been really happy today to hear so many people, beyond my staff, underscore the importance of public health surveillance and really telling the story.

We clearly need robust surveillance systems to establish the magnitude of the problem; information that we need to garner the research and intervention resources. We need surveillance to develop a research agenda that is relevant and addresses the most relevant, the most pressing problems.

We also need surveillance to identify emerging concerns, and I just want to highlight several from Massachusetts. In the last several years, what we've seen is safety hazards in floor finishing, fatalities associated with the manufacture and installation of granite counter tops, asthma, associated not only the use, but the overuse of cleaning agents that you just heard about, young worker exposure to violence in retail settings and the failure of the workplace movement to address shoplifting. We have a spike in fishing-related deaths in Massachusetts. Massachusetts is second only to Alaska in the number of fishing-related deaths. And we've seen in recent years an increase in Brazilian worker fatalities.

Each NORA sector, I think, should be mandated to address surveillance. At the same time, I think it's crucial to establish a coordinated and comprehensive cross-sector surveillance plan with appropriate cross-sector funding mechanisms. This plan should include population-based activities, such as periodic suplets (*) to the National Health Interview Survey, but it also needs our place-based [sic, state-based] approach, such as SENSOR and FACE, that link to individual workplaces and provide the detailed information necessary to develop effective interventions. And we've seen a decrease in those programs in the last several years.

While I'm very pleased to see that the practice of surveillance is included in the NIOSH program portfolio, I want to emphasize the continuing and I see as distinct need for surveillance research. That is, research to document the biases in the existing surveillance systems and to explore new surveillance methods.

Occupational health policy and practice in this country relies heavily on the BLS annual survey of occupational illnesses and injuries. This system not only omits 20 percent of the workforce, including all public sector workers, but research has consistently demonstrated that the system substantially undercounts cases that should be captured by as much as 30 to 40 percent. These research findings are strikingly discordant with OSHA record-keeping audits, which suggests that there is relatively little under reporting.

How do we explain this discrepancy? How do we explain last year's, one year's, 15 percent decline nationwide in lost-time repetitive-motion cases? There was a 30 percent decline in Michigan in repetitive-motion cases in one year. How do we explain that in this system on which we're basing so much policy?

I want to call on NIOSH to join with BLS, OSHA, and other research partners to collaborate in developing and implementing a dedicated research plan to document systematic biases in the BLS survey, and the factors, many of which you've heard about today, that lead to under reporting. We need to know which categories of workers establishing events that are being systematically undercounted. We need to understand how OSHA enforcement targeting, how behavioral safety programs, how management evaluation practices influence reporting, and then we need to test interventions to improve the system.

We also need to continue to explore innovative approaches to address chronic disease and under-served worker populations, issues that we know will never be adequately addressed in the BLS survey. And I think we need to look at community-based models, some of which are being used in developing countries, that we need to bring back here for application at the community level.

I'd like to underscore the importance of NIOSH's state-based programs, and you've heard about that here today. States have access to unique data sources that can fill gaps in national surveillance. Surveillance by definition includes the use of data for action, and states have a very solid track record of linking surveillance to practice at the state and local levels. State health agencies, which historically focus on addressing the needs of under-served groups, can play a particularly important role in identifying and addressing the occupational health needs of under-served worker populations whose occupational health needs have clearly not been addressed.

This brings me to my final point, which is needed to document and address the occupational health disparities among population groups. The sector research panels should be mandated to address these disparities. I want to weigh in with others you heard here today to particularly emphasize the need for research to address the needs of young workers and low-income immigrant and minority workers.

In Massachusetts in 2005, 37 percent of juniors and seniors in high school were employed, according to the current population survey. And 17 percent of our workforce is foreign-born; double the number or the proportion in 1980. We need research to identify the factors that place these workers at increased risk, and we need intervention research, including community-based participatory research, such as we've seen in the environmental justice partnerships to develop interventions that work.

In closing, let me say that for the last 20 years I've been involved in tracking every work-related death in Massachusetts and it's grueling. And I have never ceased to be moved by the fact that these workers died doing work that enable me and all of this in this room to lead the lives that we do every day. And I look to Max and the communication folks at NIOSH because I think we also need to learn how to better tell this story.

Thank you.

Verbal Comment 2006/03/20: Good afternoon, and happy spring to all of you. Spring rolled in about an hour ago, I think, officially; so it should be about 40 degrees warmer out there now than it was this morning. I'm sure you'll be happy to know that.

I can use some extra time to talk like this because Tish and all these other speakers have already said all the things that I was planning on saying, so... I'm Tim Morse. I'm with the Ergonomics Center at University of Connecticut Health Center, and also participate in the Connecticut Occupational Disease Surveillance Program, along with Labor Department, Health Department, and Workers' Comp Commission. We've also at UCON do a lot of research looking at under reporting, particularly of musculoskeletal disorders, and I'd like to focus on those issues in particular.

Complete accounting of occupational injury and illness is important for several reasons, Tish and some others have pointed out some of those. But, it also goes along with if there's a lot of undercounting of occupational diseases, then it tends to also affect resource allocations. So that if you don't count all of what's going on out there, you don't get as much resources going to solving the problem. It also -- We need surveillance and accurate counting in order to target those resources accurately to make sure that we're addressing the right problems, the right industries, and the right occupations that are at the bulk of the problem.

And finally, accurate counting is important for assessing interventions so that, you know, as we move towards more emphasis on intervention research, then we need better counting so that, for example, in ergonomics and musculoskeletal, we find that when we do ergonomics intervention programs in industry, a lot of times the increased awareness leads to increases in reports because they've been so

undercounted previously. You intervene and then rates go up and so you need better counting and better ways of figuring out how much is not getting reported in order to understand how effective those interventions are.

It's now reasonably well-established that there's extensive undercounting, particularly for occupational disease in the BLS and OSHA surveys. You know, from research that we've done that's both population-based, random digit-dial phone interviews, from capture/recapture analysis of comparing physicians' reports to workers' comp reports, in Connecticut our estimates are only about ten to 20 percent of musculoskeletal disorders actually get reported to workers' comp or to BLS. We used to think that that was -- the situation was much better for acute traumatic injury, but some recent capture/recapture studies that are just starting now to get reported find that even for overall occupational injury and illness we're probably only getting somewhere between 50 to 80 percent of the cases are getting reported to BLS, even for lost-time pretty severe injuries, which you'd expect to be reported pretty well.

The Lanora Azerof (*), who's here somewhere has mapped out some of these filters that we see in terms of where things don't get reported and where they don't get recognized. Part of that is physician non-recognition of occupational disease, part of it is workers not reporting to their employers, and part of it is employers not putting it on their records and getting it into the statistics.

Our studies have shown that there are characteristics that increase the reporting. For example, more severe conditions are more likely to get reported, more likely to get reported in unionized environments, in manufacturing, and among workers that have access to personal physicians.

We need to better understand these mechanisms associated with under-reporting, partly so that we can improve our reporting systems overall, and we also need to know what the extent of the magnitude of that under-reporting is so that we can adjust those known figures to try to compensate for that. And we also need to test interventions that would try to improve reporting characteristics, you know, looking at kind of the negative consequences of safety bingo kinds of programs, looking at what are some positive reinforcers that we can use to get better reporting of those conditions, and therefore help in prevention.

For the most part current data's based almost exclusively on employer-based systems, and so those numbers can be impacted by workers not informing their employers, it can be impacted by employers not understanding reporting requirements and categorization, and also by negative incentives such as the employers' perceived -- perception by employers of what the impact is going to be on the OSHA inspections or workers' comp rates. For MSD in particular, current data's also made less available due to the dropping of repetitive-trauma category from the BLS system, which has caused a break in series and also made it more difficult to understand what are the longer term patterns for MSD.

Population-based studies, such as phone or mail surveys, web-based surveys, employer-based surveys are highly useful for broadening the scope of the information. We have -- These can be pretty expensive, but they're really the only way that you can get at some of these under-reporting issues and try to understand what community burden is.

So I would advocate a few things. One is support for population-based surveys, support for NIOSH to do regular participation in things like National Occupational Exposure Survey, National Health Interview Survey so that we can get population-based systems. And then also link programs between -- funding

programs between OSHA and NIOSH for funding intervention programs that are based on surveillance data.

And I think the other stuff has been said by Tish, so thanks very much.

state programs, like the Maine Occupational Research Agenda (MORA)

Categorized comment or partial comment:

Verbal Comment 2006/03/20: Thank you, Ann. And I want to thank NORA and NIOSH for giving us the opportunity this afternoon to talk about issues that are important to us. I'd like to bring you spring greetings from Maine, but we don't get spring in Maine. In about a month we'll get mud season, and then six weeks later we get black flies, so... I don't know if you want to be greeted that way, but that's the way it is.

I am a past chair of MORA, and have a consulting firm in Maine. I'm also on the faculty of the Masters in Public Health at the University of New England, and I've had some work at the NORA level as part of the Intervention Effectiveness Committee of NORA.

What I'd like to talk to you about today is the tie that we can make between state programs like MORA - and Ann and I were trying to decide how many there are in the country, and it probably is no number that you could count on one hand, and why we have a program like this. And I think one of the keys here are the fact that many of the problems we have are local, and in a state like Maine, which is very large geographically and very small in population, it's very difficult for like-minded individuals in the area of occupational health to find each other. And we've used MORA for the past six years to have a very useful dialogue among practitioners that's been very helpful to us.

I'm not going to go into the background of MORA and its startup. My colleague, Peter Doran, will cover that in detail, but we have worked for six years. We've worked for six different areas, which Peter will mention. We've narrowed those areas down most recently to occupational asthma, cost-drivers associated with workers' comp, and better characterizing the incidence of pesticides-effected illnesses.

We work well with regional partnerships, and I think this is an extremely important aspect of our program. The ERC has been very helpful to MORA, not only have they assisted us with conferences, which has been very important, but they've also had a pilot project recently and these pilot programs have funded some programs in Maine. They are small dollars, but they go a long way in a state like Maine, and we're able to do quite a bit with them.

We really feel that there are opportunities that exist at the local state level that NORA can really take advantage of. One of these is the diffusion of research. It's difficult to reach out into the hinterlands and make sure that you are reaching a lot of companies that exist out there. With a state program like MORA, you are able to reach some of the practitioners with the research and get it defused from the ERCs and the universities into small companies that exist.

The other area is the access to small business. A state like Maine has over 90 percent of their businesses are small businesses. And in Maine we define small businesses as less than 100 employees, so it's really small. Getting into those small businesses is not easy; NIOSH has a lot of difficulty with that, and so state programs can really provide a way of doing that.

We also can leverage research dollars. In one of the pilot projects that we received funding through the ERC at Harvard, we were able to do some really initial-level work. That work has now been funded by the agency in particular that the work was done for as a second level, and it's a survey that was done using participatory methods, which will now go forward this year based on the fact that we had some pilot funding to start. So I think leveraging those small research dollars is an important aspect, and I emphasize small. Small-dollar grants in a state like Maine can go a long, long way.

Also, access to field studies. NIOSH has been in Maine studying the schools and asthma induced in schools, which have experienced high levels of mold. This kind of cooperation has been very helpful in solving some problems in Maine.

And last, advocacy. There have been many programs like MORA in other agencies in the federal government. And as we discovery with these programs, as you have more people involved at the state level and issues come up that the national level wants to have something done with we have people that can advocate, both with the senators and the congress people in our region.

So I think state programs can be helpful in a number of different areas, and I'd like to see NORA and NIOSH consider expanding and supporting those programs. Thank you.

Verbal Comment 2006/03/20: Thank you, Ann, and thanks for the opportunity to visit with you. And I can assure you that you can get to Maine from here. I want to follow a little bit from Ivan's remarks, and tell you a little more about MORA; what it is and how it functions.

MORA promotes safety and health research in Maine. We were spawned in the year 2000 at an occupational health and safety research summit, which was called by the Maine Department of Labor, and we were honored with some guests from NORA at that time who acquainted us with what NORA's all about and how it works. As a result of that we developed a steering committee, that steering committee meets monthly and it maps a strategy with action steps. The Maine Bureau of Standards provides meeting space and staff support, for quite frankly, an entirely voluntary organization.

Tell you a little bit about our accomplishments during the last six years. We're data driven, so we assess data sources. We've supported legislation to improve data collection in the Workers' Compensation Medical Only First Reports. We found until we could get medical only reports available to us from all of the insurance companies, we really didn't have good insights into prevention. We recently reported in

February to the legislature our recommendations for data collection and injury prevention and that's making a substantial difference in the electronic reporting process.

We've convened a symposium in 2003 and 2005 with NIOSH support. We received the State Government Team Work Award and we've established six major priority areas. Those priority areas, about which you've heard quite a bit today from other speakers; musculoskeletal disorders, occupational asthma, fatalities, toxic exposures at work, the aging workforce, and cost-drivers. And, with all of those priorities, what we do is to try to identify research partners and then collaborate with topic experts to identify the more specific research needs to locate funding sources and to encourage the conduct of the research specific to those.

Let me highlight just one of those areas for you, which is of particular interest to us and that's occupational asthma. We have an estimated ten to 20 percent of asthmatics who have work-related occupational asthma. We have one of the highest asthma rates in the United States in both adults and with children.

Asthma -- occupational asthma often goes unrecognized as work related. There are significant limitations in the data gathering. By understanding the magnitude of the problem, the prevalence, and the trending we can do a better job of identifying at-risk work environments and potential associations with other indoor air quality problems and then design and implement preventive interventions.

This is a collaborative kind of process. MORA's currently promoting research on occupational asthma through collaboration with the American Lung Association of Maine, which incidentally is focusing with NIOSH research help from the respiratory disease section on school buildings as an occupational source, and also the Maine Asthma Council, and the Maine Environmental Public Health Tracking Project. And we feel that this is going to be an excellent model for us to use as we work with our other priority areas.

I think my final message today, one -- I wanted to share with you that I think that a state-level research agenda can be a very cost effective, a very stimulating and exciting kind of enterprise. At the same time it would certainly be helpful to us if we could establish a federal/state program in occupational health research to provide support for state occupational safety and health agendas like MORA, and to link education and research centers regionally with the NIOSH, NORA, and state agendas. So thanks for the opportunity and don't hesitate to come back and see us during the warm months ahead.

Verbal Comment 2006/03/20: I just want to thank everybody for the opportunity to speak here today. To give you a little bit of background about myself, my name's Joel Garrett, and I work for a company called Kluber. And for those of you who don't know what we do, we make specialty lubricants for 31 different market segments, which includes food, pharmaceutical processing, the aerospace industry, as well as the automotive industry. And I'm responsible for all the day-to-day operations, which includes things like customer service, production, a laboratory, quality, facilities, on and on.

With all these responsibilities, the one that's most important to me is the health and safety of our employees. And to protect the health and safety of our employees, we must continually improve our approach toward EHS, and therefore we're always looking for best practices.

Particularly, we've done some work with behavior-based safety. Prior to starting the program, we did some background work to see if this would be effective. And the challenge here was that most of the information that we were getting with this BBS was that it was coming with a sales pitch. It was really information that was associated with a product or a service, and therefore what I'd like to see is more research on safety systems, particularly behavioral-based safety from NIOSH funded researchers with an objective approach. And this would really give the business community the opportunity to evaluate the pros and cons of different types of systems without the sales pitch. And I wish you all the best of luck, and that's all I have.

Verbal Comment 2006/03/20: Good afternoon, everyone. The topic is workplace violence prevention, and I'm reading this for my nursing colleague Susan Vickory. I have been a registered nurse in an urban Veterans' Administration Medical Center for 24 years. One of the most effective tools now being used to decrease workplace violence is the prosecution of the individuals who assault.

Too often a blame-the-victim mentality and an embarrassed staff ignore the violent behavior that would be unacceptable in the community. Inside the hospital this disruptive, abusive behavior was tolerated because the individual may have a mental illness or under the influence of substances. In other words, quote, they were not responsible, unquote. It has been my experience that if violent behavior does not have consequences that behavior will escalate over time.

When prosecution becomes the usual response, it will have a deterrent effect. It can be beneficial to those who assault to be held accountable. Filing criminal charges sends a strong message to staff and to patients that the laws apply inside the hospital.

Most people know right from wrong. Some patients and clients are able to take out their anger on staff because there are no consequences, because they can with no fear of retribution.

It takes courage to face what others choose to avoid. I would like to see violence prevention programs include prosecution of perpetrators in their programs. I would like to see administrators, police, court officers, and other nursing staffs encourage the filing of criminal charges for those who threaten, abuse, and assault healthcare workers. Violence in healthcare should never be considered part of the job. Thank you for this opportunity.

Verbal Comment 2006/03/20: My name's Paul Morse and I'm the project director for the New England Consortium, which I'll talk about a little bit more in a second. But I have to say that spending the entire day here has been a real privilege, and I want to thank NIOSH for the opportunity to be with so many inspiring people doing so much important work in our region, and I'm glad that you got to come and see it all and hear about it.

What I want to comment principally on today is to recommend that NIOSH conduct additional research into issues of effectiveness of worker health and safety training programs. Not only is it imperative and important to review the effectiveness of training, but critical to closely evaluate outcomes derived from different approaches to training.

The New England Consortium, TNEC, based here at the University of Massachusetts Lowell, is a unique regional partnership for the university and five grass-roots coalitions for occupational safety and health. The Consortium is committed to ongoing and dynamic training that regularly readjusts to reflect the ever-changing realities of workplace change and the risks associated with it.

TNEC is part of the National Institute of Environmental Health Sciences Worker Education Training Program, an extensive national network of nonprofit organizations, universities, and labor unions that are committed to protecting workers and their communities by delivering high quality safety and health training to hazardous waste workers and emergency responders.

Since 1987, the WETP has provided nearly 60,000 classroom and hands-on trainings to over one million workers in order that they are better prepared to safely and effectively respond to this nation's hazardous material incidents and hazardous waste operations. These workers are engaged every day in

handling hazardous materials, transporting them, cleaning up waste sites, restoring brown field properties, and responding to emergencies.

There are three critical issues, I think, that are related to health and safety training for workers in highly hazardous occupations that need to be addressed. While these training programs that are based -- The WTEP kinds of programs and many that you've heard about today are based on principles of popular and adult education methodology. And while they have been extremely successful in ongoing workplace controls -- improving workplace controls and conditions and in reaching a diverse worker population, it's clear that the vast majority of people working in hazardous occupations receive limited, inadequate, or no training at all; point number one.

Point number two is that workers in the response, rescue, recovery, remediation, and medical care communities are now expected to handle consequences emerging from more severe environmental disasters, industrial accidents, potential acts of terrorism, and the growing threat of pandemic disease outbreaks.

And point number three, until we are able to reverse the current climate of reduced regulation and enforcement of environmental and occupational standards, workers who lack strong unions or effective labor management structures must take health and safety protection into their own hands. What I want to say to point three, and the optimistic point, is we are going to reverse the current climate of reduced regulation and enforcement in this country. And I think it's the work of a lot of people here that is going to bring that about.

Our current experience is that reduced numbers of workers are making ever-greater sacrifices for the public good and the public protection. Often they must face these challenges with reduced resources and funding support. As we have seen from the tragedies of 9/11 and the Gulf Coast, these workers have done heroic service and far too many of them died and suffered greater injustices and illnesses than might have been necessary -- might otherwise have been necessary.

Similarly, the training arms and allied organizations for these workers have made heroic efforts to serve during these responses and recovery operations. The NIEHS WETP training programs have proved instrumental under adverse conditions to respond to these events. We know, however, that far more must be done to better prepare workers to prevent accidents, and to minimize the consequences and harm from unpreventable disasters.

Every worker injured or made ill on the job, and every life lost, devastates families and the economic well-being of our society. Too often those with the real power -- with the most power I should say -- we have a lot of power ourselves to alter the adverse conditions for workers gamble that tragedies will not happen, or they choose to calculate the trade-offs of inaction against the cost of prevention and institution of stronger systems of safety.

Under Section 21 of the Occupational and Safety Health Act, NIOSH shall provide for the establishment and supervision of programs for the education and training of employers, employees in the recognition, avoidance, and prevention of unsafe and unhealthful working conditions in employment covered by this Act.

NIOSH has been and continues to be a vital agency conducting important research that addresses the impact of work practices on the public health. Successful outcomes of effective training result in recognition, avoidance, and prevention. The difference between lesser and greater trending

effectiveness is a factor of having strong training infrastructure and training design that ensures that crucial information is understood and retained, and that workers can use it to transform workplace operations and design to prevent unsafe and unhealthful conditions.

Each year, in our annual report to the National Institute of Environmental Health Sciences, we are able to share numerous anecdotal information and examples that workers are bringing training lessons learned back to their workplaces. We know that the participatory design of our training and our program, and the investment we make each year in updating and developing new curriculum supports these outcomes.

It's a training model that empowers workers to take action and reflect on the outcomes of that action. I think a final point I want to make is that the programs that we work with also help promulgate the minimum criteria, Appendix E of the OSHA HAZWOPER Act, and it's continually worked on that minimum guidance criteria to make it apply to ever-changing situations in the workplace.

So again, I just want to really highlight that this is an aspect that I think is worth a lot more time and research. Thank you.

Verbal Comment 2006/03/20: My name's Dan DeMille. I work for the Department of Industrial Accidents, more specifically the Office of Safety. I'm coming from a little bit of a different angle for you guys today, in that the Office of Safety can be a resource for you people for funding for injuries, safety training funding for injuries that you already have within your specific organizations, in that we have a grant program that gives out \$800,000 a year in training money. It's capped at \$25,000 per organization. Since our inception, we've given money to over 650 organizations and trained over 200,000 employees.

So I'll just kind of give you an overview of the grant program. Basically, to be eligible for it you need to have Massachusetts workers' comp coverage and be in compliance with it. We've given training money to all kinds of organizations, labor, union, non-union, healthcare, government, private and public, it doesn't really matter.

Any topic can be used for the funding that would somehow improve safety in your workplace, you know, talked about needle-sticks and whatnot with nursing today, you know, something like that. Fall protection; we will give a lot of OSHA funding, so anything like that.

The process starts in October when we release our letter letting you know that the application's available. It's usually due back in March of the following year. And then approval usually takes place in April or May, and then the training would have to take place within our fiscal year, which starts July 1st and ends June 30th or June 31st of the next year.

The application process itself, basically it's a five-page narrative. You would describe the need for your training, you know, describe the injury, what type of training, how many people you're planning to train, where it's taking place, things of that nature. And then, we would need a budget explanation in that you'd want to describe where all your dollars are going to be spent and then just a summary of that, and

some required forms that come with it because it's the state and nothing can be done on an easy basis, of course.

That's basically about it. I've got pamphlets out back, if anybody is interested. It's got our contact information and where -- We'd be happy to help you guys out with problems that you guys already have established. Thanks.

Verbal Comment 2006/03/20: (Through interpreter) The reason why I'm here today is because my testimony hopefully will bring up awareness to you and to many who work with people like me. I had a work experience in my workplace. I got injured at my workplace. I fell, and as a result they took me with an ambulance to the hospital. When my employer find out about my accident that I report to him, he pretend that he did not understand what I was saying or what I was telling him about, you know, my injury. He did not support me at all. I did not know where to go for support or to look for help.

I talked to my friends, I talked to my coworkers, I asked for information about where I should go for help. That's when I find out about myself, Isabel Lopez, that they can help me. I found the support so they can recommend me how to get workers' comp through a lawyer, so they could give me workers' comp, so I can be having all the doctors to see me and the medical treatment that I needed for my arm.

The doctor sent me to the therapy. My doctor had prescribed me -- had given me a letter saying that I need to do light duty. They did not follow my doctor's advice. The doctor that I was seeing, I never saw him again -- the doctor that gave me that letter. He was the one who wrote me the letter saying that I either, you know, do light duties; that I couldn't lift the heavy lifting that I was doing before.

I just had a surgery -- from her right arm (indicating), she's lifting her right arm. And now the insurance company just suspended the payment for my therapy, so imagine what it is.

I have never felt supported by either the company, nor, you know, anybody. There is no support at all for immigrant workers. They treat us very inhumane in different ways.

I hope that my testimony help you understand what we have to go through. And hopefully we will find some support in some of you here today.

Imagine the ways and what I've been through; there are so many different people that are going through the same things that I'm going through. There are so many people out there that are going through this same situation. Thank you.

Verbal Comment 2006/03/20: Hi. Thank you for the opportunity -- for giving me the opportunity to be here today. First of all, I want emphasize on Gladys' testimonies. Her testimony is one of the typical testimonies that I hear every day in MassCOSH. And our hotline, when workers call that -- Yeah, I was injured on my job and my employer told me that, you know, you don't report it because I'm going to send Immigration to your home or it was your fault.

I don't know how you say this, mamita, it's like you're not being a man doing the construction work. So you just crying over nothing; and that's what we hear from workers when they come to MassCOSH.

And Gladys' testimony is one, like I say, one of the typical testimonies that we hear at MassCOSH every day, not only from as a worker in MassCOSH, as a labor community coordinator at MassCOSH, but also my personal experience I have. My brother and my sister who worked through the temp agencies every day, and you see -- And I see that the issues that our workers are going through, not knowing the language, not knowing what are the rights.

And being the most vulnerable to the dangers, doing the dangerous job is a very big issue that you all need to know.

Injuries and fatalities are dramatically increasing among them. And we hoping that, you know, by listen to Gladys, our workers are not getting the benefits for workers' comp, for example, because they don't know where to go. They don't know what to do because they get intimidated on the work.

And people like Gladys are, you know -- If she didn't come to MassCOSH she will be one of the workers who are not reported because she reported, but the employer did not do anything to help her. In fact, the doctor wrote her the letter and two days later, you know, after the doctor wrote the letter saying that she had to go for light duties, Gladys went back to her workplace. And because she could not lift those 15 and 25 pounds of heavy lifting, she was fired. She was fired.

And, you know, we need to -- We need to do something about this. We need to have better ways how to implement the health and safety for workers, letting them to know what are the rights, what are the equipments that they need, where to go. We're hoping that you all here today are going to put your resources to get to know -- We know that, you know, the immigrant workers are the most vulnerable, but we need to know why it's happening and what do we need to do about it. Thank you.

Verbal Comment 2006/03/20: Good afternoon to all. My name is Fausto da Rocha. I am direct from Brazilian Immigrant Center. A large number for Brazilians immigrated to Massachusetts after the 1990`s to work in residential construction, house cleaning, nursing homes, restaurants, and several other service-sector jobs. As the number for the Brazilians grew in Massachusetts, so did the number of cases of abuse and violation of labor laws.

The Brazilian Immigrant Center is an eleven-year-old community-based organization that was created to support and empower Brazilian immigrant workers in the Greater Boston Area around issues of workplace and immigration rights. The Brazilian Immigrant Center has become a place where Brazilians can meet, search for advice, and organize themselves to fight for their rights. The BIC mission is to unite Brazilian immigrants to organize against economic, social, and political marginalization in the United States.

Many Brazilian and American researchers interested in social, cultural, educational, and economic issues faced by Brazilian immigrants in Massachusetts and United States have contacted the center over the years. The center helped them with information about Brazilian immigration, key informant contacts, and access to the Brazilian workers.

Unfortunately, in most cases the end products of their research did not reach community leaders, and little information was disseminated to the community. The community was studied, but did not get much back from them.

In 2002, a few Brazilian researchers from the University of Massachusetts Lowell, proposed to me that the BIC collaborate on a community-based environmental research projects focusing on the hazards faced by Brazilian immigrant workers in house cleaning, construction, and food and restaurant service. Workers in these industries are often invisible and ignored, although they are a large segment of the workforce exposed to hazardous conditions for low wages and with limited access to healthcare.

We welcomed the opportunity to build a partnership with the Brazilian researchers who understood the health and safety problems faced by Brazilian immigrant workers. The project name is Collaboration for Better Work Environment for Brazilians, COBWEB, in Massachusetts, funded by National Institute of Environmental Health Sciences, NIEHS. From the beginning, we agreed that the community would be the center of the research efforts, not the researchers. I am happy to say that over the last three years this commitment became a reality. Let me highlight to you why this is true.

Project COBWEB has had a weekly radio program on the university radio station, WUML, for over two years now. The project also has a weekly column in the Brazilian newspaper called A Noticia, for over six months now, after ten months of columns in another Brazilian newspaper. Project COBWEB hired Brazilians to collect the health and safety survey data on Brazilian immigrant workers in places and times that are only accessible to the people who really have a deep commitment to Brazilian immigrants. It is not easy to survey people who are quite often afraid to talk to strangers, have fear of being deported, or are too busy working many hours to earn enough money to help them build a new life here in the U.S. and support their families in Brazil. Yet, we have had great success to getting Brazilians to respond to the survey, despite the perceived threat of signing an informed consent form.

Over 200 house cleaners have been training in churches to understand the hazards of chemicals they use to clean kitchens and bathrooms. After the training, it became clear to us that eliminating their workplace exposures in homes in Massachusetts residents -- we needed to eliminate or reduce the usage of hazardous chemicals.

We were fortunate to establish good linkage with Dr. David Gute, from Tufts University -- he's in the back -- who proposed to partner with the Brazilian Women's Group, another Brazilian community-based organization to create a green house-cleaner cooperative in Somerville. We hope that the project, funded by NIOSH, will allow us to contribute to the creating of health and sustainable jobs for Brazilian house cleaners in Massachusetts.

Project COBWEB was collaborated with OSHA in the investigation of fatalities for Brazilian workers in Massachusetts in the last three years. The BIC has learned the details of legal and bureaucratic process involved in those investigations. We now talk to OSHA inspectors and administrators quite often and will soon develop an alliance with OSHA. We are trying to make every death of a Brazilian worker a learning opportunity for the community.

Brazilian teenagers trained by the project COBWEB and the Massachusetts Coalition of Occupational Safety and Health, MASSCOSH, another partner in our project, have actually developed and implemented a campaign against violence in retail workplaces after the murder of the Brazilian teenager in Boston, 2004. The peer-teens surveyed other teens that work in retail and found out that most of their employers do not provide adequate training on what to do in case of shoplifting, nor do they have policies in place to prevent shoplifting.

All these examples, amongst many others that I could mention, show that community-based participatory research is a valuable approach to build partnerships between research institutions and community groups to identify the right questions and translate research findings into meaningful action. Only through such partnerships can communities get their fair share of the research effort, which includes financial resources, worker and community education, and feasible solutions to the problems measured and discovered.

It seems to me that BIC has learned a whole lot by participating in this project. We have learned how to include health and safety issues in our agenda because we now clearly understand that the same worker who is abused by not being paid overtime or even his/her salary is also exposed to hazardous substances and machinery, usually without health and safety training.

Since NIOSH is the major government agency that funds occupational safety and health research, I think that it should fund the research that studies how communities should or could be involved in what Dr. Sequeira, the Principle Investigator of Project COBWEB, calls community-based surveillance of workplace fatalities and injuries. NIOSH should also fund the research that assesses the effectiveness of non-traditional methods of worker education through mass media, as Project COBWEB has been successful doing. Thank you.

Verbal Comment 2006/03/20: Good afternoon. My name is Franklin Dalembert, and I'm the director of the Haitian Coalition. Today, I represent a larger collaboration between the Haitian Coalition and I'm going to name them -- this is the collaboration that is lead by Tufts University. And Professor David Gute is the lead investigator, he's here among us, and we have MASSCOSH, Marcy is the link between us and MASSCOSH, the Immigrant Service Provider, an organization that serves or coordinates immigrant activity in Somerville, and Kim of Alliance, which is our health partner in the collaboration, the Brazilian Woman Group, the Community Action Agency of Somerville.

Somerville, basically for those of you that know is a rainbow city. It is a very diverse city, comprised of immigrants from Brazil mostly, from the Latino, and then from Haitian. So 30 percent of the Somerville population is immigrant.

As you know, immigrants play a vital role in this country's economy and this contribution does not often appreciated and recognized. Talking from Haitian perspective, when I came here, the work that I've been doing and the work that I've done, what I went through, it was an ordeal.

We know many immigrants living here and working here do not know their rights. They do not know where to go. There is some sort of a lack of information. Immigrants in this country, most of the time are misunderstood, unappreciated.

This program is aimed to educate immigrants and also to create awareness about issues that immigrants are facing in the workplace. This program chooses to walk with the young people because we understand that young people represent the future of our society, the future of our country. We have so many of the young people that are working, we train them, we prepare them to go out and work with the community, and then many of them are bicultural/bilingual, and then they are very well connected to the community.

We really appreciate the work that they've been doing. This project also allows us to create collaboration to develop capacity building and also to research problem that exists in our community because the problem that exists, most of the time we do not recall them because of many issues that are facing the immigrant community, one of which is the immigration issues.

Many immigrants have fears. They have fears to report work-related incidents because again of fear of retaliation they're afraid to lose their job. Most of the time they have to make a choice between bringing food to the table, paying their rent, or report an incident, although they are sick, although they are hurt. Therefore, we have a lot of work-related incidents that are unreported.

With this collaboration, what will happen because of so many of the young people are coming from the community, it's easy for them to establish the choice that they have in the community. So we are really, really pleased with that collaboration.

We started in August; already the word's been spreading out in the community. We have so many young people that are committed to this project. I am going to give them the time to speak from their heart, to tell you what they've been doing. Thank you very much for listening to me.

Verbal Comment 2006/03/20: Hi, my name is Roberta Mauro. I'm 14 years old. I'm a student at Somer's Edison Middle School in Brighton. I'm a COBWEB peer leader at the Brazilian Immigrant Center.

I have been part of this program since January of this year. This program began with the tragic death of Cristian Ribeiro, a Brazilian student at Boston Latin Academy, a loving son, and a good friend. He was murdered in 2004 after chasing a shoplifter who had stolen toothpaste at a CVS store located in the heart of the Longwood Medical area in Boston. He chased the shoplifter because he had no training in how to deal with this type of situation. If he did, maybe this incident would have never occurred.

In my work at the Brazilian Immigrant Center, we are learning about safety and health in the workplace. Many young people are hurt on the job, some are even killed. How can we keep this from happening? It's not so simple, and that's why we want to educate other teenagers on their rights for protection against sexual harassment, stress, and violence at work.

We have joined with the MassCOSH teens to re-launch the workplace violence campaign. This campaign is basically about getting support from the community, and most importantly retail store owners to give their employees, especially teenagers, proper training.

The teens at MassCOSH and COBWEB wanted to have a better understanding of what really happens in the workplace in our community. They went to about 50 stores and collected 70 surveys from the teen employees, young supervisors, and store managers. Questions asked in the survey focused on health and safety training and how to deal with robbers, experience with robbers, and the existence of health and safety policies at work. Twenty-one percent of the survey respondents answered that they would not chase a shoplifter, while 54 percent said they would. Thirty percent of the respondents had experienced shoplifting in the workplace, 62 percent responded that they were not aware of the existence of health and safety policies in the workplace.

This evidence proved that most working teens have no idea of how to deal with any type of emergencies at work. To learn what really works in protecting young people on the job, we need more research that brings the youth themselves working together with people who know about workplace health and safety. This is why we need and appreciate NIOSH's financial support in helping programs to make serious research that can make a difference in helping working teenagers. Thanks for your support.

Verbal Comment 2006/03/20: Hi, my name is Renan Pinto. I'm 15 years old, and I'm a student at East Boston High School. I'm a COBWEB peer leader in the Brazilian Immigrant Center, and I've been working with the COBWEB project since late October.

We have been trying to promote laws that would protect teenage workers, and we've been working with the teenagers as MassCOSH in Dorchester since January 2006. Together, we have been trying to get more people to support our campaign to raise awareness about safety and health in the workplace.

Three weeks ago we presented three different skits on sexual assaults, stress, and armed robberies. We developed those skits to make people more aware of what teenagers can go through in their workplace, if they're not properly trained. I, myself, have learned a lot about safety and health, and want teenagers all over the U.S. to know that they have rights to protect them, if ever a situation similar to these happened to them.

Many young people are hurt on the job, some are even killed. This is a very important issue and should be taken very seriously. Yes, there is violence in our world, and we know that there is no chance of being totally safe in the workplace, but we can decrease the number of injuries or deaths in the

workplace by making sure our employers train our employees on how to deal with these types of situations.

I also think it's important to educate our community about these laws because many immigrants don't know their rights and bad things do happen. For example, a Brazilian immigrant teenager, Cristian Ribeiro, died in 2004 in Boston as a result of lack of training. A shoplifter came in CVS and stole toothpaste. Cristian, who was oblivious to the situation and had no training on shoplifting, thought that it was the right thing to do to run after the criminal, not knowing if the shoplifter was armed or dangerous. That was the worst mistake he ever made in his life; it resulted in his death. He got stabbed in the neck, while his supervisor got stabbed in the stomach. While his supervisor survived, Cristian unfortunately was not that lucky.

Bad things happen every day, and MassCOSH and COBWEB united are trying to educate teens in our community so that teens would not have to face what Cristian did.

As you can see, we need to make a change. Too many teens are getting hurt or violated in their workplace. We hear about it a lot, but at the end, not a lot of things are done about it. We usually don't do anything about it until something happens to someone close to us. We should not allow that to happen; teens should feel safe and protected in their workplace. They need to know that they have laws that protect them. Most important, all teen employees should be trained on how to deal with theft situations.

To make all of these things possible, we not only need community support, but also financial support. We are very grateful for NIOSH's support in community-based participatory research that allows teenagers to become leaders in health and safety in the Brazilian community. With the help of our community and NIOSH, we are making sure our knowledge about rights and safety working are spread to the teens. Thank you for all of those who helped.

Verbal Comment 2006/03/20: Hi, my name is Raquel Lamons. I'm 16 and attend Charlestown High School. I am a senior peer leader at MassCOSH Teens Lead at Work Peer Leadership Program. I decided to work at MassCOSH because I was interested in learning about occupational health and safety pertaining to teens.

In the past, I always heard about other teen organizations working on common issues, and I felt that Teens Lead at Work was the only youth organization that worked on unique topics. I have been working here for three years. We are currently working on strengthening child labor laws, education and outreach, and community organization through the Dorchester Occupational Health Initiative.

A little over two years ago on February 16th, 2003, a teen named Cristian Giambone, who worked as a store clerk at a popular retail store, was fatally stabbed while chasing a shoplifter. He was not trained on how to approach a shoplifter or how to handle a dangerous situation. What would you do in this situation?

Well, I know what the MassCOSH teens did, we collaborated with Cristian's mother, Taciana Sabb, and the Brazilian Teens peer leaders to form the Workplace Violence Campaign in which we are trying to

implement a policy that will make sure all employees, especially teens, are adequately trained in workplace violence situations.

Teens are most vulnerable than adults and are injured at a twice the rate of adults. The reason for this being is teens are intimidated by older supervisors who usually ask teens to perform dangerous tasks and often forced to stay late.

Teens need to work to help their families and for personal needs. Jobs are good for teens because it helps build character and teaches them responsibility. This is why teens need to work, but how can they work in unsafe conditions? For this reason, we need to protect teens in their workplace.

Situations like Cristian's happen a lot. Just a couple of weeks ago there were several violent occurrences in which retail clerks were seriously injured. I think research should be geared towards teens because we could get the word out about health and safety quickly by organizing and researching out into the community.

We teens have fun and vibrant ways of spreading information and can recruit others to join us in our fight for workplace violence and health -- I mean, workplace health and safety. I believe that with the right research we can receive the appropriate funding and build stronger communities with teen activists.

We also need more research to make sure all teen occupational topics are properly studied. This will help the doors open to organizations like ours, MassCOSH Teens Lead at Work Peer Leadership Program. This will give other communities a chance to implement a similar teen occupational health and safety program in our neighborhoods.

Because of the work we are doing, other teen employees won't have to get injured or killed. Hopefully, everyone in this room is listening, because I'm really speaking through my heart. If you're down with me, then you're trying to help the teens. So thank you for listening, and please have a great evening.

Verbal Comment 2006/03/20: Like you said, my name's Carla Bourgos, I come from Somerville. I attend Somerville High School. I'm currently a ninth grader. I work as a peer leader in Community Action Agency of Somerville. We also involved with other youth programs, one being the Haitian Coalition.

We are so happy we can be a part of this project as a bilingual teen educator. Well, this program is a very productive thing because we are learning skills, teaching other members about occupation health risks and how to avoid injuries, and also where to go if they get injured.

This program is very good because we have had the opportunity to go see where immigrants work and the environment they work in. All this training we are getting is giving us knowledge that we can teach and use for ourselves in the future. Thank you for the opportunity to speak.

Verbal Comment 2006/03/20: Hi, my name is Ricardo Bonhomme. I'm a freshman at Somerville High School. I work for the Haitian Peer Leader Program in Somerville to educate Haitian and Latino youth on safety and health hazards.

The reason why I'm doing this project is because I want to reach out as a bilingual student to represent many other Haitian community members who might not know about occupational health hazards. They also might not trust people who don't speak Creole, or who come from Haitian culture.

For all these reasons, having research into immigrant occupational health problems is important. And we thank you for your support and contribution for future years to come. Thank you again.

Verbal Comment 2006/03/20: Thank you. I just about lost my voice for the day, so I'll be brief. I come here representing myself, but I have been involved in the telecommunications equipment manufacturing industry for more than a dozen years. I don't represent the specific views of my employer, Lucent Technologies, but I think I have a fairly good perspective on the few things I'd like to mention.

I have certainly seen a lot of changes in that industry, most notably, recently things associated with outsourcing and that whole business. So my focus or the particular focus that I think would be of benefit would be to make sure that we maintain the good ability to have surveillance for introduction of new toxic materials throughout supply chains, and to be able to develop accurate means of assessing hazards and controlling those hazards. And then to develop, I guess, what you could call a global supply chain to epidemiology to look at the effects of spreading industries across many places and many different parts of the world, where there are different levels of capability for assessing the risks that might be involved with introducing new technologies and new materials. And to be able to incorporate those findings into economic models that would influence decision making on how supply chain sourcing is done. That's about all I have to say. Thanks.

Verbal Comment 2006/03/24: I want to thank everyone for being here this morning. I want to thank you all for giving me the opportunity to speak. My name is Kristen Borre and I have several roles and identities, but this morning I want to speak as the director of the Growing Up Fit Program at East Carolina University, and as an associate clinical professor in the Department of Pediatrics at Brody School of Medicine. I also want to speak from being involved with the North Carolina Agromedicine Institute for over ten years, helping form it, and working with partnerships to identify problems with our board of collaborators that we have sought funding for. And many of those problems we have been able to address through partnerships and we had some successes. I'm not going to talk about those successes this morning. What I'd like to do is talk about key issues that I think we need to pay attention to over the next ten years, and then give some suggestions about how we might address those.

First of all, I think it's very important that we continue to support basic research in agriculture, forestry, and fisheries. Basic research gives us -- there are several areas of basic research that are on the horizon, and because they're on the horizon, we need to follow up with those things. In particular, I want to mention chemical toxicities studies, pesticides and specialty biomarkers; a number of very interesting and important findings that are coming out of the agricultural health study that's being funded by NIH. We need to follow up with them as a partner and support their efforts.

Environmental health exposure, exposure to natural elements, exposure to man-made problems put in the environment as a result of our work efforts in agriculture are very important to follow up on. There's new exciting methods out there that need to be funded and looked at very carefully, especially

when they are cross-disciplinary in their approaches using both quantitative and qualitative kinds of studies and community-based studies as well as laboratory studies.

Finally, one of the most important issues that we've been struggling with in the last five years is the problems of stress in agricultural workers. Stress related to economic uncertainty, to communities that are disintegrating, to breakdowns of family systems as children become educated and move away. Parents sometimes don't want their kids to stay on the farm as life is just too hard, it's too uncertain. We have to take a community-based approach to look at that problem.

I think it's very important that we do translational research, and the research-to-practice model endorsed by CDC, and NIOSH, and NORA is clearly the way to go because there's been too many studies done that are excellent studies, but they're sitting on the shelf somewhere. We need to get them off the shelf, get the information out there, and figure out how to make a difference in the lives of our agricultural workers in their everyday life. That's the only way to build trust with our agricultural workers. When you go to do a study sometimes they sit there and they look at you and they say all right, I understand, farmers are smart, fishermen are smart, foresters are smart, they understand. But their big question is what's the benefit going to be to me and you'd better be ready to tell them if you want them to work with you in partnership. You have to hit the road running with them. You have to be where they are. Sometimes our basic researchers are too far removed and don't understand that. That's why it's very important that they partner with people from public health, from agricultural extension, and in the social sciences. They also need to partner with local groups, faith-based groups, NGOs. They need to find who is in the community. They need to partner with local businesses. Partnerships can be built in many different directions because those people all are there to care about their community. If you go there and talk to them and be patient with them, meet them on their schedule, they'll give you some good information and work with you.

Finally, I think it's very important that we address some things that are on the horizon. One of the past speakers mentioned several of these things. Agricultural workers are more likely to die of heart disease, diabetes-related illnesses, and obesity than they are to die of a tractor turnover. Tractor turnover, though, should be prevented. There shouldn't be any tractor turnovers, but we've got to figure out how to prevent the tractor turnovers in the community from happening and get farmers to use the devices. But getting back to cardiovascular disease, diabetes, and obesity, those problems are real. They're prevalent. They cause disability. That disability will lead to disability in the workplace. When a fisherman is injured, it is very hard for him to heal if he has diabetes. When a farm worker has diabetes and becomes injured, he's sometimes laid off and can't work to support his family. And most recently in a study I interviewed a 24-year-old mother of two who's a farm worker who injured her back working in sweet potatoes. She was out of work for 18 months until she lost 80 pounds so she could recover and go back to work.

We have to pay attention to the issues of aging in rural communities. We have to pay attention to the disability. The average age of farmers in North Carolina right now is 55. We have to look at their issues with access to care, and we have to look at issues with health insurance. These problems are big. These

problems are broad-based. These problems, though, are synergistic. And if we don't bring together the different people who can address those issues with our farmers, we're not going to have farmers in the future. So we need to do this and we need to do this in a way that's meaningful for those farmers.

Thank you very much.

Verbal Comment 2006/03/24: Good morning. Thank you for giving me an opportunity to share a few of my research findings and for being on the same horizon as the rest of the speakers are. My name is Avinash Tope and I'm from Kentucky State University. I'm a researcher there and I'm a part of the land-grant program. I'm here to share a few findings from my recently concluded USDS-supported project on the evaluation of genetic toxicity to farm workers exposed to pesticides. We have had a little bit of success, though we thought we could do a whole lot better. We had some genuinely constraining situations to -- that presented a challenge on recruitment of the needed number of people.

In our recently concluded project we had recruited about 30 predominately African-American farmers and we wanted to check the long-term low-level chronic exposure problems and impact of this exposure on whether or not they become predisposed to DNA damage. We happened to study them for two years. We happened to sample their blood and urine nine times a year, six times in the growing phase and three times in the non-growing phase of their agricultural cycle. We had about 18 samples overall per person. And we monitored changes such as chromosomal damage, formation of DNA adduct, which is considered to be a very significant cause behind cancers, and it was a fundamental research. And we tried to run the statistics and we figured out there was a particular biomarker that was a spiked in the DNA adduct and the chromosomal damage. And it was an awaking call. We were trying to, again, as suggested by Dr. Borre, we tried to have this information sent out to the stakeholders, the farmers that were part of the study per se, and we have tried to reach out to the community as such through some of the programs at Kentucky State University. We have farmers from the local counties who visit us every

Thursday for our special-interest programs, which cover a wide range of topics that are relevant to day-to-day lives. These usually send a message for the farmers and we are trying to send this message that there is an event of greater risks of genetic toxicity to them and ways to overcome.

Some of the suggestions that we have offered were to make it necessary to use protective wearing while they're working in farms because usually we have also observed summertime these folks do not tend to use clothing because of heat and humidity. We also emphasize the fact that it's very important that they read the instructions offered on the pesticide bottles and use the needed safety measures to help them from getting unduly exposed.

We would be interested to see more of an effort being put into this direction of fundamental research on pesticide and agricultural health. Again, African-American populations seem to be slightly higher and more predisposed to diseases such as hypertension, and cardiovascular diseases, and diabetes. We would like to see addressed that funding from CDC and NIOSH that will address some of those issues and we get to see something more meaningful reaching out to the needed clientele. Thank you.

Verbal Comment 2006/03/24: Good morning. Thank you so much for letting me come. You will quickly know from the things that I have to say that I'm not the researcher in the room. So I hope that you will bear with me. I am from East Coast Migrant Head Start Project in North Carolina. And my job is to oversee the health disability needs of migrant farm worker's children in eastern North Carolina who are ages six weeks to compulsory school age in the summer while their parents are in the fields.

In addition to that I serve on the North Carolina Farm Worker Program Board. And so I have worked very hard to do a lot of things that you're talking about, about building collaborations. Because when I first came to Migrant Head Start I really felt like I had been put on Pluto, not even Mars, but Pluto because we were so separate from the rest of the world. In coming up through a very strong system in North Carolina for birth-to-five services, I was totally lost and wondered how I could be in my home state that I had known for so long and feel so isolated.

So I've come to you to tell you some stories and to suggest to you some problems that I hope that you all who are the researchers can help figure out how we can come up with solutions and indeed put them into practice.

Recently, I had a meeting where someone said that the numbers, the statistics are people with the tears wiped away. And so I want to encourage you to remember that as you're setting your agenda. We've also heard it said many times that a picture is worth a thousand words, and so I hope you'll bear with me when I show you this picture because I think just the opposite. When I saw this picture, I was speechless. And as I tried so hard to put my comments in writing today, I could not make the words flow from my brain and my heart to my fingertips, even though I have a very strong background in developmental disabilities. This migrant farm worker baby is one of three children who were born last year to migrant farm worker mothers. These mothers all worked for a very large produce grower that raises tomatoes, those little grape tomatoes you like in your salad. They work for this producer in both Florida and North Carolina. These mothers were young and they came with the anticipation of hard work, and they didn't mind doing what needed to be done in the fields every day, even though they were pregnant with their children to feed you and I at the very minimal amount of money that they receive. There's no way to say what caused the birth defects of this young man. There's no way to say what caused the birth defects of the child who died. There's no way to say what caused the birth defects of the other child who lived in the camp. There's no way to say 100 percent what happened to the other children who were miscarried or born prematurely.

We don't know how many children there are. It's very difficult to establish causality. Why? Because we don't have surveillance data. This is an invisible population. In North Carolina, we take our statistics for our 10,000 H2A single-men workers and that's where the attention goes. No one knows about the other 90,000 farm workers, many of whom are women are children. And we went to the health departments and we asked them what do you know about this? What do you know about prenatal care? What do you know about pesticide education? One of them even had a pesticides are dangerous sign outside on the mound in front of their health department. They knew nothing about pesticides. They knew nothing about pesticide education. And they knew very little about prenatal education for women of childbearing age.

And so I want to tell you why my passion is today to speak to you about migrant farm workers. In a couple of months my son is going to marry, and he's going to marry a young woman who is a grower, a farm worker, in North Carolina. And she did not know about why it was so important that she took her precautions. She had heard it, she had been schooled on it, but she didn't do it.

So I can just tell you that while we focus today on our migrant farm workers that there are many women of childbearing age who are also regular everyday farm women that we need to make sure are being educated and taken care of. So thank you so much.

Verbal Comment 2006/03/24: Thank y'all for letting me come today. My name is Sam Wiggins. I'm county extension coordinator in Pickens County, Alabama. I have with me today Dr. Ray Rice, who is my supervisor out of Auburn University. The Alabama Cooperative Extension System is made of the land-grant universities in Alabama, which is Auburn University, Alabama A&M, and then in partnership with Tuskegee University. Today, I'm going to talk about the Alabama Agromedicine Program, and I kind of title it a full partnership. But I need to give you just a little bit of history of how it's kind of developed.

It's a very informal partnership. Through the vision of Dr. John Wheat at the University of Alabama and his love for rural Alabama, he has developed a Rural Medical Scholars Program, a Rural Health Scholars Program. The Rural Health Scholars Program is for juniors in high school between their senior year to try to get them interested in the health field. The Rural Medical Scholars Program is a program for future rural doctors to get into medical school and then go back and practice in the rural areas of Alabama, hopefully.

As part of the process, farm business was a requirement. And through this linkage we developed some relationships with the farmers throughout Alabama, and especially in my area because we're next to Tuscaloosa. And with this relationship, we expanded into now what is deemed Alabama Agromedicine. And in this, Dr. Leaper had gotten a grant to do a study of farmers. And when he met with the farm group, they were very concerned about who was going to get the information and how it was going to be used. Not that they were wanting to hide anything, but it was a level of distrust of what the federal government might can turn and use against them. So they punted that, but they came back to them and

formed a steering committee. And through this steering committee they reviewed the survey instrument that would be handed out to farmers to gather information on what were the health needs, concerns in the agricultural community. So everything is run through this steering committee, which is made up of agricultural producers, a rural medical doctor, and myself as an extension agent. And we were able to pilot this program in 2003 with our poultry growers in Pickens County, and that night we got 35 or 40 surveys back from the group that were there, and he compiled the initial data. Since that time we've also surveyed the swine growers in west Alabama and got all of them. The plans are now to expand this survey out state-wide to get input from all the different commodity and different segments of Alabama agriculture.

The preliminary early results that came from the survey that addressed the concerns of the farmers was biosecurity and bioterrorism. Then the others were the stress level that they have to face because agriculture has changed so much. I grew up on a farm and about all you worried about was the weather and crop prices. But now we're in such a world economy and there's so many things that happen that there is just an additional stress level to them.

The other concerns were the need for healthcare that's affordable; in other words, the lack of affordable insurance for them. Many of their spouses would work off the farm so that they could provide insurance. Then the other things that came across were the daily things of being in the environment that they're in. Not that the environment is bad, it's just a stressful-type environment that they're exposed to dust and other things like that. And then the concerns of people understanding what they're trying to do, and appreciating them for the value that they bring to the table.

So I encourage you, if you will, just to support research. And what we like about this partnership is that it's a genuine partnership between the land-grant universities in Alabama, the agricultural producers in the Schools of Medicine in the University of Alabama. We're going to take this research and the goal is to develop a textbook for future doctors to use so that they could have practical information to take back to the agricultural segment. Thank y'all very much.

Verbal Comment 2006/03/24: Good morning. I'm Melissa Norman. I'm a native Mississippian, but now I live in Birmingham, Alabama. I am an assistant professor at the University of Alabama in the Environmental Health Sciences Department, and I'm here as a representative for the Deep South Center for Occupational Health and Safety.

The Deep South Center is an education and research center that is funded by NIOSH. It's one of only 16 in the United States. We service Alabama, Mississippi, Georgia, Tennessee, and the Florida panhandle. Some of our programs within the Deep South Center for Occupational Health and Safety include occupational health nurses; nursing, which is with the UAB School of Nursing. We have industrial hygiene, which is in the UAB School of Public Health. We have occupational safety and ergonomics, which is housed at the Auburn University School of Engineering. And we also have a continuing professional education department, which is on the campus of UAB. Our Center's mission is to develop professionals who will work to protect and promote the safety and health of workers throughout the southeast and the United States. By doing this, we're going to conduct research on occupational hazards that are primarily relevant in the industries within the southeast. Our Center's vision is to become a regional center of excellence that promotes occupational health and safety throughout interdisciplinary activities. In some of our interdisciplinary activities, our students go out in groups of five to industry, and we have a representative from occupational health and nursing, health and

hygiene, occupational safety and ergonomics. And they all get together to tackle one specific occupational hazard that the company is concerned about. So we're teaching our students to go out into the industry and take a multidisciplinary approach to whatever the occupational health and safety hazard is so that the practicing industrial hygienist can understand what an occupational physician or an occupational health nurse may need to know to adequately diagnose or to help to prevent certain kinds of musculoskeletal disorders, as far as having them do pre-work stretches or teaching them about their work-risk cycles.

Another important aspect of our Center's planning and development is to assess the training and research needs of industries within the southeast. We do this every three years. We have a survey that is sent out to our alumni, which we have over 300 alumni from the University Industrial Hygiene Program. And we also send it out to industry within the southeast in the states that we service, and they give us feedback on the type of training that they need or emerging issues within their industry that they want us to look at to try to come up with some kind of strategy to help them tackle these occupational health and safety issues. And our primary industries in our region include forestry, wood products, papermaking, poultry processing, and automobile manufacturing. That's the new emerging occupational health and safety area that we have now. We have three automobile manufacturing companies in the State of Alabama; the newest one being Hyundai, which is down in Montgomery, Alabama. Right now, our Center is trying to work on a project to help them go in and try to prevent some of those musculoskeletal disorders. We're look at their noise problem. Also, from my understanding, these employees have never worked on an assembly-line type of process, and to try to make them understand that they have to get their rest and you have to rotate from station to station to help to prevent some of the occupational issues that are coming up. So that's a project that we're working on.

Last summer, our Center presented at a NORA-related symposium that was held down at Auburn, Alabama. We had individuals from private industry, federal and state government. We had a representative from the U.S. Congress from the State of Alabama, and a civil rights advocacy group. Some of our topics included special populations at risk, the Hispanic worker, intervention effectiveness, social and economic consequences of workplace illness and injury. Our keynote speaker was Sid. He came down and did our opening remarks for our research symposium last summer. And we had other speakers from the University of Texas Health Center. We had University of Massachusetts Medical School Center for Health Policy and University of Washington School of Public Health. So we tried to get some of the top researchers within the United States to come down and talk to us about their research and how we can take that research into practice. And one of the reoccurring problems that we are facing is that when you do research it is such a controlled environment and how do we take these controlled environments and apply it to an occupational setting where you have so many uncontrollable variables that you have to look at. One of our possible solutions to our actual research going from research to practice is to have researchers go in and use occupational workplaces and use their data or use their work populations to do their research and do their studies so you can account for some of the variables that come up from a controlled environment in the research area and some of the uncontrolled environments that come up when you're dealing with occupational health and safety. And one of the biggest issues is behavior. You may have all of your key elements in place, but if you have improper workplace behavior, all of your safety features are really null and void. So we want to try to

look at behavior aspects of occupational health and safety and try to implement those into research that we do in a controlled environment. Thank you.

Verbal Comment 2006/03/24: Good morning. James Garner from University of Arkansas at Pine Bluff. I'm the department chair for agriculture and the associate research director there. I'm also a native Mississippian, also a state retiree from Mississippi. I worked at Mississippi State University for 25 years, and retired five years ago and took a job in Arkansas.

I have a little handout to go with my talk. I want to talk about several things, but to get through this in five minutes -- We did a study on developing a rehabilitation service delivery model for minority farmers with disabilities. And that's some of the highlights of that study that I'm handing out to you; if we go through that together.

Just to give some of the high points because you can go through it completely so you can read that on your own. But just on the second page there you can see that we have some demographics of the farmers that we work with. The average age is 53 years old. The schooling average is around 12 years. The household size is 2.7. Farmer profit -- and you have to take those farm profits and that data with a grain of salt because farmers don't really like to tell the truth about what they make all the time. But if you go down to the figures and look at that marital status that mostly we had married farmers, the next largest group was single. And then gender, a little less than 600 of the farmers were male, but we also had a little over 400 female. And that's one thing that I would like for you to keep in mind from one of our previous speakers who talked about women in the farming industry and it's increasing every day. In

our study we had over 700 black, with the next largest group being white farmers, a little over 100. And again the schooling, you can see that the average is 12 years, but we had a pretty good variety of how much school most of them had.

Table four and five -- we also in this study looked at groups that served the farmers with disabilities. We looked at agricultural workers, extension agents, people that work with the NRCs, and the state vocational rehabilitation personnel. So we have some information on that group also. But going on on page 15, farmer's health and disability, I just wanted to point out in that third figure there what the major disabilities that they reported were; visual, as being the most prominent, hearing, metabolic, orthopedic, and then heart disease or cardiac problems.

Now, one of the things that we noticed in the study is that farmers were reluctant to admit that they had disabilities because they feared that if they admit that they had disabilities it would affect them as far as obtaining loans to continue the operation. So these figures may be low to what the real situation is. The other you can sort of look through, but turn back on page number 25. These are recommendations that came out of the study. Basically, what we try to do is recommend what the farmer's recommended or what the groups that we worked with recommended. So some of those you'll just have to use as information. It's not like we're trying to give you recommendations on what to do or what needs to be done, but what they feel is recommended. So some of those that I thought would stand out would be that second one where it says create literature and videos about disabilities on the farm to educate counselors about this population. Because some of the counselors that work with the disabled were not aware of the type of disabilities or the type of jobs that had to be performed by the people with disabilities. Better federal regulations to reduce financial threats for farmers who are afraid to seek help when they have a disability. Collaborate with the USDA agencies to provide information to farmers. What we're finding is that the state agencies had less contact with the farmers than some of the traditional agencies, such as the extension service or even the NRCs. And that the farmers tended to trust them a lot more and the university personnel than they did the state rehabilitation service agencies. I'm going to stop there and let you read through that at your will.

At the University of Arkansas at Pine Bluff we have what we call a regulatory science degree administered in the Department of Agriculture. In that degree we have three options. We have industrial health and technology option, an environmental biology option, and an agricultural option. All three of those degree options are administered under agriculture. We also have what we call the Regulatory Science Center, which was supported by the USDA. Since 9-11, we really lost that support once they took some of the people out and put in homeland security we sort of lost our contact and that's no longer there. They were really instrumental in helping us develop that program. The program itself is very strong. Many of our students go to work for some of the government organizations, but what we really try to do is look at policy and how it affects farming or how it affects the health status in other parts of the United States and Arkansas in general.

Along with that, we try to develop research areas that are covered under that center that we were talking about.

Now, a couple of things that we feel may be important, especially with small farmers. We try to work with all farmers, but we particularly work with small and what we call limited-resources farmers. For example, these disease problems that we're talking about every day, such as the Avian flu. I was at a large poultry producer and one of the gentlemen there told me that they thought that was a little bit blown out of proportion. I said even if that's correct, we feel that the small farmers who have a lot of poultry that's in the yard everywhere, and they handle this poultry and they kill this poultry. So I think those small farmers may be at risk if we do get that Avian flu within the United States. So we think that even with the mad cow and some of these other things that our small farmers are highly at risk when it comes to these.

We also work with medicinal crops. We have a joint project with the University of Arkansas at Fayetteville where we are looking at crops that have been reported to have health effects and we're trying to identify the active compounds of those crops. And we're also working with small farmers to try to get them to grow these crops and utilize them, especially some of those that have been said to affect high blood pressure, for example, which is prevalent among blacks. Thank you.

state Farm Bureaus

Categorized comment or partial comment:

Verbal Comment 2006/03/24: I'm Mike Blankenship. I'm the safety director and rural health director with the Mississippi Farm Bureau. Most of the time when people hear Farm Bureau, it's an insurance company. When in reality the Mississippi Farm Bureau Federation is the parent company of the insurance company. Insurance was formed as a service for rural families because they couldn't buy insurance. Don't get me wrong, the insurance company is a big organization, but they are just part of the Federation.

Through the programs in the Mississippi Farm Bureau last year we trained over 30,000 people in the State of Mississippi. We do some 14 different programs, everything from CPR to machinery safety. We formed a networking group with other states through the Farm Bureaus. Right now we have 22 states involved in it. All the Farm Bureaus have people who do training. We don't do research, okay? What we do is take the research that's been done and we put it out there to the people. We think that's where it needs to go and I know a lot of you do research, but research is not any good to me unless we have the ability to put it out there where it's going to do some good, and that's what this networking group does. Right now we have 22 states involved in it and every year it grows. We have a meeting next month in the Outer Banks of North Carolina, and we'll hopefully have around 30 states represented at that point. It's a good contact for y'all. It's a partnership through your state Farm Bureaus because a lot of them have either health, safety or a combination of the two that are involved with training for the people in the state.

Categorized comment or partial comment:

Verbal Comment 2006/03/24: I'm Kelly Tucker. I am the director of the Center for Safety and Health at Mississippi State University, which is actually located here in the metropolitan Jackson area. And as part of that job I am the program manager of the OSHA Consultation Program. I guess my talk will be geared mainly toward OSHA consultation in general and not just Mississippi.

There are 56 of these OSHA Consultation Programs. Every state has one. I think six of the territories have one. They just actually started one of the programs in the northern Marianas. They have one in the Virgin Islands. I need to go down there and check out their program on some trip. OSHA and the U.S. Department of Labor funds these programs and you can find them everywhere in state government. I know Kentucky's is in the Labor Department; part of the universities are there; Georgia Tech University, University of South Florida have the programs. Health departments, Workers' Comp Commissions. We all basically do the same thing, and that is that we provide a free service to the owners and managers of small high-hazard businesses. Unfortunately, that does not mean the farm.

We do some agribusiness here in Mississippi, but we have to track what OSHA tracks and they're riders put on the OSHA bill every year and that typically eliminates the farm. We work with Bruce on agromedicine and we attend conferences and provide guidance, but as far as actually going out to the farm, we don't. Now, some other states do.

There are basically two kinds of states as they deal with OSHA. One is called a federal state, which Mississippi is. Where the federal government does compliance work and OSHA does the consultation work -- or the state does the consultation work. In state planned states, the state does everything; Tennessee, Kentucky, the Carolinas are some that jump to mind. Those states have the compliance officers, the consultants, and they also do public-sector work. No one in Mississippi is looking at the public sector.

What we do is we go out to the small businesses. We go only where we're invited and that's nationwide. So if you have a small business owner in California or North Dakota or Mississippi to get our services they have to invite us in. As I said, we are a free service. Historically, what these programs did is they tried to OSHA-proof companies. Well, that term disappeared probably about ten years ago. And really what we're trying to do now is work with the companies and implement a safety and health system which will put emphasis back on everyone in the factory, or the business, or the hospital, or wherever we're working. Everybody takes responsibility. All of the programs that are required are in place. During Katrina we had something happen here that was real interesting. We do a lot of work in nursing homes, and one of our key sites -- well, we called all of our key sites, our recurring customers, and we called some folks to help us implement an emergency action plan. You know, in a nursing home that's somewhat difficult as we saw on TV during Katrina down in the New Orleans area. These people were so excited that this system had been implemented because everything worked right, backup power, accountability. And these are the type of things that we work with our clients on. Not just to find a physical hazard, but to try to develop a system. Again, when I'm talking about what we do, I'm talking about what all of the programs do.

We all basically have two types of people. We have safety consultants and health consultants or industrial hygienists. The safety folks are looking at machine guarding. They're looking at egress from the facility. The health consultants or industrial hygienists, whichever way they want to be called, are looking at workstation air contaminants. Are these people at a workstation where there's spray painting going on? Are they overexposed to the organic solvents? Are they running a saw? Are they overexposed to wood dust? My background is industrial hygiene, so I know that a little more. We're looking at workstation noise-abatement work. We're doing some ergonomics work. Some of the states that are well-funded, of which we unfortunately are not, have ergonomists on their staff. We do a good bit of blood-borne pathogen work, first-aid work. We are typically, though, identifiers. Some programs have training elements. We do not in Mississippi. We go out and identify hazards and the companies fix those hazards.

I was talking to some people earlier about some of the problems that we actually see that are causing hazards. I guess in different states it's different things, but the biggest cause in Mississippi is people being killed on the job while operating moving vehicles. Now, they may be the salesman traveling between clients, the over-the-road tractor-trailer truck operator. We've had several wrecks west of Jackson in the last couple of weeks attributed to fog; trucks running into each other and people being killed. Also, fatigue, we see a lot of that. We see a lot of ergonomic issues; mainly back strains, shoulder

strains, people having problems like that. We see a lot of trash in the eyes in some of the facilities that we go into, which is a lot of foundries, sand and that type of stuff getting into the eyes.

One of the services that we offer is trend analysis. We'll go into one of these facilities and look at their OSHA 300 form, which is the log of injuries and illnesses and we'll try to come up with a trend and help them to come up with solutions to solve these problems. As I said, these programs are in every state. Every state has one program except Wisconsin. They broke their safety and health program out into two programs. Then in all of the territories, including Washington, D.C., has a program. They're everywhere. OSHA is trying to get the programs that want to move into universities because universities are the masters of managing grants, and we found that when we up under Mississippi State University in 1994 that everything just smoothed out. It helps during football season too when you're working for an Ole Miss or University of Southern Mississippi client there's always something good to pick on them about.

One thing that makes us feel good, you know, sometimes I feel like that we're sort of looked at as the son of OSHA. You remember the old horror movies the son of Frankenstein? Nobody likes to see OSHA show up, EPA, any of the regulatory agencies. We sort of consider ourselves the good guys. OSHA does a lot of good work and they provide our funding. I got a letter from one of our clients not long ago who worked with a series of nursing homes and we worked with them quite a bit. He sent me a letter and said that they appreciated all of the work that OSHA Consultation had done, and that they had actually improved their situation so much that they had actually gotten a refund on their workers' comp insurance. So those are the nice things that you hear from your clients.

Like I said, people during Katrina commented that some of their plans had really played out in the proper way. Of course, we're always glad to hear that also. You can go to the OSHA homepage, which www.osha.gov, and look down on the right side of the page down to consultation which is a link there and you can go to your state and find out exactly where the program is located. One of the things that we hear quite often is we didn't know you existed. So if people ask you for safety and health work wherever it might be, we'd appreciate your referral. Thank you.

Verbal Comment 2006/03/24: Thank you. I'm Maureen Hardy. I'm a physical therapist here at Saint Dominick's Hospital here in Jackson. And last year in 2005 Time Magazine picked Mississippi as the fattest state in the nation. We have our hospital, also, which has problems with not only obesity, but the co-morbidity problems surrounding that. Our human resources is looking at ways of reducing our healthcare costs. So this year we partnered with Mississippi State University. They have an extension service for each county, and they've come to our facility -- this is free, it's part of a study they're doing -- to initiate Mississippi in Motion. It's a weight-loss program and it's really a wellness lifestyle change.

We limited it to our employees. We had over 150 applications and we could only choose 25; that's just within our employees. So we're in the middle of this program right now and I would encourage that you look at partnering with programs like the Mississippi Extension Service, which are already up and running. However, I do want to comment that although this is for adults, I really feel we need to go back to the roots, which are the children. We put three girls through public high school here. Recently, I went back to high school with my fourth child, and there was a ten-year gap because I hadn't been in this high school for ten years. I was looking forward to seeing the changes and what shocked me when I walked in the door were the number of vending machines. I counted 30 vending machines in that high school with junk food and sugar-laden soda blocking water fountains; purposefully blocking water fountains. So, of course, I went to the principal to complain and I was told, truthfully, life is about choices and these choices and this is an opportunity to learn to make right choices. I said well, where's

the good food? So the choice is either I eat or snack or I don't. That's the choice. So following this line of logic I suggested that they put in casino slot machines so the children could learn to become compulsive gamblers or not. The schools make a lot of money, and we know that, from the machines. But that's not the right answer. They have a problem and we've not gone with the right answer. So I ask you to look at the children in Mississippi.

Now, I want to switch to my role as a physical therapist. I treat injured workers from traumatic and cumulative trauma injuries on the job. And part of my role is to go back to the company with the injured worker to recommend light-work restrictions for the employee. I find that I'm talking in a different language than the company. I'm talking in the R alphabet; rate, redesign the tools, rotate your employee. And the managers are talking in the P language, which is profits, product, and productivity. We're not connecting. The employees themselves -- I work so much in the clinics teaching them safe ways of moving. I place ergonomic knives in their hands to cut the poultry. But they are not empowered when they go back in the work to make these changes. So my request to you is that we all belong to professional associations. I'm on the American Society for Hand Therapy, American Physical Therapy Association, American Occupational Therapy Association. We need the research that you're developing. And if you have systematic literature reviews, and especially any evidence-based practice guidelines that we could link on our websites with our professional organizations, we need to get this literature to the practitioners so that they can use it. So anything on ergonomic intervention that will speak to the clinician as well as to industry, help us translate this information so we can put it in practice.

Thank you.

Verbal Comment 2006/03/24: I'm Bob McKnight from the University of Kentucky College of Public Health. I have five quick things to talk about today. Each one will be fairly brief. I want to talk about one population that I think NIOSH should place more emphasis on as a population at risk. I want to talk about a geographic region that I'd like to see more emphasis in the research agenda. I want to talk about one specific hazard. I want to talk about one partnership model. And I'm going to save the fifth on to the end.

First thing I want to talk about is a population that needs more of an emphasis area. I'll sum it up with two words, older workers; those workers over the age of 55, the area of occupational gerontology. I've been to some of the international conferences on occupational gerontology and I am amazed at how the Europeans and the Scandinavians seem to be so much ahead of us in this field recognizing special issues with older workers related to adapting the worksite so that older workers may be more productive. As we have an older population in the U.S., we need to adapt the types of research and strategies that our colleagues in Europe and other nations are doing to make the workplace a safer healthier place for older workers.

Categorized comment or partial comment:

The second thing I want to talk about is a geographic region. Particularly, I'm going to sum that up in just a very quick word, rural occupational safety and health; those non-metropolitan counties, the rural areas of America. I come from Kentucky. We have a substantial rural population. You go to the next county and you're in Appalachian from where I live. So much of the emphasis that I hear about occupational safety and health tends to be either larger industries or businesses that are placed in metropolitan counties. When you go into the rural areas of any of the states, particularly in the south, you're going to find a lot of smaller businesses, in addition to farms, that are simply unaware of occupational health and safety resources that are available. These are mom-and-pop radiator shops, these are the junk yards, these are the sawmills, these can be nursing homes in rural areas. This is quite a number of businesses and industries in rural environments. Unfortunately, so many of the decision makers and leaders and researchers live in urban environments where they're things such as the Gap and Starbucks. So I would suggest a method to identify these rural counties is to get a map, make an overhead, have a plot map of the 50 states and plot out Gap Store, then I want you to take every Starbucks store and look for the regions of the country that don't have any of those dots. That way you will find rural America. It's not particularly a scientific definition, but I think it will get you there.

The other thing that I want to address is a specific hazard. And it's a hazard that has both occupational and non-occupational issues. And it is deaths and injuries from all-terrain vehicles. The all-terrain vehicle is one of the unique hazards that has both recreational and occupational lifestyle issues. They are often used in agricultural areas. They're used in ranching operations. They're used in other types of small industries as well. But at the same time, they're also a recreational vehicle. Some of the issues that we have faced is people have said we really want to study all-terrain vehicles, and I think that NIOSH might want to emphasize the occupational use of all-terrain vehicles as you begin to examine possible PARs and RFAs out there and how we can address this, really, emerging occupational health issue. There's also other funding agencies that need to address this from a recreational vehicle standpoint. And I supposed there's also in the recreational area for ATVs -- in Kentucky we have something called bush-hogging. Does everyone in here know what bush-hogging is? Well, usually it's an agricultural mowing operation, but we have a fair amount of recreational bush-hogging in Kentucky, where the guy just wants to get out on the tractor to get away from the family for two hours. But I think there's a fair amount of this going on with ATVs. It may be very hard to separate occupational from lifestyle, but let's put ATVs a little higher on that list.

Categorized comment or partial comment:

The fourth thing I want to mention has been mentioned before, but I want to put it in a little different term. And that's the issue of partnership. I want to really emphasize how NIOSH could partner more with your state cooperative extension services and your state agricultural extension services. I'm not talking here just about partnership for farm safety and health. As director of one of the agricultural health centers, we do a lot with cooperative extension related to injuries, illnesses, and exposures, and poisoning on farming operations. However, several states, including Kentucky, have developed some rather innovative strategies for putting many types of health and safety information through extension service. We could expand that to the non-agricultural small business in the rural area. So I think there's a connection that could be made between focusing more on rural occupational health and safety using cooperative extension as a conduit. We've got some examples that we're working on now that -- and I know Mississippi has a program with health extension as well. I'm familiar with Texas, who has a very good program in health extension. Kentucky has a program called the Health Education Extension Leadership Program as well. So let's look at cooperative extension as a better way of reaching these rural populations.

Now, my fifth item ties into the use of cooperative extensions. I want to address how people spell NIOSH. So many times I have found that people particularly in rural areas spell NIOSH OSHA. Even though I've never used the word OSHA in a presentation it comes out as NIOSH, oh, you mean OSHA. The bottom line here is an issue of trust. This was mentioned by the extension agent from Pickens

County, Alabama. I think that when you're dealing particularly with rural populations, with small businesses, there is a fear of the federal government that if I get involved with a funding agency that is somehow tied to NIOSH, I've got to sign all of these assurances. I've got to have all of this legalistic looking paperwork. These are the feds, and they have a suspicion there.

I think NIOSH could do a better job in developing partnerships with community groups that would help to alleviate some of this suspicion and mistrust and that initial feeling that I'm here from the federal government and I'm here to help you. We need to get over that barrier.

So my last comment is NIOSH work a little bit more on developing trust relationships with local people by using local opinion leaders to help build that trust. I don't think NIOSH can do it alone, probably they should not do it alone, but they could certainly work with local health departments, local extension services, local opinion leaders to do that. If we're going to have good research in rural occupational safety and health, we're going to have to develop stronger and more trusting partnerships.

Thank you.

Verbal Comment 2006/03/24: Hi. I'm Margo Westmoreland. I'm with the Occupational Safety and Health Administration, OSHA. I am a compliance safety and health officer, which is one of the people who go out and do enforcement in the private and federal sector.

I was listening to all of the people talking about the different research and it's one concern that I have that I would like more research done and that's with Hispanic workers in poultry plants and furniture manufacturers. What I'm noticing is that traditional jobs that other races have done, like de-boning and stuff that has caused musculoskeletal disorders, now I only see Hispanics doing those jobs. Normally, they don't complain. I don't see injuries placed on their logs, but I'm beginning to think that maybe because they're so grateful for the job and they don't speak out and they don't say anything about these disorders that they may not get put on the log. So as far as research, a partnership with someone -- I'd like to see more work done where something can be done that we can get together and find out are they still getting these musculoskeletal disorders that was traditionally given to blacks and whites and everybody who did their job previously that they were getting.

Verbal Comment 2006/03/24: I'm Kris Borre. I'm from East Carolina University. I guess now I'm going to talk as an associate scientist with the North Carolina Agromedicine Institute. In hearing the things that everyone has been saying today, it reminds me that for our work to make a difference we really have to be able to measure what is successful. What kinds of interventions and educational programs are successful? So it's very important that we develop good evaluation. Evaluation research is a little different than basic research, and I think we need to look at what the different models of evaluation research may be.

I'd like to recommend that we try to pull all of these ideas about partnership in broad-based communities together. One of those models that I find useful is a socioecological model that's often used in public health. I'd like to recommend that we look at that. But in order to do this one of the things that we have to do is be able to know who the workers are, where they are, and why they're doing the work. One of the hardest jobs that we have in research is being able to make measurements

when we don't know exactly who those people are. With our special populations, like our Hispanic workers, we often have very poor information on how many there are, where they come from, how long they're here, whether they're really migrants or they're sort of migrants. They switch and work from one industry to the other. They may start in agriculture, then they go to food processing, then they go to construction, and come back. We need to find a way to be able to count people. We need to build trust with those people in order to be able to count them. Even when we work with farmers and farm families, they're often reluctant to tell us about all of the migrant workers that they have contact with and that they're working with because they're worried that they may somehow get in trouble, and they don't want to get in trouble, and they don't want to get their good workers in trouble either.

So I think that we have to do something to build trust and dispel any kind of fear that people are going to be punished in order to keep a good agricultural workforce available to us.

Finally, I think it's really important when we look at what we're risking to lose. In the United States we have very rich farmland. We can produce to feed the world probably. One reason we're so fat is because we control all of the calories. We have more calories today than any other civilized country has ever had in their history. We have more calories here in the United States to eat, to burn, than any other nation does, and we tend to wear it on our hips. But our food supply is coming in from international locations. And if we lose the farm production in our own country we're going to be dependant internationally for our food more and more. That creates a biosecurity risk, but in addition to that, what is it doing to the tradition of our own country and our own rural areas. I think we need to think about all of those things.

So NIOSH has a big role here because NIOSH and CDC together are key in building a healthy safe rural environment where farmers want to work, where agricultural workers can work. They will be key partners with us if they will work in the local communities.

Thank you.

Verbal Comment 2006/03/24: My name is Henry Cole; people call me Hank. I'm from the University of Kentucky. I'm a part-time farmer lifelong. I thought I'd just like to comment on a couple of things here. If you look at the Bureau of Labor Statistics Census for fatal occupational injuries for 2004, they're about 5500 fatal injuries across all industries in the United States. If you look at just the injuries related to tractors, two to three percent of the farming population account for about 3.3 percent of all of those national injuries. Tractor-related injuries and tractor machine-related injuries account for about a third of all of the farm fatalities. If you add the drownings, the falls, the electrocutions, all of the other sorts of things that happen, it looks as though in that year and other years that traumatic injuries to farmers account for nearly ten percent of the annual fatalities. So that's the area that I've worked in for a long time with Bob McKnight and other people. It's the prevention of those types of injuries. Some of the things that are really important if you're going to do that are there are a lot of partners, particularly related to tractors and machinery. Some of those partners are equipment dealers. They are very, very important. That was established a long time ago by Carol Latola (*) and her work. It's been established by more recent work that we've done.

Another group that's very important are the equipment manufacturers. We had a program a number of years ago where the major manufacturers got together and they worked with the dealers to promote ROPs. It made a big difference. Then when that dropped off, for many reasons because of the international competition and all the complications in manufacturing tractors, and not the least of which is having four or five sets of standards for ROPs design, made it very complicated. One of the nice things that's happening is the National Tractor Safety Initiative. So we have nine centers plus the children's centers that are working together over a period of two three years. That group is working together on a series of projects, which include policy, engineering, looking at ROPs design, ways to make them available, ways to distribute them involving the equipment dealers. Another part has to do with the economics of tractor-related injuries and the economics of their prevention. And there's a huge, huge economic advantage of taking these easily implemented measures. In addition, there's also the social marketing aspect to this that's going on where we have 36 focus groups, I think, in nine states where we're taking the initiative to the people in the community and we're asking their advice on this and having a dialogue with them about what needs to be done and in what ways that can become involved and what ways they might want to be involved.

So I think when we're thinking about the injury area it seems to me that it's easier to get someone to put a ROPs on their tractor than it is to change their lifestyle for smoking and diet. Yet, it's hard enough to do that. Anyway, I think that's a good development and I'm very happy that we're able to be involved in this at the Southeast Center, and very happy that NIOSH initiated this tractor safety initiative.

Verbal Comment 2006/03/24: Just a follow-up comment on something that I had mentioned and Bob had mentioned also was about getting the word out and talking about rural safety and health. Of course, Mississippi is from top to bottom considered a rural state. As I had mentioned, we have problems getting the word out about our program, and they're a lot of other fine programs represented in this room. And I don't know if y'all being NIOSH have any ideas on how to get the word out about programs. It seems like we'll put on a good program and a lot of folks don't show. I don't know what the answer really is in that. I know we meet yearly here in Mississippi with the Mississippi Manufacturer's Association, and I know that OSHA puts on some presentations there. We don't really do that because of a lack of staff. I think that would be something to think about. There's got to be some way nationally to get the word out about not only occupational safety and health, but the other fine programs. I thought I'd just throw that out.

There is a need for research to prevent and treat acute chemical exposures, including the development of technology to reduce exposures, evaluation of prognostic diagnostic tests to determine if injury is likely to occur following exposure, and testing of new treatments to reduce the adverse effects of exposure including limiting antidotal therapy. Research and/or training should also be carried out to improve emergency preparedness for hazardous materials incidents. There is also need for review and updating of NIOSH IDLH levels. Particular groups within this sector, especially firefighters, are at highest risk for exposure to hazardous chemicals.

The following is a summary of input NIOSH received from attendees of the Tech Talk session focusing on Healthcare and Social Assistance Sector (HCSA) at the American Industrial Hygiene Conference and Exposition, Chicago, IL, on May 16, 2006.

1. The glutaldehyde substitute ortho-phthaldehyde (OPA) has been associated with sensitization in patients where OPA residue is present on tubes used in urologic applications, believed to be due to inadequate rinsing of tubes prior to use. Questions raised over possible sensitization of healthcare workers. Proper disposal of spent OPA is also a concern. There is a need for a validated sampling and analytical for OPA.

The issue of nonionizing radiation health effects needs to come to the 21th century in the USA. The public is exposed to many radiating products as a primary or secondary outcome of the products` use. Energy efficient products are popular but how about encouragement in producing/promoting low-EMR products too? This would obviously improve worker safety and public acceptance of modern technology.

Categorized comment or partial comment:

Verbal Comment 2006/02/23: I offer the following thoughts for the ongoing support of occupational surveillance generally, and occupational disease surveillance specifically. Occupational surveillance lacks the prominence of a Sector or Cross-sector program within the National Institute for Occupational Safety and Health (NIOSH) Program Portfolio structure. So, as NIOSH moves forward under the Program Portfolio framework, NIOSH leadership should be mindful of the importance of injury, illness, hazard, and exposure surveillance data for establishing research agendas, making judgments about research priorities, and developing program performance metrics. Many of my remarks speak to disease surveillance, but are generally applicable to occupational surveillance.

Surveillance defined. Surveillance is the collection, analysis, interpretation, and dissemination of data describing a health related event, exposure, or hazard. Surveillance is critical to effective occupational safety and health programs. It enables decision-makers to identify the problem and the affected group of workers. Surveillance also describes the magnitude and severity of an issue, and assesses progress made in reducing the burden of occupational injuries and illnesses. As a result, surveillance programs create added value by establishing baseline and trend data, assisting in priority-setting and providing information to guide research, interventions, control, or prevention.

Congressional oversight in the 1980s. In passing the Occupational Safety and Health Act of 1970 (OSH Act) [29 USC § 651 et seq.], Congress mandated extensive authority to the Secretaries of Labor and

Health and Human Services to develop regulations requiring employers to record and report occupational illness, to conduct medical examinations, and to notify employees of clinically significant results [29 USC §§ 655(d)(7), 657(c) and (g), and § 669(a)(5)]. In addition, the OSH Act requires the Secretary of Labor to "compile accurate statistics on work injuries and illnesses which shall include all disabling, serious, or significant injuries, and illnesses, whether or not involving loss of time from work." [20 USC § 673(a).] This authority has been delegated to the Bureau of Labor Statistics (BLS). Unfortunately, much of this broad authority remains unused.

Accurate and reliable data on occupational disease is essential for informed public policy decisions, employer and employee awareness of health problems, and employers' ability to correct harmful working conditions. Congress recognized the importance of good information systems when it passed the Occupational Safety and Health Act of 1970 (OSH Act) [29 USC § 651 et seq.] Today, 35 years after its passage, the state of present national disease surveillance systems is - as described by Dr. J. Donald Millar, the former Director of the National Institute of Occupational Safety and Health (NIOSH) - "90 years behind...[surveillance] of communicable disease." No reliable national estimates exist today, with the exception of a limited number of substance specific studies (such as on asbestos), on the level of occupational disease, cancer, disability, or deaths. It cannot be meaningfully determined if diseases from chronic exposures to hazardous substances represent a greater problem today than when the OSH Act was passed in 1970. The lack of complete, reliable, and accurate injury and illness data greatly hampers any broad-based evaluation of the occupational safety and health programs, and threatens the statistical foundations for the current NIOSH Program Portfolio of Sector and Cross-sector research. Furthermore, the existing data from employer logs, used in BLS's Annual Survey, are generally viewed as unreliable and under-report occupational disease.

Accurate and reliable data on occupational disease is essential. For public policy, these data assist the Occupational Safety and Health Administration (OSHA) and NIOSH in setting and revising health standards under § 6 of the OSH Act, as well as setting enforcement and research priorities. The early reporting of disease causing exposures to vinyl chloride and kepone heightened the public awareness of previously undisclosed dangers of occupational exposures. Occupational disease information is also essential to employees and employers in alerting them to disease patterns as early as they become clinically significant. This is particularly important to the health of the worker, and is also significant to the employer who can take corrective action and understand the full economic cost of doing business.

BLS's ability to implement an occupational disease statistics program is hampered by the nature of occupational disease study, where expertise in epidemiology and occupational medicine is required. If the purposes of the OSH Act are to be achieved – if effective measures of prevention of occupational disease through elimination of hazards in the workplace are to be developed, and the effectiveness of these programs is to be evaluated – NIOSH must find solutions to the problems of obtaining adequate data on occupational diseases.

Future Directions and Challenges for NIOSH

Many of the following comments reflect the ongoing national dialogue on developing and improving the nation's occupational surveillance. The major "bullets" are distilled from the work of the NIOSH NORA Surveillance Research Methods Team.

- NIOSH must maintain a strong national surveillance program to establish priorities. Future surveillance should (1) maintain ongoing surveillance and disseminate of surveillance data as guided by

the NIOSH Surveillance Strategic Plan, and (2) respond to emerging occupational health and hazard issues.

Problem: Federal surveillance of occupational disease is fragmented among many agencies; i.e., NIOSH, NCHS, NCI, SSA, and CDC. The current activities of these federal agencies do not assure the nation's workers access to comprehensive occupational surveillance data in the United States.

Comment: Comprehensive information for occupational disease, disability, and mortality is needed to (1) develop effective measures of prevention of occupational disease through elimination of hazards in the workplace, and (2) evaluate the effectiveness of these programs. The one agency which focuses on the surveillance of occupational disease is NIOSH. NIOSH has long-standing expertise both in the study of occupational disease and in focusing research toward better a understanding of the etiological association between disease and workplace hazards and exposures. NIOSH is well-equipped to take on the central role and responsibility for the ongoing collection, analysis, interpretation, dissemination and use occupational disease statistics.

Problem: No reliable national estimates exist today on the magnitude and trend of occupational cancer, disability, and mortality.

Comment: It cannot be meaningfully determined if diseases from chronic exposures to hazardous substances represent a greater problem today than when the OSH Act was passed in 1970. State and local mortality, cancer incidence, and disability data have significant potential as data elements within a comprehensive surveillance system for occupational disease. Such data have yet to realize their potential because of incomplete or inconsistent data collection through local and State-level data sources, insufficient resources to support State and local agencies to collect or compile these data, as well as limited and inconsistent coding and classification of employer\employment (i.e. SIC or NAICS codes) and occupation (Census occupational titles and codes) information.

Problem: Employers are unable to record, and thus report, many chronic and latent occupational diseases.

Comment: Employee and household surveys are excellent alternative sources of data on the prevalence of disease in working populations. The National Health Interview Survey (NHIS) was adapted in 1988 for occupational surveillance purposes, gathering a wide range of occupational health and safety data. Medical examinations provide more accurate methods for determining occupational disease, disease precursors, and biomarkers. The National Health and Nutrition Examination Survey (NHANES) is used by CDC to gather a wide range of population demographic and health data. The NHANES could be adapted to monitor the population for selected occupational conditions and exposure measures.

Problem: BLS surveys of nonfatal occupational illnesses are unable to identify or report diseases with a long latent period. There is no adequate evaluation of the extent of under-recognition, under-reporting, or over-reporting of nonfatal occupational injuries and illnesses.

Comment: NIOSH should establish a dialogue with our federal partners, OSHA and BLS, on the feasibility of undertaking a comprehensive Quality Assurance Program on the OSHA logs. This dialogue should explore options to assess the accuracy and reliability of employer logs and the differences, if any, in levels of occupational disease as found in medical records, the OSHA logs, the Annual Survey forms, and employee surveys. NIOSH should provide epidemiologic, industrial hygiene, medical consultation and other assistance as needed. Such efforts could be expanded to general recordkeeping and reporting for

nonfatal injuries. As possible collaborators in such a program, NIOSH's state-based surveillance partners have significant experience in state-level data sources. These data sources should be explored to better understand disease under-reporting.

- NIOSH should support new program initiatives and projects to develop and adapt methods for state and non-governmental partners. New surveillance programs and research methods are advocated in the NIOSH surveillance strategic plan, as well as the reports of NORA research priorities for cancer, emerging technologies, exposure assessment methods, musculoskeletal disorders, traumatic injury, reproductive outcomes, and workplace organization factors.
- NIOSH should link the results from state-level surveillance to intervention and prevention activities. This could produce significant improvements in occupational safety and health. Recent evaluation and planning activities reinforce the importance of expanding and enhancing state-based occupational surveillance.
- NIOSH should advocate an expanded surveillance research program that focuses upon smaller employment establishments in a private sector surveillance research initiative. An estimated 7 million private sector establishments employed 115 million workers in 2001. Establishments with 19 or fewer employees accounted for 85.7% of all workplaces, but only 24.1% of all employees. Establishments with 100 or more employees accounted for only 0.7% of all workplaces, but over 46.8% of all employees.
- NIOSH should establish Collaborating Surveillance Research Centers of Excellence to guide the development of surveillance to prevention practices including new R & D teams that harness the strengths of occupational health researchers, non-government organizations, insurance carriers, and public health agencies. Specific activities within the Centers should include (1) providing technical assistance and consultation with respect to developing and evaluating occupational surveillance methods; (2) establishing outreach programs to identify specific methodological and research needs, evaluate occupational surveillance follow-up methodologies, and develop and evaluate innovative strategies for improving the quality and utility of surveillance data; and (3) expanding surveillance and surveillance research that focuses on smaller scale employment establishments.

A manufacturing sector roundtable was held during the 2006 American Industrial Hygiene Conference and Exposition in Chicago on May 16. Six people attended and each provided comments in what was a good and lively interactive discussion. Participants were from OSHA, private industry, consulting, and academia, which made for a well rounded group of discussants. Below is a summary of those discussions expressed as concerns shared:

- Workforce: Downsizing of workforce in the United States
- Workforce: Aging of the U.S. workforce
- Workforce: Outsourcing of jobs to other countries
- Migrant Workers: the makeup of a constantly changing workforce makes addressing hazards difficult. Workers that are trained on one day may move to a different job/worksite within a few days. Medical monitoring of these transient work populations is difficult and makes surveillance of health effects difficult.

- Hazard Communication: Some thought needs to go into how to better communicate hazards to the workers. Current method of cataloging MSDS's and providing them in a binder are not useful in communicating with the worker.

- Hazard Communication: Need better communication strategies to account for varied workforce. NIOSH has many good publications in Spanish but not in many other prevalent languages (like Vietnamese and others). These strategies must also consider workers who are not literate in any language (consider use of pictograms).

Categorized comment or partial comment:

- Noise: Need more practical guidance on how to control noise hazards. NIOSH used to publish a noise control booklet which was very useful but it is no longer available. Employers need specific guidance on simple methods for noise abatement.
- Noise control: Need guidance on good abatement methods--commenter sees more problems in noise control than control of chemical hazards.
- Noise: need better dissemination of noise control measures. Need assessment of hearing conservation programs. Need to develop new/better hearing protection devices/schemes. Need evaluation of hearing protection effectiveness like we do for respiratory protection.
- Noise: Need improved performance of hearing protection and conservation programs. Lack of predictive measures for hearing loss make prevention difficult--only trailing indicators are available (e.g. hearing loss).

Protecting Workers from the Known and Emerging Health Risks of Non-ionizing Radiation - Presentation to NORA Town Hall Meeting

-- Definition on non-ionizing radiation (NIR) - electric and magnetic fields (EMF) which are weaker than X-rays and gamma rays that ionize molecules, but can still have biological effects at higher intensities.

-- Although UV, visible light, lasers, and IR all have well-known health risks, NIOSH research has focused on radio frequency (RF)/microwave radiation (300 gigahertz - 10 megahertz) and EMF at power frequencies (50/60 Hz).

- o As a rule, NIR toxicity increases with frequency. So RF radiation is more toxic, but power frequency EMF is more prevalent.

-- Known health risks from high intensity EMF:

- o tissue heating from RF (e.g broadcast antenna construction and maintenance, plastic heat sealers)

- o electrostimulation of nerves from power-frequency EMF (e.g. high-voltage transmission line workers and induction metal furnaces)

- o exposure limits exist for these health effects, so DART's research agenda has concentrated on control technologies:

Research priorities on NIR control technologies - from 'NORA at Nine' [Editor's note - published as "The Team Document - Ten years of leadership advancing the National Occupational Research Agenda," DHHS (NIOSH) Publication No. 2006-121. and available at <http://www.cdc.gov/niosh/docs/2006-121/pdfs/2006-121.pdf>, see p. 92]:

- Improve instrumentation and techniques to address measurement and control exposures in the near-field

- Improve engineering controls, personal protective equipment (PPE), and monitoring instruments for dealing with NIR exposure in the workplace.

- Encourage participation of both industrial hygienists and management to address NIR workplace hazards effectively.

- Improve worker and safety professionals' awareness of NIR issues through training

-- Possible health risks from EMF exposures below the exposure limits.

- o Power-frequency magnetic fields are a Possible Human Carcinogen, according to the International Agency for Research on Cancer (IARC) and NIEHS. These evaluations are based on epidemiologic studies of cancer and neurodegenerative diseases at levels less than 1/1,000 th of the exposure standards.

- o New epidemiologic evidence of acoustic neuromas and brain cancer from long-term use of cell phones.

- o DART research has concentrated on improved methods of exposure assessment for occupational epidemiologic studies conducted with partners at IARC, NCI, and the Electric Power Research Institute. The goal is to determine whether these low-level EMF are truly a health hazard, and therefore the present paradigm for setting health standards needs to be re-examined.

- o DART and EID also starting risk assessment research on how to manage workplace exposures to these "possible" health risks.

-- Surveillance of emerging wireless technologies.

- o Cell phones are an example of potential public health impact of any unforeseen health effects from the new wireless technologies.

- 65% of the US population are cell phone subscribers

- Cell phones at maximum power can expose the brain to radiation up to 97% of the current US health standard.

- o New wireless technologies are coming out constantly for communication, surveillance, tracking inventory, data transfer, and computing. An implantable chip has just come on the market.

-- NIR and NORA

- o NIR is a multi-faceted health hazard that fits into many of the present NORA categories, but is currently recognized only by Engineering Controls.

Below are all the places where NIR might fit within the new NORA Program Portfolio.

Sectors:

- Manufacturing

- Transportation, Warehousing & Utilities

- Public & Private Services

Cross-sector Programs:

- Cancer, reproductive, cardiovascular, neurologic & renal diseases

- Global collaboration

- Health hazard evaluations

Coordinated Emphasis Areas:

- Exposure assessment

- Engineering controls

- Surveillance

O Suggested NIR Research Priorities

- Maintain NIOSH's expertise in NIR research.

- An epidemiologic study of occupational RF and chronic health effects (cancer, neurologic, etc.) – collaboration with IARC

- RF protective suits

- Epidemiologic studies of power-frequency magnetic fields with the new exposure assessment tools developed by DART

Interventions to reduce occupational exposures to power-frequency EMF
Health Hazard Evaluations and surveillance on new NIR technologies.

Categorized comment or partial comment:

Verbal Comment 2006/02/23: MSDs are significant problem across all sectors. The problem is that MSDs are multifactorial disorders and therefore difficult to study. They account for a significant fraction of the cost of all occupational injuries and illnesses. Low back pain alone accounts for 35% of all occupational injuries and illnesses. A single case of back injury costs all most double in comparison of all injuries and illnesses. Nurses - 1 in 12 leave because of back pain. Intervention studies, especially prospective, have been neglected. It is true that there are a lot of biases and confounding factors in this type of research, but it is nonetheless important. Need to look at economics as well. For example, lost workdays are a tremendous cost to society. Companies may not be willing to participate in interventions unless they can be shown to save money - studies have shown that some ergonomic programs pay for themselves in reduced costs to the employer over time. Look at interaction of MSDs and aging - what are the crossover effects?

Verbal Comments 2006/02/23: Infertility is an issue among workers. Evidence has shown that workplace exposures to chemicals as well as stress and ergonomic factors have an adverse effect on reproductive health. However, these issues are not necessarily something that a company will observe. When people are having fertility problems, there may not be public discussion - may not tell anyone. It's not like other occupational health issues (i.e., back pain, hearing loss) - not something that companies track, so it is much more difficult to gather this sort of data. Our research has been at looking at reproductive health as a fertility status, not pregnancy loss. The process has often been looking at literature on toxicology studies of animals or reviewing case studies. I suggested that we look closely at the scientific evidence as we move forward - There needs to be a mechanism to look at the scientific literature and at trends occurring in certain workplaces or sectors so that we recognize these things and reproductive health is not forgotten as a large sector does not have worker complaints.

Grower faces record fines for pesticides

The state wants to know whether use of the toxic chemicals led to birth defects in workers` babies

Francisca Herrera, a former migrant worker for Ag-Mart, holds her son Carlos Candelario, 9 months old, at home in Florida City, Fla. Carlos was born without arms or legs. His mother worked in Florida and North Carolina. This photo was taken in September.

Palm Beach [Fla.] Post Photo by Taylor Jones

Kristin Collins, Staff Writer

The corporate tomato grower Ag-Mart was virtually unknown in North Carolina four years ago when it planted hundreds of acres of grape tomatoes in a swath of coastal plain.

Today, the Florida company is accused of the worst pesticide violations in North Carolina history. And state health officials are investigating whether pesticide exposure is to blame for three deformed babies born to Ag-Mart employees -- one with no arms and legs and another with no visible sex organs.

Last fall, the N.C. Department of Agriculture's pesticide section fined Ag-Mart \$184,500, the department's largest fine ever. Inspectors say it exposed workers to a host of poisonous chemicals, some linked to birth defects and other health problems. Four months later, Ag-Mart and the state are still negotiating payment.

"It's cheaper for them to pay fines than it is for them to operate aboveboard," said Fawn Pattison, head of the N.C. Agricultural Resources Center, a nonprofit that opposes the use of toxic pesticides.

Ag-Mart declined to comment about the violations.

"Our products are safe and have always been safe, and Ag-Mart stands behind its commitment to its workers, retail customers and consumers," said Leo Bottary, a company spokesman.

Since the violations were issued, an Ag-Mart worker named in the state's report says he was fired for talking with agriculture department inspectors. The company did not respond to questions about the firing.

N.C. Agriculture Commissioner Steve Troxler, whose department oversees enforcement of pesticide laws, declined to comment about the company.

Ag-Mart sells its tiny tomatoes, which it grows in North Carolina, Florida, New Jersey and Mexico, under the brand name "Santa Sweets" at grocery chains all over the United States. Their distinctive packaging features three cheerful tomatoes named Tom, Matt and Otto.

Wal-Mart, the nation's largest grocer, pulled the tomatoes off shelves because of concerns over pesticide violations. Last week, Florida Legal Services, a federally funded advocacy group for the poor, said it was trying to negotiate a settlement for hundreds of Ag-Mart workers who say they were sprayed with pesticides in North Carolina and Florida.

History of violations

Ag-Mart faces a \$111,200 fine for pesticide violations in Florida. And Ag-Mart's problems in North Carolina were not its first here.

In 2003, the state Labor Department fined the company \$12,600 for failing to properly train employees using pesticides and for not giving them proper protective equipment. The company paid just over \$10,000.

At the same time, labor officials found hundreds of Ag-Mart workers living in unregistered housing that didn't meet basic safety regulations. The company did not provide housing for its legion of seasonal workers, many of whom said they were in the United States illegally. It left arrangements to crew leaders, who supply labor for the company.

Labor officials said they wanted to fine Ag-Mart for the housing violations but could not. Under the law, Ag-Mart did not "own or control" the housing. Three crew leaders who arranged the housing paid more than \$15,000 in fines.

"I feel strongly that they could do a better job," said Regina Luginbuhl, chief of the Labor Department's agricultural safety and health bureau, which handled the 2003 violations.

Last week Ag-Mart officials refused to say how much land the company farms in North Carolina or how many seasonal workers it uses. State officials say it has about 1,100 acres, requiring about 500 workers, in Brunswick and Pender counties.

The Agriculture Department fined the company for 369 violations of state pesticide laws when it visited farms last spring. Ag-Mart was using 18 pesticides on its crop, six of which the U.S. Environmental Protection Agency classifies as among the most dangerous to workers and the environment.

Job conditions faulted

According to the October violation notice, the company failed to train workers who handled pesticides, using an unqualified trainer who showed an unapproved video. It didn't supply workers with proper safety equipment and didn't have adequate water for them to rinse their eyes.

The notice says the company was also burning empty pesticide containers beside a field, a violation of state law.

"They knew that they should not burn pesticide containers" in North Carolina, the notice says, an Ag-Mart manager told inspectors, "but Ag-Mart President Mr. Donald Long told them to stop sending empty containers to the landfill and to burn them on site."

The company applied one of its most dangerous pesticides more than three times as often as law allows, the notice said. And it allowed employees to work in freshly sprayed fields that weren't safe to re-enter for up to seven days, the notice said.

One worker told inspectors that he sometimes worked in the fields while the pesticide methyl bromide was being applied. By law, workers cannot re-enter a field until 48 hours after the application of methyl bromide, which is known to deplete the ozone layer. At least one study has linked methyl bromide to cancer in farmworkers.

The worker, Oscar Hernandez, said in a telephone interview last week that during the 16 months he worked for Ag-Mart, tractors often sprayed fields without warning while he was collecting debris and working on irrigation systems in them. He also worked as a pesticide handler and said he received no training for the job.

Hernandez, 36, said through a translator that he sometimes felt dizzy and agitated, almost drugged, while pesticides were being sprayed. He said he still suffers from headaches, nervousness and memory loss -- all documented effects of pesticide exposure.

Hernandez said he was given no drinking water while he worked. He said his managers got angry if he asked for it.

Hernandez left the company in the summer of 2005 and now works in construction in New Orleans. He has retained a lawyer, Carol Brooke of the N.C. Justice Center, a nonprofit advocacy group for the poor.

Brooke said Ag-Mart fired Hernandez because he talked with state pesticide inspectors. Hernandez has filed a claim with the Department of Labor's employment discrimination bureau and may file a lawsuit. He is not the only former employee threatening to sue.

Babies deformed

A few months before state inspectors arrived at the North Carolina farms, three former Ag-Mart workers bore babies. The women lived in the same labor camp in Florida when they became pregnant, and all worked for Ag-Mart in Florida and North Carolina during their pregnancies, said their lawyer, Andrew B. Yaffa, who practices in Florida.

The first baby, born in December 2004, had no arms and legs. The second, born in early February 2005, had a severely underdeveloped jaw. The third, born two days later, had a missing nose and ear and no visible sexual organs. That baby died within days.

The company has since stopped using five chemicals linked to birth defects.

Ann Chelminski, an epidemiologist with the N.C. Department of Health and Human Services, said she is studying whether the deformities could have been caused by exposure to pesticides. She said she expects her report to be completed in a few weeks.

Florida health officials did a similar study last fall, looking at the mothers' exposure while they worked there. The Collier County Health Department concluded that pesticides could not be definitively linked to the deformities.

Bottary, the Ag-Mart spokesman, said the Florida county's report showed pesticides were not to blame. "An independent study found no link between birth defects and pesticide use at Ag-Mart," he said.

Those who study pesticides say it is difficult to prove that pesticides cause specific health problems. Yaffa, the women's lawyer, said he sees no other explanation. He said he plans to sue on behalf of the boy with no limbs, Carlos Candelario, in the next few months.

He said that since the three women came forward, he has found a fourth former Ag-Mart employee whose baby was missing a part of its brain and later died.

He said two of the women had aborted fetuses with deformities.

"They're living in the same place," Yaffa said. "They're working in the same fields. It's screaming. The alarms are going off. Something's wrong."

Tomato grower Ag-Mart has been charged with the largest violation of pesticide laws in North Carolina history. But state officials say they can do little to ensure that the company changes its ways.

Ag-Mart's 1,100 acres in Brunswick and Pender counties will get more frequent checks from state Agriculture Department inspectors, said Patrick Jones, the pesticide section's enforcement manager. But there are only seven inspectors to check on more than 26,000 private pesticide applicators in North Carolina, he said.

"We can check and check on them," Jones said. "But we can't just stay there all the time."

Ag-Mart, based in Florida, established its North Carolina farms in 2002. It sells its grape tomatoes nationwide under the brand name "Santa Sweets."

Before last spring, when the federal Environmental Protection Agency tipped off North Carolina officials about problems with Ag-Mart's pesticide use in Florida, the state Agriculture Department had never inspected Ag-Mart's farms.

Agriculture officials didn't inspect in 2003, after the N.C. Labor Department cited the company for pesticide violations -- which they found while investigating illegal worker housing. The Labor Department has authority to cite some pesticide violations, even though it is the Agriculture Department's duty to enforce those laws.

When Agriculture inspectors visited the farm last April, they found the state's worst pesticide violations ever.

According to the state's report, field hands were working in freshly sprayed fields that weren't safe to re-enter for up to seven days. Workers had inadequate training and protective gear. One toxic pesticide was applied more than three times as often as the law allows.

North Carolina health officials are investigating whether the chemicals are to blame for three deformed babies born to former Ag-Mart workers. One has no arms or legs, one an underdeveloped jaw, and one no visible sex organs.

Ag-Mart denies breaking any laws and says the birth defects are not related to pesticides.

"Ag-Mart not only obeys the law, but sets a higher standard when it comes to worker and product safety," the company's publicist, Leo Bottary, said in a statement. "We do so because we value and depend upon our people; because we, too, are consumers of our product; and because it's the right thing to do."

Agriculture Commissioner Steve Troxler said this week that he had not read his department's report on Ag-Mart and had not been briefed on the case.

Troxler said most farmers do a good job of obeying pesticide laws. The department, he said, pursues scofflaws with vigor. "We will take every step we can take to make sure it stops," Troxler said.

In fact, his powers are limited. Administrative fines are virtually the only enforcement tool, and state law limits them to \$500 per violation. Fines cannot dent the budget of a multinational company such as Ag-Mart, which is owned by a Philadelphia conglomerate and has farms in three states and Mexico.

Ag-Mart is still negotiating with the Agriculture Department, and the company will almost certainly pay less than the \$184,500 the state seeks. State law requires that agencies try to settle fines to avoid costly legal hearings.

Beyond fines, the state Pesticide Board can revoke a farmer's license to apply pesticides. But that would have little impact on Ag-Mart because those licenses go to individuals, not companies. Ag-Mart could simply bring in new employees to apply pesticides next year.

Jim Burnette, head of the pesticide section, said fines are ineffective in cases such as Ag-Mart's. But he said he hopes scrutiny and public pressure will force the company to improve its practices.

Already, the Florida press has lambasted Ag-Mart, and Wal-Mart has removed Ag-Mart products from the shelves. Under pressure, Ag-Mart announced that it would stop using five pesticides linked to birth defects.

Burnette said there is nothing he can do to ensure that the company keeps its promise to stop using those pesticides. But he said he thinks the company is making "meaningful changes."

"There are people who say, if you have these significant violations, you should fine them, you should put them out of business," Burnette said. "If you put the company out of business, those workers are out of jobs."

Ag-Mart employs about 500 workers, most of them seasonal migrants, in North Carolina, state officials estimate.

Critics say state officials don't want to crack down on companies such as Ag-Mart.

Most state departments, including agriculture, are both advocates and law enforcers for industry. Their commissioners are elected and rely on contributions from industry leaders to finance their campaigns.

"The enforcement agencies see themselves as allies of the businesses that they're trying to enforce these rules against," said Carol Brooke, a lawyer with the N.C. Justice Center, a nonprofit advocacy group for the poor.

Regina Luginbuhl, head of the Labor Department's agricultural safety and health bureau, said she knows the frustration of trying to protect Ag-Mart workers.

In 2003, she found many of them living in an abandoned hotel strewn with trash and infested with roaches. Because the company used labor contractors to arrange worker housing, she couldn't hold the company responsible. Instead, she fined three labor contractors.

Today, Luginbuhl said, she has no way to know whether Ag-Mart's workers live in better conditions. She has no authority to inspect unless the company or its labor contractors arrange the housing.

Kristin Collins, Staff Writer

Two field workers who gave birth to deformed babies were illegally exposed to pesticides more than 20 times each while they picked tomatoes in Eastern North Carolina, N.C. Department of Agriculture data show.

A third worker, who spent most of her pregnancy working in Florida, was exposed four times during the less than six weeks she worked in North Carolina, the data show.

All worked for Ag-Mart, a Florida-based tomato grower, and they were illegally exposed to a host of chemicals as often as three times a week, the documents show. Three of the 15 chemicals are linked to birth defects in lab animals.

One baby had no arms or legs. Another had a deformed jaw. The third had no nose and no visible sex organs and died soon after birth.

The women's exposures were illegal because they worked fields too soon after pesticides were sprayed, agriculture data show. To protect workers from harmful effects, many pesticides require that workers be out of the fields for anywhere from a few hours to two days after spraying.

Ag-Mart says that none of its workers were illegally exposed to pesticides and that the Agriculture Department misinterpreted its records.

Andrew Yaffa, a lawyer who represents the three women, said the documents tell only part of the story.

"Sometimes it was more than once a day," Yaffa said. "They would come out of the fields covered. Their clothes would be green with pesticides. Their throats would be dry. They would be coughing. They were suffering from skin ailments."

Ag-Mart, which is privately held, grows about 1,100 acres of grape tomatoes in Brunswick and Pender counties, 125 miles southeast of Raleigh. The company employs about 500 people there during the growing season. It sells tomatoes under the brand name Santa Sweets.

State officials have been investigating Ag-Mart for nearly a year. The Agriculture Department has charged the company with 369 violations of state pesticide law, the largest pesticide case in state history. The company will have a hearing before the state Pesticide Board on March 28.

The state Department of Health and Human Services is investigating whether the three babies' deformities are linked to pesticides. That report is expected in the next few weeks.

Until now, the evidence against Ag-Mart has remained private, because neither the state Health Department nor the Agriculture Department has finished its investigation. Last week, the Agriculture Department opened its files to The News & Observer.

State agriculture officials went through reams of data that Ag-Mart provided to determine whether workers went into fields too soon after pesticides were sprayed.

The News & Observer looked at the dates of violations and at the work records of the three mothers to determine how often they were working in fields where violations occurred. The data show that the women frequently worked in fields on days when pesticides were applied.

Ag-Mart spokesman Leo Bottary said last week that pesticides were always applied to sections of the field where workers were not present. He said the company's records aren't detailed enough to show which part of a field each worker was in.

"There's nothing in those records that would put anybody in a particular section" of a field, Bottary said.

The company will keep better records in the future, he said.

State agriculture officials say they can work only with the data the company provided. "We put the burden of proof on them," said Patrick Jones, enforcement manager for the Agriculture Department's pesticide section.

Worker advocates who have spent years following Ag-Mart employees say Ag-Mart often exposes its workers to pesticides.

Greg Schell, a lawyer with Florida Legal Services, said his staff surveyed 89 Ag-Mart workers in June. About half said they had been sprayed with pesticides within the past three months. Some, whose job it was to apply pesticides, said they sprayed fields filled with workers, Schell said.

"We've interviewed applicators who said they did that all the time for Ag-Mart," Schell said. "They just told us all kinds of stories, and I don't think they're all making it up."

Exposed in pregnancy

In 2004, the three women, Francisca Herrera, Sostenes Salazar and Maria De La Mesa Cruz, were among hundreds of Ag-Mart workers who traveled with the harvest, picking tomatoes in the company's fields in North Carolina, Florida, New Jersey and Mexico. All three are illegal immigrants.

Herrera and Salazar became pregnant in April, De La Mesa Cruz in May.

Yaffa said none of the women were available to comment for this story. With Yaffa's help, Herrera filed suit against the company Feb. 28, claiming that pesticide exposure is responsible for her son's deformities. She is asking for an undisclosed amount in damages.

The agriculture records show that Herrera, whose boy was born in December 2004 with no arms and legs, started working in North Carolina in mid-April. During her first trimester, when a baby's limbs form, she was illegally exposed on 11 different days, the Agriculture Department data shows.

By the end of September, she had been exposed on 22 days. On four of those days, records show, she was exposed at least twice -- once at the company's Brunswick County farm and once at the Pender County farm.

Salazar, whose son had a severely underdeveloped jaw, started work in North Carolina in June 2004. She was illegally exposed on 25 days during the next 3 1/2 months, the analysis shows, seven of them during her first trimester.

De La Mesa Cruz, whose child died, didn't start work in North Carolina until mid-September. She was exposed four days by the end of that month, the analysis shows.

Salazar and De La Mesa Cruz also worked in Florida and were exposed to pesticides there during their pregnancies, a Florida study shows. Their babies were born in February 2005.

Among the chemicals that the women were exposed to are Monitor, Agri-Mek and Penncozeb. Ag-Mart has dropped those three because some studies link them to birth defects.

The Collier County (Fla.) Health Department studied the women's exposure there and concluded last fall that there was no definitive link between the deformities and pesticide exposure in that state. That study did not look at the women's exposure in North Carolina.

North Carolina officials say they are looking at the workers' exposures in both states.

Experts say it is nearly impossible to prove that pesticide exposure caused a specific baby's birth defect.

Ted Schettler, a Massachusetts doctor and science director with the Science and Environmental Health Network, an Iowa-based nonprofit that studies the impact of pesticides on health, said medical literature is full of stories about farmworkers with deformed children. But he said he doesn't know of a single completed study in which farmworkers were monitored during their pregnancies. As a result, when a deformed child is born, no one knows what pesticides, if any, were in the mother's bloodstream during her pregnancy.

"Assigning responsibility here is incredibly difficult," Schettler said. "The reality is that we don't know what causes most birth defects."

Grower faces new allegation

Ag-Mart worker says he was denied protective gear while he worked with a pesticide

KRISTIN COLLINS, Staff Writer

The state is investigating a new allegation that tomato grower Ag-Mart failed to protect its workers from pesticides.

The company, which farms about 1,100 acres in North Carolina, already faces the state's largest fine for 369 pesticide violations. State health officials are studying whether pesticide exposure is to blame for birth defects in three severely deformed babies born to Ag-Mart workers.

Now, a worker claims that his supervisors refused him protective gear last week while he was working with methyl bromide, a gas that kills organisms in the soil and can have serious health effects for people who are overexposed. State pesticide officials said they are investigating.

"He was being exposed to something, and his face was burning," said Carol Brooke, an attorney for the N.C. Justice Center, which advocates for the poor and represents some Ag-Mart employees.

The worker called Brooke, and she complained to the state Department of Agriculture's pesticide section. Brooke said the worker wants to remain anonymous.

Pat Jones, pesticide enforcement manager, said an inspector visited one of the company's two farms in Brunswick and Pender counties Wednesday. Jones would not say whether any new violations were found because the case is under investigation.

The brand of methyl bromide that Ag-Mart typically uses, MBC Soil Fumigant, requires that workers use a face shield or a respirator when working with the chemical.

Ag-Mart spokesman Leo Bottary said the complaint comes as a surprise. He said Ag-Mart has a hot line for workers to report problems -- and hasn't heard anything from North Carolina workers this year.

The North Carolina growing season has not yet begun for Ag-Mart, a Florida company that also grows tomatoes in Florida, New Jersey and Mexico. Brooke said only a handful of employees are in North Carolina preparing fields for the planting of grape tomatoes.

The company sells its tiny tomatoes under the brand name "Santa Sweets." It also packages tomatoes for several major grocery chains.

Settlement efforts

The company is still trying to settle the violations for which the state Agriculture Department handed out a fine in October. On Tuesday, the state Pesticide Board took an unusual step and sent the case to

the Office of Administrative Hearings. An administrative law judge will hear the evidence and make a recommendation to the board.

The board, composed of volunteers appointed by the governor, will make the final decision on the company's punishment.

Board members said they aren't qualified to sort through days' worth of legal evidence. State law allows them to send the case to a judge.

"All the details have got to be right," said board member Benson Kirkman. Trying to handle the hearing "would've been sort of like walking through a minefield with shoes that are 3 feet long," Kirkman said.

State pesticide inspectors took six months to build the case against Ag-Mart. They interviewed workers and sorted through reams of records and employee work schedules.

According to the October violation notice, the company failed to properly train workers who handled pesticides. It didn't supply workers with proper safety equipment and didn't have adequate water for them to rinse their eyes.

The company applied one of its most dangerous pesticides more than three times as often as law allows, the notice said. And it allowed employees to work in freshly sprayed fields that weren't safe to re-enter for up to two days, the notice said.

The notice also says the company was burning empty pesticide containers beside a field, a violation of state law.

The \$184,500 fine was a landmark for a department that typically fines farmers who violate pesticide laws less than \$1,000.

Ag-Mart officials have said that state inspectors misinterpreted company records. The company says it never sent workers back into treated fields before the law allowed.

Ag-Mart spokesman Bottary said the company welcomes an impartial hearing. "We obviously feel very confident about our position," he said Tuesday.

The company's Raleigh attorney, Mark Ash, said Ag-Mart has not given up on negotiating a settlement, which is how most pesticide violations are handled.

But after months of unsuccessful negotiations, some Pesticide Board members said the time for a settlement has passed.

"It's beyond that," said board Chairman Scott Whitford after Tuesday's meeting. "We're going to court now."

Board members said they knew nothing about the new allegations against Ag-Mart.

State can't prove birth defect link

A report calls for a great increase in oversight in the use of the chemicals

Sostenes Salazar with son Jesus, who has jaw deformity.

Palm Beach Post File Photos

Story Tools Printer Friendly Email to a Friend

Enlarge Font Decrease Font

Three cases of birth defectsFRANCISCA HERRERA

Child`s birth defect: No arms or legs

Pesticide exposure: Was exposed during the period when the baby`s limbs formed to chemicals that cause limb defects in lab animals

Other risk factors: None known

Prenatal care: Began in fourth month of pregnancy; denies use of alcohol, tobacco, drugs or medications

Her statement: Herrera told state investigators that she was sprayed with pesticides while working in the fields, that she was never warned about entering fields where pesticides had been sprayed, and that she was not given equipment to protect her from pesticides.

Report`s determination: "Data indicates a plausible association between possible pesticide exposure and the limb deficiencies."

SOSTENES SALAZAR

Child`s birth defect: Deformed jaw

Pesticide exposure: Worked with 13 pesticides while her baby`s jaw was forming

Other risk factors: Father has small jaw; one previous stillbirth

Prenatal care: Began in fifth month of pregnancy; denies use of alcohol, tobacco, drugs or medications

Her statement: Salazar did not claim she was sprayed with pesticides but said she was never given protective equipment and was rarely told when it was safe to re-enter fields after pesticide applications.

Report`s determination: "An association between possible pesticide exposures in North Carolina and the jaw and palate abnormalities ... cannot be ruled out; however, there is evidence to suggest familial inheritance."

MARIA DE LA MESA CRUZ

Child`s birth defect: Missing nose, no visible sex organs, died after birth

Pesticide exposure: None in North Carolina during the critical early stages of pregnancy; some documented in an earlier Florida study

Other risk factors: None known

Prenatal care: Unknown

Her statement: None taken

Report's determination: "She did apparently work five days in fields in Florida in ... situations when exposure to pesticide residues above levels considered health protective is likely." The birth defects included "some that have been reported in lab animals after pesticide exposure."

Basnight calls for open budget talks

Kristin Collins, Staff Writer

A link is possible between pesticides and the births of three severely deformed children to farmworkers who labored in Eastern North Carolina, state officials say, although they don't have the data to prove it definitively.

But a report released Tuesday says the children's problems -- and the lack of information about what caused them -- should be a call to action.

Health officials called for closer communication among the state's Agriculture, Labor and Health departments. They want more outreach to farmworkers and stricter enforcement of state pesticide laws. And they outline a program, to begin in October, that will track pesticide illnesses.

"Right now, there are different agencies doing bits and pieces," said Sheila Higgins, a nurse with the Department of Health and Human Services who helped write the report. "But nobody ever really pulls the data together to try to describe the number of cases [of pesticide poisoning] that are really occurring, and who it's happening to."

The report is the result of a 10-month study of three children born to migrant farm laborers who picked tomatoes for Ag-Mart, a corporate grower. One child has no limbs, another has a deformed jaw, and a third, who died, had no nose or visible sex organs. They were born within seven weeks, from December 2004 to February 2005.

The study began last summer after the Agriculture Department heard about the children. The department's pesticide section charged the company with 369 violations of pesticide law and asked health officials to investigate the cause of the birth defects.

Agriculture Department inspectors say that Ag-Mart failed to keep workers, including the three pregnant women, out of the fields for required intervals after spraying pesticides.

Ag-Mart is contesting those charges. Company officials say that their workers were protected from pesticide exposure and that the state misinterpreted their records.

Not enough data

Ag-Mart, a Florida company, grows more than 1,000 acres of grape tomatoes in Eastern North Carolina and employs hundreds of migrant workers during the growing season. It markets its tiny tomatoes under the brand name Santa Sweets and also sells them under store labels.

In Tuesday's report, state health officials said that without knowing how much of the chemicals the women absorbed, there is no way to prove that pesticides caused the children's deformities. But the report says that all three women, at critical times in their pregnancies, worked in fields treated with pesticides known to cause birth defects.

Ag-Mart officials said the report established no link between chemicals and the deformities.

"We would all like answers to the questions regarding the birth defects of the three children," Ag-Mart President Don Long said Tuesday in a statement. "We sincerely hope that we'll learn the truth someday soon and that it will offer some level of consolation to the families."

Andrew Yaffa, a Florida lawyer who represents the three women, said the study bolsters his case that pesticides are to blame for the children's defects. He has sued Ag-Mart on behalf of Francisca Herrera, whose son was born without arms or legs. Yaffa says Herrera often was doused with chemicals while pregnant.

"If you read between the lines, this report screams that there's a problem," Yaffa said.

The state's strongest evidence is in Herrera's case.

She spent dozens of hours working in fields freshly treated with the fungicide mancozeb, the report says. That chemical has caused limb defects and missing bones in the offspring of lab rats.

Herrera was exposed to mancozeb during the period when most fetuses develop limbs, the report says.

Sostenes Salazar, whose child has a deformed jaw, worked with 13 pesticides during the time her baby's jaw was forming, the report says. Studies link six of the pesticides to birth defects, and one, Penncozeb, has chemicals that have caused jaw deformities in the offspring of lab rats, the report says.

But Salazar's husband has a small lower jaw, which also could have contributed to the child's problem, the report says. It concludes that pesticide exposure and heredity might have worked together to cause the problems.

In the last case, Maria De La Mesa Cruz, whose child died, did not work in North Carolina during the critical phase of her child's development, the report said. But investigators noted that she did work with chemicals in Florida that have been known to cause similar birth defects in animals.

A Florida study, completed by the Collier County Health Department last October, found no link between the women's pesticide exposure in Florida and the birth defects.

No study has looked at the women's exposures in both states.

More personnel

Other state agencies were still wading through the 37-page report Tuesday. But Brian Long, a spokesman for the Agriculture Department, said his department has asked the legislature for three new pesticide enforcement employees this year, at a cost of \$194,000.

Some worker advocates say the state should go further by pushing to ban certain pesticides that are harmful to workers.

"You can educate farmworkers all day long, but it's not like they can say to their employers, 'I'm not going in there.' They'll just get fired," said Fawn Pattison, director of the N.C. Agricultural Resources Center, which opposes pesticide use. "The big recommendation that's missing is to stop using stuff that causes birth defects."

The following 4 issues were identified at the meeting of the Advisory Board of the Midwest Center for Occupational Health and Safety, 4/13/06, Minneapolis, MN

- 1) Difficulty identifying workers and keep up with safety training due to transience and large number of non-English speakers
- 2) Lack of translated safety materials, e.g., pesticide labels, for the large number of non-English speaking workers
- 3) Safety and health of children in the fields (being watched, not working)
- 4) Theft of chemicals used to make methamphetamine causes competing risks for those entering buildings, e.g., bullet-proof vests v. respiratory protection

The following issues and research suggestions were identified at the meeting of the Advisory Board of the Midwest Center for Occupational Health and Safety, 4/13/06, Minneapolis, MN:

- 1) Safety measures are often not in place on construction sites and the education that exists is either not serious or there isn't enough of it. Contributing factors include the fact that penalties for accidental death are often built into the budget, little or no control over sub-contractors, accelerated building schedules, low employee retention (no training over time), language problems with training non-English speaking workers, and long hours, especially in small companies. Research suggestions include: 1) Use accident records over 5 years to identify "safe" and "unsafe" contractors, determine characteristics that contribute to more and less accidents 2) Compare safety records companies that work with business or trade associations with those that don't 3) Long term studies of simple interventions like targeting the critical first and last days of the work week, often don't see benefits if intervention trials are too short term
- 2) Occupational violence--no recourse when a problem occurs, reporters are penalized

The following 4 problems were identified at the meeting of the Advisory Board of the Midwest Center for Occupational Health and Safety, 4/13/06, Minneapolis, MN:

1) Safe patient handling: Lifting is seen as the single biggest cause of hospital employee health problems, more important than employee vaccination programs or hazardous drug programs. When a patient is the product, it's harder than having an inanimate product. In industry, the motto is "if something is falling, let it fall", which can't be done with patients. There are no engineering controls that work, are affordable, and that people accept.

Verbal Comment 2006/03/20: Good morning. Mine is not a formal presentation, rather a few questions. When I read the NIOSH web pages, I thought about it and I had some questions and wanted to present it here.

I'm on the Harvard ERC Advisory Board or Committee. I wondered, you know, how NIOSH is going to support all the ERC, you know, develop new centers for research and training in the future?

Second one is, NIOSH research agenda for the next ten years; is that for research support for outside research, I mean, you know, contracted, et cetera, or also for their own research so that, you know, in the past we have so-called agreement, a cooperative agreement from schools or public health associations and associations of medical schools. I wonder if it's still the case to support this kind of research.

And the last one is the small business addressed already by Scott. I think, you know, small businesses like auto body industries, they have less financial resources to support exposure control, but they also are less regulated by OSHA. So I think, you know, their concerns should be addressed as well.

Thank you.

I am often contacted by individuals in the manufacturing field with their concerns about health-effects of indoor air pollution such as passive smoke and animal feces. The individuals are not comfortable processing a HHE. I wish there would be a way for an outside source; such as a health department, to tip-off NIOSH to health hazards and they could investigate first by talking confidentially with employees to see if there is enough demand to perform a HHE. Fear is a huge motivator NOT to act in all of us. Health is not effectively being defended within the manufacturing sector.

Input from the Professional Landcare Network (PLANET) for NIOSH's National Occupational Research Agenda

Submitted by PLANET Safety Specialist Barbara Mulhern July 20, 2006

The Professional Landcare Network (PLANET) is a trade association representing approximately 4,400 green industry service provider companies and suppliers nationwide that specialize in design/build/installation, interior landscaping, lawn care, and landscape management. Our member companies employ more than 100,000 workers.

The workers in our industry are engaged in numerous tasks that expose them to potential hazards. Among these are: the use of heavy equipment (skid-steer loaders, backhoes, etc.) in landscape installation (construction);

the use of other powered equipment such as chain saws (which can result in vibration hazards and many other hazards); ergonomic hazards from lifting, bending, and other manual material handling activities (such as moving trees and shrubs); repetitive motion injuries (from such activities as reaching overhead to trim bushes for long periods of time); mowing-related hazards (including potential cuts, lacerations, or amputations from sharp blades; equipment overturns; eye injuries; and/or hearing loss); falls (from jumping in and out of truck beds); motor vehicle injuries (while working in highway "work zones" or when traveling to job site to job site); and hearing loss or eye injuries from other sources.

PLANET and OSHA have a strong national Alliance, and have developed a Web page that lists many of these hazards and potential solutions. I would encourage NIOSH to review this Web page at: <http://www.osha.gov/SLTC/landscaping/index.html> for more information. Below is one example of the information included on this Web page:

Potential Hazards and Possible Solutions (General)

Hazards which are of concern across the Landscape and Horticultural Industry include:

-- Cuts and Amputations (<http://www.osha.gov/SLTC/landscaping/solutions.html#machinerytools>)

- Electrical (<http://www.osha.gov/SLTC/landscaping/solutions.html#electrical>)
- Ergonomics (<http://www.osha.gov/SLTC/ergonomics/index.html>)
- Heat and Cold Stress (<http://www.osha.gov/SLTC/landscaping/solutions.html#heatcold>)
- Lifting and Awkward Postures (<http://www.osha.gov/SLTC/landscaping/solutions.html#lifting>)
- Motor Vehicles (<http://www.osha.gov/SLTC/motorvehiclesafety/index.html>)
- Noise (<http://www.osha.gov/SLTC/noisehearingconservation/index.html>)
- Pesticides and Chemicals
(<http://www.osha.gov/SLTC/landscaping/solutions.html#pesticideschemicals>)
- Slips, Trips, and Falls (<http://www.osha.gov/SLTC/landscaping/solutions.html#slipstripsfalls>)

In addition, our PLANET-OSHA Alliance identified four major hazards within our industry - strains resulting from manual material handling; motor vehicle crashes; amputations; and slip and trip injuries. For bilingual Safety Tips Sheets (English-Spanish tailgate training) we have developed on each of these hazards, please visit this Web page: <http://www.landcarenetwork.org/cms/programs/safety.html>.

Among the major areas where we would like NIOSH to focus its future research and prevention activities are: ergonomic hazards (resulting from manual material handling and from repetitive motion tasks); motor vehicle-related hazards; improved personal protective equipment (PPE) and alternative hazard prevention strategies to reduce the need for PPE; continued development of an AutoROPS for zero-turn radius mowers; noise hazards that can result in hearing loss; fall prevention (such as when working from aerial lifts); and heat and sun-related illnesses. Thank you for considering our input.

hello :)

could you please advise me of who i could converse with regarding the long term effects of electric shock...my sister was diagnosed 8 years ago with bipolar and takes a cocktail of prescribed drugs ...she is in medium assisted accommodation and receives the care of a psychiatric team...we recently deduced that my sister`s condition may have been triggered by an electric shock at work,,,a hairdressers,,, about 15 years ago as a number of us including myself,,,my sister and a member of the care team have experienced contra indications not applicable to my sister`s diagnosis...in a recent discussion with my sister i suggested that offering herself as a case study to a medical research team might shed some light on her condition,,,which hopefully would better inform her primary healthcare team thus a more appropriate treatment plan...my sister said she would be happy to pursue this direction...we would very much appreciate your directive and consideration in this matter..thankyou

Are illnesses **really** considered a workers' comp issue? Colds, flu, bronchitis, etc? I don't think so, even though lip-service is paid to illness. The Ohio BWC doesn't like discussing illness as a compensable condition in the workplace. How well does the US DoL report illness as compensable?

Cubicleland and other high-density offices make it easy for germs to spread. The space management practice of 'hotelling' brings germs from other places into offices; perhaps spreading to those who have less immunity to such germs. Emphasis on working "smarter" not harder usually means working longer not shorter hours. Stress leads to weaker immune system leading to illness.

Reportedly, overcrowding leads to reproductive health problems. Longer work hours and coming home from work tired is a symptom of reproductive health problems.

It's also a symptom of boredom at work. According to the Ohio BWC, boredom in factories is a workers' comp issue. What about boredom in offices? Everyone a computer programmer, such as my having to enter this into your web site, is boring. All day of this as many people are now forced to do is really boring. Not to mention eyesight problems no one wants to discuss. Carpal tunnel syndrome. Back, neck, and shoulder problems. Leg problems. Women complaining about their hips widening from having to sit too long. Joint problems in the hand and elsewhere. Employers complaining about

smoking problems (a symptom of boredom, I suspect) and weight issues (what kind of food do they serve at work?).

Then, what about those sick buildings employers deny having (County of Pierce, WA Govt, for one). What about those buildings built for fewer persons and no computers that now hold more computers than persons and greater number of persons than originally designed for? All those computers must have a negative impact on air quality. Ozone blowing on one`s body from an HP printer all day is not pleasant.

What about those buildings that do NOT provide potable drinking water to their employees? If one building served by an aquifer does NOT have potable water, do any of the buildings served by that aquifer have potable water? Can I safely use the restroom? Wash my hands? If one company has buildings served by that aquifer, then why don`t all of those buildings follow the same practices with respect to providing bottled water for employees to drink? Are soap dispensers in the restrooms really safer than a bar of soap? Is plain, potable water safer? If the drinking water tastes bad, what is an employee to do? Especially, when one hears rumors in the media about employer(s) who have polluted the Region`s aquifer.

Over my 20 years as an Employee Health Nurse, I have seen a dramatic increase in the number of overweight individuals who come to my office. Often Diabetes, joint pain, hypertension, cardiac, and respiratory problems accompany the obesity. As I walk through the halls of the hospital I observe individuals whom I've known for many years gradually gaining weight.

It's frustrating to have individuals come to my office for blood pressure checks while they continue to gain weight and de-condition due to limited physical activity. Often they request blood pressure checks following a change in medication when the medication they were on for years "no longer works".

When I suggest getting into a regular walking program that is known to impact blood pressure through weight reduction, individuals tell me hip pain or shortness of breath limit their ability to exercise. Consequently they are relying solely on medication to control blood pressure.

Obesity's economic impact on employers and the nations' health insurance is only going to escalate.

Here are my thoughts on health care injury prevention research & application:

In consideration that it is not possible to manually move patients without exceeding NIOSH body stress standards to providers, due to the angles and body positions required, that nursing staff spend approximately 20% of patient care time in stressful positions, that 62 % of patients would be classified as bariatric using the body-mass index, that an estimated >80% of patient care staff reportedly work with back pain, that an estimated 60% of patient care staff reportedly fear a disabling injury from moving patients, and the Healthcare workers have the highest frequency of back injuries compared to other professions and trades, I suggest elimination or extreme reduction of manual moving of patients as a research project. Transfer the work to equipment - but maintain the person to person contact.

Study and adapt material handling techniques from other industries. The overhead patient lifts are an example of how industrial material handling methods can be adapted to health care. Electric powered bed and cart pushers are another example of how shopping cart pushers have been adapted to health care.

Create algorithms for all types of patients and movements, indicating the type of equipment to be used for the processes, including choices of equipment where possible. Promote the algorithms as standards of care, not merely suggestions.

The current situation among Day Laborers in construction is that accidents in construction are the number one cause of death among Day Laborers. Other factors that contribute to this situation are lack of instruction on equipment use and safety precautions. I would propose providing instructional programs to Day Laborers that focus on proper equipment usage and safety. Proper instruction and safety knowledge may decrease medical service utilization (although there have not been studies to prove this) which is another area that requires investigation.

Good afternoon and thank you very much for this opportunity to speak to you today. I am speaking on the issue of protecting young workers, those under the age of 18, who are our future adult workforce. I will begin with comments about youth working in all industries, and then continue with issues regarding youth working in agriculture.

While focusing on the issues of a specific industry, it is important not to lose the track of the cross-cutting issues unique to this special and vulnerable population regardless of industry sector and subgroup within it, such as immigrant workers.

When I began working at the Washington State Department of Labor and Industries (L&I) in 1991 and I was assigned to an advisory group charged with updating our non-agricultural child labor regulations. The agriculture regulations had been changed in the prior couple of years. My first question was to ask what do the data tell us about where kids are injured and possibly killed? That sent me on the path I continue today to look at the data trends beginning in 1988 to the present, in our workers' compensation program; as well as searching the literature for others doing this work. The field was fairly limited at the time. In addition, health and safety professionals did not consider the issues facing young workers typically, and those in pediatric or adolescent injury prevention did not acknowledge work as an important contributor to morbidity and mortality in those under age 18. We have made progress, but there is still much to be done.

I want to acknowledge the remarkable work that NIOSH has done to bring us where we are today regarding the body of knowledge on teen workers, both through primary research or in supporting

research by others. As a result, we can proceed with new directions in addressing causes of injuries and prevention strategies. We have identified a great deal in the patterns of injuries and where they are happening, but not necessarily the why or how to fully prevent them from happening.

My initial thought when I first began to work in this arena was "What could be more mom (or dad) and apple pie, than to keep kids in school and keep them from getting injured or killed at work? After all, their primary "job" at this point is to get a basic education to be able to have more job and career options. My next realization when I started to look at the data and the literature was dismay at how frequently they were getting injured, often severely or even killed.

I work in a regulatory arena and jurisdiction is an issue that determines where youth can and cannot work and when; and so protecting them becomes a political issue no different than for adults. However, I believe youth are different and deserve special protections by those who claim to be responsible for their well-being - all of us. Risk to youth should be addressed regardless of industry and irrespective of regulations. Youth face the same hazards as adults but are at a disadvantage to protect themselves.

Concepts about the benefits of work are often influenced by reflections from adults and their own youth; often the nostalgia includes some survival story or gruesome event that almost serves as a rite of passage. In many instances, jobs held as teens by many adults today may have had a skill-enhancing component or opportunities for promotion and career development. Our teens do not encounter the world of work in quite the same way today. Often teens want to work more hours as well, without fully understanding the consequences this may bring. Adults need to provide the guidance and protection they need and deserve. Work is certainly valuable for teens but only if it is not at the expense of their health, safety and well-being, and balanced with other equally important age-appropriate activities.

We know that there are different protections for teens depending upon which industry they are working in – in agricultural settings, teens can do far more dangerous activities and at a younger age than they can in non-agricultural settings. And on family farms there are no protections in the form of work restrictions, unlike non-agricultural family businesses.

From 1988 to the present, in Washington we have seen a decrease in the annual number of accepted workers compensation claims among youth under the age of 18, from 4,000 per year to 2,500, then to approximately 1,200 per year in the last several years. This decrease is likely attributed to changes in our regulations around 1990 and 1993 in agriculture and non-agriculture, respectively; increased outreach and education; and changes in employment patterns in youth. However as we were seeing the beginning of this decrease, we then had 3, 16-year-olds killed in one week in August of 2003. It was a serious wake-up call that we need to do more.

The patterns I have seen in Washington are similar to those in other states and national data – most of the teens working and getting injured are 16- and 17-year-olds, more are males, particularly in certain industries; proportions of injuries align with where most teens are working – retail, service, construction and agriculture. Many of these injuries occur during the first 6 months on the job. Teens under the age of 18 have been found to be injured at a rate two times higher than adults. A majority of the injuries are minor, so to speak, such as lacerations, strains and sprains, contusions, and burns. However many include amputations, concussions, dislocations, fractures, head injuries and multiple injuries – injuries with potential to have severe long-term consequences.

Like adults, most of the claims cover medical costs only – approximately 85% are for medical costs and 15% for lost work time. But to qualify for a time loss claim, the injured worker must lose a specific number of days of work; here in Washington that is 3 days, elsewhere it may be more. Therefore, we cannot compare the severity in the same way we would for adults – they do not have typical patterns of work and therefore probably do not miss sequential days of work indicating that their lost-time injuries could be more severe. They may also be missing other equally important age-appropriate activities during this time such as school, sports, music and theater classes, and other community and family activities.

Research needed

-- There is little or no data on the consequences of these early work experience injuries - either in terms of their psychological impact, including their general attitudes about work and risk; the affect on future career options and potential loss of earning power; and long-term disability and associated costs. This needs further study.

- o Canada is finishing one of the first studies to look at the long-term impact of injuries among youth in relation to utilization of health care services.

Categorized comment or partial comment:

We in Washington have an amazing database of our workers' compensation claims with the majority of Washington employers insured through the state fund managed by the Department of Labor and Industries (L&I). It is an administrative database that can point us in the right direction, but has limitations. Through the claims data alone, we cannot fully understand the circumstances that surrounded the occurrence of the injury. There is also the issue of underreporting for various reasons, or that teens may be working informally and do not come to the attention of the system when injured. My anecdotal evidence in talking to hundreds of teens over the years is that they are unaware of this right and benefit. In addition, Pediatricians and Adolescent Health Providers may not know about workers' compensation for injured youth.

Given that a large proportion of youth are uninsured in this country and may work for employers who do not provide insurance benefits, or their parents lack insurance through their jobs, workers' compensation for teens is imperative for to be able to access appropriate care for an occupational injury as soon as possible to mitigate the severity or complications. Similar to adults, there is about a 10% rejection rate of claims in our system - the reasons why injury claims filed by youth but rejected by the system, are unknown.

Research needed:

-- It is important that research be done to evaluate the utilization of the workers' compensation system by young workers, including the extent of underreporting; knowledge among teens about compensation

benefits; and awareness by primary health care providers such as pediatricians, family practice physicians, and nurse practitioners.

Gender

Boys are injured more often than girls are - why is that? Are they working in more dangerous jobs, are they taking more chances? Do they report injuries more often? One Agricultural employer stated that he has found boys to be less coordinated than girls at the same age - a classic developmental difference between boys and girls during adolescence.

-- More research is needed in this regard.

Industry

In Agriculture we see that the proportion of time loss claims is higher in Agriculture and construction than in all other industries - 21% receive time loss payments compared to the 15% mentioned earlier. We also see that younger employees have more injuries and more severe injuries in Agriculture compared to other industries, likely because they are allowed to do more dangerous work activities than in non-agriculture. There may also be special characteristics of this younger group that have not been identified for prevention.

Research needed:

-- Since 1988 we have had at least 14 fatalities that we know of - all in either agriculture or construction; all males. National data indicates that youth under age 15 have a risk of death in AG two times higher than 16- and 17-year-olds. There is a similar, if not a higher, risk of fatal injury among youth working in construction.

In the Pacific Northwest the brush-picking industry is a subset of agriculture that needs special focus. We have had multiple fatalities in the last several years in Washington due to highway accidents; one recently included a 16-year-old who was killed when thrown from a van. Many of the harvesters are from Guatemala or Mexico; it is often difficult to identify an employer who is responsible for the health and safety of these workers. We have a special emphasis program to try to address the employment issues but more research is needed to address the risk factors and interventions, but much is still unknown.

Culture

Data indicate that Hispanics and other immigrant workers, particularly youth, have additional risks and vulnerabilities that may be additive. Many of these youth are working in Agriculture or construction. A recent BLS report indicates that while fatalities among non-Hispanic whites dropped during the late 1990s, work fatalities among Hispanic youth doubled; and in Agriculture, forestry and fishing, their count more than tripled. FACE investigations in recent years reveal a majority are fatalities among immigrant youth in Agriculture or construction. They are often male, and if they are foreign-born they are likely to be in the U.S. without and a parent or guardian.

-- Multiple factors may be place them at higher risk that needs further evaluation, such as language barriers, literacy, poverty, unstable living conditions, legal status, among others;

o Research of Latino immigrant youth by University of North Carolina researchers found that there was a low level of safety instruction provided to them.

Other Topics - in need of further research

The world of work continues to change and many of the protective restrictions for youth have not kept pace with the changing hazards. More research is needed to address additional activities not covered by regulations in Agriculture and non-Agriculture sectors alike. Collaboration and partnerships with industry organizations is a key element for the success of moving prevention strategies forward. Increasing the communication to those in need of the information - teens, parents, teachers, and employers - is critical to reducing injuries among this age group.

2002 NIOSH Report on the Hazardous Orders

-- At the request from USDOL's Wage and Hour Division, NIOSH evaluated the work activities prohibited by the federal child labor regulations, for 16- and 17-year olds. The evaluation was limited by the scope of the request. Further evaluation of work activities allowed by other age groups is needed. The evaluation did not include:

- o Review of the regulations for those under the age of 16 in non-agricultural jobs.
- o Review of the duties allowed for 16- and 17-year-olds in agriculture;

-- It is necessary to identify types of hazards and exposures similar to those currently prohibited that are of comparable risk, including tools and equipment regardless of industry setting, such as manufacturing, construction, and agriculture. We need more understanding of the types of powered tools - whether hand-held or fixed, that should be limited or allowed, based on specific criteria regardless of application or setting; equipment is constantly changing and specific tools cannot be updated in the regulations efficiently. These criteria would include but are not limited to their size, speed of rotations (RPM), torque produced, amount of power required and source of power; and whether or not there is access to inadvertently allow a body part to get close to the hazard.

Hazards:

-- Pesticides and other hazardous chemicals - pre-teen and adolescence is a time of major growth and development. Exposure to pesticides and other hazardous chemicals or substances like solvents, lead, asbestos, and silica, may have greater impact during this time, and add to years of cumulative exposure in some instances if begun early. Exposure limits have been determined for adult males and are likely too high for younger workers.

- o Research on the acute and long-term affects of early exposures is needed.

- o Under current national policy, farmworkers must be at least 16 years of age to mix, load and apply toxicity category I and II pesticides. We differ in Washington by prohibiting all minors from these activities. However, some categories III or IV pesticides have been associated with long-term health effects, including cancer or adverse reproductive effects and need further study. Re-entry levels that have been set for adult males and females, do not address the impact on very young workers (12- and 13-year-olds) currently allowed to do certain agricultural tasks.

Working Conditions

-- Organizational factors - how do these factors influence risk: supervisory style; work organization; pace of work and stress level; complexity of job tasks and hazards; work that is not connected to career goals; limited control or opportunity for promotion; power dynamics for young workers - supervisor/manager vs. employee; adult vs. child. Are mentors in the workplace an option to provide increased attention to new workers. This could be accomplished either by other experienced teens or adult workers and may be an option for providing guidance that does not involve a supervisor who cannot be in all places at all times, and could be less threatening to a new worker.

-- Work schedules - what are the impacts of the hours of work on health and well-being, school achievement and incidence of injuries; the hour of work needs further evaluation - how many, how early, how late; if teens are working late, how are they getting home, is driving when fatigued an issue?

The use of HazMat ensembles for response and drilling has increased across the nation in training drills and real or precautionary responses. The increase is largely in response to increased availability of the equipment through Homeland Security funding sources for the equipment. We have large numbers of personnel doing similar drill and response tasks now in, from what I have seen so far is a fairly limited selection of models of "A" and "B" level response suits. Across the country we have everything from all volunteer fire departments and small town police up to sophisticated and dedicated urban area HazMat units.

The application of ACGIH heat stress guidelines in such situations is not an easy thing and not always well understood or followed by many emergency entities thrust into HazMat roles. Not every response entity has trained people who can do physiological monitoring on every response or drill scene. Simpler guidelines based on a hazmat response operations is needed.

It would be great to have the physiological effects of these PPE ensembles fully characterized for personnel specifically performing typical leak stopping, diking and damming, recon and similar common hazmat response activities. I also suggest including the bomb squad blast suit ensembles as those have become much more common as well. Based on that science, seek to define clear and realistic in/out or work/rest guidelines for A and B ensembles, and provide guidance for allowance for common types of cooling vests and other heat stress aids.

This e-mail is a brief message concerning occupational exposures to radon gas.

Radon gas is a known human carcinogen and impacts the lives of millions of Americans, both in their homes and while on the job. Being a naturally-occurring radioactive gas, radon is seeping into buildings in excessive amounts in nearly all parts of the US. I have attached an EPA map, which shows the radon zone designation by county. Since many states with large populations, such as Illinois, Indiana, Minnesota, Ohio, Pennsylvania, New York, New Jersey, and Virginia, have large areas designated with the highest risk, tens of millions of workers are breathing unnecessarily high levels of radon. The US EPA has set an "Action Level" of 4.0 pCi/L. This means that EPA recommends that a home is fixed if the annual average in the home is 4.0 pCi/L or above, however mitigations are recommended down to as low as 2.0 pCi/L since no level of radon is safe.

In contrast, OSHA, NRC and other Agencies have been working with outdated policies for decades which are placing workers at increased risk of developing lung cancer. The following quote was taken from an OSHA on-line publication from a December 23, 2002 letter from Richard E. Fairfax, Director, Directorate of Enforcement Programs (found here:

http://www.osha.gov/pls/oshaweb/owadisp.show_document?p_table=INTERPRETATIONS&p_id=24496);

"The still applicable 1971 radon-222 exposure limit for adult employees is 1 x 10⁻⁷ microcuries per milliliter (μCi/ml) [100 picocuries/liter (pCi/L)] averaged over a 40-hour workweek. However, OSHA would consider it a de minimis violation if an employer complied with the current NRC radon-222 (with

daughters present) exposure limit for adult employees of 3×10^{-8} $\mu\text{Ci}/\text{ml}$ [30 pCi/L] averaged over a year (DAC-derived air concentrations)."

How can they stand by 35 year old policies when recent research by the National Academy of Sciences, the World Health Organization, the University of Iowa, etc. have all concluded that even policies created in the late 1980s greatly underestimated the risks of radon induced lung cancer. I have attached two graphs from a recent EPA publication that shows the risks of elevated radon. Obviously residential exposure duration can be quite different than occupational exposures, but compare the statement from Richard E Fairfax's statement that 100 pCi/L is OK, to the 20 pCi/L risks from EPA's A Citizen's Guide to Radon.

I think that NORA would be doing a great public service by looking at current occupational limits for radon gas and help to create the research necessary to bring the other Agencies into the current century. With a great deal of the radon risk studies being compiled some 20+ years after the NRC and OSHA regs, they must be held accountable for ignoring the current findings.

Agricultural Research Priority Comments of
California Rural Legal Assistance Inc. and
California Rural Legal Assistance Foundation
Introductory Comments

Agriculture continues to be a major, national employer of low-wage workers. The occupational injury and death rate for farm workers is consistently high, relative to other occupations. Costs of job-related agricultural injuries for 1992 have been estimated at \$4.57 billion (Public Health Reports. May-June 2001, Volume 116). Agricultural labor is mostly non-union and is of a temporary or seasonal nature. Union and safety committees extant in other industries are virtually non-existent in the fields and provide no counter-balance to the employers and supervisors' desire to compel the greatest production possible from every worker, every day. Most farm workers have no health insurance. As a workforce, farm workers tend to be extremely vulnerable to exploitation due to limited or no formal education, illiteracy, language and cultural differences, immigration status and/or the labor gluts in some regions.

CRLA and CRLA Foundation have represented farm workers throughout California for nearly 40 years. We consistently find that farm workers complain of painful and debilitating conditions that are difficult to diagnose, difficult to treat and yet appear clearly linked to a specific work task or job, such as repetitive lifting. Other times, chronic injuries appear to result from the cumulative effects of many different work tasks or jobs. Nonetheless, symptoms are often consistent worker to worker illustrating that there are a set of injuries and illnesses directly related to the agricultural workplace that can be prevented. Further research is needed to both identify the injurious practices and determine appropriate interventions.

Specifically, we propose that research be developed and funded to address the following issues related to work place injuries and illnesses in agriculture. If you would like to discuss these comments in greater detail please contact Anne Katten, of the CRLA Foundation Pesticide and Work Safety Project at [deletion by editor for web version], or Georgina Mendoza of CRLA Inc. Agricultural Workers Health Project at [deletion by editor for web version].

I. Methodology Considerations

Studies of Long-term Work Exposure Impacts on Farmworkers are Needed

Studies which follow populations of farm workers over time or look at past exposures to pesticides, dust and the musculoskeletal strain of work involving prolonged stooping and repeated lifting are urgently needed to examine the long term health effects of such exposure. As long as these impacts remain nebulous and unquantified, they are easier to ignore. For example, the expense of switching from scheduled applications of an old, off-patent high toxicity pesticide to newer pest control methods is easy to quantify, but data on the health impacts of continued use of the high toxicity pesticide is scarce.

Study Communities and Worker Populations Need to be Involved in Study Design

Researchers need to be aware that a study design which worked well with a farmer population will need to be reworked in order to produce reliable results from a worker population. It is important to involve focus groups of workers and their advocates in the design of such studies so that interview approaches and questions will be culturally sensitive, relevant and understandable.

II. Specific Research Areas

A. Respiratory and Dermal Health Impacts to Farmworkers from Dust, Pesticide, and other Chemical Exposures and Interventions to Reduce these Exposures

NIOSH has funded much important background research in agricultural dust exposure, pesticide bio-monitoring, and farmer work exposures and health status. More research is needed to increase understanding of the immediate and long-term health effects of exposure to certain pesticides and to track the health and work exposures of farm workers. Research examining the incidence among farm workers of different types of cancer, asthma and other respiratory disorders, Parkinson's disease and other neurological disorders, and reproductive disorders, in association with pesticide and dust exposure data needs increased funding. Research is also urgently needed to evaluate the effectiveness of currently available engineering interventions to control dust and pesticide exposure, such as enclosed tractor cabs with and without pesticide filters and to develop and help implement improved controls such as modifications to soil preparation and nut harvesting machinery that will reduce the amount of dust put into the air.

Pesticide label directions and worker safety regulations allow some reentry into treated fields without respiratory protection only four hours after pesticides have been applied, but the validity of this generic inhalation reentry period has never been verified with personal air monitoring data. We recently spoke with a tractor driver who developed symptoms consistent with organophosphate poisoning while applying fertilizer in a field that had been treated six hours earlier with two organophosphate insecticides (oxydemeton-methyl and diazinon). He reported no contact with treated plants. His tractor had an enclosed cab without pesticide filters.

According to industrial hygiene hierarchy, personal protective gear should always be considered the last line of defense because it is uncomfortable, cumbersome and prone to failure, especially during active work. However, in agriculture it is frequently the main form of protection relied upon with little research into its effectiveness. Last year USEPA approved the use of disposable cotton glove liners under chemical resistant gloves to increase comfort and possibly reduce dermatitis but as far as we know, no studies have been conducted as to how hand exposure to pesticides is affected when such liners are used.

B. Sulfur

In recent years, reported pesticide application of elemental sulfur in dust or wettable powder formulations to grapes, peaches and some other crops has increased. On the positive side, sulfur is being used as a substitute for other fungicides and miticides which are probable carcinogens or reproductive toxins.

However, field workers, particularly in grapes, peaches, date palms and greenhouse grown blackberries, frequently complain that their skin and eyes burn from exposure to sulfur dust residues, particularly when it is hot. Sulfur is the leading cause of reported pesticide illnesses in California, some from field residues and some from drift between fields. Some workers have left agricultural work because they developed an allergy to sulfur. There appears to be a disconnect between these illness reports and toxicology texts which describe elemental sulfur as a mild skin and eye irritant.

Research is needed to better characterize the immediate and possible long-term health effects of elemental sulfur and oxidized sulfur compounds which are formed after sulfur is deposited on plant foliage. Research, in cooperation with pest control experts, is needed to develop interventions to reduce exposure to sulfur foliar residues and drift, including evaluating adequacy of restricted entry intervals and how rate and frequency of application and type of formulation correlate with worker complaints about eye, skin and respiratory effects.

C. Soil Fumigants

Soil fumigants, including 1,3 dichloro-propene, methyl bromide, metam sodium and chloropicrin are widely used to fumigate soil before planting certain crops including strawberries, tomatoes, onions, potatoes, carrots, peppers and sometimes in orchards and vineyards. Fumigants are all highly toxic gases or volatile liquids applied at rates up to several hundred pounds per acre. As a result, pesticide handlers, fieldworkers and agricultural communities can be heavily exposed during periods of the year when a lot of fields are being fumigated. Entire neighborhoods have experienced acute poisoning symptoms when stagnant weather conditions and unsafe application practices led to drift of metam sodium degradation products and chloropicrin (O'Malley 2004 AJIM and MMWR 8.20.04). Further research is needed to

evaluate the health status of current and former soil fumigation applicators, and fieldworkers and other residents of rural communities who have been exposed to fumigants in documented drift incidents.

D. Mental Health and Neurological Effects of Traumatic Workplace Accidents and Chemical Exposures and Effective Interventions

Witnessing a serious or fatal workplace accident is highly traumatic, but it is our impression that counseling or other follow-up treatment is rarely provided to agricultural workers, especially if they are short term employees. It is very difficult to obtain mental health treatment under workers' compensation.

We have repeatedly observed that workers exposed to pesticide drift or overspray in the field or to leaks of chlorine gas and other chemicals in packing sheds experience both acute and chronic health impacts. Follow-up briefings providing information on the chemicals involved, potential health effects, and steps taken to prevent future incidents seem to be rarely given by employers. Some workers report long lasting symptoms including anxiety, forgetfulness, and fatigue which affect their quality of life. These symptoms may in some cases be the combined result of neurological effects of chemical exposure and some form of post-traumatic stress. All too often, ongoing symptoms are dismissed by employers, physicians, and regulatory agencies as "just anxiety" without any provision of counseling or other mental health treatment or critical review of toxicology data. Many types of pesticides, such as, for example, pyrethroid and chloro-nicotinyl insecticides, are known to be neurotoxic when exposures are very high, but data on health effects of less extreme exposures are not well tracked. Research is needed to increase understanding of the neurological and mental health effects of traumatic workplace accidents

and chemical exposures, and to evaluate appropriate follow-up explanation, counseling and other interventions and facilitate provision of these services.

E. Interventions to Reduce Heat Illness

Between 1995 and 2004, Cal-OSHA investigated twenty-three work-related heat fatalities in agriculture (10), manufacturing (2), construction (9), and wild land fire fighting (2). In 2005 alone, when California experienced prolonged heat waves, Cal-OSHA investigated eight possibly heat related fatalities and concluded that five of these fatalities were related to heat exposure. Four occurred in agriculture and one in construction. Workers suffering heat illness also experience fatigue, impaired judgment and other symptoms that increase the risk of workplace accidents.

Press reports on work-related heat fatalities suggest an association between machinery-paced work, piece rate and other incentive pay systems and increased risk of heat illness which need to be investigated. While training workers in recognizing symptoms of heat illness and encouraging water drinking are widely accepted as necessary interventions, research is urgently needed to evaluate what additional interventions are vital to prevention of heat illness. Such study should include field research to evaluate the effect of access to shade during scheduled rest breaks and implementation of more frequent rest breaks, such as those recommended by the American Conference of Governmental Industrial Hygienists, on the risk of heat illness in agricultural workers. Research into development and use of practical portable shade structures for both work areas and rest areas is also needed.

F. Night-time Work Hazards

>From anecdotal observations by CRLA and CRLAF it appears that night-time harvesting and pesticide application are growing more common in California. Onions, blueberries and potatoes are harvested at night in Kern County, corn and tomatoes in Imperial County and the Coachella valley, garlic in Fresno, celery and raspberries in Ventura County, lettuce in Monterey County, fresh market tomatoes in Imperial, canning tomatoes in the Sacramento Valley and wine grapes by machine in at least Sonoma, Napa, and Stanislaus counties.

While heat and sun exposure are reduced at night, some other hazards are increased. These hazards include tripping and falling, eye strain due to insufficient light, poor positioning of lights casting shadows that reduce visibility, walks in the dark to unlit bathrooms and washing facilities, sexual assault, driving in the dark and/or fog to and from remote worksites on narrow roads near canals, and increased risk of exposure to pesticide drift or overspray due to poor visibility and stagnant nighttime air conditions. In addition workers report wild animals in the fields at night including bobcats, mountain lions, wild boar, snakes, skunks, wild dogs, coyotes, and rats.

Some of these hazards could be substantially reduced by providing adequate generalized illumination of the work area using suitable portable lighting. Research would be useful towards determining effective ways of providing adequate illumination of night-time field work. A worker survey of reported hazards in night-time pesticide and harvest work would be useful because Cal-OSHA and county pesticide safety

officials rarely conduct routine inspections at night and are sometimes reluctant to respond to complaints about nighttime hazards.

G. Work-related Musculoskeletal Disorders

Agricultural work correlates strongly with work-related musculoskeletal disorders (WMSDs), because such work requires workers to undertake high risk activities: 1) lifting and carrying heavy loads, 2) repeated and/or sustained body bending, such as stoop labor, 3) highly repetitive hand work such as pruning, picking and weeding, and 4) piece-rate, production quotas and other incentives to work quickly and forego rest breaks. Studies have shown that there is a high risk of WMSDs among field crop workers (Murphy, 2003). Further, the incidence of such injuries among nursery and vineyard workers is very high (NIOSH, 1995), and well above the rates targeted by the United States Public Service in Healthy People 2000 (AgConnections, Vol. 1, No. 4). Unfortunately, "interventions aimed at reducing musculoskeletal injuries through changing only worker behavior...have generally failed to show any statistically significant effect on injury incidence" (Id., citing NRC-IOM, 2001). As a result, workers can only take limited actions to protect themselves.

While studies show that agricultural work presents high risks for WMSDs, adequate research has not been conducted on the long-term debilitating aspects of this work. Such research is needed, in part, because thirty-six percent of farm workers have worked in agriculture ten or more years (Worker Health Chartbook, 2004). And there is a strong correlation between the number of years worked in agriculture and the percentage of workers who have experienced joint or muscle pain and/or other health conditions. (Id.) Perhaps not surprisingly, there is a steep drop-off in the ratio of workers who work in agriculture beyond age thirty-four. (Id.)

CRLA proposes that NORA commission a study of the long-term effects of WMSDs among farm workers. Does some agricultural work cause WMSD which does not resolve when the work is discontinued? Does some agricultural work cause permanent musculoskeletal injury? What types of activities and/or which types of employment cause long-term and/or permanent WMSDs? Such a study should compare farm workers with other private sector employees for factors such as type of WMSD, and age of the worker at the onset of disability and/or pain.

Specific research should be targeted at the impact of the design of tools and equipment on the incidence and severity of WMSD. The repetitive use of tools such as clippers, scissors, pruning shears and knives impacts the hands and wrists to no lesser degree than the use of a keyboard or mouse, yet far less research has gone into determining how these tools could be designed to minimize injury.

NIOSH should also continue and increase funding of studies of interventions which would limit the immediate and long-term and/or permanent effects of WMSDs, such as the California agricultural ergonomics research on interventions in the wine grape harvest (California Agriculture Vol. 60, no. 1, 2006), nursery work and tree fruit harvest.

H. Incidence of Reporting Injuries Compared with Incidence of Injuries

Thirty-six percent of all farm workers in the United States work on California farms (NAWS, 2005). California farms employ at least 648,000 workers. Nearly all are Hispanic; 91% were born in Mexico. (Id.) Nearly sixty percent are undocumented workers. (Id.) Almost all farm workers speak Spanish. (Id.) Fewer than ten percent speak or read English. Typically, the farm workers queried had completed six years of education. (Id.) During the twelve months prior to the study, 24% of the workers suffered from musculoskeletal pain, nearly 20% had respiratory problems, and 12% experienced skin conditions. (Id.) Twelve percent of the farm workers reported they thought they were not covered by Workers Compensation, while twenty-three percent stated they did not know if they were covered. (Id.)

The above statistics indicate there are potentially hundreds of thousands of farm workers in California who suffer work-related pain and or injury each year. There are also potentially hundreds of thousands of farm workers who are unaware of or unsure of their right to Workers' Compensation protection.

Anecdotally, CRLA is aware that many work-related illnesses and injuries go unreported to employers and insurers. There are many barriers to reporting: inability to speak or read English, inability to speak or read Spanish, fear of retribution due to immigration status, education level which correlates to low literacy, lack of awareness of availability of benefits, fear of employer retribution, fear of partial or permanent loss of employment, etc. Anecdotally, CRLA is also aware that many illnesses and injuries are aggravated by late reporting or non-reporting of the accident or condition. Repetitive motion injuries become debilitating and force the worker to withdraw from the workforce, for instance eye injuries which become infected may result in permanent loss of sight.

CRLA encourages NIOSH through NORA to commission a study to examine the rate of reporting of on-the-job injuries among farm workers. Such a study should compare the incidence of injury with the incidence of reporting injuries to the employer and/or insurer. Included should be an analysis of the significant barriers to reporting, combined with suggestions of what can be done to eliminate or alleviate those barriers. This study should also examine the relationship between delayed reporting or non-reporting of injuries and the increasing severity of the injury or condition due to delayed medical care, exacerbation from ongoing exposures and other factors.

I. Dairy

Based on conversations with dairy workers, it is clear that certain hazards are commonly present in California dairies. For example, many workers are injured in accidents involving interactions with cows. Workers' hands and feet are broken or otherwise injured from being stepped on. Workers sustain back injuries when they are cornered in a pen by the animals, and either fall or are smashed up against a wall. Back injuries also occur when workers lift calves. We hear of faulty equipment which results in injuries, such as gates with broken latches from which animals escape, or gates that get stuck, thereby trapping the worker with the animals. Such injuries could be avoided through the implementation of policies and procedures to prevent workers from being cornered by animals and improved training.

Other commonly-occurring injuries result from slip-and-fall hazards. In some dairies, the floors are often contaminated with slippery substances, such as milk, feces, cow placenta and mud.

Dairy employees are also regularly exposed to chemical inhalants such as fly sprays, bleach and other chemicals, such as an anti-fungal powder that is mixed with water and applied to the animals' hooves. Most dairy workers we speak to tell us that they are not provided with protective equipment such as masks and eye wear.

Confined space hazards continue to exist, despite several highly-publicized fatalities several years ago caused by workers suffocating from lack of oxygen in manure pits that they were required to enter without proper equipment or other legally-required safeguards. Other life-threatening hazards include the danger of workers being crushed by containers or feed bales falling on them.

Some dairy and calf ranch workers complain that they are required to give injections to cows with hypodermic needles without being provided with gloves or other hand protection, or without appropriate training.

As smaller dairies are replaced by the mega dairies increasingly found in California's Central Valley, workers are expected to process hundreds of more cows per day. They are experiencing the same kind of production speed-ups associated with the mechanization of any job task. Studies should be conducted to determine the impact of such speed ups on the incidence and severity of acute injuries, and to determine whether there are long-term impacts.

Research is needed to assess the unique working conditions workers face in modern dairies. Focused research identifying common types of injuries among dairy workers through interviews and analysis of accident and illness reports, will provide a basis for developing interventions to prevent these injuries. Examples of interventions could include development of calf-lifting equipment, design standards for gates, appropriate protective footwear, and improved training materials and techniques for working safely around animals.

J. Mechanization, Industrial Farms and Production Rates

Agriculture continues to develop as an industry which relies more and more on highly expensive and efficient machinery to perform critical aspects of the harvest. Increasingly, farms and dairies are becoming larger operations while the number of workers in the barns and in the field crews decreases. The pace of work is often a function of progress or speed of a machine. In other circumstances the pace of crew production rates are set by younger workers capitalizing on a piece rate incentive. There is widespread violation of mandatory meal and rest break provisions in California agriculture. Anecdotally we see reports of increased injuries, increased susceptibility to heat stress and related illnesses when breaks are missed. Studies should be designed to determine the effect of piece rate and bonus rates on work pace and injury rate. They should also address the question of whether an enforced, regularized, break schedule will reduce musculoskeletal pain and injury and the high rate of slipping, falling and vehicle related accidents.

Agriculture, Forestry, and Fishing Sector

Fatal and Non-Fatal Injury and Illness Surveillance Information

(A version with tables and active links is available in [Appendix 1.](#))

The following summary of fatality, injury, and illness rates in the Agriculture, Forestry, and Fishing sector is provided in order to help identify the most important safety and health problems in this sector. The North American Industry Classification System (NAICS), which was used to designate the NORA sectors, was also used by the Bureau of Labor Statistics (BLS) during the collection of their 2003 data. NAICS codes all economic activities using a six-digit hierarchical coding system with industry sectors, subsectors, industry groups, NAICS international industries, and National industries coded with 2, 3, 4, 5, and 6 digits, respectively.

The following sector-based summary is derived from 2003 BLS Census of Fatal Occupational Injuries (CFOI), and the annual Survey of Occupational Injury and Illness (SOII) (BLS, 2005a; BLS, 2005b). BLS non-fatal injury and illness data are based on a survey of 183,700 (of an estimated 7 million) US business establishments and do not include the self-employed, farms with fewer than 11 employees, private households, and governmental agencies. Where possible, references are made to specific BLS tables. In order to encourage internal comparisons, we have converted BLS rates, which are expressed as cases/100 full-time workers/year and cases/10,000 full-time workers/year, to cases/1,000 full-time workers/year.

As with the original BLS tables, the rates reported in our tables cannot be directly calculated from the numbers of cases and numbers of workers provided in our tables. This is because BLS makes post-

sampling adjustments of their data and they use the equivalent of full-time workers (not workers) in their rate denominators (BLS, 1997). Using denominators based on person-time rather than numbers of workers results in rates that provide more accurate estimates of actual risk. Full-time workers are defined as working 40 hours per week for 50 weeks. Denominators for non-fatal injury and illness rates are calculated based on work hours data BLS receives from reporting establishments. Denominators for fatal injury rates come from the Current Population Survey.

According to the BLS-Quarterly Census of Employment and Wages (QCEW) program, there were 965,000 workers in the agriculture, forestry, and fishing sector in 2003 (Table A1). Workers in crop production, support activities for crop production, and animal production comprised 45%, 28%, and 14% of the sector workforce, respectively.

BLS [2005a]. Census of fatal occupational injuries (CFOI) - current and revised data. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics, Safety and Health Statistics Program. [www.bls.gov/iif/oshcfoi1.htm]

BLS [2005b]. Nonfatal (OSHA recordable) injuries and illnesses. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics, Safety and Health Statistics Program. [www.bls.gov/iif/home.htm]

BLS [1997]. BLS handbook of methods. Chapter 9. Occupational safety and health statistics. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics. [www.bls.gov/opub/hom/pdf/homch9.pdf]

Fatal occupational injuries

Transportation accidents accounted for 50% of fatal occupational injuries in the agriculture, forestry, and fishing sector (the largest proportion of these involved non-highway accidents). Contact with objects and equipment accounted for 29% of fatal occupational injuries in this sector (52% involved the worker being struck by an object) (Table A3).

Nonfatal occupational injuries involving days away from work

Sprains and strains were the most frequent nonfatal injury type involving days away from work with an incidence rate within the sector of 6.93 cases/1000 full-time workers/year (Table A4). The incidence rate of sprains and strains was highest among the Forestry and Logging subsector, which had an incidence rate of 15.86 cases/1000 full-time workers/year. Amputation rates were highest in Support Activities for Crop Production (NAICS 1151).

Total nonfatal occupational injuries

The incidence rates of total nonfatal occupational injuries were highest in Cattle Ranching and Farming (NAICS 1121) and Hog and Pig Farming (NAICS 1122), which had incidence rates of 87 and 83 cases/1000 full-time workers/year, respectively (Table A5).

Within the Agriculture, Forestry, and Fishing sector, the incidence rate of traumatic injuries and disorders involving days away from work was 19.26 cases/1000 full-time workers/year, compared to an incidence rate of total nonfatal injuries of 58 cases/1000 full-time workers/year (Special Request and Table A5). This suggests that the total injury rate was three-fold larger than the injury rate involving days away from work.

Nonfatal occupational injuries and illnesses involving days away from work

This incidence rate of pain (without a medical diagnosis) was highest in subsector Forestry and Logging (NAICS 113) and the industry group Fruit and Nut Farming (NAICS 1113) (Table A6). Musculoskeletal system and connective tissue disorders had an incidence rate of 0.29 cases/1000 full-time workers/year for the sector; 38% of these cases were diagnosed with tendonitis (Special Request).

Categorized comment or partial comment:

Nonfatal occupational illnesses

Vegetable and Melon Farming (NAICS 1112) had an incidence rate of nonfatal occupational skin diseases and disorders of 4.60 cases/1000 full-time workers/year, which was 2.5 times larger than the sector average (Table A7).

Support Activities for Forestry (NAICS 1153) had an incidence rate of nonfatal occupational respiratory conditions of 2.37 cases/1000 full-time workers/year, which was more than 11-times larger than the sector average (Table A7).

Fruit and Nut Farming (NAICS 1113) had an incidence rate of nonfatal occupational poisonings of 1.21 cases/1000 full-time workers/year, which was more than 5 times larger than the sector average (Table A7).

The incidence rate for all other nonfatal occupational illnesses was highest in the Other Crop Farming (NAICS 1119) industry group, which had an incidence rate of 9.52 cases/1000 full-time workers/year (Table A7).

Appendix

Notes on Limitations and Interpretation

One of the limitations of occupational safety and health surveillance data is the underreporting of illnesses, which occurs because: 1) some diseases (e.g., cancer and pneumoconiosis) have long latency periods so that reporting mechanisms, such as OSHA logs, as used by BLS, fail to capture many of these events; 2) many diseases have multiple potential causes (e.g., asthma and cardiovascular diseases); and 3) workers and physicians do not recognize an occupational contribution.

BLS data sources do not allow: characterization of occupationally-related illnesses, if these illnesses are not skin diseases and disorders, respiratory conditions, or poisonings; or quantification of fatalities due to occupationally-related illnesses. Other sources have suggested that the occupational illness fatalities in the US workforce outnumber occupational injury fatalities by about 8:1. For example, using 1997 disease fatality numbers, it was estimated that occupationally-related illness and injury deaths numbered, respectively, 25,910-72,121 (Steenland et al., 2003) and 6,238 (BLS). Estimates of 1997 occupationally-related illness deaths by disease category are as follows: 6,805-26,685 for non-malignant respiratory disease; 12,086-26,244 for occupationally-related cancer deaths; 6,037-18,253 for occupationally-related coronary heart disease; and 328-580 for occupationally-related renal disease (Steenland et al., 2003). Sector-based occupationally-related illness fatality data are not provided in this surveillance data summary.

Other limitations of the data include the following. (1) Only BLS data for a single year (2003) are presented. However, data for a single year may not be representative of the long-term experience and health impacts of a sector due to economic, political, technological, or weather characteristics of that year. (2) Many of the rates are based on small denominators, so that a few additional or a few less cases in the numerator might cause a large fluctuation in the magnitude of the rate estimate. Therefore, what may be quantified as large differences in risk may simply be the result of the “random” occurrence of a few cases. (3) Rates are not adjusted for any potential confounders, the most important of which may be age. Research has shown that younger workers may be at increased risk of injury due to a variety of factors including experience and training. Older workers may be more susceptible to certain occupational illnesses because of pre-existing medical conditions. Therefore what is perceived as a true difference in risk based upon crude rates between two groups may simply be the result of differences in their age distributions. (4) Differences among rates for subsectors and industries of the sector are not tested for statistical significance. Without statistical testing, one cannot conclude that rates are really any different than some of the other rates in the sector.

Discussion of the data focuses on rates, although many of the tables also provide data on the number of workers affected. A subsector or industry which has the highest rate of injuries or illnesses within the sector may have few total workers. Implementing prevention strategies within another subsector or industry within the sector with a high rate of injuries or illnesses and a larger number of workers, may result in a much larger public health impact. If these data are used for planning and priority setting, we suggest that the number of adverse health outcomes and the number of workers potentially impacted be considered concurrently to identify worker groups towards which research should be directed.

From the perspective of employer based Disability Case Management, I recommend that NORA add to its research agenda some of the important issues concerning the stay-at-work and return-to-work (SAW/RTW) process that are highlighted in ACOEMs report, entitled "Preventing Needless Work Disability by Helping People Stay Employed." The report is addressed to a broad audience of medical and non-medical readers and is an informative, sensible, and enlightening overview of the SAW/RTW process with both general and specific suggestions on how to improve it.

NORA Comments 1-18-2006

Subject: Rock Bursting in Underground Metal/Nonmetal Mines

Presenter: Ted Williams, NIOSH Spokane Research Lab

Introduction: Rock bursts are the sudden, violent failure of rock in deep hard rock mines. Rock bursts pose a very significant risk of injury or death to miners working in the vicinity of the failure. The rock burst problem was one of the reasons the Spokane Research Laboratory was founded in 1951 and even though much progress has been made it is still a problem in the US, Canada, and South Africa. A large amount of research has been conducted to determine the conditions that cause them and what can be done to control them and protect the miners from them. The inter-relationship between geology and mining geometry in rock burst areas is an important area investigated by SRL researchers. Researchers at SRL have developed cemented backfill, destressing, and underhand mining to alleviate the hazards but the bursts still occur. Researchers also developed PC based in mine seismic systems to identify rock burst failure mechanisms, and an internet based seismic monitoring system for real time surveillance of seismic activity at targeted mines. The timely use of monitoring information and successful use of rock burst intervention strategies has reduced the risk to this group of miners.

Despite all this past research, rock bursts continue to create hazards for underground hard rock miners. There are currently five underground hard rock mines in the United States that have geologic and mining conditions that could result in rock bursts. In 2003 these mines employ 2,205 workers of the 11,549 workers in the Metal/Nonmetal Mining industry (19%). Other mines may also become rock burst prone as they get older and start mining deeper where stresses will be greater.

Recent advances in technology have provided researchers with new tools for investigating rock burst related phenomena. The application of advances in monitoring technology could result in new tools to assess rock burst hazards. This could lead to a better understanding of bursts and may lead to solutions that will protect miners. Strain monitoring using instrumented rock bolts and miniature data acquisition systems (Midas) has shown promise with the identification of anomalous conditions in the footwall of a burst prone stope. Successful identification of the cause of this condition could lead to ways to mitigate it and reduce miners' exposure to the hazards it creates.

Also, the recent development of low cost high speed (10 million samples per second) data loggers have made it possible to monitor high frequency electromagnetic waveforms and also ultra sonic waves to determine if either may be a precursor to rock bursts. Successful identification of a rock burst precursor could lead to an early warning system which would be used to evacuate miners prior to the burst.

Current partners in this research are:

Hecla Mining Company, Lucky Friday Mine, Mullan, Idaho Coeur Silver Valley Inc., Galena Mine, Osburn, Idaho Stillwater Mining Company, Stillwater and East Boulder mines, Nye, Montana Montana Bureau of Mines and Geologies Earthquake Studies Office, Butte, Montana Montana Tech of the University of Montana, Butte, Montana University of Memphis, Center for Earthquake Research and Information (CERI)

The rock burst work at SRL is scheduled to be terminated at the end of FY 2006. It is my opinion that NIOSH should continue this work in order to protect the safety of the 2,205 workers at the mines that are at risk to rock bursts

Categorized comment or partial comment:

This comment addresses the use of the real-time measurement of elemental carbon (EC) concentrations for the monitoring of diesel particulate matter (DPM) in underground mines. This method involves direct measurement of elemental carbon (EC) concentration, which is important as the Mine Safety and Health Administration (MSHA) has recently replaced the total carbon (TC) standard with an EC standard for quantifying DPM for the regulatory interim limit (MSHA 2005: Diesel Particulate Matter Exposure of Underground Metal and Nonmetal Miners. Final Rule. 30 CFR Part 57). While the NIOSH 5040 is well established for EC and TC measurements in mine air, it relies on thermal analysis of filter samples that is limited to a time resolution of several hours and may take weeks to months to accomplish after sampling. The peak DPM concentration can be an order of magnitude higher than the time-integrated averages and frequent short-term exposure to extreme toxic levels may be the main reason for health damage. In addition, a high-time-resolution measurement is required to develop a "ventilation on demand" scheme that will lower the DPM level in mines in a most cost-effective manner.

The real-time EC measurement is based on an innovative photoacoustic technique (Arnott et al., 1999) that has been shown to be equivalent to the filter-based thermal/optical methods for analyses of primary diesel exhaust dominated by EC (Arnott et al., 2005). Its performance needs to be verified when applied to the challenging conditions in a mine where elevated rock and mineral dust and oil mists may interfere with EC measurements. This tool can be used to assess average and peak miner exposure to DPM under various ventilation schemes in active gold mines. Based on such measurements strategies for developing effective mine ventilation systems to protect the mineworkers can be developed.

National Occupational Research Agenda Town Hall

February 21, 2006, Los Angeles

Comments from

Barbara Materna, Ph.D., CIH, Chief, Occupational Health Branch,

California Department of Health Services

850 Marina Bay Parkway, Building P, Richmond, CA 94804

(510) 620-5730; bmaterna@dhs.ca.gov

I want to thank the National Institute for Occupational Safety and Health (NIOSH) for convening these meetings around the country to hear input from many people and organizations about the workplace health and safety needs that should be addressed in the next 10 years of the National Occupational Research Agenda (NORA).

I represent the Occupational Health Branch in the California Department of Health Services, a non-regulatory public health program that conducts research and provides services to prevent injury and illness among California's workers. Our program was created in 1978, after exposure to dichlorobromopropane was found to cause sterility in a group of manufacturing workers despite the existence of studies showing the chemical had this effect in animals.

One of the important responsibilities of our program is to translate scientific data into practical information for employers and workers to use in creating safe and healthy workplaces. Another is to collect and summarize statistics describing worker illness and injury. As a public health agency, we are charged with investigating the causes of illness and injury and making recommendations for their prevention and control. To carry out these functions, we have the legal right to enter California workplaces, review health and safety records, and interview both employer representatives and workers.

Meeting the occupational health and safety needs of California workplaces and workers is a daunting challenge. We have over 16 million workers and over 1 million worksites that fall under OSHA jurisdiction. Some are located in large urban areas such as Los Angeles, the nine-county San Francisco Bay area, and the rapidly-growing Central Valley. Our state's large geography includes vast rural regions where many other workers are employed.

California borders both Mexico and the Pacific Rim and, as a result, large numbers of recent immigrants enter our workforce from Mexico, Central and South America, and many different Asian countries. The language, literacy, and cultural challenges of providing effective health and safety training to our workforce are enormous.

Twenty-five percent of California's workforce is employed in the private services sector, where many jobs provide low wages, long hours, significant health and safety risks, and no benefits such as health coverage. Another 15% of our workforce is in government services where the working conditions and benefits are likely to be somewhat better, but musculoskeletal disorders related to computer use are widespread, and stress due to inadequate staffing and looming layoffs takes its toll. Other important industry sectors in California include agriculture, with over half a million workers, and construction with almost 900,000 workers.

California workers are exposed to long-recognized hazards like silica in sand and gravel mining and falls on construction sites. But our state is also a center for new high-tech industries like nanotechnology and biotechnology, with a host of potential hazards that may not yet be identified or well understood.

It is extraordinarily difficult to reach the large numbers of small businesses in our state with the latest health and safety information; over 87% of California firms employ fewer than 20 workers. Like other states across the country, we are seeing changes in the nature of work that include fewer regular, full-time permanent jobs with benefits and, instead, more use of contract and temporary jobs, where health and safety is often not a priority.

Given these challenges, the Occupational Health Branch has to make difficult decisions about where to focus our limited resources. One of our priorities is to identify and address the unique concerns of low-wage, immigrant, and underserved workers. Under this focus, we have, for example:

- Collaborated with others to develop safer workstations to reduce musculoskeletal disorders in Asian and Latino garment workers;

- Provided educational seminars and materials statewide to improve the quality of safety training in construction (“BuildSafe California”);
- Investigated deaths among Latino and other workers in Los Angeles County; and
- Promoted the creation of the Working Immigrant Safety and Health (WISH) Coalition, a unique network of community-based organizations and others who are concerned about these workers and their communities.

Our program has a long history of collaborating with NIOSH, public health departments in other states, and many other organizations on these projects. We are one of 13 states currently funded by NIOSH for occupational health surveillance and prevention activities, with a particular emphasis on work-related asthma and pesticide illness. NIOSH funding has played a crucial role in enabling our program to track many types of injuries and illness, to investigate worksites and formulate recommendations for prevention, and to carry out special projects to address health and safety problems in high-risk industries and occupations.

We recommend that NIOSH consider the following priorities for the next decade of NORA:

1. Place special attention on supporting research and other activities that will improve working conditions for low-wage, immigrant, and underserved workers.

These workers are found in large numbers in the services sector, as well as in other sectors that are high-hazard and significant in California, including agriculture and construction. NIOSH should support and promote efforts that:

- Determine the most effective ways to provide health and safety information and training that is appropriate to the languages, cultures, and literacy levels in the workforce;
- Develop effective interventions for preventing and reducing musculoskeletal disorders, a major contributor to workers’ compensation costs and cause of lost work days and disability (often unreported and uncompensated);
- Disseminate available information that can be used to improve working conditions (i.e., hazard information, research findings, best practices), particularly to reach large numbers of small businesses and their diverse workers;
- Involve partnerships between occupational health professionals/researchers and community-based or other organizations that have special access to these workers and knowledge of their needs; and
- Determine how best to address health and safety within the context of other important problems and issues these workers face (e.g., language barriers, poverty, working long hours and/or multiple jobs, limited education, lack of access to health care and/or permanent employment, exploitation, other life stressors).

State Public Health Departments

Categorized comment or partial comment:

2. Enhance and expand partnerships between NIOSH and state public health departments for conducting occupational injury and illness surveillance and intervention activities, and to assist in translating research findings into safer workplace practices (NIOSH's Research to Practice initiative, or R2P).

We work closely with many NIOSH staff who understand that state-based programs are uniquely positioned to carry out these efforts; for example, we:

- Have legal right of access to workplaces to carry out public health investigations;
- Have statutory access to data sources (e.g., California's Doctor's First Reports of Occupational Injury or Illness and electronic Workers' Compensation Information System) for conducting epidemiologic analysis and "sentinel event" case follow-up investigations;
- Are part of the state's public health infrastructure, with useful ties to colleagues in communicable and chronic disease control, environmental health, family health, and health services delivery;
- Have existing relationships with local partners including trade associations, unions, community-based organizations, health professional organizations, and local health departments;
- Have a long history of collaborating with other states, NIOSH, and the Council of State and Territorial Epidemiologists (CSTE) to share information and experience, and to promote a growing network of state-based programs to prevent occupational injury and illness.

NIOSH support, collaboration, and technical assistance have been critical to many of these state-based activities. We have been successful in encouraging more states to expand their efforts in this important area of public health. More states are gaining expertise in doing this work and are able to identify important state priorities that need to be addressed, propose well-conceived research efforts, and write competitive grant applications. Therefore, we recommend that NIOSH:

- Increase the total amount of funding for activities conducted by state public health departments;
- Provide enhanced funding for projects that involve developing and implementing intervention projects;
- Support proposed partnerships that allow states to work with stakeholder groups to address health and safety issues identified in a participatory group process (such as the BuildSafe California construction industry training effort funded under the NIOSH Core Surveillance cooperative agreement); and
- Partner with states on efforts that involve widespread dissemination of research findings and adoption of the best health and safety practices in our states' workplaces.

We look forward to working with NIOSH and others in creating new opportunities and approaches for promoting workplace health and safety in California over the second decade of NORA. Thank you again for the opportunity to offer these comments.

NORA PUBLIC HEARING

Public Testimony

January 17, 2006 Town Hall Meeting

Seattle, Washington

I'm Paul Gunderson, a farmer whose operation straddles the Continental Divide, and who serves on the Advisory Board, High Plains Intermountain Center for Agricultural Health and Safety. If you and I were to read the book entitled "Through the Looking Glass and What Alice Found There" by Lewis Carroll, we would discover the Red Queen running frantically just to stay abreast of circumstances. This futile race is suggestive of the evolutionary forces that keep both pathogens and their targets alive. I postulate that such is the nature of infectious zoonoses which are ubiquitous in agricultural settings. Changes in both climatic conditions and agronomic and husbandry practice have permanently altered human exposures to zoonoses within the North American agricultural worksite. And, demographic change in the agricultural workforce in many regions of the United States has also altered perception of risk by individual workers due to life experiences from abroad which are different from generations of domestic American farmers, growers, and ranchers. The emergence of *B. anthracis* as an infectious bacterium in cattle, cattle handlers, pen riders, and veterinarians on the northern high plains in the summer of 2005 is but one example of a worksite risk perpetrated by both (1) a change from cool and dry weather to a warmer moist climate, and (2) change in agricultural technologies which incentivize biographic diaspora,

workforce interaction with domestic livestock, and the emerging concentration of livestock enterprises. Other examples might include *Coxiella burnetti* (Q fever), numerous hantaviruses, campylobacteriosis, swine brucellosis, and T fever (cat scratch disease). Most high plains states will report 100 or more cases of campylobacteriosis each year to the CDC; all typically occur within human populations exposed through work tasks to domestic agricultural livestock.

Because these infectious diseases occur within populations exposed to agricultural risk, they are likely to go unrecognized and unreported in this nation's disease reporting networks. This occurs because (1) presenting symptoms are often similar to other prevalent sequelae, (2) agricultural workers are culturally conditioned to avoid primary medical care, (3) rural clinicians may not possess resources or clinical acumen capable of detection, (4) patient triage among rural clinicians may be poorly orchestrated or non-existent, and (5) non-recognition of clinical significance and presenting symptomatology by exposed working populations renders the rural medical care system impotent. As a nation we can do much better.

NIOSH is in a unique and favored position to promote resurgence of our nation's capability to detect and interdict infectious zoonotic disease. NIOSH could encourage its funded agricultural centers to focus added resources on (1) targeted local surveillance within selected high-risk agricultural settings which would serve to elucidate host characteristics and transmission modalities, (2) development of additional laboratory capability, and (3) development and field-testing of educational materials and strategies for use within working agricultural populations, including veterinarians. Additionally, NIOSH itself needs to hold on to its present laboratory capability as well as its occupational hygiene capacity so that it stands ready to assist state public health departments, local public health agencies, and local medical facilities and veterinarians in interdicting zoonotic disease, preventing its spread, and identifying opportunities for its prevention at local agricultural work sites. Included could be (1) development of new laboratory and rapid field-based detection technologies and assays, (2) additional state-level and regional laboratory certification assurance, and (3) development and distribution of training materials for laboratory technologists.

Exposures of children (as well as the elderly) on agricultural operations and associated injuries and consequences. Agricultural operations are unlike other workplaces, given the fact that the very young and elderly -- in addition to the typical aged work force is subjected daily to numerous and extraordinary exposures that place them at great risk. Resulting injuries also result in a great burden to the overall operation. Through several major research efforts, this is evident as a major problem.

Violence in the workplace is a major cause of occupational mortality and morbidity. It is also a major problem that may vary in the manner in which it is manifested among occupations, and by types of worksites. Only limited analytical research has been conducted, to date, to identify specific risk factors that can be used as a basis for appropriate development of interventions.

Radon in the workplace is a serious issue. Thousands of Americans die each year from radon induced lung cancer in their home and workplaces. Occupational limits for radon exposure that are much more health protective than that of OSHA's current limits should be explored.

Categorized comment or partial comment:

I strongly encourage NIOSH to examine the workplace exposure of a wide variety of workers to radon and radon decay products. Residential exposure is responsible for about 21,000 lung cancer deaths per year in the U.S. Other than underground miners, we have either no or insufficient exposure data for other workers such as those in water plants, fish hatcheries, phosphate plants, utility and subway tunnels, oil refineries, and those who work in spaces in ground contact (plumbers, heating service personnel, radon mitigators). I encourage NIOSH to work with the American Association of Radon Scientists and Technologists and EPA on this issue. Thank you.

Radon in the workplace is a serious issue. Lung Cancer survival rate is poor and Radon is the second leading cause of Lung Cancer. 22,000 deaths a year attributed. We worry and spend about too many things that claim just a few lives but ignore the ones that kill thousands? Don't understand the risk vs reward to what we put our efforts towards.

Industry makes money off the backs of their workers they need to be forced to have safety their number one concern and not their number 167th behind what they ate for breakfast. Unions did a lot for safety and they get a bad rap in Kansas but they had their interests right in most cases.

Radon in the Workplace, The OSHA Ionizing Radiation Regulations

Robert K. Lewis

PA DEP, Bureau of Radiation Protection, Radon Division

Harrisburg, PA USA

INTRODUCTION

The Occupational Safety and Health Administration (OSHA) is the federal agency responsible for the safety of American workers. Their overall mission is to save lives, prevent injuries, and protect the American workforce. The vast majority of American workers are covered by the Occupational Safety and Health Act of 1970. One specific part of the OSHA mission is to protect the American workforce from unnecessary exposure to ionizing radiation, and as it relates to this paper the radioactive gas Radon-222. Due to the fact that the OSHA ionizing radiation regulations have not been updated since their inception in 1970, some confusion has arisen as to what is the applicable limiting exposure value for Rn-222 in the workplace.

The Act: To assure safe and healthful working conditions for working men and women; by authorizing enforcement of the standards developed under the Act; by assisting and encouraging the States in their efforts to assure safe and healthful working conditions; by providing for research, information, education, and training in the field of occupational safety and health; and for other purposes.

The primary duty under the Act: Each employer shall furnish to each of his employees employment and a place of employment, which are free from recognized hazards that are causing or are likely to cause death or serious physical harm to his employees.

What's covered under the Act: OSHA covers all radiation sources not regulated by the U.S. Atomic Energy Act of 1954. This would include X-ray equipment, accelerators, accelerator-produced materials, electron microscopes, betatrons, and some naturally occurring radioactive materials.

Who's covered under the Act: This Act shall apply with respect to employment in a workplace in a state - Section 4 Applicability of this Act. OSHA covers the private sector in States that do not have an approved OSHA plan. OSHA also covers federal workers except some Department of Defense workers. There are approximately 6.5 million workplaces covered by Act.

Who's not covered under the Act: Miners, construction workers covered under 29CFR1926, and State and local workers in the 26 states that have not entered into an agreement with OSHA to enforce their regulations. Pennsylvania is an example of one state that has not entered into an agreement with OSHA, and therefore its state and local government employees may be covered by the Pennsylvania Department of Labor and Industry, local codes, or nothing at all.

State OSHA Programs: OSHA encourages States to develop and operate their own job safety and health programs. There are currently 22 States and jurisdictions operating complete State plans, covering both private sector and State and local government employees: Alaska, Arizona, California, Hawaii, Indiana, Iowa, Kentucky, Maryland, Michigan, Minnesota, Nevada, New Mexico, North Carolina, Oregon, Puerto Rico, South Carolina, Tennessee, Utah, Vermont, Virginia, Washington, and Wyoming. There are four States, which cover public employees only; Connecticut, New Jersey, New York, and Virgin Islands. Under these State plans OSHA relinquishes its authority to the States to cover occupational safety and health matters. If an employee finds a health and safety hazard they would bring their complaint directly to the State. In States without an OSHA Program, OSHA is the responsible agency for workplace health and safety issues.

What is an Occupational Illness: Any abnormal condition or disorder, other than one resulting from an occupational injury, caused by exposure to environmental factors associated with employment. Included are acute and chronic illnesses or diseases that may be caused by inhalation, absorption, ingestion, or direct contact with toxic substances or harmful agents.

Occupational Exposure: It should be pointed out that the term "occupational" is used to describe two different groups of workers by the Nuclear Regulatory Commission (NRC) and OSHA. NRC regulates exposures to "persons licensed", who are potentially exposed to radiation as part of their jobs, such as nuclear power plant workers or medical personnel. NRC occupational exposure is specifically from licensed material. This type of occupational exposure does not include exposure to natural background radiation. The January 27, 1987 Federal Register helps to explain this type of worker. OSHA regulates exposure to "employees." These people may be exposed to natural background as part of their jobs, with the most likely source of that natural background radiation being Rn-222.

Ionizing Radiation under the Act: The ionizing radiation standard was issued in 1971. In 1996 OSHA re-designated the standard as 29 CFR 1910.1096, which is also the current designation. OSHA references Nuclear Regulatory Commission regulations as found in 10 CFR 20. The ionizing radiation regulation can be found at www.osha.gov, under Laws and Regulations select Standards, then select Part 1910 (Occupational Safety and Health Standard), then scroll down to 1910.1096 (Ionizing Radiation).

Now we must make a major distinction that is possibly the cause of some confusion. When OSHA issued their Ionizing Radiation Standard in 1971, they referenced 10 CFR 20 (NRC Regulations). They obviously

had to reference the NRC regulations in place at that time, which was the 1969 version of 10 CFR 20. The NRC revised their 10 CFR Part 20 regulations in 1991. The problem that arises is that individuals looking at the OSHA Ionizing Radiation Regulations today find no mention that OSHA is referencing NRC regulations and Tables that are over 30 years old, and in fact now are different then they were in 1969. The table 1 below shows the differences of the NRC Appendix B Tables from 1969 to 2003.

Table 1, 10 CFR 20, Appendix B, Limits for Radon-222

	1969	2003		
	Table I	Table II	Table 1	Table 2
	Column 1	Column 1	Column 3	Column 1
	MPC (μCi/ml)	MPC (μCi/ml)	DAC (μCi/ml)	Air (μCi/ml)
Rn-222	1E-7	3E-9	3E-8	1E-10
Rn-222 (pCi/L)	100	3	30	0.1

Note: 1970 Table I concerns occupational exposure and Table II concerns effluent releases similarly, in 2003 Table 1 concerns occupational exposure and Table 2 concerns effluent releases. The effluent columns are concerned with the assessment and control of dose to the public. The NRC updated the 100 pCi/L MPC to the 30 pCi/L DAC in the 1979 CFR. The Table 1, Column 3, 2003 ed. also expresses the limit for Rn-222 plus daughters as 0.33 WL.

From the above Table it can be easily seen how someone would use the most current Table I value (2003) and come up with 30 pCi/L (3E-8 μCi/ml) for the Rn-222 value to use to define an “airborne radioactivity area”, or 25 percent of that value, 7.5 pCi/L, also to define an “airborne radioactivity area.” This seems to be where a 1993 Radon News Digest article on “Radon in the Workplace” misunderstood the regulations. Not only did Radon News Digest make this mistake but OSHA also made the same mistake! In a letter to Mr. Richard A. Schreiber of the Georgia Radon Program, in which they were requesting OSHA interpretation of 29 CFR 1910.1096, OSHA responds in part “an airborne radioactivity area would exist in an area where an employee worked for 40 hours per week and the radon-222 concentration in the area exceeded 7.5 picocuries per liter.” Subsequently, OSHA caught their mistake and will edit this plus two other letters and provide the correct information. The mistake continues to propagate itself in the literature. A paper in the 1996 International Radon Symposium by an author from the National Institute of Occupational Safety and Health (NIOSH) quotes the “...PEL of 0.33 wl (30 pCi/L) based on 8-hour per day exposure throughout the work year ...” AARST was also led into believing that the workplace radon concentration of 7.5 pCi/L (25% of 30 pCi/L) was the value for defining an “airborne radioactivity area”. Finally, OSHA again makes the mistake in their Sampling and Analytical Methods, Method #ID 208, where they quote “OSHA PEL of 30 pCi/L (10 CFR part 20, App. B)”. Not only did the above references use the incorrect value, but some of them also seem to be using it in the wrong context. Some seem to be confusing posting requirements with exposure limits. See “Posting Requirements” and Exposure Limits” below.

In support of using the 1969 10 CFR 20 Table, Richard E. Fairfax, Director, Directorate of Enforcement Programs, OSHA writes in a December 23, 2002 letter to the Department of the Army “Case law supports the interpretation that the original version of a referenced federal regulation is the enforceable

regulation. Therefore, the 1969 version of Appendix B to 10 CFR Part 20 that was referenced in the original OSHA ionizing radiation standard in 1971 is enforceable.”

More confusion arises from the fact that one Federal agency (OSHA) references another Federal agencies (NRC) regulations, and the two agencies deal with different groups of people. OSHA regulates the employer for the health and safety of the employee, and NRC regulates the licensee for the health and safety of the workforce and the general public. As already noted OSHA ionizing radiation regulations point to 10 CFR 20, NRC regulations. Now, there is one major conflicting problem! The scope of 10 CFR 20 applies to persons licensed by the Nuclear Regulatory Commission to receive, possess, use, transfer, or dispose of byproduct, source, or special nuclear material ... The limits in this part (10 CFR 20) do not apply to doses due to background radiation ...

Based upon the above considerations, it would seem that naturally emanating Rn-222 would be excluded from Government regulation. Most general public employers do not have licenses for or posses NRC regulated material, and the agent of concern (radon) is due to natural background radiation, which (strictly interpreted) 10CFR20 does not apply to. However, all is not lost!

In 1989 Patricia Clark, Acting Director of OSHA Compliance Programs wrote a letter providing interpretation for the standard for ionizing radiation, 29 CFR 1910.1096. In that letter she wrote “An employer possesses radioactive material and comes under the scope of 29 CFR 1910.1096 if there are artificially enhanced concentrations of environmental radon-222 in the workplace. If environmental radon-222 concentrations have not been artificially enhanced, they are very much lower than permissible exposure limits (PEL). Accordingly, only artificially enhanced concentrations of environmental radon-222 would be sufficiently high that provisions of 29 CFR 1910.1096 would go into effect. The most common places for significant artificial enhancement of radon-222 concentrations to occur are inside of buildings or other types of enclosures constructed on or in the ground.”

Interestingly, OSHA even considers the employer to “posses” the Rn-222 if the presence of the Rn-222 in a structure controlled by the employer exposes employees to hazardous concentrations of airborne radiation as set forth in the standard. If that were the case then 29 CFR 1910.1096 would apply. This places a further liability on the employer.

An additional letter from Ruth McCully, OSHA Director Office of Health Compliance Assistance, dated October 6, 1992 further helps clarify the radon issue. She writes, “29 CFR 1910.1096 covers Naturally Occurring Radioactive Material (NORM). Accordingly, the definition of airborne radioactive area applies to areas that contain airborne NORM.”

Thus it would appear that Rn-222 is indeed “covered” by OSHA regulations, as indeed it is.

Who does the testing: It is the responsibility of the employer to do the testing. As stated in 1910.1096 (d)(1) “Every employer shall make such surveys as may be necessary for him to comply with the provisions in this section. Survey means an evaluation of the radiation hazards incident to the production, use, release, disposal, or presence of radioactive materials or other sources of radiation under a specific set of conditions. When appropriate, such evaluation includes a physical survey of the location of materials and equipment, and measurements of levels of radiation or concentrations of radioactive material present.”

What does one say to an employer who says ‘I didn’t know I was supposed to test!’ According to Assistant Secretary for OSHA Gerard Scannell (1991) “an employer who knows, or could have known

with the exercise of reasonable diligence of the existence of artificially enhanced concentrations of environmental Rn-222 in its workplace, must conduct a survey as described above.”

Mr. Scannell in a 1991 letter to Senator John McCain clarified that “an employer could know of a potential hazard with the exercise of reasonable diligence if the media has reported excessive radon exposure in the area the workplace is located.”

How is the testing done: The OSHA Technical Manual, Section III, Chapter 2, Indoor Air Quality Investigation says “a rapid, easy-to-use screening method for measuring radon gas concentrations is available from the Salt Lake Technical Center.” This method is listed as ID-208, and in fact is the electret ion chamber method. OSHA then goes on to quote from the EPA Citizen’s Guide To Radon and says that screening samples less than 4 pCi/L probably do not require follow-up, and screening samples greater than 4 pCi/L should have follow-up measurements performed.

The standard in 29 CFR 1910.1096 defines three types of restricted areas that must be identified and have their boundaries demarcated with special warning signs. They are “radiation area,” high radiation area,” and airborne radioactive area.”

Restricted area means any area access to which is controlled by the employer for purposes of protection of individuals from exposure to radiation or radioactive materials. The OSHA regulation does not define restricted area in terms of exposure to airborne radioactive materials, therefore, areas that do not qualify as “unrestricted areas” are “restricted areas.” Based on the definition below of unrestricted area this would imply that any work area which had Rn-222 concentrations greater than 3 pCi/L would be considered a restricted area.

Unrestricted area means any area access to which is not controlled by the employer for purposes of protection of individuals from exposure to radiation or radioactive materials.

Patricia Clark goes on to say that an “unrestricted area for airborne radioactive materials are areas where concentrations do not exceed the limits specified in Table 2 of Appendix B to 10 CFR 20. Table 2 (1970 edition) shows a value for Rn-222 of $3E-9$ μ Ci/ml, which equates to 3 pCi/L. This concentration may be averaged over a period of one year.

Radiation area means any area, accessible to personnel, in which there exists radiation at such levels that a major portion of the body could receive in any 1 hour a dose in excess of 5 millirem, or in any 5 consecutive days a dose in excess of 100 millirem.

High radiation area means any area, accessible to personnel, in which there exists radiation at such levels that a major portion of the body could receive in any one hour a dose in excess of 100 millirems.

The radiation area and the high radiation area are concerned with external exposure and will not be discussed further in this paper since we are concerned with the inhalation exposure from radon and daughters.

Posting Requirements

Airborne radioactivity area means any room, enclosure, or operating area in which airborne radioactive materials, composed wholly or partly of radioactive material, exist in concentrations in excess of the amounts specified in column 1 of Table 1 of Appendix B to 10 CFR Part 20, 1970 edition (100 pCi/L)

Or

Any room, enclosure, or operating area in which airborne radioactive materials exist in concentrations which, averaged over the number of hours in any week during which individuals are in the area, exceed 25 percent of the amounts specified in column 1 of Table 1 of Appendix B to 10 CFR Part 20.

Please be aware that the above two paragraphs are concerned with posting requirements for airborne radioactivity areas. If either one of the above two situations arise then the area must be posted, "Caution, Airborne Radioactivity Area." The two paragraphs differ in that the first paragraph has no mention of individuals, and it uses the limiting value as found in Appendix B. The second paragraph introduces individuals into the work area and because of this reduces the Appendix B limiting value to 25% of the limiting value (25 pCi/L). The second paragraph has no mention of employee time in the area. Technically, if employees were in the room for one hour and the average Rn-222 concentration over that one hour was greater than 25 pCi/L, then the room must be posted.

Therefore, if one placed a continuous monitor in an area, occupied by the workforce for 40 hours per week and the average concentration for those 40 hours was greater than 25 pCi/L you would have an airborne radioactive area and all of the implications that go with it, that is, employee monitoring, restricted access by the public, and the area would also have to be posted with a sign bearing the radiation caution symbol and the words "Caution, Airborne Radioactivity Area."

Exposure Limits

There is only one OSHA Rn-222 exposure limit and that is found in 10 CFR 20, Appendix B, Table 1, Column 1, and that value is $1E-7$ mCi/ml or 100 pCi/L. This exposure limit is specified for 40 hours in any workweek of 7 consecutive days, and applies to exposure in a restricted area (see definition page 5). OSHA apparently set this limit based on Federal Radiation Council guidance to the President in December 27, 1968, and U.S. Department of Labor hearings on Radiation Standards for Mining under the Walsh-Healey Public Contracts Act, November 20 and 21, 1968. This guidance said that occupational exposure to radon daughters in underground uranium mines be controlled so that no individual miner receive an exposure greater than 12 WLM per year, and that exposures should be kept as far below these values as practicable. The guidance went on to say that the uranium mining industry should continue to strive to meet the anticipated 4 WLM standard that would go into effect on January 1, 1971. Note: The 100 pCi/L OSHA maximum permissible concentration results in an exposure of 12 WLM/yr (See Appendix E).

If an employer has a work area that is occupied by their employees for 40 hours per week and the Rn-222 concentration is greater than 100 pCi/L, then the employer must either reduce the number of hours worked in the area or introduce engineering controls to reduce the concentrations. If the area is occupied it would also need to meet the posting requirements. If the number of hours worked in an area are less than 40 hours the limit specified in Appendix B may be proportionally increased, and if the number of hours worked are greater than 40 hours, the limit shall be decreased proportionally. For instance, if individuals were only in the work area for 20 hours the Rn-222 exposure limit would now be 200 pCi/L.

OSHA Permissible Exposure Limits (PEL): PELs are set to protect workers against the health effects of exposure to hazardous substances. PELs are regulatory limits on the amount or concentration of a substance in the air. PELs are based on an 8-hour time weighted average exposure.

There are permissible exposure limits for about 500 substances. These lists are found in 29CFR1910.1000, Tables Z-1, Z-2, and Z-3, "Limits for Air Contaminants". Radon-222 is not found in these tables. The OSHA, Radon-222 PEL is actually the NRC Maximum Permissible Concentration (MPC), which is found in 10CFR20, part 20, appendix B, 1970 ed. This value as listed in Appendix B is $1\text{E-}7$ $\mu\text{Ci/ml}$ or 100 pCi/L for 40 hours per week.

Understanding 10CFR20, Appendix B: Appendix B, Table 1 lists activities (μCi) and concentrations ($\mu\text{Ci/ml}$) of radionuclides necessary to keep worker radiation doses below the occupational exposure limits of 5 rem whole body or 50 rem to an organ or tissue. Values are listed for both ingestion and inhalation. We will concern ourselves with the inhalation values. Column 2 lists the inhalation annual limit of intake (ALI), which is the annual intake of a given radionuclide that would result in a committed effective dose equivalent of 5 rem or a committed dose equivalent of 50 rems to an organ or tissue. For Rn-222 with its daughters present the current NRC ALI is 4 WLM. Column 3 lists the inhalation derived air concentration (DAC), which are limits intended to control chronic occupational exposures. The DAC for Rn-222 with its daughters present is 0.33 WL or at 100% equilibrium 30 pCi/L (10 CFR 20, 2003 edition). The DAC value is based on a 2000-hour work year.

The DAC and the ALI are related. The DAC (in $\mu\text{Ci/ml}$) = $\text{ALI}(\text{in } \mu\text{Ci})/2.4\text{E}9$ ml, or put another way the DAC is the concentration of radionuclide in air, which if breathed for a work-year (2000 hrs) would result in the intake of one ALI. In terms of Rn-222 this would mean that in an environment with 30 pCi/L (DAC) for 2000-hours per year, one would accumulate 4 WLM (ALI) of exposure, which would produce a 5 rem whole body or 50 rem lung dose. For comparison purposes, if exposed to the average ambient radon concentration (~ 0.3 pCi/L) one would accumulate 0.2 WLM of exposure per year. See Appendix D.

Over the years a very broad range of occupational dose limits for radon exposures have been presented, values have ranged from less than 1 WLM/yr to greater than 20 WLM/yr. In 1967 the Environmental Protection Agency (EPA) used a value of 12 WLM/yr. In 1969 they put forth 4 WLM/yr on a trial basis, and then on July 1, 1971 they made the 4 WLM/yr final for miners. This reduction in exposure limits was based on earlier studies of uranium miners showing increased lung cancer incidence. This recommendation by EPA was also extended to other Federal agencies in 1971. See Appendix G.

The EPA recommends 4.0 pCi/L of radon-222 as its action level for mitigation in residences and schools; EPA has no guidance that applies directly to the workplace. The EPA guideline is not an occupational safety and health standard and does not carry the weight of law.

OSHA is considering revising its radiation protection standards in the near future. OSHA has also entered into an agreement with the Health Physics Society to provide consultation services regarding radiation safety matters. It would certainly appear that the OSHA ionizing radiation regulations require an update. In particular as they relate to Rn-222 exposure in the workplace, these standards need to clearly cover occupational exposure to naturally emanating Rn-222 and be brought more in line with current radiation safety regulations and guidelines.

Conclusions

The OSHA ionizing radiation regulations, 29 CFR 1910.1096 are in need of revision to bring them in line with the most current information on radiation health effects and exposures in the workplace.

If normalized to 100% equilibrium (100 pCi/L equals 1 WL), a continuous exposure in the workplace (2000 hrs/yr), at the OSHA exposure limit of 100 pCi/L results in a cumulative exposure of 12 WLM/yr.,

compared to a continuous exposure in the home environment (6570 hrs/yr), at the EPA guideline of 4 pCi/L resulting in a cumulative exposure of 1.5 WLM/yr. Thus, the current OSHA Rn-222 workplace limit results in an exposure over six times greater (12 WLM Vs. 1.5 WLM) than the current EPA guideline of 4.0 pCi/L. See Appendix F.

President Ronald Reagan in a 1987 memorandum gave recommendations for numerous federal agencies, including OSHA to update previous regulations for the protection of workers exposed to ionizing radiation. This has yet to be accomplished.

Many authors and agencies over the past 10 years or so have mistakenly used the incorrect, although more conservative, limiting value for Rn-222 as found in post-1978 10 CFR 20 editions, Appendix B, and have confused Posting Requirements with Exposure Limits.

If the employer, with the exercise of reasonable diligence, knows or could have known about the existence of artificially enhanced concentrations of environmental Rn-222 they must conduct a survey.

Appendix B, OSHA Posting Requirements

Airborne Radioactivity Area

Unoccupied Room or Area 100 pCi/L

Occupied Room or Area 25 pCi/L

Appendix C, Radiation Areas

Unrestricted Area < 3 pCi/L

Radiation Area > 5 mrem/hr External >3.6 pCi/L

High Radiation Area >100 mrem/hr External >150 pCi/L

Note: The picocurie/liter values for radiation area, and high radiation area are derived values and not specifically applicable to these areas.

Appendix D

DAC to ALI

Rn-222 DAC equals 0.33 WL or at 100% equilibrium 30 pCi/L

Rn-222 ALI equals 4 WLM per year

Therefore: $\{(0.33 \text{ wl}) (2000 \text{ hrs/yr})\} / 170 \text{ hrs per month} = 3.88 \text{ wlm or } \sim 4 \text{ wlm}$

ALI to Committed Dose Equivalent (CDE)

Therefore: $(4 \text{ wlm}) (0.6 \text{ rad/wlm}) = 2.4 \text{ rad}$

$(2.4 \text{ rad}) (20) = 48 \text{ rem or } \sim 50 \text{ rem to TB region of lung}$

Appendix E

Maximum Permissible Concentration to WLM

Assume 100% equilibrium ratio and 2000 hours/year exposure.

OSHA MPC equals 100 pCi/L or 1WL, therefore

$\{(1 \text{ WL}) (2000 \text{ hrs/yr})\} / 170 \text{ working hours per month} = 11.76 \text{ or } \sim 12 \text{ WLM/yr}$

Appendix F

Work Exposure verse Home Exposure

Work: Assume (OSHA Limit) 100 pCi/L = 1WL, and 2000 hours/yr worked

$\{(1 \text{ WL}) (2000 \text{ hrs/yr})\} / 170 \text{ hrs/month} = 11.76 \text{ WLM } \sim 12 \text{ WLM}$

Home: Assume (EPA Guideline) 4 pCi/L = 0.04 WL, and 6570 hours/ yr at home

$\{(0.04 \text{ WL}) (6570 \text{ hrs/yr})\} / 170 \text{ hrs/month} = 1.54 \text{ WLM}$

Appendix G

A Brief History of the Rn-222 Occupational Limits

Much of the Federal guidance given below was based on studies starting in the early 50's of uranium mines on the Colorado Plateau. The U.S. Public Health Service, primarily led by Duncan Holaday and his colleagues were the first group to raise concern about the potential health effects from radon daughter exposure in the mines. There was already evidence coming from the "European Experience" where increased lung cancer rates were seen in the miners. However, there was great reluctance by the miners to take radon seriously, they were making good money. The mine operators were also reluctant to disturb operations. However, in spite of the reluctance, the Public Health Service was able to start getting into mines to take samples and also have physical exams performed on many of the miners. It was too early yet to see any malignancies in the miners, however, the air samples were certainly alarming. One sample at a working face in a Utah mine showed 26,900 pCi/L, another at the entrance incline was 14,000 pCi/L. These samples are compared to what was seen in some German and Czechoslovakian mines with 1,000 and 1,500 pCi/L, respectively. It was becoming obvious that something had to be done. The Public Health Service estimated that a maximum allowable concentration of 100 pCi/L of radon would be safe in a mine. This was also the European standard. The only radiation standards at the time were those established by the NCRP in 1940. Finally, Dr. John Harley at the Health and Safety Laboratory found that it was not the radon but the radon daughters that were the significant health concern. It would be up to the Atomic Energy Commission to set the standard, see below.

December 1968 the Federal Radiation Council (FRC) submitted three memorandums to the President concerning radiation protection guidance for Federal agencies. The recommendations contained in the memorandums were based on FRC Report No. 8, "Guidance for the control of radiation hazards in uranium mining", September 1967.

The first memorandum was published in the Federal Register on August 1, 1967. The FRC considered exposure guidance of 36, 12, and 4 WLM per year. Based on a balance between risks to miners and exposure control capability in the mines they choose the 12 WLM per year limit.

The second memorandum was published in the Federal Register on January 15, 1969. In this memorandum the FRC gave guidance to Federal agencies concerning underground uranium mining. They put forth eight recommendations, two of which are most important to this discussion. 1) Occupational exposure to radon daughters in underground mines shall not exceed 12 WLM in any consecutive 12-month period, and 2) The uranium mining industry is urged to continue to lower exposures so that the anticipated 4 WLM per year standard can be attained by January 1, 1971.

A very significant study from NIOSH by Lundin, et. al., 1971 provided very conclusive evidence that there was a statistically significant excess of respiratory cancer observed in white uranium miners at cumulative exposures down to and including the 120-359 WLM range. Furthermore, it was concluded this excess respiratory cancer was due to radon daughter exposure. This report would be significant in setting the new 4 WLM standard.

In the May 25, 1971 Federal Register the Environmental Protection Agency (EPA) provided further guidance to Federal agencies concerning underground mining of uranium ore. They concluded that 4 WLM per year was technically feasible, and that the 4 WLM standard would not have a severe impact on the uranium mining community, and that a standard greater than 4 WLM would probably result in dosages greater than those permitted for other occupational exposure situations. This recommendation of 4 WLM per year was approved by the President and published in January 15, 1969 Federal Register, and was to become effective January 1, 1971. This date was later extended to July 1, 1971.

Based upon the May 25, 1971 Federal Register announcement by EPA of the 4 WLM/yr standard public comments were received. The EPA responded to those comments as published in the July 9, 1971 Federal Register and concluded that no change would be made to the 4 WLM/yr standard.

In the June 24, 1974 Federal Register the Atomic Energy Commission (AEC) considered an occupational concentration value for Rn-222 daughters in their Table 1, Appendix B. The limit for Rn-222 would be replaced by a limit for the daughters since they are the major health hazard. This change would bring the limit to 4 WLM/yr as recommended by the EPA, which was about 1/3 of the current 10 CFR 20 value. This change was in conformance with the ICRP Publication 2, "Report of Committee II on Permissible Dose for Internal Radiation", published in 1959, which recommended a limit on Rn-222 of $3E-8$ mCi/ml (30 pCi/L) with daughters present. NCRP also recommended the same limit in their NBS Handbook 69, 1959.

The AEC considered (June 24, 1974 Federal Register) expressing the Rn-222 daughters concentration in terms of working levels but rejected this because it would add a new unit to the table and add confusion. It was therefore proposed and amended that the current Appendix B, Table 1 limit for Rn-222 be deleted and a new line for Rn-222 daughters be added beneath the Rn-222 line. The Rn-222 daughters limiting value would be $7E-8$ mCi/ml (70 pCi/L). This limit is based on a one-week average. A Rn-222 value of $3E-8$ mCi/ml (30 pCi/L) appears under Table II, Column 1.

As published in the October 31, 1975 Federal Register, the AEC decides to express both radon and its daughters in conventional ways. Thus the Federal Register announcement of June 24, 1974 was amended to show Rn-222 concentration limit of $3E-8$ mCi/ml (30 pCi/L), under Table 1. A footnote gives alternate limit of 1/3 WL for daughters. This amendment becomes effective January 29, 1976.

The Nuclear Regulatory Commission (NRC) changed the averaging period for the Rn-222 limit from one week to one year in the July 7, 1978 Federal Register.

The Rn-222 limit of 30 pCi/L (0.33 WL) that became effective on January 29, 1976 did not appear in the NRC, 10 CFR 20 Appendix B table regulations until the 1979 edition. Prior to that it had been 100 pCi/L.

There have been numerous studies regarding health effects of radon and miners. There is a need to determine radon exposure in the general work place. It is not necessary to work in an underground facility to be exposed to radon.

Radon exposure is a significant problem for workers in this industry. Radon is a gas which leads to lung cancer, and comes ultimately from uranium in the earth's crust. This is a problem for people in their homes, and is even more of a problem for people who work in underground space. More research is needed into this area to determine "safe" levels of exposure, if any, to come up with a real standard and a requirement for employers to protect employees.

Radon is a serious problem and here in WY we have NO regulations governing Radon in any way. It is VITALLY IMPORTANT that Radon be addressed in the workplace as EVERYONE works somewhere; ie. daycare, schools, factories, office buildings, etc. Right now I am breathing Radon in my office building as I type this message. Please put more teeth and resources into Radon testing, mitigation, regulation, education, etc.

Thank you.

i would like others in nursing and healthcare to know about the allergies that can be associated with wearing gloves. i was an er nurse who developed systemic mold infection and then systemic reaction to mold (the occlusive nature of the gloves produced mold with my sweat which caused a systemic reaction). i am on my 4th year of allergy injections and had to change my job and i am working in a call center. My immune system is very low as i now have low t and b cells. There are more to allergies than just latex. It was a difficult situation, also because i had to hire a lawyer. The hospital was not helpful or supportive.. thanks pat e roscoe, bsn, rn

I would like to know if any study has been done on chronic low-level carbon monoxide poisoning? I have lost four jobs and have to refuse work in other settings because of an occupational-environmental-type illness that has given me varied symptoms creating real health concerns since relating the difficulty to air in October of 2002. I have not been able to find a doctor who would acknowledge the cause of my illness or at least admit that the continuing problems are a result of the CO exposure after stating that initially I was so exposed. My case is extremely important to the health care system because it proves a very real connection between low-level long term CO exposure and numerous illnesses-diabetes, chronic back pain, heart problems, etc. It would seem to me that with the current environmental issues this CO problem should be revealed so that doctors and labour board people could no longer pretend ignorance. Thankyou.

DATE: March 1, 2006

TO: John Howard, M.D.

Director, National Institute for Occupational Safety and Health

FROM: Muriel Dando, President

Human Ecology Action League, Inc. (HEAL)

RE: National Occupational Research Agenda (NORA)

Thank you for the opportunity to contribute to the National Occupational Research Agenda.

We urgently recommend that NORA undertake research to investigate work-related asthma in nurses and teachers, to identify workplace exposures related to asthma in nurses and teachers, and to recommend ways to reduce or eliminate these exposures.

Nurses and teachers are of critical importance to the nation, as they are entrusted with the well being of our most vulnerable citizens - the sick, and children. The Department of Labor anticipates a dramatic increase in demand for workers in both professions in the near future, yet current data indicate that worker turnover is high in both professions. We believe that work-related asthma may be playing a role in worker turnover in nurses and teachers, and that preventing workplace asthma exacerbations could help increase worker retention and productivity in both fields.

Our concern about the workplace health of nurses and teachers arises from the purpose and goals of the Human Ecology Action League, Inc. (HEAL). HEAL is a national nonprofit education and information organization concerned about the health effects of environmental exposures, particularly low-level exposures common in daily life and in many workplaces. One of the oldest environment and health organizations in the country, HEAL is an independent organization, funded solely by membership fees and donations. While HEAL has a primary responsibility to serve its own members, it also has an important responsibility to educate and inform the general public.

We have received reports from nurses and teachers about workplace conditions that they believe are harmful to their respiratory health. As the attached report illustrates, this perception is widespread in both professions. We believe that there is enough evidence to warrant a vigorous and extensive research effort to uncover the extent and nature of the problem of work-related asthma in nurses and teachers, to identify contributing factors that undermine respiratory health in these workers, and to recommend effective means of mitigating or eliminating these factors.

We hope that you will consider including this issue in the NORA agenda.

Note: The text above was entered from the letter embedded in submission E51. The full report is available in [Appendix 9](#).

The interim fall protection STD 3-0.1A needs to be reviewed and modified to reflect the present work practices and materials being used. Asking framers to set trusses and second floor joists from ladders is an alternative but is it really safe? Additional work and research needs to be conducted on temporary anchor points during the framing process and other residential construction tasks such as building decks, installing siding, and other tasks requiring work above 10 feet. When can one tie off of trusses? Does installing an anchor point on a wood frame meet the 5000 lb anchor point requirements? These are issues that have had no research conducted. How do you expect workers to tie off if there is no anchor point.

Categorized comment or partial comment:

More outreach programs are needed for the small contractors. Residential construction is conducted by many small contractors with less than 10 employees and most of them are hispanic. Communication issues is a great problem. How do you convince sub contractors that are piece workers to work safely and spend money on equipment that is going to slow them down? Guides that help small contractors develop their safety program and communicate to their workers the need to work safely is lacking. To top if off the residency status of many workers makes it more difficult to assure them that they have a right to a safe work place. They are afraid to speak up when asked to do unsafe tasks.

The training materials and classes need to be accesible to all that are doing the work. There are great resources on the internet but most of the small contractors do not use computers. They rely on verbal and written communication. Training Materials should include pictures with symbols.

Focus groups should review existing work practices and evaluate if they meet OSHA requirements. Specific regulations focusing on residential construction need to be developed and implemented.

Due to the high rate of infectious diseases that patients contract in hospitals, nursing homes, rehabilitation centers, etc., cleanliness, sterilization, disinfection and washing of the hands of nurses and doctors as they go from one patient to another, is of the utmost importance.

My question is: Do hospitals and other health facilities actually hire enough workers to clean, disinfect, sterilize, patient's rooms and bathrooms? Seems years ago, patients rooms and bathrooms were cleaner and cleaned more often. As the years go by, it appears that these rooms are not kept as clean, no matter which state you may be in.

Also years ago, many things in the patient's room were made of stainless steel. Now there is so much plastic and wood. These items are more porous and can retain bacteria. I also believe that for each new patient, the divider curtains around the beds should be freshly cleaned. And food should be served on China-style dishes and cups that can be sterilized properly with stainless steel food covers instead of plastic.

Nowadays patients are given booties to put on their feet and wear them to go to the bathroom or walk down the facility's hallway or take the elevator or stairs to other locations of the facility and then they go back to their room and into their bed with the same booties on their feet. Many germs are brought right into their own bed.

The poor nurses have so much paper work to do and it makes them always in a hurry when attending their patients that they don't always take the time to wash their hands between touching other patients.

Maybe some of these observations can be of help.

January 15, 2006

To Whom It May Concern:

I am writing as a Chemistry professor at Heritage University (Toppenish, Washington), a researcher focusing on alternative (primarily non-food) uses of agriculture, and a member of El Proyecto Bienestar (a partnership among the University of Washington, the Yakima Valley Farm Workers Clinic, the Northwest Communities' Education Center, and Heritage University dedicated to protecting the health and well-being of local agricultural workers and their families).

For several years, my students (90-percent of whom are Hispanic or Native American) and I have been making and testing biodiesel fuels, ethanol, producer gas, pelletized solid fuels, biolubricants, polymers, composite materials, specialty papers, inks and wood stains, skin creams and cosmetics, nutritional supplements, baking ingredients, animal feeds, soil amendments, and other products (more than two-dozen items in all) derived from agricultural byproducts discharged from local industrial operations.

To date, we have been accident- and injury-free during the conduct of this work; since we observe the proper safety and environmental procedures.

My concern regards the implications of scaling-up these technologies and moving them out of the laboratory environment (where skilled students and faculty use proper protective gear and training to

ensure the safe handling and management of chemically and biologically active materials and equipment) into the field.

I am supportive of efforts to expand the scope of agriculture to address our nation's energy, materials, chemical, nutritional, and pharmaceutical needs. These measures could lead to a substantial improvement in the availability and affordability of these items and create related jobs and businesses in economically depressed areas while reducing our dependence on foreign sources and minimizing the adverse environmental impacts of current practices.

These measures could also lead to a substantial increase in the number of chemical, biological, electrical, mechanical, and perhaps radiological risks faced by agricultural workers and their communities, to the extent that the commercial deployment of these new technologies proceeds in a modular, distributed fashion (i.e., close to the farm in order to reduce the costs of transporting low-value materials).

Among these risks are toxic substances (e.g., methanol, carbon monoxide, methoxides), flammable substances (e.g., methane, ethanol, hexanes), biological substances (e.g., many micro-organisms, plants, and their substrates that are new to commercial agriculture and have different characteristics and properties), electrical components (e.g., inverters, switch gear, transformers, network interconnects), mechanical components (e.g., shredders, mixers, pelletizers, gasifiers), and possibly radiation sources (e.g., gamma-rays and e-beams for sterilizing, pre-conditioning, or reacting biomaterials).

Accordingly, I urge that - in anticipation of these new directions in agriculture - communication, education, and training programs (in English and Spanish) be developed, based on the best available research and understanding of these risks and incorporating the best available detection and control technologies, and disseminated to ensure that these enterprises can proceed without exacerbating the risks of injury and illness already faced by our agricultural workers and their families.

Thank you for your consideration of this important matter. I would be pleased to respond to any related comments or questions.

Sincerely,

Eric Leber

National Occupational Research Agenda

Seattle Town Meeting: January 17, 2006

Psychosocial Factors affecting Worker Health and Safety

Thank you for providing us with this opportunity to address an issue that has a profound effect on workers in this country. That issue is occupational stress, a hazard that is present in one form or another in virtually every workplace in America.

The Problem

The adverse effects of stress have been well documented in the literature. These effects include an array of psychological conditions (e.g., depression, anxiety, sleep disturbances) and physiological responses (e.g., cardiovascular, gastrointestinal, musculoskeletal disorders as well as impaired immune functioning); for example, one study found that exposure to even a month of high levels of job stress dramatically increased an individual's susceptibility to common upper respiratory viral infections (Cohen

et al, 1998); and another identified a direct relationship between low worker control and poor health (Schaubroeck et al, 2001). Inordinate workplace stress may lead to work performance decrements, decreased attention/concentration, increased distractibility, increased muscle tension, and poor judgment. The results of stress are lowered productivity, burnout and increased risk for accidents (Ghosh, Bhattacharjee, Chau, 2004; Knardahl, 2005; Miranda et al, 2005; Simpson et al, 2004). In more extreme cases, exposure to workplace stressors may be a risk factor for violent acts such as homicide, suicide or other forms of assault to self or others.

What is Known

The following headlines from a Wall Street Journal demonstrates the prevalence and concern among business professionals about the problem of occupational stress:

Can Workplace Stress Get Worse?

Incidents of Desk Rage Disrupt America's Offices

At Verizon Call Centers, Stress is Seldom on Hold

Impossible Expectations and Unfulfilling Work Stress Managers, Too

Seeking the new Slimmed-Down Workday: 9 to 5

What were once considered normal hours are luxury for burnt-out employees

Extreme Job Stress: Survivors' Tales

Occupational stress is ubiquitous; causes of stress are multifactorial and difficult to quantify; and occupational stress is costly.

Occupational stress is ubiquitous. Studies suggest that close to half of workers view their jobs as somewhat or extremely stressful; and the majority feels that their jobs have become more stressful in recent years (Daniels, 2004; NIOSH, 1999). In one study, about half of the respondents indicated that job stress adversely affected their health, their personal relationships and their job performance.

Causes of stress are multifactorial and difficult to quantify. There are numerous factors that contribute to occupational stress such as increased workload, declining job satisfaction, unsafe working conditions and management/leadership styles. Worker stress levels are related to the structure of work, the organizational culture and climate, and interpersonal relationships at work.

And lastly, occupational stress is costly. Claims for stress-related conditions are the most expensive claims in the workers' compensation system on a per claim basis. Other costs related to stressful working conditions include increased absenteeism rates, on the job injuries, tardiness, increased health insurance costs, workplace malfeasance and higher worker turnover.

What Needs to be Done

It is increasingly clear that although psychosocial hazards may be more nebulous and less tangible than other categories of workplace hazards, they nevertheless exert a pervasive influence on the health and safety of American workers. There are no quick fixes for the multitude of stressors experienced in the workplace. Indeed, recent strategic advances in our understanding of occupational stress must continue and even be accelerated. Despite the number of studies that have effectively documented the causes and adverse effects of occupational stress, there is still a great deal of uncertainty and confusion about

the “nature and definition of stress, the evidence linking working conditions to health (and safety) and the breadth of problems attributed to stress” (Daniels, 2004). While much has been accomplished since NIOSH first identified occupational stress as one of its top ten priorities, there is still much work to be done.

The conditions that lead to adverse health and safety outcomes are deeply embedded in the climate and culture of organizations; and unfortunately, competition and near-sighted economic priorities often lead to unhealthy and unsafe compromises. Organizations are constantly dealing with competing priorities, and sometimes a choice must be made between short term profit and worker safety. We need to continue in our efforts to understand how work-related stress affects workers and to also determine what factors cause the greatest burden; and more importantly, we need to develop and test interventions to ameliorate the conditions that lead to adverse stress responses that affect workers, their families and our communities.

Categorized comment or partial comment:

I recommend that NORA add to its research agenda some of the important issues concerning the stay-at-work and return-to-work (SAW/RTW) process that are highlighted in the attached report, entitled "Preventing Needless Work Disability by Helping People Stay Employed." The report is addressed to a broad audience of medical and non-medical readers and is an informative, sensible, and enlightening overview of the SAW/RTW process with both general and specific suggestions on how to improve it.

As one specific example, I particularly recommend that NORA fund research to improve the accuracy, reliability, and practical everyday availability and usefulness of methods by which work capacity is estimated as well as the functional demands of jobs are described, as called for in Section IV of the paper, entitled "Invest in System and Infrastructure Improvements."

This report was developed by the American College of Occupational & Environmental Medicine's College's Stay at Work and Return to Work Process Improvement Committee. At its October 27, 2005 meeting in Chicago, ACOEM's Board of Directors approved it and announced its availability to members with the following comment: "At a later date, shorter versions of this document will be developed as ACOEM position papers and will be specifically directed to different audiences. However, because of the importance of this topic, the 34-page paper is being made available to the membership as a committee report."

The first part of the document describes the stay at work/return to work (SAW/RTW) process, how it works and how it parallels other related processes. The second half discusses factors that lead to needless work disability and what can be done about them. Sixteen sections containing specific recommendations are grouped under four general recommendations:

--I Adopt a disability prevention model.

--II Address behavioral and circumstantial realities that create and prolong work disability.

--III Acknowledge the powerful contribution that motivation makes to outcomes and make changes that improve incentive alignment.

--IV Invest in system and infrastructure improvements.

The most important areas needing more study and research are discussed in Section IV concerning the need for investments in system and infrastructure improvements.

I chaired the committee that wrote the report, and will be happy to answer any questions you may have.

Cordially,

Jennifer Christian, MD, MPH

Dear NORA,

Dr. Christian`s advice regarding the Stay at Work / Return to Work is right on! The process of disability management is critically important to the nation. The evidence is clear that important improvements can be achieved. NIOSH can provide important tools to advantage this work.

More generally, NORA should fund much more work that will improve processes of clinical practice of occupational medicine; this strategy will create better outcome much more effectively than basic research on the nuances of toxicity- related OEM problems, most of which has been adequately studied and most of which are no longer important clinical problem of current practice.

Generally, Medicine is moving toward a redesign of the health care system that will make much greater use of digital health information systems to:

- 1) create processes and tools that make skilled OEM practitioners (who are in short supply) more efficient
- 2) detect variation and use that variation to improve quality
- 3) involve the patient more in their own care
- 4) refocus OEM practice on prevention

5) allow greater collaboration between economic stakeholders and different professional groups in managing cases and root causes

I am hopeful that NIOSH will help OEM be a leader in these important directions.

Best,

George Anstadt MD FACPM FACOEM

Past President, ACOEM

To Whom It May Concern:

I am writing to support further research into Stay at Work / Return to work. I am currently working with Transitional Work and Case Management at various levels in various organizations. Ohio has given grants to companies to begin Transitional Work Programs. I personally have seen the benefits to both workers and employers = Transitional Work is truly a win-win proposition! Our highly paid professional athletes benefit from "stay at work" programs. They are gradually and carefully re-conditioned to do their sport. Why can't the American worker receive the same benefit and concern? One only has to watch a factory worker do his job for a day, and consider the physical demands of the job to realize the parallels with the injured athlete and how important it is to not allow that worker to "de-condition". Research should be done on re-injury rates with stay at work programs or return to work programs vs. off work to immediate full duty policies. I hope your organization looks at the high cost of disability in today's workplace, and chooses to allocate funding for research into this topic. Thank you for your consideration of this important matter.

Sincerely,

Pamela Frigy, RN, BSN, COHN-S

SAW/RTW Process deserves a place on the NORA agenda

I recommend that NORA add to its research agenda some of the important issues concerning the stay-at-work and return-to-work (SAW/RTW) process that are highlighted in the attached report, entitled "Preventing Needless Work Disability by Helping People Stay Employed." The report is addressed to a broad audience of medical and non-medical readers and is an informative, sensible, and enlightening overview of the SAW/RTW process with both general and specific suggestions on how to improve it.

As one specific example, I particularly recommend that NORA fund research to improve the accuracy, reliability, and practical everyday availability and usefulness of methods by which work capacity is estimated as well as the functional demands of jobs are described, as called for in Section IV of the paper, entitled "Invest in

System and Infrastructure Improvements."

This report was developed by the American College of Occupational & Environmental Medicine's College's Stay at Work and Return to Work Process Improvement Committee. At its October 27, 2005 meeting in Chicago, ACOEM's Board of Directors approved it and announced its availability to members with the following comment: "At a later date, shorter versions of this document will be developed as ACOEM position papers and will be specifically directed to different audiences. However, because of the importance of this topic, the 34-page paper is being made available to the membership as a committee report."

The first part of the document describes the stay at work/return to work (SAW/RTW) process, how it works and how it parallels other related processes. The second half discusses factors that lead to

needless work disability and what can be done about them. Sixteen sections containing specific recommendations are grouped under four general recommendations:

--I Adopt a disability prevention model.

--II Address behavioral and circumstantial realities that create and prolong work disability.

--III Acknowledge the powerful contribution that motivation makes to outcomes and make changes that improve incentive alignment.

--IV Invest in system and infrastructure improvements.

The most important areas needing more study and research are discussed in Section IV concerning the need for investments in system and infrastructure improvements.

I chaired the committee that developed the report, and will be happy to answer any questions you may have.

Cordially,

Tim Pinsky, DO, MPH

I would like to see additional research on the use of patient lift equipment, lift policies and teams in preventing injuries in health care workers.

I work as a nurse practitioner in Employee Health at El Camino Hospital in Mountain View, CA and oversee the Patient Lift Injury Prevention Program.

I received my master`s degree in Occupational Health through NIOSH-sponsored ERC at UCSF and PhD at UC Berkeley in Health Services Research and Policy Analysis. I would be interested in working collaboratively with NIOSH and other hospitals and educational institutions on a grant to study this topic.

Thank you for this opportunity,

Sincerely,

Beverly Nuchols, RN-C, OHNP, MS, PhD, COHN-S El Camino Hospital, Employee Health 2500 Grand Rd.

The Center to Protect Workers' Rights

8484 Georgia Ave, Suite 1000, Silver Spring, MD 20910

Comments on NIOSH NORA 2 Town Hall Meeting on Construction

Chicago, IL

December 19, 2005

The Center to Protect Workers' Rights (CPWR) is a non-profit research institute affiliated with the Building and Construction Trades Department, AFL-CIO. CPWR is a committed partner with NIOSH in advancing research on the prevention of occupational injuries and illness in construction, and is supportive of most of the research goals as currently proposed. Since 1990, CPWR and an affiliated consortium of university researchers have been actively engaged in conducting construction occupational safety and health research in partnership with NIOSH. Research to support evidence-based decisions for controlling or eliminating risks on construction sites is our principal criterion in evaluating the proposed goals. We appreciate the ongoing opportunities for input into the NIOSH goals setting process as it relates to construction, and encourage NIOSH to consider the following comments:

1. Clarify Differences Between PART Performance Metrics, NORA2 Research Priorities, and Management Systems such as Sector Councils

NIOSH should develop a lead paragraph or section which clearly distinguishes: (1) the NORA2 research and injury and illness prevention priorities; (2) PART performance measures/metrics which are proxies for but do not reflect the full scope of NIOSH research priorities; and, (3) NIOSH management/organizational systems for development and continuous adjustment of research and prevention priorities such as the proposed construction sector councils and NIOSH construction steering committee. These PART metrics provide reasonable but simplified proxies for NIOSH research performance, for consideration by the Office of Management and Budget (OMB). The current PART

draft may give the impression that these represent the anticipated outcomes for all NIOSH research and services.

NIOSH should reconsider the value of fixed time frames for some of these initiatives. Management systems such as the industry councils can take several years to develop and once put in place should be continuously improved rather than identified as 10-year strategic goals. Initiating a new management system every decade is a poor use of resources. Management and organizational structures should be established with the expectation that they will continue indefinitely with incremental improvement. PART performance metrics should be reviewed at least annually but are required to include strategic (10+ year), intermediate (3 to 5 years) and annual goals. Research priorities should change based largely on scientific and public health progress. High priority research objectives will remain high priority until our knowledge in that area advances, or surveillance or objective evidence indicates that other occupational health priorities should be given preference.

Categorized comment or partial comment:

2. Evidence/Surveillance Based Research Priorities

Defining the quality and limitations of baseline surveillance data, and the magnitude of misdiagnosis, misclassification, and under-reporting of occupational injury and illness should be a NIOSH priority. Surveillance should be more closely integrated into ongoing injury and illness prevention intervention research.

A basic principal of occupational public health practice is to focus on high-risk populations and tasks, in order to maximize the health benefit given limited funds and personnel. NIOSH should clearly state that the NORA2 industry sector councils are not intended to result in equal emphasis or equal funds across all sectors, and will continue to follow good public health practice by allocating funds and prioritize efforts based on which research and interventions are likely to result in the greatest public health impact. This may result in very limited resources being applied to some sectors, unless NIOSH receives increased total funding. Construction and several other sectors (agriculture, fishing, lumber, mining) face disproportionately high risks compared to the general working population. Equal expenditures and effort in each of the eight industry sector councils and cross-sector councils proposed in NORA2, would have the effect of decreasing the value of NIOSH activities. Rather than equal distribution, allocation of resources should be based on best available scientific evidence. Dr Janie Gittleman will discuss construction surveillance priorities later this afternoon.

3. Hierarchy of Controls

A basic principal of occupational public health practice for industrial hygiene is the hierarchy of controls. NIOSH should recognize and formally consider the hierarchy of controls in the research and R2P goal-setting process. Given limited applied research resources, research to evaluate efficacy of interventions should lead to a long term strategy emphasizing re-design to eliminate recognized hazards or provide engineering controls, in preference to personal protective equipment (PPE), except where other control options are not feasible. This is addressed to some extent with the crosscutting effort related to engineering controls. However, PPE is likely to continue to be the most common control action in the construction industry for decades to come. Near term research must focus on evaluating the efficacy of engineering controls, and comparable PPE options, for high-risk construction tasks. NIOSH NPPTL has important regulatory and research responsibilities related to PPE. A NIOSH management priority should be to improve the integration of research teams involved in PPE, engineering control evaluations, and intervention effectiveness research. Currently these efforts are rarely coordinated even among NIOSH intramural researchers.

NIOSH should also plan for long term intramural and extramural research capacity. While intervention research and research to practice are current NIOSH priorities, NIOSH human resources continue emphasize surveillance. Although NIOSH has significant engineering expertise targeting mining operations, continuing effort and resources must be allocated for expanding these efforts as they relate to construction. NIOSH should also recognize that descriptive engineering evaluation, field testing, and incremental product or process development do not fit well within its existing processes for reviewing and awarding extramural/intramural research, even though critical in moving research into practice.

4. Professional Resources and Training

NIOSH and its extramural research and education centers play a critical role in training professionals in occupational medicine and nursing, industrial hygiene, and safety. There should be performance metrics related to the expansion and sustainability of the occupational safety and health professional workforce. An assessment of training among construction safety personnel would suggest that construction is currently poorly served by these existing education systems. Existing university-based safety engineering programs are extremely limited and most have minimal faculty research. Given the small size of construction employers (80% have fewer than 10 employees), para-professional training and other innovative approaches should be considered. NIOSH should have as an objective an assessment of unique professional and para-professional training needs in construction, perhaps including initiatives targeting civil and mechanical engineering, government contracting and procurement officers, architecture and design, as well as the more traditional safety and health professionals. This should also recognize that most skill training in the construction sector continues to be provided by joint labor management multi-employer apprenticeship and training programs, which train new workers, journeymen, stewards and foremen.

5. Emphasis on R2P and Intervention Research

CPWR strongly supports NIOSH's increased emphasis on intervention effectiveness and dissemination research. While NIOSH has emphasized initiatives to move research results into practice in the workplace (R2P), research evaluating the efficacy of specific interventions in the construction workplace remains fragmented in NORA2 priorities on communication and dissemination, small business assistance and outreach, and others. Intramural and extramural funding mechanisms should be evaluated to consider their effectiveness in identifying and prioritizing proposals for development, dissemination, or practical field-testing of exposure controls. Rarely do proposals include funding for systematically moving the product of research initiatives into the work place to prevent injury and illness. Current review mechanisms support development of new generalizable knowledge, but are ill-suited for moving those research results into practice. While the peer review process effectively identified research priorities, this process does not adequately prioritize proposals for engineering development or dissemination of specific control options. For example, research evaluating balance and visual cues should be low priority, even if research results may allow workers to reduce fatal falls a few percent, because redesign of the structure and existing fall arrest and prevention systems can reduce fatal falls to zero. Similarly, research on human air bags should be lower priority than research on fall arrest anchorage points or other engineering controls because of the hierarchy of controls, because current prototypes fail to address head injury (the primary cause of death in fatal construction falls). Organization of work in construction, which is characterized by contractual shifting of risk, makes it unlikely that such complex PPE would be selected, purchased, maintained, and used in a manner such that it would work when needed. Prioritization of R2P projects, including engineering development and dissemination proposals, should take into consideration factors that are different than if the same proposal were reviewed by NIH as basic research.

6. Expanded public policy and regulatory analysis and recommendations

Cross sector emphasis on "Authoritative Recommendations Development" is an important focus where NIOSH should consider not only recommended exposure limits, but also evaluation of other public health policy alternatives. NIOSH is given an important mandate in the Occupational Safety and Health Act, which includes conducting research and making evidence-based recommendations to OSHA for consideration in regulatory rulemaking. NIOSH should have performance goals related to OSHA policy evaluation and providing OSHA with recommendations where health and safety risks are identified which threaten the public health in US workplaces, identifying key research deficiencies, and updating those recommendations as the underlying science advances.

7. Evaluation of Education/Training Injury and Illness Prevention Interventions

NIOSH should include a cross-sector program related to evaluation of training interventions. Although it is well recognized that training plays a central role in prevention of injuries and illness, methods and research quantifying this effect is extremely limited. NIOSH should also assess its human resources with the expertise to conduct research in health education and training evaluation. This should extend beyond NIOSH's traditional emphasis on post-graduate students, and consider training, licensing, certification, apprenticeship, etc.

Categorized comment or partial comment:

8. Economic and Social/Organizational Incentives and Costs

The NIOSH coordinated emphasis area on economics is described as "exploring the economic conditions that influence the incidence and severity of occupational injury or illness." This should be expanded to consider the institutional structures that lead to certain economic incentive structures and incentives or barriers to adoption of specific efficacious control measures. This goes beyond the issues of work hours and stress. It requires an understanding of how construction sector institutions function, contract and bidding/specification practices, and how decisions are made in various parts of the construction industry. It is well accepted that costs and institutional incentive structures and market forces play key roles in determining the success of interventions to prevent injuries. This should also consider management systems and liability issues. Small businesses, which dominate the construction industry, face different economic circumstances than multinational corporations. Dissemination of interventions requires not only an understanding of costs, but also mechanisms for shifting costs and liability to society, workers, taxpayers, and other employers. Unionized work sites provide distinctly different organizational and incentive structures, as do informal sector day laborers. Focusing on improving the man-machine interface for use of a high-risk tool is of little value if you have no knowledge of how purchasing decisions are made and what economic pressures drive those decisions.

10. Exposure Assessment

We encourage NIOSH to consider an increased focus on task-based exposures and statistical evaluation of infrequent peak exposures, which present specific challenges in construction. These construction concerns are not mentioned in the description of this coordinated emphasis area. As continuous manufacturing processes decline in the US, task and batch-processes contribute an increasing fraction of occupational exposures.

Categorized comment or partial comment:

11. Government Construction

We encourage NIOSH to consider research to practice opportunities in partnership with other federal and state agencies, perhaps as part of the "Authoritative Recommendations Development" cross-sector program. Government is a major client of construction services, and with appropriate partnerships would provide valuable research access to worksites for R2P and intervention initiatives. Government safety practices often lag far behind the best performers in the private sector. NIOSH is in a unique position to conduct research, access and evaluate epidemiological data, make recommendations for injury prevention, and move research results into practice on government owned sites. NIOSH should have as a priority the formation of such interagency partnerships and development of R2P research initiatives on these projects.

I would like to thank NIOSH for this opportunity to comment, and look forward to continued cooperation with NIOSH in the conduct of research to prevent occupational injuries and diseases among construction workers.

NOTE: Text entered from submission E-39. This is an expansion of verbal comments presented at the NORA Town Hall meeting in Chicago, which were submitted as W-312.

I would like to see NIOSH take a proactive approach to hard metal lung disease. I am aware of 2 cases from one small company here in Lorain County. I have tried to work with this company to prevent more cases, but I have little support from regulations and federal agencies. I have talked with other occupational medicine colleagues with similar experiences. Both individuals have severe lung disease; one had to have a lung trnsplant to survive, and both are severely disabled by their hard metal lung disease. We not only need basic research on the cause and mechanisms of this disease but also we need clear medical surveillance recommendations and detailed engineering controls and ventilation recommendations for industry. The small company in my area has few resources and does not see that they can do much more, particularly when their cobalt and tungsten carbide air levels ae within OSHA regulations.

Hard metal disease is a good example of a severe disease with a small attack rate and poor prognosis. Chronic beryllium disease is another example. Substitution would obviously be the best solution to preventing disease. But, as this is not a viable option at present, we need to aggressively pursue better industry control measures, personal protection of workers and comprehensive surveillance programs. - Kathleen Fagan, MD, MPH, Medical Director, Occupational Health Program, Community Health Partners, Lorain OH

Re: Input for NORA: Fatigue Countermeasures Research

Sir/Ma'am:

In this paper I will highlight the growing problem of fatigue as a major contributor to workplace accidents, impaired performance, and poor health. I will advocate for fatigue countermeasures research to be a priority on the National Occupational Research Agenda.

We now live in a society that prides itself on 24-hour-operations. Ever since the first electric light bulb was switched on in the late 1800's and night was transformed into day, Americans have stayed awake longer and slept less. According to a 2005 National Sleep Foundation poll, most adult Americans now report sleeping on average 6.8 hours per weeknight, which sleep researchers tell us is at least one hour less than they actually need.(1,2) Sleep is too often viewed as a luxury, instead of as a physical necessity, for which there really is no substitute. As a result, many Americans are chronically sleep-deprived, tired, and subject to impaired performance during their waking hours at work. Despite this fact, we know surprisingly little about the long-term health effects of the chronic sleep deprivation that pervades our society, especially in our working population.

Americans have not only changed how much they sleep, but they also have changed when they sleep. Six to eight million Americans are night shift workers, whose work environments are out-of-sync with their internal circadian rhythms.(2) What few sleep studies have been performed on night shift workers have shown that these workers never really adapt to their disrupted sleep-wake schedules. They are working when their bodies would have them sleep. We do know that many night shift workers do not maintain their daily sleep patterns on their days off. In addition, they typically get less sleep than day-workers, and the sleep they do get is of poorer quality.(3) Even if they could maintain a regular sleep-wake schedule, most shift workers rotate regularly to different schedules before their bodies can adapt to the previous shift. As a result, these workers are susceptible to chronic fatigue which can degrade their performance and contribute to workplace mishaps.

Unfortunately, fatigue is difficult to measure objectively. There is no biomarker for it. This fact may be one reason that fatigue is under-recognized as a major contributor to workplace mishaps. Another is that fatigue is more often an indirect cause of mishaps and thus less immediately obvious. For example, the Exxon Valdez oil spill in 1989, the near meltdown at Three Mile Island (as well as at Chernobyl), and the explosion of the Space Shuttle Challenger all have highly publicized direct causes. However, accident investigations later determined that all were associated with significant fatigue-related lapses in judgment.(3) Long, irregular work hours were factors contributing to the fatigue.

Research into fatigue countermeasures can help to maintain job performance and enhance occupational safety and health. Several strategies have shown promise and should be considered for further research. These strategies include the use of bright artificial light in the workplace and/or melatonin supplements to help the worker adjust to new schedules, proper shift-work schedules that either do not rotate or rotate in a clockwise manner to accommodate circadian factors, authorized "strategic" napping to counteract performance decline from sleep deprivation, wellness programs that educate supervisors and workers on circadian issues and proper sleep hygiene, and as a last resort better stimulants such as modafanil (recently FDA approved for shift-work sleep disorder).(3)

Current thinking in occupational safety and injury prevention acknowledges that human error is inevitable but that, rather than blaming the operator, the focus should be on designing devices that can better accommodate the operator. Recent prevention efforts have thus tended to focus less on the human factor and more on engineering and administrative controls. In contrast, fatigue countermeasures focus on both the worker (e.g., improved sleep hygiene) and the engineering/administrative controls (e.g., designing shift work schedules that are more in-sync with circadian factors). As a result, I believe that funding fatigue countermeasures research will benefit both the worker and the employer. The worker will be healthier and safer on the job, as well as more productive for his employer.

Respectfully,

Allan Ward, M.D.

Docket NIOSH-047

Robert A. Taft Laboratories (C-34)

4676 Columbia Parkway

Cincinnati, OH 45226

Re: National Occupational Research Agenda, Health Care and Social Assistance Sector Grouping

To Whom It May Concern:

On behalf of the Oncology Nursing Society (ONS) - the largest professional oncology group in the United States composed of more than 33,000 nurses and other health professionals who are dedicated to

ensuring and advancing access to quality care for all individuals affected by cancer - we are writing to express our appreciation at the opportunity to submit comments and suggestions to the National Occupational Research Agenda (NORA). Our comments will focus on matters relevant to the Health Care and Social Assistance Sector Grouping as the Society is the world's largest professional organization of healthcare workers involved in the direct delivery of care to individuals with cancer.

Issues related to chemical exposures in the workplace are a principal concern of the Society as oncology nurses maintain responsibility for the admixing and administration of chemotherapy; many types of chemotherapy are highly toxic and could pose serious health and safety risks to the individuals responsible for handling these drugs. The potential hazards posed by chemical exposures in the healthcare workplace affect millions of workers; in oncology, the groups affected include nurses, physicians, pharmacists, social workers, laboratory technicians, physician assistants, nurse assistants, etc. The availability and application of new information about risk and hazard reduction in the practice of oncology has the potential to have a positive impact on tens of thousands of health professionals and other members of the cancer care delivery team. As such, the Society believes that the new NORA should prioritize issues related to chemical exposure in the workplace, particularly for health professionals delivering direct care to patients.

ONS and Workplace Safety

ONS has a long history of advocacy and education for its members related to protecting healthcare workers. Each year the Society collects and analyzes data about cancer nursing trends and ONS member needs. Information is compiled from a variety of surveys, needs assessments, member comments, and other sources and used to develop an annual "Education Blueprint." Workplace safety - defined by the Society as maintaining the health, well being, and physical safety of health care providers as they provide services in any health care setting - was a top tier area of interest and concern for oncology nurses in 2005. Similarly, in 2004, in response to a NIOSH alert, member concerns, and recent studies showing that safe handling precautions were not consistent, ONS launched a new strategic educational course aimed at protecting healthcare workers. The objectives for this comprehensive course included: the ability to define hazardous drugs, describe the potential health risks of handling hazardous drugs in oncology nursing practice, and identify the appropriate personal protective equipment needed for safe handling of hazardous drugs during preparation, administration, disposal, and spill containment. ONS also offers the publication *Chemotherapy and Biotherapy Guidelines and Recommendations for Practice* that covers basic safe handling issues and procedures.

Occupational Risks of Chemotherapy Warrant Renewed Attention and Response

Information about the occupational risks of chemotherapy and other hazardous drugs has been available for more than 20 years. Early studies documented the risks of healthcare workers' exposure to chemotherapy. Fourteen studies since 1992 have reported hazardous drug residue on work surfaces in pharmacies and drug administration areas. This provides evidence for the continued risk for healthcare worker exposure. The most recently published documents by American Society of Health-System Pharmacists, the National Institute for Occupational Safety and Health (NIOSH), and ONS discuss the limitations of the current guidelines. Among them:

- Biological safety cabinets (BSCs) provide imperfect protection against hazardous drug exposure.
- Routine handling activities can result in contamination of the worker and work environment.

- There is frequent and persistent contamination of the environment where hazardous drugs are handled.
- Dermal absorption of hazardous drugs as a result of contaminated surfaces is another potential route of exposure.
- Failure to use personal protective equipment can result in inadvertent contamination of clothing.
- Workers who are not directly involved in activities related to hazardous drug handling are at risk for exposure.

With very few exceptions, the technology of controlling chemical exposures in healthcare has not advanced since the Occupational Safety and Health Administration (OSHA) published its first recommendations in 1986. With the passage of a 20 year period that saw the advent of new drugs that bring potentially new exposure-based health risks and threats, changes in drug admixture and administration, and other cancer care delivery changes, ONS believes the time is well overdue for the development and implementation of new engineering controls, better personal protective equipment, and improved work practices to protect the tens of thousands of nurses who handle hazardous drugs on a daily basis.

Conclusion

ONS maintains that the nation's oncology nurses should not have to put their health and safety at-risk as they deliver life-saving therapies to others. While health professional societies such as ONS can do much to educate and train their members regarding safe practices, to ensure maximum risk-reduction and the promotion of the safest workplace environments possible, the Society believes the federal government must take a leadership role. Much-needed improvements in workplace risk-reduction and health promotion practices only will be identified with a coordinated research effort, led by NIOSH vis-à-vis NORA. ONS urges NIOSH and other stakeholders involved in the creation of the new NORA to prioritize the issue of chemical exposures in the workplace as it plans the agenda for scientific research that will prevent work-related illnesses for the healthcare sector.

ONS welcomes the opportunity to collaborate in a public-private partnership to take action to protect healthcare workers – and patients – and improve workplace safety overall. Please know that we stand ready to work with NIOSH and other stakeholders as the new NORA is developed and implemented. We commend NIOSH for providing this opportunity for public comment and appreciate consideration of our views. ONS maintains its long-standing commitment to ensuring that the delivery of quality cancer care is provided in environments that are safe for all involved in both the receipt and delivery of cancer care.

Should you or your staff have any questions, please contact us, or our ONS Health Policy Associate in Washington, DC, Ilisa Halpern (202/230-5145, ihalpern@gcd.com). Thank you again for your consideration of our views.

Respectfully submitted,

Karen Stanley, RN, MSN, AOCN®, FAAN
President

Pearl Moore, RN, MN, FAAN
Chief Executive Officer

Date: January 16th, 2006

To: < NIOCINDOCKET@cdc.gov> Docket NOISH -047

RA Taft Laboratories (C-34) 4676 Columbia Parkway, Cincinnati OH 45226

RE: Docket NIOSH 047:

Comment about the national occupational research agenda for the Agriculture, Fishing and Forestry Sectors at the Seattle WA Town Hall NORA meeting, January 17th, 2006

A research agenda for the Agriculture, Fishing and Forestry sectors could benefit by carefully considering:

1. previous work that's been accomplished to develop a research agenda for agriculture, (see Endnote i)
2. previous critical scientific reviews of existing agricultural safety and health research, (see Endnote ii)

3. previous work that describes agriculture's current health and safety problems, (see Endnote iii) it's unique problems versus other industries, (see Endnote iv) and evidence about the changing nature of the industry. (see Endnote v)

Special consideration should be given to

1. intervention evaluation research in general (see Endnote vi)
2. interventions addressing agricultural technologies that couple safety and profits (see Endnote vii)
3. interventions that address agricultural musculoskeletal injuries and stoop labor (see Endnote viii),
4. interventions to develop and encourage adoption of engineering controls for evident farm work hazards, (see Endnote ix)
5. interventions that rely on university Extension (see Endnote x),
6. interventions that address noise-induced hearing loss in agriculture, a largely preventable disorder affecting much of the workforce, (see Endnote xi)
7. measures to improve injury and disease surveillance so as to capture the levels of case ascertainment and injury detail typical in other US industries. (see Endnote xii)

ENDNOTES:

i. A number of research and practice "agendas" for improving agricultural occupational health and safety have already been published with detailed, specific recommendations (e.g. Petrea, 2003; Donham and Storm, 2002; Fathallah et al., 2006; Merchant et al., 1989). In addition, research agendas have been published by NIOSH NORA groups with implications for agriculture (e.g. National Occupational Research Agenda for Musculoskeletal Disorders 2001-117, Traumatic Occupational Injury Research Needs and Priorities 1998-134, Prevention of Musculoskeletal Disorders for Children and Adolescents Working in Agriculture 2004-119).

ii. A number of serious, scientific critiques of current efforts have also been published (e.g. Hartling et al., 2004; DeRoo and Rautaiinen, 2000; Kennedy et al., 1995). Excerpts include:

De Roo and Rautiainen, 2000: reviewed published evaluations of farm safety interventions. Out of 118 papers examined, 25 were selected for the review. Some of the points made in the review included:

-- "There is a need for more rigorous evaluation of farm safety intervention programs. Suggested study design improvements include randomization of study subjects when appropriate, use of control groups and the objective measurement of outcomes such as behavior change and injury incidence."

-- In some cases, farm injury prevention "...programs have been in place over 20 years with little or no evaluation to determine their effectiveness."

-- "Without the results from well-conducted evaluations, farm communities have little evidence that the time, effort and money spent on programs are making a difference in reducing injuries ...".

-- "The results of epidemiologic studies of farm injury risk factors..." (have) "...found no statistically significant difference in the incidence of injuries among farmers who had ever participated in any type of safety training program compared to those who did not."

-- "Although (farm safety audit) studies relied on unverified self-reported outcomes, their results were suggestive that a farm 'walkabout' was useful in helping some families recognize and modify environmental hazards, even without the assistance of an expert."

-- One unusual study (Lundqvist, 1999) in the review provided small subsidies for farmer adoption of work equipment modifications that improved profitability as well as work safety. A retrospective evaluation of 164 dairy and beef farms that served as their own controls determined that there was a "22% decrease in the injury rate, 29% decrease in musculoskeletal disorders, (and a) 16% decrease in work time."

Hartling et al., 2004: The review in Pediatrics provides an extensive, detailed critique of current agricultural safety research. A lengthier version of the critique is available in the final report submitted by the same authors to Safe Kids Canada available from William Pickett by email (Pickett et al., 2003). Excerpts from this final report follow:

Few studies of engineering controls (p. 6 and p. vi): "Engineering controls have great potential to be effective in preventing farm injuries, but only if they are voluntarily accepted and adopted by farmers...We did not identify any studies meeting our criteria that evaluated the effectiveness of regulatory or engineering approaches to farm injury control."

Educational approaches are inadequate (p. vii): "Educational initiatives are important but appear to be insufficient to eliminate recurrent injury control problems."

Interventions need to focus on farm managers (p. vii): "There is a need to develop and evaluate targeted prevention initiative that are aimed at the responsible authorities. These are generally farm owner-operators."

Study methods lack rigor (p.e493 and e494, col. 2): "Overall, there is a paucity of controlled studies evaluating the effectiveness of interventions aimed at the prevention of childhood farm injuries...Irrespective of study type, there was a lack of methodologic rigor in many studies. Recurrent weaknesses were related to issues of confounding, statistical power, and generalizability. Few observational studies adequately controlled for potential confounders, reducing our confidence that the results reflect the interventions in question. Few studies reported a calculation for sample size or statistical power. Without such information, we were unable to determine whether the studies were large enough to detect important effects. Findings indicating a positive intervention effect might have been missed. The external validity (generalizability) of studies was also generally poor, which makes the application of results in the planning of injury control interventions challenging. The majority of studies evaluated short term process outcomes (e.g. knowledge acquisition or changes in attitudes or behavior). Few studies evaluated injury occurrence. The timing of outcome assessment was also less than optimal. Outcomes were typically measured immediately or shortly after the intervention was delivered. It would be useful to determine the long-term effects of these interventions. Moreover, studies did not distinguish between programs directed at youths who work on farms and children who live and play around the farm worksite."

Public funding of research needs to be better focused on effective results (p. 20): "There has been a substantial injection of public funds in recent years to address the childhood farm injury problem... Given this investment, the lack of new knowledge that has been forthcoming is striking. There is a great list of these projects, some of which are chronicled in this review, but very few publications of high caliber. This could reflect the fact that many of these projects are still in progress, but it could also reflect the need for rigorous standards for the funding of these projects. The general lack of a final product is disconcerting"

iii. Reviews of agriculture's health and hazard situation include Frank et al., 2004; McCurdy and Carroll, 2000; Murphy, 1992.

iv. The historic, effective absence of traditional OSHA regulatory enforcement for most operations in production agriculture places farm managers at a competitive disadvantage and contributes to a remarkably high, yet often avoidable, toll of injuries and disease for the production agriculture workforce (e.g. Frank et al., 2004; Petrea, 2003; Donham and Storm, 2002; Fathallah et al., 2006). The most direct activities that could reduce agricultural workforce safety and health problems all involve changing this state of affairs so that all work operations in the agricultural sector are subject to the same (where advisable) OSHA regulatory provisions that other US industries abide by. There is scientific support for the prevention benefits of traditional safety and health regulation as a means of preventing

injury and illness among children, youth and adults in agriculture. However, at present, historic, path-dependent trends and the lack of an overwhelming political consensus, along with the industry's heterogeneity and the sheer numbers of small operations where new regulatory enforcement would be required prevent this kind of change. In the absence of well-enforced OSHA regulatory efforts that cover operations of all sizes and control the wide range of hazards presented in agriculture, all other measures are extremely poor substitutes. Still, given the extremely dire state of affairs in agriculture, where the rates of fatal and nonfatal injuries and certain occupational diseases lead or rank high among all other US industries, even "half measures" warrant serious consideration.

v. Emerging developments, including trends among producers and consumers as well as the diffusion and adoption of technologies continue to reshape this industry. For example:

1. More conventional producers are shifting to organic methods, encouraged by both non-profit and government programs to make the conversion. A county in Iowa even gives a sizable tax break now to farmers who convert. University Extension is now teaching organic methods in most Midwest states. This trend is different than 10 years ago, when there was a greater split between organic and conventional, and the organic farmers tended to be new to agriculture. The conventional grower who shifts to organic will have to do more hand labor than before, and manage larger crews to do this labor (DeLate, 2004; USDA, 2003).

2. With more urban and suburban dwellers moving to the country, agriculture production methods are suddenly of interest to the new neighbors who want some control over what they see and smell, such as manure management issues. Agriculture producers and newcomers have to come to terms over land use issues in ways they never needed to before (Sooby, 2003).

3. More intense growing, like hoophouse production for off season vegetables and earlier fruit (Lehnert, 2005).

4. In landscaping work: more intense installations that make the outside an expansion of the house, for example outdoor party rooms with fireplace and grills, ponds, backyard studios or play areas, areas meant for morning coffee and newspaper, areas lit up at night, and lots of stone work to create these areas. All of this requires more hand labor than the earlier simpler landscape designs of a broad lawn and a few evergreens planted at the house foundation. People are getting more sophisticated in what they want from their landscape, and they have the money to pay for it (Konya, 2005).

5. More agritourism, more farms adding an agritourism or entertainment "agritainment" component to their crop production. This means that larger numbers of the general public are visiting farms, and it also means that on those farms there are larger potential health hazards and risks. The farmers have to learn stricter food safety measures, and also have to learn crowd control and risk prevention, for example with petting zoos and wagon rides (Che et al., 2005; Anonymous, 2005).

vi. The NIOSH Community Partners for Healthy Farming grant program has been supporting innovative research to practice projects for over ten years. For reviews of this program, see (Ehlers and Palermo, 2005; 1999).

Two NIOSH publications have been devoted to intervention evaluation (Guide to Evaluating the Effectiveness of Strategies for Preventing Work Injuries 2001-119, Does It Really Work: How to Evaluate Health and Safety Changes in the Workplace 2004-135).

Specific intervention recommendations in an editorial by Chapman, 2000 included:

-- "Pay great attention to the bottom line. For example, experience with soil and water conservation efforts in agriculture has provided evidence that individual firms very often require a clear profit incentive (in the absence of a strong monetary penalty) before shifts toward prevention and problem-solving occur industry-wide."

-- "Prove that it works, repeatedly, and they will come. For example, workplace health promotion programs were in much the same state as production agriculture injury prevention efforts 20 years ago. Federal funding for intervention effectiveness research in health promotion that emphasized fairly rigorous evaluation requirements (e.g. control groups, objective outcomes, interventions that moved beyond mere training to workplace and work policy modifications coupled with careful evaluation of program costs and benefits) have pushed this area to the point where `what works` is almost a formula and `how to do it` and `how to evaluate it` are becoming familiar and relatively reliable in producing the desired results. Workplace health promotion efforts are widely employed and valued by many managers in firms of all types and sizes today. Although we may argue that they have an easier row to hoe than agricultural health and safety, the tide seems to be running their way."

-- "Move beyond training individuals to act safety around hazards. For example, success in many public injury prevention campaigns turned the corner when a concerted effort was made to move from traditional safety education toward intervention efforts that identified and began to systematically eliminate hazards with workable alternatives. From infant cribs to aspirin containers, passive vehicle restraints to more forgiving playground equipment and surfaces, the case has been clearly made that environmental modifications are the preferred option because they work, largely because they do not rely on repeated vigilance and action by individuals."

vii. Interventions in agriculture that seek to modify traditional practices can be successful and worthwhile endeavors provided that they recognize and build on:

1. the effective absence of effective regulation and the primary concern of farm managers (profitability);
2. the traditional fiscal conservatism and risk avoidance of small operation managers the requires interventions to promote safer, more profitable practices for five years or longer before significant numbers of managers will begin to adopt a "better practice."

Two NIOSH extramural grant programs have made inroads in these directions: the Agricultural Safety Promotion Systems projects in the early 1990s (Hard et al., 1992; 1995), and the Community Partners for Healthy Farming projects (1995 to the present) (Ehlers and Palermo, 1999; 2005).

The abstract from Ehlers and Palermo, 2005 follows:

"ABSTRACT. The purpose of the Community Partners for Healthy Farming Intervention

Research (CPHF-IR) program is to implement and evaluate existing or new interventions for reduction of agriculture-related injuries, hazards, and illnesses. Objectives include the development of active partnerships between experienced researchers, communities, workers, managers, agricultural organizations, agribusinesses, and other stakeholders. Specific intervention projects were selected by the competitive review process in response to a request for proposals. The second series of projects (funded 2000-2003) targeted: improved ergonomics for handling grapes (CA) and for small-scale berry growers (WI, IA, MI, MN), engineering controls (KY, VA, SC) and training (IN) related to tractors, private-sector financial incentives for safety (IA, NE), and reducing eye injuries in Latino farmworkers (IL, MI, FL).

Partners have provided their unique resources for accessing the target population, planning, implementation, dissemination, and evaluation. They have produced useful engineering controls, educational and motivational tools, and helped build infrastructure for promoting agricultural health as essential to sustainable agriculture. Additional outcomes have included: increased interest among participants in collaborating in further research, the feasibility of Latino lay health advisors as active partners in research, and the value of process evaluation of a partnership to enhance intervention sustainability. NIOSH is utilizing the model created for Simple Solutions: Ergonomics for Farm Workers, a document related to earlier CPHF-IR projects, for a comparable document for construction in both English and Spanish. This program has confirmed that such partnerships can produce not only sustainable interventions but also products and models with the potential to expand farther geographically than originally anticipated and even into other sectors, e.g., for primary prevention among healthcare workers and adolescents, and to introduce public health in social studies and language classes."

viii. For example, the text and recommendations from the executive summary in (Fatallah et al., 2006) follow:

Executive Summary

"Stooped postures have probably been with us since the first human ancestors began walking upright. In the modern world, it might appear that stooped postures are confined to work in developing countries or less mechanized workplaces. However, nothing could be further from the truth. Stooped postures are commonly found in agricultural, construction, mining, and other workplaces all around the world. Stooped postures are common wherever physical work is undertaken. Further, work requiring stooped postures is strongly associated with high incidence of low back disorders (LBDs).

Nonetheless, the terms `stooped` or `squatting` postures are not commonly found in ergonomics studies or literature. These facts taken together led to the questions that stimulated this conference of experts:

- (1) what do we know about the scope of stooped postures in the workplace;
- (2) what scientific basis is there for understanding the effects of stooped postures; and
- (3) what do we know about strategies for controlling stooped postures?

Speakers at this conference made clear that the problem of stooped and squatting postures in the workplace is global in scope and widespread in many industries. Further, evidence presented made clear that stooped postures are commonly associated with work that has a high incidence of LBDs. Nonetheless, stooped postures have been little studied as a primary risk factor for LBDs. Most attention on risk factors for LBDs has been focused on manual materials handling and whole-body vibration. Stoop (sustained bending of the spine) has been largely neglected. In part, this may be due to the lack of an accepted definition of stooped or squatting postures. As this conference ended, we accepted the following as initial working descriptions: a stooped posture can be defined as 'a bending forward and down from the waist and/or mid-back while maintaining relatively straight legs'; squatting can be described as a 'bending of the knees so that the buttocks rest on or near the heels'.

The full scope of the problem is not well reflected in occupational injury data because current reporting methods do not examine the relatedness of an injury to stooped and squatting work postures. Workers' Compensation programs focus more on delivering benefits than prevention efforts, and claims data collection is driven by injury (an 'event') rather than cumulative trauma. Reducing the incidence of work-related LBDs in these jobs will require a new focus on identifying and describing stooped and squatting postures as specific LBD risk factors in the workplace.

Biomechanical research shows that high spinal compression forces occur in stooped postures, and that sustained or repeated flexion of the spine may disturb the neuromuscular stability of the lower back and increase the risk of fatigue, leaving the back more vulnerable to injury. What is missing (as is the case with many ergonomics risk factors) is definitive etiology demonstrating the causal role and mechanisms linking stooped postures with MSDs.

While there is considerable epidemiological evidence associating working in stooped, kneeling and squatting postures to LBDs, it is mostly focused on those postures in combination with other risk factors such as bending or twisting or heavy loads. The literature combining stooped, squatting or kneeling postures with load handling shows rapid and severe spinal damage. There is much less in the literature regarding the health effects of these postures in an unloaded situation.

Kneeling and squatting are often seen as alternatives to stooping; as a way to work at low levels without bending the back as much. In agriculture and construction, workers often resort to stooping because it demands less energy expenditure than the alternatives, and they can exert higher force and have increased mobility than when kneeling or squatting. There is good biomechanical reason to view these postures as significant contributors to MSDs of the knee and low back. There are generally few studies of knee injuries associated with these postures, and conclusive, causal studies are still lacking. Efforts to improve jobs should reduce overall risk factors, rather than just shift the strain from one part of the body to another.

Determining which controls are available as interventions to the problem of stooped work is challenging for the industries of concern, especially agriculture, construction, and mining, because they have tremendous variation in their workplace environments. Four classes of interventions were discussed at the Conference, and successful interventions in all these areas were presented:

1. Reduce or Eliminate the Need to Stoop or Squat (e.g., raised planting beds, Portable tables or carts, Lifting aids and handles)

2. Mechanical Worker Protection or Worker Aids (e.g., devices for kneeling, prone workstations, and load transfer devices)

3. Mechanical Assists to Allow the Employee to Work in a Standing Position (e.g., tool extensions, mechanical harvesting, roofing equipment)

4. Administrative Controls (e.g., programmed breaks, reducing the number of working hours, or hiring more workers during peak periods to reduce the demands on the individual worker).

However, intervention experts were unanimous in noting that interventions must be task and situation specific to be both adoptable and effective. This means that few interventions can be expected to travel un-adapted between jobs or tasks. In order to improve our understanding of the relationship of stooped, squatting and kneeling postures and MSDs and their prevention we must increase and improve research focused on these risk factors. A necessary first step will require differentiation by the research community between stooped posture and stooped work by determining at what exposure level assuming a flexed posture becomes `stooped work`, and establishing a consensus definition of stooped work (e.g., work below knees > 40% of time).

Secondly, there is a need to develop practical and objective measures of exposure to stooped work (degree of bending, duration, frequency) and refine the epidemiological case definition of outcome (symptoms, physical findings, diagnoses) for a deeper focus on the effects of stooped work.

To seriously begin to improve our understanding of the etiology and causal relationship between stooped and squatting postures and MSDs we need to increase our understanding of the biomechanics of the spine and the lower extremities in these positions. There is a need for research studies designed to evaluate the effects of these postures on tissue responses under various conditions and loading patterns. Research is required to understand how the intervertebral disc, the meniscus of the knee, and other passive tissues respond to repetitive versus static loading. Such research may point the way to understanding the relationship of degrees of postural stress and disease and, similarly, how much postural relief is needed or useful in preventing disease. Epidemiology and biomechanics provide much of the basis for understanding the effects of working in stooped and squatting postures, and the knowledge gained from such study needs to be incorporated into the case definition of stooped work, and in job design criteria that take into account the tissue fatigue generated by static postures.

Finally, there is need for an improved system of intervention research that both disseminates the evaluation of alternative strategic approaches in different workplaces and also supports the development of workplace specific adaptations of known approaches. Interventions which are not both acceptable to workers and employers and which fit the work system without serious detriment to productivity will not be widely adopted. Development of such interventions is neither an automatic nor guaranteed result of publication of research results or successful demonstrations in other industries.

Suggestions for improving prevention of musculoskeletal disorders caused by stooping, squatting or kneeling postures.

A. Suggestions for assessing high risk jobs

1. Evaluate the effectiveness of different methods of risk assessment attention to predictive ability and field utility.

B. Suggestions for surveillance research

1. Develop a national registry of musculoskeletal hazards and health outcomes.
2. Add supplements to existing surveillance systems for stooped and kneeling postures.
3. Conduct surveys in high risk industries (agriculture, construction, mining).
4. Determine the number of workers exposed and what jobs they are doing.
5. Record the exposure in identified jobs: time in stooped and squatting, by `zones` of mild, moderate, and severe positions
6. Identify the specific job or task elements requiring stooped postures, and why.
7. Conduct cross-sectional and longitudinal studies to develop and validate a list of high risk jobs and significant health outcomes

C. Suggestions for intervention research

1. Develop new partnerships with agencies, academia and industry to support intervention research focused on stooped and kneeling work, including national and regional partnerships focused on industry- or task- specific applications
2. Increase the number and range of intervention research underway
3. Encourage higher-quality intervention evaluations using randomized trials, quasi-experimental designs and blended evaluations
4. Document and broaden the dissemination of successful/ proven interventions.

D. Suggestions for etiological research

1. Conduct studies to improve understanding of specific biomechanical stresses and musculoskeletal disorder development during stooped and kneeling postures
2. Develop and evaluate improved standards and methods for assessing exposure, health outcomes and other etiological factors for stooped and kneeling work.
3. Conduct population, clinical and laboratory studies to evaluate the short-term impacts of different types of exposure to working in stooped or kneeling postures on musculoskeletal disorder development and early indicators of such disorders.
4. Conduct population, clinical and laboratory studies to evaluate the long-term impacts of different types of exposure to working in stooped or kneeling postures on musculoskeletal disorder development and early indicators of such disorders."

xi. text and recommendations from McCullagh, 2002 include: "Research to date indicates that farmers experience accelerated hearing loss compared to non-farmers, that loss progresses with age, that onset of loss occurs early in life, and that the damage follows a pattern consistent with noise-induced hearing loss..."

1. Expand the Scope of Research

"Several important areas of inquiry were not addressed in the extant research. There is a need to further investigate farm noise hazards, their spectral characteristics, and the relative contribution of various sources of noise to NIHL. Improved methods of noise exposure measurement in the farm setting will be necessary to produce meaningful studies. In response to engineering modifications to produce quiet farm equipment, new research is called for that investigates the short- and long-term effectiveness of these engineering modifications on noise levels in the farm work environment, and on hearing ability of their users.

More research is also needed to find ways for farmers to detect and reduce noise hazards, and to accomplish their maintenance engineering role in ways that minimize noise exposure for operators.

More research will be needed to identify common ototoxic chemicals used in farming, and methods of eliminating, replacing, or protecting workers from them. There is a need for more prospective studies of hearing ability in order to explain the natural history of NIHL in the farming population, and for studies that explore the reasons for low use of hearing protectors among farmers."

2. Use Improved Research Methods

"Future progress in intervention research will be advanced with use of improved research designs. Future studies employing larger samples and controls for multiple threats (e.g., temporary threshold shift, conductive loss, patency of the external canal) may contribute to an explanation of the contribution of non-occupational noise exposure to farmers' NIHL. Use of consistent definitions of variables (such as farmer, noise, and hearing protector use) will facilitate comparisons across studies. Improved methods of noise exposure measurement in the farm setting will be necessary to produce meaningful studies. An increased number of intervention studies using quasi- or true experimental designs will enhance the ability to infer causal relationships. Studies are most informative that use designs that compare the outcomes and costs of alternative programs, such as comparing an innovative prevention program to a "standard" program currently in use."

3. Examine Effectiveness of Intervention Programs

"There is an obvious deficiency in the number of intervention studies showing ways to reduce and eliminate hearing loss among this population. Research is needed to compare costs, benefits, and feasibility of multiple intervention strategies, including engineering, education, and policy development.

There is evidence that using a theory-based approach in intervention programs will yield benefits to the program, including strengthening program justification, promoting effective and efficient use of resources, improving accountability, and assisting in establishing professional accountability (D'Onofrio, 1992, as cited in McKenzie and Smeltzer, 1997). Intervention studies that employ a theory-based approach will augment what is already known about these health protective behaviors, and will facilitate future research."

4. Invest in the Agricultural Research Infrastructure

"Recent public outrage toward the injury and fatality statistics for the population, together with increases in NIOSH funding, have resulted in encouraging improvements in the volume and quality of farmer hearing health research. However, occupational health research is marked by multiple challenges, including difficulties in obtaining equivalent comparison groups, measuring outcomes over time, and avoiding selection bias. With the farm population, these challenges become even greater due to the geographic dispersion of program participants, independent ownership of multiple small enterprises, and strong individualism among workers. Other complicating factors include seasonal variations in work, intermittent noise exposures, variations associated with geography, crop type, production size, and farmer role (i.e., manager, part-time employed, full-time employed, and non-paid farm worker) (Murphy, 1992).

A well-developed research infrastructure will be needed to overcome these challenges. There is a need for interagency collaboration in funding and conducting research, including agribusiness; farm groups; local, state, and federal government agencies; and academic institutions.

The problem of NIHL is illustrative of the need for a multidisciplinary approach to farm health and safety. Because the problem of farm-related noise is amenable to engineering, administrative, and

behavioral interventions, a comprehensive farm-based hearing preservation program will require efforts that exceed the skills of any single discipline. Collaborative approaches using multidisciplinary teams of researchers with input from community stakeholders are necessary. Including the disciplines of nursing, industrial hygiene, audiology, occupational medicine, safety engineering, Cooperative Extension, farm groups and others should result in enhanced program effectiveness.

There has been a recent shift in the field of farm health and safety from an industrial model toward a public health model (Murphy, 1992). Agricultural health and safety has historically employed an industrial safety and health approach to the control of occupational hazards on the farm. These approaches typically included the "three E's" (engineering, education, and enforcement), human factors engineering, and behavioral management methods such as McGregor's Theory X (McGregor, 1967). However, agriculture is characterized by a larger number of diverse, independently owned and operated, non-hierarchical establishments than industry (Murphy, 1992). Because of these characteristics, there is less control over work forces, work environments, and workplaces than in industry, making the industrial health and safety models less effective in the agricultural setting. The slower decline in agricultural injury rates in comparison to other industries may serve as evidence of the need to approach agricultural health and safety from new perspectives (Kelsey, 1994).

The public health approach, on the other hand, involves applying comprehensive strategies to reduce illness, injury, and early death. These approaches, including epidemiology and behavior change, are more consistent with the unregulated, diverse, and family-based nature of most farming enterprises. Public health also reframes lifestyle and occupational injury and health problems as social concerns, similar to the problems of drinking and driving, and control of the spread of HIV (Murphy, 1992).

While the public health approach shows promise for improved health outcomes for this worker group, it requires certain elements, including adequate financial resources, a surveillance system, a body of epidemiologic data, and a cadre of public health professionals trained in the specialized health and safety needs and methods of this worker group (Merchant et al., 1989). There is a need to increase support to agricultural health and safety field workers and early-career researchers in academia in their production of high-quality research."

5. Develop Culturally Sensitive Interventions

"Many intervention activities that may be effective in other worker groups may not be useful among farmers due to the unique characteristics of farm work life. For example, corporate safety and health programs, regulatory requirements, workers' compensation policies, engineering controls, and loss-control programs are not available to most farmers (Murphy, 1992). Health professionals may find they will rely more on innovations in voluntary consensus standards and educational programs. For example, educational programs may want to increase their focus on the personal, social, and economic costs of hearing loss, including reduced quality of life, impaired communication, diminished work effectiveness, lost productivity, increased injuries, and expenses for hearing aids (NIOSH, 1996a). Furthermore, intervention studies should accommodate farmers' fiscal and time restrictions, limited access to providers, limited insurance coverage, dynamics of the farming industry, and farm practices of the target group.

Farmers generally lack the benefits of a work-based hearing conservation program. As a result, most farmers do not receive regular audiograms, education about noise hazards, or ready access to a variety of protection devices (Axelsson and Clark, 1995). There is a need for research addressing the

development of hearing health delivery systems for farmers, including provider education and improved access to preventive services."

6. Focus Resources on Highest-Risk Groups

"The changing demographics of farm workers implies a need for new research directions. The impact of off-farm employment on farmers' preventive behavior and hearing loss is an unexplored issue. Epidemiologic studies should include the full spectrum of farm workers, including women, seasonal workers, children, and recreational farmers. Development of systems of classification of exposure by farm operation, geographic region, and crop type may assist researchers in identifying groups of farmers at highest risk for hearing loss, and help in prioritizing limited resources."

xii. DOL and NIOSH should coordinate the development of a comprehensive national nonfatal injury surveillance system comparable to the Census of Fatal Injuries (see Petrea, 2003, p 8.). Some improvements in surveillance can be accomplished with only fairly modest modifications of existing systems. For example, in Petrea, 2003, p 29 "Include occupational injury and illness reporting, with location of injury, as a supplement to the annual National Health Interview Survey as an interim step until a mechanism to offset data omissions within current Bureau of Labor Statistics-based surveys can be implemented."

I hope research on levels of brominated flame retardants in workers exposed to PBDEs, HxBDD, and others will begin in 2006. Such work has not yet been done in the USA.

Hopefully also health studies will follow these exposure studies.

PBDEs are similar to PCBs and have gone from not detected in blood from USA population in 1973 to the highest in the world by several orders of magnitude compared to Europe. European levels are believed higher than levels in persons living in less developed countries.

Sincerely,

Arnold Schecter, MD, MPH

To: Soderholm, Sid

Subject: RE: Dermal Exposure Research Program/reply

Importance: High

Dear Dr. Soderholm,

You have my permission to forward my e-mail to you anyone you like. I have some other data that may be of interest as well-on the larger topic of skin cancer screening. I just wish there was more of an appreciation for the kind of risks UV and chemical exposures pose for outdoor workers today (surely for the risks they pose for skin cancer within industry). MSHA does not even require any kind of monitoring or testing for skin cancer exposures for miners exposed to arsenic-even though NIOSH says its a good idea to do it. NIOSH can't compel industry to do anything. They are not a regulatory agency.

It is my firm belief, that there has to be an "incentive" built in to this process somehow to move industry to embrace this idea further. Even if you come up with great, new and compelling evidence with regard

to dermatological exposures that might warrant this type of screening-without a "driver" once again I fear the impact of your research on the individual worker and his health will be minimal. Nobody wants to spend money on healthcare if they can avoid it, I understand that-but if we can show there is a financial benefit in reducing the risk and long term exposures to the health of the outdoor (or exposed) worker and make that case to industry (ultimately through lower health premiums) then we may really have something that will force a change in the way this issue is addressed today....

I forwarded a copy of your note to me to the CEO of my company for his comment and review. I am honored to even be asked to be associated with your NORA Sector Research Council, but I am sure there is someone eminently better suited (and qualified) than I within my company who could be a more valuable contributor for you. Skin Check will take your offer seriously, and for my part I shall remain available to assist you in any way I can. I for one-believe that what you are about to embark on is both valuable and important to the health of the American worker.

With Kind Regards,

Scott P. DeWeese

Subject: RE: Dermal Exposure Research Program

I will share your E-mail with others in NIOSH who are particularly interested in the oil production industry or in occupational skin diseases.

If you give me your permission, I will forward your E-mail to the NORA Docket Office (NIOCINDOCKET@cdc.gov). That way, your comments and documents can be included in the information to be considered by the NORA Sector Research Councils in setting occupational safety and health research priorities in the oil and gas production industry. In addition, your input will be useful to other NORA Sector Research Councils that are considering hazards to the skin.

If you would like to volunteer to be considered as a member of a NORA Sector Research Council or to be a reviewer of their draft documents, please let me know. In that case, receiving a brief CV would be helpful.

In any case, I hope you have or will subscribe to the NIOSH eNews (<http://www.cdc.gov/niosh/enews/>) and/or will visit the NORA website occasionally (<http://www.cdc.gov/niosh/nora/>) to keep up on developments in NORA and NIOSH.

Let me know if you need additional information.

Thank you for your interest in NORA!

Subject: Re: Dermal Exposure Research Program

Dear Mr. Soderholm,

I note with interest the that The National Institute for Occupational Safety and Health (NIOSH) and approximately 500 external partners have created the National Occupational Research Agenda (NORA). As Director of the Dermal Exposure Research Program. I note that the overall goal of the program is to promote the development of improved NIOSH policies and recommendations for identifying and controlling dermal overexposures. I think we can help.

Skin Check Mobile is the only mobile skin cancer screening "clinic" in the US. We go onsite to where the worker is exposed using trained skin cancer specialists and the latest digital dermoscopy. We typically look for lesions and melonomas-because that has the most resonance with the public and employers. We work with the oil and mining industries now in evaluating chemical and UV exposures (see copies of several studies regarding worker exposure in the oil industry) and I don't see much of a stretch in getting involved with your group-as we bring the something to the table that no one else in the US is doing.

Let me know if you see any value in our services. I have enclosed a link to our website. Check out the tab that says Industrial Mobile Services @ <http://www.skincheckus.com/>

I look forward to hearing from you.

Sincerely,

Scott P. DeWeese
Vice President
Skin Check Mobile

NOTE: The following text was entered from Attachment 1:
Cancer Causes Control. 1997 May;8(3):444-72.

Cancer risk from occupational and environmental exposure to polycyclic aromatic hydrocarbons.

Boffetta P, Jourenkova N, Gustavsson P.

Unit of Environmental Cancer Epidemiology, International Agency for Research on Cancer, Lyon, France.

Epidemiologic evidence on the relationship between polycyclic aromatic hydrocarbons (PAH) and cancer is reviewed. High occupational exposure to PAHs occurs in several industries and occupations. Covered here are aluminum production, coal gasification, coke production, iron and steel foundries, tar distillation, shale oil extraction, wood impregnation, roofing, road paving, carbon black production, carbon electrode production, chimney sweeping, and calcium carbide production. In addition, workers exposed to diesel engine exhaust in the transport industry and in related occupations are exposed to PAHs and nitro-PAHs. Heavy exposure to PAHs entails a substantial risk of lung, skin, and bladder cancer, which is not likely to be due to other carcinogenic exposures present in the same industries. The lung seems to be the major target organ of PAH carcinogenicity and increased risk is present in most of the industries and occupations listed above. An increased risk of skin cancer follows high dermal exposure. An increase in bladder cancer risk is found mainly in industries with high exposure to PAHs from coal tars and pitches. Increased risks have been reported for other organs, namely the larynx and the kidney; the available evidence, however, is inconclusive. The results of studies addressing environmental PAH exposure are consistent with these conclusions.

Petroleum mineral oil refining and evaluation of cancer hazard.

Mackerer CR, Griffis LC, Grabowski Jr JS, Reitman FA.

C and C Consulting in Toxicology, Pennington, New Jersey, USA.

Petroleum base oils (petroleum mineral oils) are manufactured from crude oils by vacuum distillation to produce several distillates and a residual oil that are then further refined. Aromatics including alkylated polycyclic aromatic compounds (PAC) are undesirable constituents of base oils because they are deleterious to product performance and are potentially carcinogenic. In modern base oil refining, aromatics are reduced by solvent extraction, catalytic hydrotreating, or hydrocracking. Chronic exposure to poorly refined base oils has the potential to cause skin cancer.

NOTE: The following text was entered from Attachment 2:

[What do we know about chemical hazards in offshore work?]

[Article in Norwegian]

Moen BE, Steinsvag K, Braveit M.

Seksjon for arbeidsmedisin, Institutt for samfunnsmedisinske fag, Universitetet i Bergen, 5018 Bergen.
bente.moen@isf.uib.no

BACKGROUND: Norway has been an oil-producing nation for more than thirty years and a large number of Norwegians have been or are working on oil rigs. There are several chemical substances present on the oil platforms, and these factors may influence workers' health. **MATERIAL AND METHODS:** The international literature on offshore chemical exposure and health is summarised. **RESULTS:** The most important groups of chemical substances used on oil rigs are described: crude oil, production chemicals, asbestos and drilling chemicals. Different types of exposure during maintenance work are described as well. Very few exposure data are published. Acute, irritative health effects from chemical exposure are described, as well as chronic health effects like skin disorders and cancer. These workers seem to have a higher risk, that may be related to benzene exposure, of developing acute myelogenous leukemia. **INTERPRETATION:** Physicians who are treating patients working in the oil industry are advised to be aware of possible adverse health effects from the work environment on the rigs. Further exposure studies and research in this area are highly recommended, as the literature is scarce.

Ann Occup Hyg. 2003 Apr;47(3):201-10.

Overview and characteristics of some occupational exposures and health risks on offshore oil and gas installations.

Gardner R.

Offshore Division, Hazardous Industries Directorate, Health & Safety Executive, Merton House, Stanley Road, Bootle, Merseyside L20 3DL, UK.

This review considers the nature, and recognition and control, of health risks in the offshore oil and gas industry from the occupational hygiene point of view. Particular attention is given to the changes in the nature of exposure and control of inhalation risks from substances hazardous to health in the UK sector, but other risks (e.g. dermatitis, noise and vibration) are also considered. The amount of published information on exposure to these hazards in the sector, or indeed on long-term health outcomes of working offshore, is limited. The approach taken to occupational health and hygiene in the sector has to be set in the context of the challenge of working in a remote and hostile environment where attention to safety and the need for emergency response to acute, rather than chronic, medical events are vital. However, changes in attitudes towards occupational health in the sector, legislation, the impact of environmental protection requirements and technology have all contributed to increasing the attention given to assessment and control of chemical and physical hazards. The health risks and benefits associated with the abandonment of installations, the application of new technologies, recovery of oil from ever deeper waters, lower staffing levels, environmental changes, the ageing workforce and the recognition of exposure patterns needing further attention/control (sequential multiple exposures, smaller workforce, peak/short-term exposures, etc.) are other current and future occupational hygiene challenges.

THE IMPORTANCE OF FILLING

RESEARCH GAPS FOR NANOTECHNOLOGY

NATIONAL INSTITUTE FOR OCCUPATIONAL SAFETY AND HEALTH

Docket NIOSH - 047

Town Hall Meeting on the National Occupational Research Agenda

College Park, Maryland

December 5, 2005

Comments of Kenneth R. Meade

Wilmer Cutler Pickering Hale and Dorr LLP

Good morning. My name is Ken Meade, and I am a partner in the Washington DC office of the law firm Wilmer Cutler Pickering Hale and Dorr. First I would like to thank NIOSH for hosting these town meetings and providing the opportunity for public input on the National Occupational Research Agenda. While there are many areas where scientific research is needed to prevent work-related injuries, illnesses and death, I would like to focus on the importance of the ongoing National Nanotechnology Initiative, and specifically the Nanotechnology and Health and Safety Research Program.

We represent clients in many sectors that are involved in the development of nanotechnology, from investors to research and development institutions and startup companies to manufacturers and secondary processors of nanomaterials. If you talk to people in each of these sectors they are united in their belief that nanotechnology is critical to the future of manufacturing, both here and around the world. In addition, all would agree that minimizing workplace exposure to nanoparticles should be a priority.

In our experience, however, there is also universal agreement that we simply do not currently have an answer to two of the most fundamental questions that are asked in the pursuit of these goals: (a) are there practicable methods to measure or assess workplace exposure to nanoparticles in a specific scenario, and (b) are there practicable methods or equipment that may be effective in minimizing exposure in that same scenario.

There are many institutions and organizations that are spending a tremendous amount of time, effort and money studying myriad issues involving nanotechnology, but we believe that nanotechnology must continue to be a priority area for further NIOSH scientific research. Studies have shown that worldwide government investment in nanotechnology increased almost ten fold from 1997 to the 2003 level of \$3 billion, and some have predicted that by the year 2012 the global impact of nanotechnology-related products will exceed \$1 trillion. Thus, it is not surprising that there are so many applications that are being studied, or that so many institutions, organizations and companies are pursuing the development of nanotechnology. It is critical for the success of these global efforts that we learn as much as possible, as quickly as possible, about potential workplace exposure, and that we develop, again as quickly as possible, effective and practicable methods for reducing such exposure.

There is much discussion and emphasis on studying the toxicology of nano substances. While we believe that this research is also necessary and fully support continued efforts in this area, from discussions with our clients and others involved in the various aspects of nanotechnology research and

manufacturing we believe that the industry is starved for information to fill the rather large knowledge gaps that currently exist with respect to workplace exposure.

With respect to the issue of measurement, there is a critical need for more research into the development of new and improved methods and strategies that can provide effective and reliable assessment of exposure to nanoparticles. There are so many different applications in which nanomaterials are handled, studied, manufactured and processed, and each presents its own challenge in terms of how to determine whether there are releases of nanoparticles and, if so, how to measure potential exposure in the workplace B whether such exposure is through inhalation, dermal contact, or ingestion. It is also critical to recognize that workplace exposures can occur farther down the production chain than just at the research, development and manufacturing stages. The so-called secondary processing of nanomaterials, or materials that contain nanomaterials, can involve cutting, sanding, or other machining that may create occupational exposure to nanoparticles, and these potential exposure scenarios must be considered as part of the overall study of measurement metrics.

The issue of reducing workplace exposure to nanomaterials is similarly in need of much more study. There are a wide variety of potential strategies for reducing workplace exposure that need to be evaluated for their effectiveness, both alone and in tandem with other strategies. While research in this area obviously depends in part on the success of efforts to develop appropriate methods for measuring nanoparticles in the workplace, research should not be delayed or postponed while we wait for measurement methods. Research needs to focus on evaluating all potential strategies, from equipment such as filtration systems or PPE to various work practices to strategies for maximizing ventilation efficiency. In addition, research must not focus solely on control strategies for addressing inhalation of nanoparticles; control strategies for reducing exposure via dermal contact as well as ingestion must also be evaluated.

In conclusion, we strongly support the National Nanotechnology Initiative, and NIOSH's commitment to partnering with the many national and international public agencies and institutions, as well as private organizations, that are involved in the ongoing effort to address workplace exposure issues and challenges presented by this new technology. Given the important role that nanotechnology and nanomaterials plays and will continue to play in the worldwide economy, it is critical that this area of study be given very high priority in the context of the ongoing planning for NORA and the identification of areas where research dollars and efforts can have the greatest impact on workplace safety.

Thank you again for the opportunity to provide our perspective on this important issue.

John Howard, M.D.

National Institute for Occupational Safety and Health (NIOSH)

Hubert H. Humphrey Bldg.

200 Independence Ave., SW

Room 715H

Washington, DC 20201

Dear Dr. Howard,

I am writing today to ask NIOSH to include a study on worker exposure to polybrominated diphenyl ethers (PBDEs) in the National Occupational Research Agenda (NORA).

In the modern era, dangerous chemicals have regularly been produced and widely distributed before scientists could discover hazards to human health and the environment. The problem arises from inadequate testing and regulation of industrial chemicals. Dozens of examples exist, from DDT, a pesticide that nearly caused the extinction of bald eagles, to PCBs, an industrial insulating chemical that

caused developmental problems in exposed humans. Both of these chemicals have become global contaminants, persisting in our environment despite being banned in the United States. Both can still be found in our bodies to this day. Over the last five years, scientists have uncovered yet another emerging threat to human health. The central figure in this new story is a group of chemicals known as polybrominated diphenyl ethers (PBDEs), or toxic flame retardants. Widely used in foams, fabrics, and plastics to delay the spread of fire, these chemicals can now be found practically everywhere scientists look. Despite the claims of the chemical industry, evidence continues to accumulate that PBDEs threaten human health:

-- Industry stated that flame retardants would not escape from treated products into the environment. Scientists have found them in rapidly increasing amounts in all parts of the world, from the blubber of harbor seals and polar bears to the blood and breast milk of humans. In particular, women's breast milk and breast tissue in America contain some of the highest levels of PBDEs found anywhere.

-- Industry assured the public that the chemicals were non-toxic, yet scientific studies have shown that exposure to toxic flame retardants during critical windows of development can interrupt brain development in mice, permanently impairing learning and movement.

-- Toxic flame retardants also have been linked to disruption of thyroid function, cancer, immune system harm, and reproductive system damage.

-- Contamination levels in humans have grown rapidly to the point where little margin of safety exists. Flame retardants found in some American mothers and fetuses are approaching the levels shown to impair learning and behavior in laboratory studies.

-- Some subset of the population likely already carries PBDEs at levels that could be harmful to fetal development.

PBDEs are persistent, bio-accumulative, and harmful. They persist for long periods of time both in the environment and in our bodies and travel through a variety of media, including air and water. They bio-accumulate, meaning they find their way into the bodies of humans. These chemicals are also toxic and may be harmful to human and ecological health.

Manufacturers of common household products routinely add PBDEs to plastics, fabrics, and foam in order to delay the spread of fire and improve product safety. The chemical industry produces and sells three different mixtures of PBDEs: Deca, Octa, and Penta. In 2001, more than 66 million pounds of PBDEs were used in North America.

Despite the growing evidence of the health threats posed by this class of chemicals, only Sweden has yet conducted an occupational health study. We urge NIOSH to study which workers may be exposed, how much exposure can be decreased, and what the health consequences are of workers and general population exposure.

Sincerely,

Luke Metzger

Categorized comment or partial comment:

As it has been established that disability has a greater morbidity and mortality for the same disease process than those who are at work, it would be a significant public benefit to develop sound processes and procedures to promote work and stay at work. I would like to recommend that NORA add to its research agenda some of the important issues concerning the stay-at-work and return-to-work (SAW/RTW) process that are highlighted in the report, entitled "Preventing Needless Work Disability by Helping People Stay Employed." The report developed by ACOEM is addressed to a broad audience of medical and non-medical readers and is an informative, sensible, and enlightening overview of the SAW/RTW process with both general and specific suggestions on how to improve it.

Categorized comment or partial comment:

We also are supportive of AFSCME's pandemic flu OSHA petition, and we are nearing the home stretch of a CalOSHA Airborne Infectious Disease Standard that at this point is actually quite good.

SEIU's California based H&S Rep John Mehring can provide anyone who is interested with more details on how it is proceeding.

Categorized comment or partial comment:

Your address was forwarded to me as an organisation becoming interested in environmental EM health issues.

I have been involved in work on electromagnetic interactions with living systems for the past 30 years.

I am attaching my bibliography which may contain something of use for you. Sincerely, Cyril Smith.

NOTE: The following text was entered from the attachment:

Bibliography on Electrical Hypersensitivity and Water Phenomena

Cyril W. Smith,

Honorary Senior Lecturer (Retired),

School of Acoustics and Electronics,

University of Salford, Salford M5 4WT, England.

RE: National Occupational Research Agenda (NORA)

Dear Dr. Howard,

Thank you for this opportunity for the American Latex Allergy Association, A.L.E.R.T., Inc. to participate in the public meeting to develop the National Occupational Research Agenda (NORA). Unfortunately we are unable to attend this meeting to present our testimony in person. We would like to submit the following information as written testimony.

The current statistics for people sensitized to natural rubber latex (NRL) are broken down by risk groups and are as follows:

- 8-17% of health care workers
- Up to 68% of children with spina bifida (related to frequent surgeries - anyone who has multiple surgeries is at risk)
- Less than 1% of the general population in the U.S. (about 3 million people)

During the past 10 years significant strides have been made to address the many occupational health issues related to natural rubber latex allergy (NRL).

Unfortunately, there still remain many areas where attention is so desperately needed.

The American Latex Allergy Association website www.latexallergyresources.org receives over 6,000 visits per month and we receive over 400 calls and e-mails every month that bring our attention to the continued issues of natural rubber latex allergy (NRL).

The following are excerpts from actual e-mails we received in the last year.

"My daughter has spina bifida and has a latex allergy. She's considering going into cosmetology - particularly doing nails at the local technical school. Could you tell me if there's a latex problem with that profession?"

"Hello, I am interested in updating our latex policy at my hospital. Our current screening tool is very general and requires all patients with any sort of reaction to latex to be isolated. Do you have a more detailed screening tool to help classify patients between contact and airborne allergies? Do you have any sample latex policies for hospitals to use?"

--- One of the main factors contributing to the inability of latex allergic individuals to return to work is occupational asthma. According to the American Academy of Asthma Allergy and Immunology "up to 15% of adult asthma cases in the United States have job-related factors, and it accounts for approximately 24.5 million missed work days annually." Latex allergy is included in the listing of job related risk factors. (AAAAI Press release: Reducing exposure can reduce symptoms of occupational asthma: 1/05/2006). Additionally, two articles that recently addressed this issue are Latex Allergy and Occupational Asthma in Health Care Workers: Adverse Outcomes, Sania Amr; Mary E. Bollinger Environ Health Perspect. 112(3):378-381, 2004 concludes "special attention should be given to the patient's work and home environments, because timely control of exposure is important to minimize further damage and long term adverse effects." Grand Rounds: Latex-Induced Occupational Asthma in a Surgical Pathologist Judith Green-McKenzie; Debra Hudes, Environ Health Perspect. 2005;113(7):888-893 a 43 year old surgical pathologist with latex allergy was unable to continue working. The article states "The provision of a latex-safe environment was explored with the hospital administration and deemed not feasible at that time. A full-faced dual cartridge respirator was recommended and tried in consultation with a certified industrial hygienist. However, it interfered with the patient's ability to communicate, and he was unable to tolerate wearing it for an 8-hr day. We felt that he was at risk for potentially fatal anaphylaxis, as well as irreversible and impending structural damage to his lungs, given his long history of exposure and disease severity."

Continued research is needed to address the issues of Latex Allergy related Occupational Asthma.

--- Many feel that the risk of natural rubber latex allergy in health care workers is gone. We are still being contacted by health care workers experiencing new allergic reactions, many of them are as severe as those seen 10 years ago. The following is an excerpt from an e-mail:

"I have just recently been denied a position at a hospital because of a latex allergy. Is this legal? It seems like some sort of discrimination? Please let me know. Also, I am wondering if there are many hospitals out there that have this policy Thanks,"

--- Diagnosis of latex allergy is still controversial due to the lack of a reliable (FDA approved) skin prick test reagent. The RAST tests currently available have 25% false negative results. Diagnosis currently is made based on a thorough health history. Not having a definitive diagnostic test very often makes the diagnosis controversial. Here is an excerpt from an email:

"I have been a nurse for 15 years, and about 14 years ago, I noticed that each time I went to work, I broke out in hives. I even had to be sent to the ER by my supervisor. At that time, I had read an article about latex allergy. The strange thing was, that prior to becoming a nurse, I had noticed that when I blew up or played with a balloon, used a condom or chewed gum, I seem to have a reaction. I saw my dermatologist and he diagnosed me as latex allergy. I required surgery 2 years ago, and they demanded

a blood test in spite of the diagnosis from my dermatologist. I agreed. The test came back negative. They said you are not latex allergy. I since then have received a diagnosis of skin cancer, and had to see a specialist from the ----- Clinic. I discussed this with him, and he said, by all means I should be considered a latex allergy patient."

--- There are restaurant workers handling food wearing latex gloves, these individuals are at risk for developing latex allergy.

The following is an excerpt from e-mails:

A chef from Washington who is unable to work in her profession writes: "The use of latex gloves is as prevalent in the Food Service industry as it is in the medical professions...It is with mixed emotions to have found ALERT. Sad to know, and believe me, I know the pain and suffering everyone affected with latex allergy copes with, and relieved to know that I am not alone and over reacting to what I fear is a life threatening risk that is being overlooked."

--- There have not been any studies addressing the protein levels of these non- medical grade latex gloves that are routinely worn. In addition, this also poses a risk to individuals with latex allergy eating food prepared by individuals wearing latex gloves.

--- Many non-health care workers are now routinely wearing latex gloves as part of their job. Examples of this are: auto mechanics, food handlers, beauticians, grocery store employees, toll booth takers...

"Hello,

My name is ----. I am an automotive technician and I use latex and or nitrile disposable gloves every day at work. I have been using them for the past 7 years with no incident or allergic reaction what so ever.

Recently within the past 3 months or so, I seem to be "allergic" to both types of gloves (latex and nitrile). My hands seem to get itchy after wearing them. It stops bothering me when I stop wearing them.

Can you recommend a particular type and brand of glove that is not latex or nitrile that I can try, and where I can purchase them?

Thank you for your cooperation,"

--- Day care workers are routinely wearing latex gloves for diaper changing. According to the 2002 Census statistics 2, 335,000 children were enrolled in day care. There currently are not statistics to document how many of those children are exposed to natural rubber latex (NRL) on a daily basis. We are seeing an increasing number of children being diagnosed with natural rubber latex allergy (NRL). Research needs to be done to determine the risk to both the employee (day care worker) and the children who may be repeatedly exposed to natural rubber latex (NRL).

--- There are thousands of products that are manufactured that contain latex. This may pose a risk to the employees in the manufacturing process as well as the consumer using the products. Consumer products containing natural rubber latex (NRL) are not labeled. Research is needed to know if the manufacturing process is a risk to employees and if the products produced are a potential risk to already sensitized natural rubber latex (NRL) individuals. Here is an excerpt from a few emails:

"Are there universal labels that can be applied to products to state `latex-free`? "

"I am trying to gather information on whether the latex used in adhesives for food packaging seals could pose a threat for people with latex allergies. In particular, if someone licked the product off the packaging material, and have latex allergens, could this pose a threat, and how serious a threat?

Any information on this issue would be greatly appreciated."

"My wife tests 2 out of 4 on a RAST test for latex allergy, which heightened my awareness of how ubiquitous latex is in our society. I had noticed for years that there was a "scum" on the inside of lids from cans of fruits and vegetables. Most recently, I visited the ----- website and to my amazement they use latex in the cans in a machine called a "seamer" to help seal the lid to the can. If - (manufacturer)- does it, do all canned food processors? And what about overseas processors? I am alarmed at the potential for there to be latex in every can of food consumed by the American public. As the signature association for the latex allergy problem, I am passing this information to you in the hopes that you will investigate and determine that it is a non-issue, advise people who have latex allergy to avoid canned foods through the media, or compel canned food processors to change their process. Any information that you have on this subject to date would be appreciated. Thank you in advance."

--- There still is not treatment for natural rubber latex allergy (NRL). Avoidance is still the only recommended treatment. Medications to manage the symptoms are utilized, but are not a treatment for the latex allergy itself. Research into immunotherapy needs to be continued.

--- The role vigilance plays in the issue of natural rubber latex allergy (NRL) can not be overstated. All involved professions, organizations and agencies must remain vigilant to there rolls in the many complex issues of natural rubber latex allergy (NRL).

Thank you for the last 10 years of having Natural Rubber Latex Allergy (NRL) on the research agenda. Please consider these important issues and keep Natural Rubber Latex Allergy (NRL) on NORA's agenda for the future.

If you need further explanations we would be happy to provide more information.

Sincerely,

Sue Lockwood

I apologize for not making the meeting today - but an unexpected emergency came up. Below are the comments that I intended to provide to the committee. I hope it is not too late for inclusion in your discussions.

Testimony NORA Town Hall Meeting

March 13, 2006

Anna Gilmore Hall,

Executive Director

Health Care Without Harm

Good morning

I am here this morning giving comments from HCWH and as a Registered Nurse. HCWH is an international coalition of 500 organizations in 42 countries. Our mission is to transform the health care industry worldwide, without compromising patient safety or care, so that is ecologically sustainable and no longer a source of harm to the public health, people who work within health care and the environment.

Introduction. Between May 2005 and January 2006, we conducted an on line survey to explore the relationship between a nurse's health and on-the-job exposures to chemicals, drugs and other harmful

agents. 1,452 nurses completed the survey designed by the Environmental Working Group (EWG), American Nurses Association, University of Maryland, School of Nursing and Healthcare Without Harm.

The survey was designed for three purposes:

- to serve as an outreach and education tool to nurses not already engaged in the environmental health movement,
- to provide preliminary research findings that may indicate the need for further research on particular aspects of nurses' chemical exposures and health outcomes,
- to provide potential content to generate media interest in Nurses Week, May 2006.

Currently, we are analyzing the data within these completed surveys to identify health and exposure relationships that may merit further study.

-- Total number of surveys completed: 1,452

-- Current job category for survey respondents: Registered nurse (RN) (1,091 responses); Advance practice registered nurse (APRN) (190 responses); Licensed practical nurse or other healthcare professional (171 responses).

-- Current state of residence: Nurses from 50 different states and Washington, DC responded to the survey.

-- Job history: Information was collected on history of nursing positions held by respondents, including years of employment in each position, major practice area, and type of facility where employed.

-- Chemical and radiation exposures: Information was collected on eight exposure categories (including cleansing and disinfection products, specialty healthcare chemicals, radiation, anesthetic gases, and others), and nine specific chemicals or relevant medical devices within those categories.

-- Health outcomes for survey respondent: Information was collected for 20 major health outcome categories and year of diagnosis for each, ranging from primary cancer to infertility to osteoporosis, as well as for 55 individual cancer sites or types. These outcomes also included miscarriage, medically necessary abortions, and Latex sensitivity.

-- Health outcomes for each of the respondents' children: Information was collected on the same health outcomes outlined above.

-- Opinion survey - environmental health: Information was collected on survey respondent reactions to statements concerning the importance of chemical exposures in health outcomes and the emphasis placed by their facility on environmental health and safety.

Plan for data analysis. Data analysis will be conducted in three phases, the first an exploratory phase to identify overall response content and gross relationships between health condition, exposure, and years and type of employment; the second a manual review of individual data records for particular health outcomes or exposures of interest; and the third a follow-up phase to explore in further detail relationships of interest identified in phases one and two. We can adjust for age, smoking, and alcohol consumption if needed, for some of these analyses.

Phase one – initial data exploration. This phase of analysis will likely include, but not be restricted to, the following analyses:

-- Survey response rates (and totals) by geographic region, nursing title, major practice area, level of education, and years of practice. These rates will serve to guide segmentation of data during subsequent analyses of correlations between employment, exposure, and health factors.

-- Summary analysis of the responses to the "Environmental Health Statements" section of the survey, which requests information on how the respondent perceives the influence of chemical exposures on health and the emphasis placed on environmental health and safety at their facility.

-- Comparison of background rates of health problems in the general population, versus rates seen among survey respondents. Note that we believe the pool of survey respondents may be biased toward those with health problems, so comparisons against background rates are for informational purposes only, to guide potential further research. The outcomes we will investigate include:

1. Health outcomes of survey respondent: 20 major health outcome categories, ranging from primary cancer to infertility to osteoporosis, as well for as 55 individual cancer sites or types. These 20 also include miscarriage, medically necessary abortion, and Latex sensitivity.

2. Health outcomes of survey respondents' children (as above).

-- Relationships between health outcomes and employment history. We will explore relationships between health outcomes and job history, including total years employed as nurse, nurse title (e.g., RN or APRN), and nurse practice area. Health outcomes for both the respondent and their children will be considered. For these analyses, we do not expect a bias among respondents – we would assume that a health affected nurse in one practice area would be as likely to respond to the survey as a health affected nurse in another practice area.

-- Relationships between health outcomes and exposure history for survey respondent and children. We will explore relationships between the exposure history of the respondent, and the health outcomes of the respondent and their children, including preliminary assessments of reported disease or health condition rates relative to each exposure category, chemical, or relevant medical device. These assessments will also account for the duration of employment in jobs related to the relevant exposures, if appropriate based on initial analyses.

Phase two – manual review of individual data records. In this phase of analysis we will manually review data records associated with individuals who reported unusual diseases or unusual numbers of diseases, for themselves or their children. We will search for any factors in the survey responses that may be linked to these reported conditions and that may not have been identified in the Phase one analyses.

We will also manually review the survey responses for those nurses who completed the detailed shift-specific exposure survey, documenting the products, chemicals, and devices used over one shift. A manual review of this data will guide decisions on how or if it is used in further statistical analysis in Phase three.

Phase three – follow-up analyses. In this phase of analysis, we will further explore additional statistical relationships in the data as needed and as guided by our findings in Phases one and two. Examples might include detailed segmentation by job history or exposure factors compared against rates of a particular disease outcome or aggregated disease rates. The final analyses to be included in this phase will be determined after the first two phases of analysis are complete.

Conclusion:

While we are pleased to be able to do this kind of informal data gathering, it is clear by the initial response to the survey, that this is a major concern of nurses. As we continue to face an expanding nursing shortage, and increasing hazards in the health care work place, it is imperative that the health care industry and the government do everything we can do ensure that the workplace becomes safer for nurses and other health care professionals.

At this time, our analysis is not complete, however, it is clear that further research is necessary, We urge NIOSH and OSHA to expand your research and explore these issues for nurses and other nursing personnel. As soon as our analysis is complete we will be presenting the information in May during National Nurses Week and will be happy to provide our findings with you.

Thank you for the opportunity to present this morning.

NOTE: Text entered from submission E-36.

Comments at NORA March 13 Town Hall Washington DC

I want to speak to the benefit of collaborations with global partners in NORA (employers, workers, governments, public health, researchers, etc) for the benefit of both US workers and workers internationally, but particularly in developing countries.

Global Collaborations is a priority at NIOSH and is one of the Cross-cutting programs to support the Sector Program activities. The Sector structure of this second decade of NORA brings us new opportunities to ensure health and safety of workers if we are wise in seeing the possibilities.

I will give an example of an international initiative in existence for 10 years that has missed the problem of workers and the opportunities that workplaces provide to tackle problems. This is the Global Road Safety initiative, for which a UN General Assembly resolution was approved in December 2005.

I participated for NIOSH in February in a meeting sponsored by the World Bank/USAID/CDC/NAS/DOT, where it became apparent that the excellent Global Road Safety Initiative of WHO/World Bank/UN has not understood the importance of worker health and safety issues. (Priorities are still helmets, seat belts, etc. for the general public.)

It is time to advance recognition and attention to the problems of workers on roads and the opportunities in use of workplaces for action. For example, all multinational companies want to keep their workers safe while traveling on roads, and all manufacturing multinationals use trucks on the roads in other countries. Thus, there seems to be benefit in including the global road safety in the NORA Transport Sector and in the NORA Manufacturing Sector. Actions by multinationals and international unions and NGOs in developing countries would advance road safety in all countries, particularly as partnerships with international development agencies are possible.

Another worker aspect ignored to date is that the global road safety initiative needs to plan for and address those unintended consequences experienced by workers who carry out road safety initiatives. India is noting the very high incidence of silicosis (other problems as well) from stone crushing operations to build MILLIONS of miles of roads that are part of the effort to improve road safety.

Another function of Global Collaborations for all NORA sectors will also be to share good practices found elsewhere (EU Agency has 178 documents, for example, at http://europe.osha.eu.int/OSHA/search_rss?SearchableText=Road+Safety).

I want to encourage NIOSH and all of us to think about global partnerships to improve the lives of US workers and workers everywhere.

Cincinnati, OH 45226

RE: Docket NIOSH-047

Dear Director Howard and NIOSH Staff:

In response to the National Institute for Occupational Safety and Health's (NIOSH) call for public commentary on the second National Occupational Research Agenda (NORA II), the American Public Health Association (APHA) would like to submit comments and recommendations on behalf of its

membership. APHA is the oldest and largest organization of public health professionals in the world, representing more than 50,000 members from over 50 occupations of public health. Within APHA, occupational health and safety policy resolutions and policy are developed with input from the Occupational Health and Safety Section, whose 1000+ members include occupational health specialists, union organizers, occupational hygienists, safety professionals, health care providers, nurses, physicians, educators, administrators, epidemiologists, and attorneys. APHA has a strong history of expressing support for NIOSH, having passed numerous policy resolutions expressing support for NIOSH's leadership role in occupational safety and health.

APHA supports NIOSH's efforts to prioritize its occupational safety and health activities and funding with a second research agenda. NIOSH fulfills an important function within the Centers for Disease Control and Prevention, that of sponsoring, promoting, and conducting scientific research, surveillance, intervention and other activities aimed at improving workplace safety and health for all American workers. APHA appreciates the opportunity to participate in the development of NORA II by submitting the following comments.

1. Comments on the proposed sector-based approach.

APHA supports the development of a research agenda to guide and prioritize NIOSH's work. However, we urge NIOSH to expand the formal scope of NORA II beyond sector-based goals, objectives and action plans. The sector-based approach will allow NIOSH to identify important physical and other risk factors for injury and illness within industry groupings. However, we feel strongly that fundamental public health activities, e.g., surveillance, special focuses on priority populations, attention to new and emerging hazards etc., should also be given equal consideration as potential priority areas for NORA II. Many of NIOSH's important functions are not confined to industry-sector specific activities. In addition, the importance of these functions argue against their eventual determination by a "cross-sector research council." Rather, development of NORA II should include explicit identification of such topics and inclusion in NORA as focus areas in addition to, or instead of, sector-specific topics. Below are specific examples of topics that cross industry sectors, that we believe merit consideration as NORA priority areas.

2. Specific recommendations for cross-sector research priorities

Strengthen surveillance of work-related injury and illness

Surveillance is often the basis for the appropriate targeting of interventions. NIOSH should strengthen the surveillance systems for identification and recording of cases of work-related illness and injury, in order to work toward a goal of comprehensive national surveillance of work-related conditions. Gaps in the surveillance systems for occupational disease are well-documented. Surveillance of non-fatal occupational injuries is not adequate for determining the extent and distribution of injuries to American workers. New and innovative means of collecting this needed data, including efforts to establish population-based data collection, should form part of any national agenda for occupational health research and activities. For example, NIOSH should work with other agencies to facilitate occupational health surveillance through current national health surveillance systems (i.e., surveys such as NHIS), expanding the occupational variables collected by well-established, ongoing national health surveys. Investigation into reporting practices (i.e., underreporting) and the validity of estimates of work-related injury rates is equally important, as the biases in current data collection methods are widely acknowledged.

Conduct hazard surveillance

Reliable data on the prevalence of workplace exposures and the number of workers exposed to potential health hazards is needed to prioritize occupational health and safety research and activities.

Strengthen Health Hazard Evaluations

NIOSH should increase its conduct of Health Hazard Evaluations (HHE), investigations to determine toxicity of materials at concentrations used or found in the workplace, which are explicitly defined in the law to provide a mechanism to investigate emerging hazards. These investigations also present opportunities to reveal previously unrecognized, emerging occupational health hazards. Workplaces and job tasks continue to change throughout all industries making expert assessment of new hazards essential. Further, HHEs provide an unparalleled service to American worksites and workers when faced with challenging exposures that are not easily characterized.

Conduct research to support standard-setting activities of the Occupational Safety and Health Administration (OSHA) and the Mine Safety and Health Administration (MSHA)

NIOSH's "criteria for a recommended standard" documents are important for the support of OSHA's and MSHA's activities to protect the health of workers. APHA urges NIOSH to consider annual or frequent publication of criteria documents, and to prioritize research activities that provide needed evidence for new standards.

Focus on priority populations

Demographic, workplace and economic trends point to the continued and increasing employment of distinct sub-groups of workers, such as young and older workers, immigrants, women, and persons with disabilities. The ever-changing profile of the U.S. workforce presents significant need to address work-related factors that result in disparate risks for occupational injury and illness. For example, young workers continue to experience higher rates of on-the-job injuries than all workers combined, while older workers re-entering the workforce have special vulnerabilities as they perform in new occupations. Additionally, many of the most dangerous jobs are typically filled by recent immigrants resulting in more severe health consequences that often go untreated. Because these sub-groups of workers largely participate in the parttime and contingent workforce, attention should also be paid to the effects of temporary, unstable employment. NIOSH, through NORA II, must continue taking leadership in guiding efforts to advance research on the unique needs of these groups of workers.

Fund and conduct intervention research

NORA II should include a focus on the investigation of methods to reduce occupational exposures and prevent adverse outcomes. Whenever possible, these interventions should be implemented to demonstrate utility across multiple industry sectors. Lessons learned from the first NORA can inform this research.

academic and labor communities

Categorized comment or partial comment:

Encourage innovative research methodology, design, and approaches

NORA II should encourage the development and use of innovative methods, techniques, and approaches for researching and solving occupational safety and health problems. Examples include international projects, mixed method investigations (combined quantitative/qualitative studies), participatory action research, and advanced hierarchical regression modeling. Collaboration with academic and labor communities would help to disseminate and promote such innovative research among a variety of work settings.

Hazards that cross industry sectors

Hazards prevalent across industry sectors, particularly those that have been underinvestigated are in danger of being neglected within a sector approach. Several such important hazards are discussed below.

-- New and emerging hazards

NIOSH should have the capacity to respond to important, new issues in occupational safety and health. We suggest that NORA II include language that allows NIOSH to prioritize emerging threats to worker safety and health, such as those introduced by new technologies or shifts in work organization practices. Again, the HHE format should be considered as a tool to investigate potential new threats to worker health.

Capacity building

Partners

labor and community groups, e.g., Committees on Occupational Safety and Health

Categorized comment or partial comment:

3. Recommendations for approaches to funding

Build capacity within NIOSH partners

Cross-disciplinary work is increasingly important as occupational health and safety experts and researchers attempt to meet the needs of a diverse workforce in a changing economy. To most effectively protect the needs of the nation's workers, occupational safety and health expertise must be cultivated within related disciplines. Fostering the development of occupational health capacity within NIOSH partners, including those partners with networks into priority working populations, will enhance NIOSH's ability to improve worker safety and health.

Encourage community-based and collaborative work

Community-based work builds occupational safety and health capacity that workers can readily access. Funding of labor and community groups (e.g., Committees on Occupational Safety and Health) and of collaborative projects with academic entities can result in innovative research that reaches workers and their families at the community level.

4. Need for expanded funding of occupational safety and health research

NIOSH is the only federal agency that provides significant funding research into etiology of work-related injury and illness, estimation of rates of work-related outcomes through surveillance, the effectiveness of intervention programs and other research activities aimed at providing for safe workplaces. In a time of rapidly changing workplace technology, an unprecedented number of chemical products in use in the workplace, and changing work organization, funding of NIOSH activities and priorities has never been more important. APHA strongly supports maximum funding of those activities identified by NORA II as

priorities areas for NIOSH`s work in the prevention of work-related injuries and illnesses to the nation`s workers.

We appreciate the opportunity to provide our views to NIOSH.

Sincerely,

Rachel Rubin, MD, MPH

Chair

Occupational Health and Safety Section

Comments re: docket number NIOSH-047

Ladies and Gentlemen:

I wish to comment on the apparent decision both to remove any consideration of electromagnetic field effects from the agenda of concerns about safety in the work place and, more crucially, to remove from NIOSH any expertise that can evaluate whether future concerns are worthy of attention. While standards now exist that apply and seem according to current science to cover well the immediate effects of exposure to low- and high-frequency fields-primarily electric shock injuries at low frequencies and thermally-related injuries, including burns, at higher ones-the standards note that they do not cover any possible long-term effects of lower-intensity fields. Such long-term effects have not been confirmed scientifically, but as the standard-setting groups note, they also have not been well-studied, particularly for high frequencies and various modulation patterns. They do not seem severe; otherwise they would likely have already been identified. However, electromagnetic field-emitting devices are becoming increasingly common in all parts of the workplace.

While many of the workplace field-generating sources expose the general public, either in the same workplace as workers or because they are also used both at, the worker is much more likely to experience the fields for a longer period and often, due either to his/her position with respect to the device or to the use of heavier-duty equipment, at a higher intensity.

Therefore, NIOSH will continue to require expertise to be able to evaluate the unique areas of exposure experienced by workers as the scientific literature on effects of exposure evolves. Furthermore, NIOSH's mission should include work to determine accurately the extent of workers' exposure as new applications are introduced and devices for old ones are refined. In addition, other agencies' funding of research into the effects of lower-level exposure is presently decreasing, so NIOSH's role in monitoring and ensuring that research continues into suspected effects on workers will be increasingly important.

Using NORA's "sector-based approach," one can easily identify a few examples of current, emerging or possible field-emitting devices used by workers for each. In all areas, workers will increasingly use wireless communication devices, including cell phones and wireless computer networking systems, and computers, including laptops where some field-generating parts, though their field intensities decrease quickly with distance, are often very close to parts of the body. One should also recall that any electric current creates a magnetic field and that heavier currents create stronger ones in the machine and also in the electric cables. Battery-operated devices are usually low-voltage and high-current; some that require voltages step up the battery voltage with internally-generated high frequencies. Both motors, especially poorly-maintained ones that spark internally, and modern semiconductor-based device controllers can create large amounts of higher frequencies in addition to the basic 60 Hz.

RI Committee on Occupational Safety and Health

RICOSH remarks for National Institute for Occupational Safety and Health (NIOSH) Town Hall Meeting, 3/20/06 Lowell, MA to provide input for the National Occupational Research Agenda (NORA).

NIOSH recommended standard on infectious disease - An Idea Whose Time Has Come?

NIOSH develops recommendations for workplace safety and health standards under both the Occupational Safety and Health Act (29 USC 1900) and the Mine Safety and Health Act (30 USC 80).

NIOSH criteria documents are designed to pull together current scientific and critically reviewed information on a particular hazard and then offer a comprehensive worker protection standard that includes control measures and methods, exposure limits, medical surveillance, training and recordkeeping.

These can often morph into enforceable OSHA standards (though the lag time from NIOSH recommendations to OSHA standard rule can be considerable).

NIOSH has produced criteria documents in three broad categories.

- Safety and health standard for hazardous agents
- Safety and health standard for physical hazards
- Safety and health standard for specific industries, work processes and work environments.

Infection Control Policy

We are here proposing as part of the NIOSH NORA ten year plan that NIOSH develop a comprehensive criteria document on infection disease control in the workplace. A range of infectious or communicable diseases has emerged in recent years as unique workplace hazards: TB, SARS, hemorrhagic fevers, and, the potential for pandemic flu. Nosocomial transmission of SARS was often associated with noncompliance with the basic level of infection control precautions (standard precautions). In addition, numerous studies have documented the lack of compliance with hand hygiene, a major component of standard precautions.

Since the range of infectious or communicable agents is endless an agent specific standard would not be efficient. An infection control plan will shift target and focus depending on the characteristics of the infectious agent - its virulence, transmission mode (air, bodyfluids, surfaces), attack rates (in different age groups), vaccine protection (if any), susceptibility to medication, and response to other treatments. However, there are certain generic features or thematic principles all infection control programs need to address:

- criteria for a "case"
- criteria for exposure
- isolation practices and standard and contact precautions
- respiratory protection policy (airborne and droplet exposures)
- management of patient/ client
- standard environmental/engineering controls
- role of vaccines and meds and related therapies (e.g. drugs that interrupt mediators of sepsis, e.g.)
- principles of post exposure treatment.

Previous NIOSH publication 88-91900 "Guidelines for Protecting the safety and Health of Health Care Workers" while valuable in its time is out of date especially in the realm of infectious disease control. In addition several authoritative documents exist which can guide NIOSH in formulating a comprehensive standard.

- CDC, Guideline for infection control in health care personnel, 1998
- International Society for Infectious diseases, A Guide to Infection Control in the Hospital (2004)

Skyjack and the Aerial Work Platform industry

Categorized comment or partial comment:

Skyjack, Inc.
55 Campbell Road
Guelph, Ontario, Canada N1H 1B9
www.linamar.com

March 13, 2006

Good morning Ladies and Gentlemen.

My name is Brad Boehler and I am pleased to be invited to speak to you today about the need for further collaborative research efforts involving the Aerial Work Platform industry and the National Institute for Occupational Safety and Health.

I am the Director of Product Safety for Skyjack, a manufacturer of Aerial Work Platforms, and likely the largest producer of scissor lifts in the world. As well, I am here to speak to you as a representative of the industry as a whole. I am a committee member of a number of standards committees relating to aerial lifts. These include the American National Standards Institute (ANSI) A92 Aerial Platforms Main Committee and various A92 sub-committees, the US Technical Advisory Group to ISO Technical Committee 214 Elevating Work Platforms, and the Canadian Standards Association (CSA) B354 Elevating Work Platforms Technical Committee. I am also a contributing member of various industry associations

including the International Powered Access Federation (IPAF) and Aerial Work Platform Training (AWPT). The latter is a North American subsidiary of IPAF and is dedicated to standardizing the training of aerial work platform operators throughout North America. Skyjack is an AWPT training centre, and I am a registered AWPT Operator Instructor. Further, I have presented papers regarding safety and standards within the industry at both Aerial Platform Safety Conferences to be held to date.

As a result of my participation in these committees and groups, I regularly meet with representatives from other manufacturers, regulators, equipment owners, end users and safety professionals. Some of the basis for my comments, result from the points of concern expressed at these various meetings. Other portions are my own thoughts and opinions based upon my own examination of; and experience within the industry.

Studies of accident data, such as "Deaths in construction related to personnel lifts, 1992-1999" by Michael McCann of The Center to Protect Workers' Rights, indicate that aerial lifts are associated with nearly 4% of all construction related deaths during the period of the study. Recommendations of Mr. McCann include: "following OSHA regulations, wearing personal fall protection equipment, adequate maintenance, inspection before use, and training on the model of lift used."

Aerial Work Platforms are designed and produced as tools to place workers and their materials at height in order to perform tasks. Placing individuals above any support surface, regardless of method, is inherently dangerous, and ultimately a great responsibility. I believe that any manufacturer of aerial lifts understands their responsibility to safeguard the user, and these producers are actively pursuing methods to create machines that are practical and safe for use. However, although extremely important, the design and manufacture of Aerial Work Platforms is just the first step in ensuring the safety of the worker using this equipment. For a worker about to be placed at elevation, many other factors are involved in the safe completion of their assigned tasks at height.

-- Their lifting equipment must be the proper type for the jobsite conditions. For example it must be able to travel and elevate on a particular the jobsite terrain, it must be of sufficient elevating height and load capacity for the task.

-- The equipment must be properly maintained and ready for safe use. Unfortunately, regular maintenance is not a priority on the many jobsites. In fact, in some cases, safety devices are deliberately overridden, as they are deemed to hinder productivity. A proper, pre-use inspection could eliminate many poorly maintained lifts from immediate placement into service.

-- And, the operator must be properly trained.

I cannot emphasize the training requirement enough, as a properly trained operator is able to ensure that the equipment they are about to use is in an adequate state of repair for safe use, that it is the appropriate tool for their task, and that the surrounding environment is acceptable for safe use of that lift. With complete and competent training, an operator will understand that staying within accepted limits increases the likelihood that they may go home uninjured that evening.

Currently, the industry is struggling with various issues, some of which derive, to an extent, from the lack of clarity within the regulations as laid out by the Occupational Safety and Health Administration (OSHA). One such example is the use of fall protection on scissor lifts. OSHA defines scissor lifts as mobile scaffolds, although many interpret this incorrectly and group them with Aerial Lifts. As mobile scaffolds, a guardrail system is the required method of fall protection. However, some manufacturers,

owners, users and safety professionals still require the use of a harness and lanyard. The fall protection question is additionally convoluted when the question is asked whether or not the fall protection should be in the form of restraint or arrest.

Skyjack and I have entered into a collaborative effort with NIOSH. Dr. Christopher Pan and his team in Morgantown, West Virginia continue to work on a project, entitled "Fall Prevention for Aerial Lifts in the Construction Industry" and have thus far completed physical testing of a scissor lift, and has found that the subject lift does far exceed the requirements set out in the ANSI standards for stability. Human subject testing has determined the amount of force that a worker can actually impart to the lift while performing various tasks. The preliminary data indicates that the maximum force exerted is close to the 100 lbs (445N) specified in ANSI standard. This collaboration has been of great benefit to the manufacturer, the scientific community and the industry as a whole, and I will endorse and support the continuation of this initiative in any way I can.

How can NIOSH continue to help the Aerial Work Platform industry to create the safest at height environment for workers? The current project needs to continue with the completion and validation of a computer simulation of a generic scissor lift. Data already collected will be used to ensure that the virtual lift reacts in the same manner as it's physical counterpart. As well, actual, in use, construction site data, could be collected to confirm the laboratory findings. This model can then be placed into various scenarios to find the true limits of the unit, and determine if there are any areas where improvements can be made. My belief is that we will find that the lifts, if used within the parameters set forth by the manufacturer's are safe, and that we are correct to concentrate on training operators to know and stay within these guidelines for their own safety. Evaluation of the requirements and effectiveness of this operator training could also be another NIOSH research project.

Continuing research could also attempt to clarify the use of fall protection within scissor lifts specifically. Studies could be performed to determine whether lanyards and harnesses are the appropriate fall protection device in any given situation and if so, what type should be used. Other testing could be undertaken to determine the consequences of an arrested fall on a typical scissor lift anchorage system.

In conclusion, my personal goal is to ensure the safe use Aerial Work Platforms. There are a variety of different approaches to pursue to achieve this, one of which is having some of the brightest and best researchers investigate various methods of mitigating the hazards associated with elevating personnel. Skyjack and the Aerial Work Platform industry will cooperate and collaborate with NIOSH wherever possible to pursue this goal. Ultimately, "Education in Elevation" will create a safer workplace for everyone performing tasks at height using an Aerial Work Platform.

Thank you for your kind attention.

Brad Boehler, P.Eng, Director, Product Safety & Quality Assurance

Re: Research Proposal - Transportation & Warehousing - NIOSH 047

Attachment: BIO/Resume

Recommendation for further Research:

The correlation between Employee Injury Rates (both DART and OSHA recordable) and Total Lost Workdays and the Employee Relations Index Data, which companies use to measure and reflect the employee/management relations harmony, trust and employee perception of control over the safety of their work environment.

Preface:

Over my 35 years as a Safety manager, Human Resources manager, general manager and member of multiple safety advisory boards, I have observed that most of the research has focused on Facility/Equipment design and Work Process/Behavior and very little on what I refer to as the "3rd leg of a 3 legged stool"- employee perception and attitude. My past research has indicated to me that measuring these "employee management relations perceptions and behaviors," and then implementing

joint management/employee interventions does enable, support and yield the desired outcome, which is fewer injuries and less lost workdays per event.

Perhaps because much of the research and initiatives have come from those with engineering and employee training backgrounds, we as a community have focused on primarily on these two legs from viewpoint of these disciplines. Achieving the balance of this "three legged safety stool" is a precarious effort of the art and science of management design. We can improve our outcomes if we invest more research into the 3rd supportive leg of an effective safe work process.

Past Research Data:

While working to improve the employee safety for a large transportation company I began to have statistical correlations examined between OSHA, Lost Time Rates and our company's annual confidential Employee Relations Index (ERI). This ERI was a measure of employee management relations.

Within the 80 questions of the full ERI survey there were a series of 10 questions that had been identified by the prior Corporate Safety manager by identifying those questions which had a statistical correlation to high or low injury rates for work groups.

These discrete questions were then extracted and are referred to as a "Health and Safety Factor Index" (HSFI). The responses were then used for conducting small, follow-up, focus group discussions to with management and hourly employees to work towards improving cooperative efforts and partnering in joint safety initiatives.

I had the ERI data for each of 1700 work group composed of thousands of employees, compared to the OSHA and Lost Time Injury Frequency of these same work groups that make up our thousands of employees. To summarize we found that the Work Groups with the highest ERI scores had achieved the lowest injury frequencies. Work groups with improving ERI scores had improved injury frequencies compared year to year.

Finally we found that Work Groups with the lowest ERI scores had the highest or worst injury frequencies. Anecdotally, we also observed and found that as we moved key successful "people" managers as measured by the ERI from one building to another that injury rates reflected their arrival. So also we found the contrary for less effective managers.

Effective Management Interventions Based upon the Research:

Once we had this data we were also able to look at the more specific question responses and then inform and coach managers regarding the sort of management behaviors which resulted in the best or improved injury rate. We were able to identify which managers to place in facilities with work groups that needed safety improvement. We also determined that the individual and group sense of employee of participation in and control over their environment resulted in improving injury rates.

The injury rates improved over 40 percent in 5 years and lost time days were reduced eventually by the same or greater percent. They have continued these improvements.

In fact it is my experience that these interventions were as effective as, or more effective than some major financially monumental, work automation investments we made over the same time period. These automations may have lowered aerobic energy rates and fatigue but they were no more effective in reducing injury rates than other facilities that did not have such automations.

Future Research:

Based upon this significant, real world, "pilot research" and results, I recommend that NORA and NIOSH further research this area. I am interested in assisting and participating in this research process. I believe that this research can be applied and extrapolated to other industry sectors with similar benefits. The data responses are not collected by individual, but by job category and location so individual privacy issues. I do not see a barrier to research.

Other organizations both with union employees and non-union work forces do conduct similar Employee Relations Surveys, but may not ask the most appropriate questions that can be used as a Health & Safety Factor Index (HSFI). They do present early opportunities to do this research cost effectively.

Advancing an Occupational Health Agenda for Farmworkers

The National Institute of Occupational Safety and Health (NIOSH) is the only agency that can adequately address the occupational health and safety of migrant and seasonal farmworkers in the United States. If NIOSH places priority on applied research designed to yield practical results for this population, researchers will be responsive to that lead.

The National Agricultural Workers Survey (NAWS), is the only national information source addressing this population. It reported that 62% of farmworkers live in poverty and they represent almost half (42%) of the population employed in seasonal agricultural work. (ref. 3) Spanish was reported as the native language for 81% of farmworkers. Forty-four percent reported that they could not speak English and 53% could not read English "at all". The average individual income of farmworkers was between \$10,000 and \$12,499 with a total family income averaging between \$15,000 and \$17,499. Fifty two percent of workers reported that they would not be covered by workers` compensation for a work-related illness or injury and only 23% percent said they were covered by health insurance. (ref. 3)

Culturally appropriate interventions are needed for all Spanish speaking, farmworkers. (ref. 22, 23, 24) In my years working with migrant educators the potential avenue for occupational health and safety curricula is an avenue to reach young farmworkers` programs. This partnership approach is demonstrating the building capacity for promoting occupational health and safety education and to develop sustainable programs that are workable and effective. In my experience, many agricultural employers welcome partnerships with researchers. They are willing to collaborate to find out what practices work better to prevent occupational diseases and injuries among their workforce. These types

of collaborations are a genuine opportunity for researchers, for employers and for NIOSH, but they will be much more likely to occur if NIOSH specifies these types of projects in their calls for research.

The National Occupational Research Agenda (NORA) recognizes that no single organization has the resources necessary to conduct occupational safety and health research to adequately serve the needs of the diverse workforce in the U.S. Partnerships and coordination addressing the scarcity of bilingual resources in occupational health and safety research are required to determine the efficacy of intervention techniques and strategies. The research initiatives set forth in NORA should be applauded, but they could be strengthened through integration of a specific call for applied collaborative research projects targeting Spanish speaking farmworkers.

Lisa Brosseau, University of Minnesota

Small Business Health and Safety

I'd like to talk today about a sector of the economy unlikely to receive adequate representation at these hearings. Small and medium sized businesses are very important to the U.S. economy. There are approximately 6.5 million business establishments with fewer than 100 employees in the U.S., employing approximately 97 million workers. Many of these small business establishments have significant health and safety hazards. In the manufacturing sector, businesses with 50-250 employees generally have the highest injury rates when compared to their smaller and larger counterparts.

Some of the reasons for higher hazards, exposures and injury rates are obvious - health and safety requires time money and specialized expertise. Small business owners have limited resources and generally their staff have minimal background in health and safety.

I have met and worked with a lot of owners of small businesses in the past decade. All of them say that health and safety is important to them, but admit they are not always sure what is required or the reasons underlying requirements. Many of them are not convinced that the things health and safety professionals recommend will add value to their business.

In my opinion, NIOSH needs to put more emphasis on helping small business owners make the connection between health and safety and business productivity. Some of the things we need to make this possible include:

1. Simple, easy-to-use, valid measures of health and safety. For example, personal samples are generally not affordable, often do not provide a representative picture of exposures that are frequently changing, and are not applicable to many types of hazards. We need measures that are applicable to a wide range of hazards that can be implemented by anyone with a minimal amount of training.
2. Easily understandable methods for connecting health and safety improvements with both health and safety outcomes AND business outcomes. In other words, we need to be able to demonstrate that improving health and safety will lead to fewer injuries and illnesses as well as higher productivity and lower costs.
3. Methods for translating and communicating highly technical information to simple, easy-to-use advice and solutions. I believe there is much we could apply from health communication in other public health arenas.
4. Identify the few key activities that will ensure high levels of health and safety. For example, we talk a lot about management commitment and employee participation, but do we know what these things really are and can we measure them?

In addition, I think that NIOSH needs to work on finding ways to combine environmental and occupational health problems and solutions, so we are not simply transferring exposures from the community to employees. In addition, small business owners do not think of these as separate issues.

The most important target of any research in small businesses must be at the management level, since this is where the resources reside, the policies are made and enforced, and the training is initiated. NIOSH should focus on helping business owners and managers make their workplaces safer by improving their processes, eliminating hazards, and using engineering controls wherever necessary. While we need to build employee skills, I believe that the type of skills employees need are in recognizing hazards, developing solutions and communicating with their supervisors and managers to encourage the necessary improvements. We need to convince small business owners that their employees are their best resource.

Thank you.

NIOSH Testimony

January 23, 2006

My name is David Coultas. I am a pulmonary physician and chairman of medicine and physician-in-chief at the University of Texas Health Center at Tyler. As a pulmonary physician and epidemiological researcher I have had a longstanding interest in occupational and environmental lung diseases, health disparities, and prevention of chronic lung diseases. Thus, my comments today regarding the second decade of the National Occupational Research Agenda concern occupational lung diseases.

During my training as a pulmonary physician over 20 years ago my perspective on occupational lung diseases was largely limited to the classic dust-induced lung diseases from inorganic dusts including asbestosis, silicosis, and coal workers pneumoconiosis and organic dusts such as farmers` lung. Subsequently my knowledge about occupational lung diseases was greatly influenced my clinical and research work with miners in New Mexico and Colorado. Over the past 20 years we have learned that many more workplace exposures are associated with a much wider range of acute and chronic lung

diseases. Occupational exposures are associated with non-malignant diseases such as asthma, chronic obstructive pulmonary disease (COPD), and "idiopathic" interstitial pneumonias, and malignant respiratory diseases.

Chronic airflow obstruction from asthma and COPD has huge public health and economic impacts in the US and a substantial proportion of morbidity from CAO is attributed to work-related exposures. Of the over 16 million adults with asthma in the US up to 33% or over 5 million are estimated to have work-related asthma, either caused or worsened by exposures at work. And of the 12 million persons with COPD growing evidence over the past 10 years strongly suggests that up to 25% or about 3 million cases of COPD may be attributed to workplace exposures. In addition, of all the causes of death in the US such as heart disease, stroke, and cancer, COPD is the only one with a rising rate of mortality.

While these estimates for the number of persons affected by CAO from workplace exposures are large, these numbers probably underestimate the true number of affected because asthma and COPD are frequently under-diagnosed. Furthermore, the proportion of persons with CAO affected by workplace exposures varies between racial and ethnic groups estimated at 22% among whites, 23% among African Americans, and 50% among Mexican Americans. A wide variety of workplaces have been associated with an increased risk for chronic airflow obstruction including the armed forces, rubber, plastics and leather manufacturing, utilities, textile product manufacturing, construction, metal and automobile manufacturing, food product manufacturing, and agriculture.

While the chronic fibrotic lung diseases including asbestosis, silicosis, and coal workers' pneumoconiosis are among the classic occupational lung diseases there is growing evidence that other fibrotic lung diseases may also be associated with other occupational and environmental exposures. For example, the "idiopathic" interstitial pneumonias, or chronic pneumonias with no known cause, may in fact result from a wide variety of occupational and environmental exposures including farming, metal and wood dust exposure, silica, and cigarette smoking. In a meta-analysis I conducted of six case-control studies of idiopathic pulmonary fibrosis also known as IPF, the population-attributable risk for cigarette smoking is estimated at 49% and 20% for farming. While the idiopathic interstitial pneumonias are not as common as asthma and COPD, there is no effective therapy for IPF, and this evidence suggests that there may be an opportunity for prevention.

Similarly, effective treatment for lung cancer is very limited and prevention offers the greatest hope. Nearly 60 agents found in a wide variety of workplaces are established or suspected human carcinogens including environmental tobacco smoke. While the vast majority of lung cancer may be attributed to cigarette smoking, established causes of lung cancer among nonsmokers include asbestos, radon, and environmental tobacco smoke. Estimates from various studies on the proportion of lung cancer attributed to workplace exposures have ranged from 5% to 35%, and it is estimated that in the US over 16,000 lung cancer deaths result from occupational exposures.

In summary, we have strong evidence that combined, chronic respiratory diseases from workplace exposures in the US result in a substantial public health burden. Moreover, workplace exposures that cause respiratory diseases disproportionately affects non-white and lower socioeconomic populations who have traditionally been overexposed in hazardous industries such as agriculture, demolition, textile and other manufacturing industries. While these diseases are largely preventable through various methods available to control exposures, little work has been conducted on prevention. The exposures I have referred to are complex including mixed dusts and fumes, and often combined with cigarette

smoke. Better understanding of how these complex exposures cause disease may guide future prevention efforts. In the near future our opportunities for prevention may be expanded further as research is conducted to examine genetic variation that likely contributes in part to differences in susceptibility to occupational and environmental exposures. Research over the past several decades has dramatically advanced our understanding about the scope and impact of occupational lung diseases, but large gaps remain in our knowledge, particularly about prevention and ongoing research in this arena needs to be a priority in the National Occupational Research Agenda.

Thank you for the opportunity to present.

Research Priorities for the Second Decade of NORA

December 19, 2005

Chicago, Illinois

Presentation by

Patricia McGovern, PhD, Associate Professor

University of Minnesota School of Public Health and the Midwest Center for Occupational Health and Safety

Purpose: to recommend that NIOSH include work organization as a NORA research priority

1. Background

In the first decade of NORA "work-organization" was identified as a research priority. This term covered issues such as the hours, schedules, and job design factors associated with employee health. Continued research on these issues is needed, with particular attention to the dual role many employees have tending to work and family commitments.

How many people are affected by these issues?

Data from the USDOL for 2003 reveal the following (ref. 1) Among married couple families with children ages 6- 17 years, 67% have both partners in the labor force, and among those with children under 6 years, 53% have both partners in the workforce. Among families maintained by single mothers with children ages 6- 17 years, 77% are in the labor force, and among those with children under 6 years, 64% are in the workforce.

This work-family stress is particularly acute among female employees who traditionally shoulder more of the daily child care and home responsibilities as documented in time studies in the US.

Why emphasize these issues for women, don't men also have work-family commitments?

Yes, men also face these challenges. However, findings from two national studies of time use revealed women and men's paid labor time has become more similar than their housework time.(ref. 2-3) Moreover, the nature of home responsibilities differed by gender with implications for paid work. Men spent more time on activities that are discretionary in terms of scheduling (e.g., home and lawn maintenance and financial management) while women spent more time on non-discretionary activities (e.g., meal preparation and child care). Thus women's home responsibilities have a greater potential for conflicting with paid work, as such tasks are not always easily rescheduled. These trends are likely to be exacerbated by the recent trend of increasing annual work hours reported for the US relative to other wealthy industrialized countries.(ref 4)

Americans work about 200-400 more hours per year than workers in France, Germany, Norway, Sweden or Denmark. This translates into 5- 10 more weeks per year. The magnitude of work hours highlights the stresses many families face trying to balance work and home commitments.

But how do work hours and role conflict affect health?

Studies from Sweden have documented that role conflicts and work overload are reflected in women's elevated stress at work and at home, which may induce symptoms of cardiovascular, musculoskeletal and immune system disorders with implications for long term health.(ref. 5-10) Lundberg and colleagues report that female workers employed full-time have a greater total workload and experience more stress and role conflicts than men.(ref. 10) The gender difference increases with the number of children. The difference between men and women's total workload increased to 20 hours per week in families with three or more children. Women's total workload approached 90 hours per week.

What does this mean in real world terms?

My example comes from one of my former research staff, I'll call Jane, who works two part-time jobs. She recently had a two-week spell where either one or both of her children were sick. Her one year old had diarrhea for 10 days and her 3 year old ran a temperature, had a respiratory infection and pink eye. Her day care did not accept the children because of appropriate policies on infection control.

What did it mean for Jane? First she called her mother who drove 3 hours to come baby sit on day one. Jane then identified a sick child care service which promised to send someone for day two. At 6:30 am

on day two the service called to cancel. Next she called a babysitting service. They sent someone in the nick of time for her to make to an important meeting. And so it went, with Jane putting together a patchwork of childcare services so she could show up to work each morning. During this period she rarely slept more than 4 hours a night due to her children's nighttime awakenings. Jane developed a respiratory infection, and by the end of the 10 days, spoke of quitting one of her jobs if things didn't get better soon as her fatigue and stress were getting to be too much.

So what does work have to do with it? Aren't these problems the result of personal choices that Jane and her family need to deal with?

The point of the story is that one of her part-time jobs is more flexible than the other. It allows her to work at home when needed to balance work and family. At that job there is also social support from coworkers who are young mothers. One of the jobs also provides her a lot of autonomy, so that she can work with her supervisor to help set the week's priorities and workflow. These are all work factors that help her address the inevitable conflicts of paid work and family.

This story focuses on a woman who is well educated and middle income. She has a supportive husband and a mother who lives within driving distance. One of her two jobs is flexible. Now imagine a single mother with limited financial resources, no mother in the area, an inflexible job(s) or unsupportive supervisor. What is the potential for role conflict and strain? Might it influence her health over time? What job factors might serve as protective factors for her health?

So what work is needed?

Debate exists on how best to model the health effects of work-family conflict. While most investigators agree that work can interfere with family function (e.g., excessive work hours spilling over onto family time) and family can interfere with work (e.g., the story of Jane), few studies have examined both types of conflict in relation to health. Research is needed to identify the effects of work-family conflict on the health of employees with children, and in particular, to identify those work factors which can be modified to enhance health and productivity.

But don't we know a lot about job stress already?

Yes, we do. For example, early research on job stress and strain revealed that the lack of autonomy, under use of skills, and lack of recognition of accomplishments were associated with specific occupations that employ high concentrations of women (e.g., clerical work). (ref. 11-14) Karasek's demand and control model of job stress (ref. 16-18) has been used extensively to document that job strain results in adverse health effects such as cardiovascular and musculoskeletal symptoms, impairment of the immune system and mental strain. However, studies (ref. 18-19) recommend that this model be modified, particularly for workers in the service industry (more commonly women) to identify patterns of associations for health.

Moreover, in a study I have underway on women's health upon return to work after childbirth, preliminary findings suggest that Karasek's model does not apply to these women, although other factors such as perceived job stress, total workload (hours of paid and unpaid work) and job flexibility had significant effects on women's general mental health and/or postpartum depression in the first 18 months after childbirth. Moreover, workplace support had a strong, positive effect on women's health.

So what else needs to be done? Our work suggests a continued need for research investigating the effect of work hours and schedules, job stress, job flexibility and workplace supports on work-family

conflict and health, particularly in women with children from a variety of racial and ethnic backgrounds and income groups. As risk factors are identified for various subgroups, workplace factors that enhance health and productivity can be identified and tested in intervention studies.

What about NIOSH's desire to organize research by industries and occupations?

While women in all industries and occupations likely face these issues, Census 2000 tells us that 36% of women work in management, professional and related occupations, 18% in service occupations, and 37% in sales and office occupations. (ref. 20) Moreover, the 10 occupations that employ the most women are secretaries and administrative assistants, teachers, registered nurses, cashiers, retail salespersons, bookkeeping/accounting, nurse aides, customer service representatives, childcare workers and waitresses. (ref. 20)

Summary of Research Gaps and Needs for Further Research

Pathogenesis of WMSDs in nurses

-- Biomarkers of musculoskeletal damage from manual handling

-- How early in career trajectory (from admission to nursing school to practicing at the bedside) do symptoms begin?

-- What is the length of time from early pathogenesis to disablement/reporting injury?

Exposure Assessment

-- Improved ways to assess whether nurses are using safe patient handling equipment available at their worksites

-- Improved ways to capture nurses' total manual handling burden, including burden not related to patients (such as pushing equipment)

-- Ways to capture manual handling exposures in nursing students

Under-reporting of WMSDs

-- Reasons why nurses working with MSD pain do not report workers` comp injuries

-- The factors that prompt a nurse to report a WMSD

Contributions of psychosocial factors to WMSDs in nurses

-- Whether psychosocial factors an independent, moderator, or mediator variable in producing WMSDs

-- Whether interventions aimed at reducing psychosocial risk factors reduce WMSDs once physical hazards are controlled

Patient handling technology

-- Engineering solutions for turning patients from side to side

-- Elimination of having to reposition a patient to put a sling under them for full body lifts

Adoption of technology

-- Best practices for changing practice so that nurses use safe patient handling technology

-- Most effective ways to promote employer investment in safe patient handling and movement program and technology

Relationship WMSDs to quality of care and patient safety

-- Relationship between quality of patient care and WMSDs in caregivers

-- Relationship between patient safety and nurse safety

Lisa A Pompeii Ph. D, The University of Texas

NORA Town Hall Meeting

January 23, 2006

Return to Work Issues Among Nurses` Aides

I received a career development award (KO1 OH07996-01) from the National Institute for Occupational Safety and Health (NIOSH) in October 2003. This study, titled "Back Pain and Work Disability Among Health Care Workers", has been the primary focus of my research over the past two years. The main purpose of this cohort study is to examine risk factors for occupational back pain (OBP), and to examine the impact of work disability resulting from OBP among nurses and nurses` aides at Duke University Medical Center (DUMC). Information in the occupational health literature about nurses and nurses` aides largely consists of studies that have analyzed these two occupations together, portraying them as being very similar when, in fact, they are not. As a result, aspects of the nurses` aide job that may contribute to disparities in their health have not received adequate attention. At DUMC, African-American women hold more than half of the nurses` aide jobs, while holding only 14% of the registered and license practical nursing jobs which is consistent with national labor trends (BLS, 2002). Nurses` aides are paid less, they perform more lifting, bending, twisting in their job (Videman et al., 1984), are at greater risk for OBP (Engkvist et al., 2000), lose more time away from work from these injuries (BLS, 2002), and have fewer options for job transfer or change in the event of an injury compared to nurses.

The reporting structure within a typical nursing unit places nurses' aides at the bottom, possibly making it difficult for them to negotiate for lighter work assignments or restricted work duty when returning to work after reporting OBP. They may fear retribution or job loss if they refuse to perform work duties that are difficult, placing them at risk for further injury. Disparities in health already exist among nurses' aides with regard to their significantly higher rates of OBP compared to the general workforce, but they are at risk for further health disparities if they incur additional injuries and/or lose their job and the benefits of employment because of these injuries.

Work as a Basis for Health Disparities

Health disparities related to race, ethnicity, socioeconomic status and gender have been highlighted in the literature, with factors such as education, access to quality medical care, and the availability to health insurance considered as possible explanations for these disparities. However, some have argued that work should be considered "explicitly" as a potential explanation for health disparities (Lipscomb, R01 ES10939-05, Work and Health Disparities). Individuals can benefit considerably from employment since it usually offers financial gain, health insurance and retirement benefits, and psychosocial support. However, some work groups may endure hazardous working conditions so that they can receive these benefits, placing them at risk for injuries and illness, and ultimately losing these benefits if they can no longer work. Historically, employers in the U.S. have sought to reduce labor costs by hiring workers from less advantaged groups, notably women and racial minorities, who are perceived as willing to accept lower pay and poorer working conditions (Levine 1989). Relative to European (white) Americans, African-Americans have more difficulty finding work, and when employed, are more likely to hold jobs that pay less and are of lower quality (Tomoskovic-Devey. 1993). The U.S. labor force remains profoundly segregated by race and gender, such that men, women, whites, and African-Americans frequently perform distinct functions and receive different levels of salary and benefits (Tomascovic-Devey, 1993). In the past, African-Americans in particular were openly selected for unpleasant, "dirty" jobs, which were regarded as unsuitable for other workers (Baron 1983). Some of these discriminatory practices have had documented adverse health consequences, including silicosis (Cherniak, 1986) and cancer (Davis et al., 1995). More recently, researchers have observed higher occupational injury rates among African-Americans (Robinson, 1990), in addition to higher fatality rates due to workplace injuries compared to whites (Robinson, 1997; Loomis and Richardson, 1998).

DUMC Nurses' Aides and OBP

At DUMC inpatient nurses (n = 3,241) and nurses' aides (n = 709) make up 32% of the DUMC workforce with African-American women holding more than half (52%, n = 367) of the nurses' aide jobs compared to 14% (n = 471) of the registered and license practical nursing jobs. From 1997 through 2001: there were a total of 621 OBP cases reported among nurses (n = 443) and nurses' aides (n = 178). Nurses' aides and nurses had the second and third highest rates of OBP claims, respectively, preceded only by skilled craft workers. However, the rate of OBP among nurses' aides [8.43 per 100 Full-Time Equivalents (FTE)] was more than twice that for nurses (3.98 per 100 FTE). Among female nurses' aides only, African-American women had higher rates of OBP (9.3 per 100 FTE) compared to their white female colleagues (7.8 per 100 FTE). With regard to the impact of these injuries, a higher proportion resulted in lost (20% vs. 12%) and/or restricted workdays (56% vs. 42%) for nurses' aides compared to nurses, respectively.

Workers who sustain OBP have been found to be less likely to return-to-work, or have delayed return if their jobs involve high physical work demands (Dasinger et al., 1999; Krause et al., 2001). Return-to-

work strategies including modified work (also referred to as restricted duty) and physical rehabilitation have been noted to facilitate injured workers to remain at work in a protected work environment or to return more quickly (Tate et al., 1999) improving long-term employment outcomes (Daly, 1996). However, focus group conducted as part of a questionnaire pilot test for this study revealed differences in experiences with how nurses and nurses' aides returned to work post OBP. A group of DUMC African-American nurses' aides indicated that although they had received prescribed work restrictions from their physician, their jobs had not been appropriately modified to match those restrictions. They expressed feelings of frustration about having to manage a heavy workload while trying to recover from their injury, as well as feeling afraid that they would re-injure their backs. Poor staffing of nurses' aides on some floors contributed to some feeling that they had no one to help them with their work, forcing them to ignore their work restrictions. In addition, they did not feel comfortable talking to their managers about their need for a lighter work assignment and did not believe that their managers were willing to help. In contrast, a group of white registered nurses indicated that they felt that their jobs had been adequately adjusted and that they received considerable support from their coworkers. They also indicated that if their work assignments were too heavy, they were able to negotiate with their supervisor or charge nurse to reduce their workload. Evidence of racial and gender differences with regard to return-to-work experiences was reported by Strunin and Boden (2000) who noted that post workplace injury, minorities and women were less likely to be allowed back into the workforce and were less likely to be offered assistance in their return which is consistent with our pilot data.

Although both nurses and nurses' aides are at risk for OBP (Choi et al., 1996), the impact of this type of injury could be detrimental to the health of nurses' aides. When the same nursing groups at DUMC were asked "Has your back pain ever made you feel like you should not work, but you went to work anyway?" the nurses' aides unanimously indicated that they felt this way and went to work anyway because they could not afford to take time off of work, while the group of nurses informed us that they did not feel like they had to go to work when in pain. When already injured nurses' aides are "going to work anyway" they are placing themselves at risk for further injury, and possible job displacement if the re-injury prevents them from being able to work. Unlike nurses, nurses' aides have no place for advancement or promotion in their jobs. At DUMC new clinical nurses have the opportunity to advance through four stages of clinical nursing (accompanied with financial incentives), as well as the opportunity to transfer out of floor nursing into management or research. If nurses' aides were no longer able to do their job because of a back injury they sustained at work, they would have to either change professions or terminate their employment. Studies that have examined the impact of displaced workers observed that displaced women lose a greater proportion of pre-injury earnings than men and are less likely to acquire new skills after being displaced (Jacobson et al., 1993).

Future Research

Research is needed to examine the impact of work disability among nurses' aides who sustain a work-related back injury. These workers are particularly vulnerable to significant injury and possible job loss. Because their experiences of return-to-work appear to be different from that of other health care workers, injury prevention strategies, as well as return-to-work strategies will need to be tailored specifically for this occupational group.

Future studies need to be interventional where researchers test various types of return-to-work strategies among nurses' aides. These studies need to involve multiple hospital/nursing home sites in order to examine various settings, as well as to obtain adequate sample size.

Town hall meeting - Construction

National Institute of Occupational Health

National Occupational Research agenda

University of Illinois

Topic: Reduce Construction workers fatalities and injuries with falls to a lower level.

Good Day to you all.

I am pleased to have been given this opportunity to speak today on a topic that I have seen personally and heard of from many friends, coworkers and other craft's families to have been devastated from.

My name is John P. Shine Sr. I have been in my trade, Pipecoverers, since 1973. I have worked for Local 17's Apprentice Program since 1987. I have been very involved with safety training, program development and research.

When I worked in the field as a helper, apprentice, journeymen and foremen, I worked around, saw, and heard about, many falls and the resulting injuries. I, at first, thought that this was the chance you took, to be paid. As I went along from, job to job, I noticed that the foreman and companies were interested to keep this problem to a minimum. These were, are motivated people. People would, could and did get hurt. These people said there is a better way.

I have since then, been teaching fall protection and prevention at our Apprentice school. One day at work, when I was in the field, I saw a painter fall from a height. He had no fall protection on at all, it was not used then. I will not go into the details here but his family should have never gotten that phone call, that day. There was a better way to do his job, that day.

I know there are better ways to protect workers. I had a young apprentice fall at work from a scaffold and another young man about to come in to the apprentice program fall from a pipe rack at work. These both, were terrible waste of excellent young man, who would have been a credit to our union. These are but a few stories, I hear about at work. I listen to workers in class and give their stories back to my membership who attends our SMARTMARK(copyrighted) program on Construction site Safety training and my apprentice classes. The incidences, I speak of, come from them, as well as my own experiences.

When we reduce this injury and fatality rate, we can keep smart, productive and interested people on the jobsite, building the facilities, ON BUDGET, the RIGHT WAY, THE FIRST TIME.

There are many directions this study can go and each should be addressed;

1. Training is for every one, workers, safety directors, supervisors, superintendents, estimators and owners. Each one in this process, needs to know what the other is doing and if they are doing it correctly. I think, as I go through the other issues, this will become evident as to why it is important.
2. Anchorage points are a big issue. You would be surprised to hear and see what is done. What workers are told to do? Some of it does not make sense. Electrical conduit, light fixtures. How does a worker anchor to a 5,000 pound anchorage point when no one knows or will tell them what constitutes a 5,000 pound anchor? Try to get an answer. This might put more fun in your day. Is it a 4 inch steel pipe sitting on a concrete beam? Could it be a 3 inch electrical conduit? Do not even think of a light fixture conduit. What do I do, as a worker, when there is nothing of substance to attach to? DO I put on a show and wrap the lanyard around the ceiling joist to make the safety guy happy! If I don't, I might get laid off for not following the safety rules. It might not make sense but you might do it any way. If I do say something, all I am doing is COMPLAINING. I might lose my job as a trouble maker. He asks too many questions. There are also some other issues, people express as tripping hazards, such as lanyards hanging down around their ankles.
3. The next issue could be pre-planning at the engineering stages. Anchorage points have been put in place during the erection of floors ad ceiling and left in place for future use. This has been successful on jobs lately. This will put the anchorage point above the workers heads, where they should be. This also minimizes the pendulum effect if people fall and minimizes swinging into, in place items.
4. Inconsistency of regulations such as, the OSHA standard has two different heights that we work from. One is 6 feet for falls but 10 feet for scaffolds. How about inconsistency of one facility to another. One site goes to an extreme of having you in a harness on a six foot ladder while another site lets you walk around on beams 40 feet in the air with nothing but a smile. This leads into construction companies can not compete on an even field if one is safety conscious like the ones I deal with and others don't not care. The bad ones are willing to take a chance on your life and will push the workers to get out their or lose a wage paying job. Let`s get these workers and all companies on the same playing field so the government is also, not paying for these needless injuries through Medicare, when these workers don`t have health insurance. I am not even talking about Lawsuits that can be avoided if company`s and supervisor do what can be done to prevent these types of problems

5. Lack of knowledge of what equipment is proper, for the job at hand. There are many different type harnesses that can be used. One type doesn't do it all. The various trades have harness types, they use on a regular basis. This does not mean that every job is the same. I have already spoken of anchorage so I won't go in to this again. Let everyone know what happens to some one when their body hits a solid object. They might pay more attention to this problem of length of lanyards. I feel that when people do not know about an issue, they are afraid of what could happen. When people become informed, they understand how to deal with it. Good solutions can become a normal answer to an every day problem. I saw this when we started to training people for asbestos abatement.

As an example, in 1988, I heard that no one would do all this stuff, required in the new OSHA standard for asbestos. As time went on we not only did the first requirements but had three rewrites that made it even safer for all. It can be done, you just have to prove that it is economical to be safety conscious. I can prove this. We could look at the workmen comp rates then and now and see the difference. The mod rates for insurance went down dramatically.

6. Lack of rescue planning for Suspended scaffold. What happens if some one falls from a great height and needs to be brought down from this same height? We need to make sure that there are people who understand this idea. When the accident happens is not the time to start thinking of how to get them down from the height. I have story's that curl your hair.

7. Ladders. The use of ladders on job sites is an issue that can not be over looked. When everyone is using the various types step, straight and platform to get done what they have been tasked to do, it is a huge job for the company and foremen to be sure that the right one is used for the job at hand. Not every job has the correct type and length for what needs to be done. Some of you here today have done things at home with ladders, that you said "Whao", what was I thinking, when you were on solid ground again. This issue needs to be addressed.

8. Lastly, I would like to go back to where I started, my first issue that I spoke on, TRAINING. I have made my living at it since 1987. I will not say that I am the world's greatest trainer, Far from it, but I know the issues. This type of safety training is not done enough. It is done quickly, to say that it was done, in some incidences. I work very hard at what I do. I can not site examples of people using their training and not getting hurt. This would be impossible. I can tell that people tell me of what could have happened, if they did not think ahead of time, of the possibility's that could happen. I believe if you train from past happenings, you show the result of no preparation. Workers then understand the need to think of, how to avoid problems. We also need retraining. There is all types of retraining formal and informal. Any one here today knows it takes repetition to get it in our own heads.

9. We also here have to make sure that all construction companies, have to do the same thing. I work for companies that want to make sure they keep their employees safe. A well trained worker with his or her craft and some one who works in a manner that is on the job, not home injured gets the job done on time on budget and a head of schedule. This is what we as Union people and Contractors strive for. When everyone goes home uninjured, we also do not put a burden on our government for help when Medicare has to pick up a bill to help these people get better, at the hospital. I have insurance at work. I am very fortunate that I work for contractor who help pay our medical insurance, Not every one is that lucky. Let's get everyone on the same playing field.

10. Thank you for letting me speak here today.

National Occupational Research Agenda (NORA)

Town Meeting Houston, January 23, 2006

Texas Nurses Association Testimony

Prepared by: Stephanie Tabone MSN, RN

Director of Practice

As a representative of the Texas Nurses Association, I would like to thank you for the opportunity to provide input into the future research agenda for occupational health and safety in the area of health care.

Registered nurses constitute the largest health care occupation group in the country. Then NIOSH director Linda Rosenstock testified before Congress in 2000 that nursing personnel have one of the highest job related injury rates of any occupation, and she related in that same testimony that the rate of injury for RNs was greater than that of workers in construction and agriculture. In fact, construction and agricultural work is safer now than it was a decade ago according to your own website - a fact that is not the case in health care. Moreover, characterization of the nursing profession by the Bureau of Labor Statistics lists hazards that include acquisition of infectious disease, exposure to chemicals, back and other ergonomic injuries, shocks from electrical equipment, and hazards posed by compressed gases not to mention emotional strain from close contact with critically ill patients.

The statistics and characterizations of the work of nurses reinforce the perception that providing patient care is hazardous and that nursing is undesirable work. Because RNs make up such a large component of health care delivery systems, hazards to nurses in the workplace constitute a serious public health

concern. This is true; not only in terms of real injury, but in their potential to impact the capacity of the health care system to deliver essential services to those whose health is compromised. It is also the case that most hazards that accompany the delivery of patient care are preventable, or at least can be mitigated by improving safety processes.

Texas Nurses Association would like to commend NIOSH for its research in the area of health care and in particular for resulting guidance in the areas of violence prevention and recent guidelines for lifting in long term care settings. This work has enabled the Texas Nurses Association to advocate for, and get enacted, legislation that requires nurses and health care organizations to work together to develop policies that decrease the incidence of ergonomic injuries and violence in the workplace. Such policies benefit not only the nurse providing patient care but also increase the safety of patients. Safe patient handling initiatives decrease injuries that cause harm to patients and result in increasing the cost of care, while violence prevention has the compassionate outcome of helping to limit persons, in moments of crisis, of hurting themselves or others. Evidence based guidance and best practices provide essential components when nurses seek to improve the delivery of care.

The need for continuing research in health care in the area of workplace safety cannot be overstated. As the population ages the need for provision of care is projected to increase while the number of persons available to deliver that care is projected to decrease. It is essential for us to develop safety processes that increase the desirability of nursing as a profession by eliminating, to the extent possible, unsafe practices in all delivery settings as well as identifying ways that an aging health care workforce can continue to deliver care safely.

To this end, the American Nurses Association and the Texas Nurses Association have set out talking points for the continuation of research in those areas that have the potential for the greatest impact on safety improvement in our profession. As we review how each of these issues impact the nursing profession, we must remember that those things that are unsafe for nurses have an equal and sometimes more profound impact on the health of those for whom we provide care. Exposure to hazards such as falls, chemicals, infectious disease, or omissions of care as the result of fatigue hurt not only nurses but their patients.

Safe Patient Handling

-- According to the Bureau of Labor Statistics (BLS) in 2004 nurses had 8,810 reported work-related musculoskeletal disorders (MSDs) which resulted in an average of 7 days away from work

-- This was the 9th highest rated profession in this category of injuries, behind such heavy lifting professions as stock and material movers, janitors, and construction laborers, and ahead of professions such as carpenters and maids and housekeepers

-- Research to prevent back and other MSDs needs to promote nursing education and training in the use of assistive equipment and patient-handling devices

-- Research needs to be done on reshaping federal and state ergonomics policy to highlight the ways technology-oriented, safe-patient-handling techniques benefit patients and the nursing workforce

Categorized comment or partial comment:

Chemical Exposures

-- RNs are routinely exposed to a variety of hazardous chemicals, including some drugs, chemicals used in hospital labs, and chemicals used for hospital cleaning and sterilization purposes

-- Many of these have been associated with both acute and long term health effects (e.g. reproductive, respiratory irritation and asthma; eye and skin irritation; nausea; headache; difficulty in concentration; and even cancer)

-- Research needs include examination of health effects, employee surveillance, and other efforts to protect nurses

Categorized comment or partial comment:

Worker Fatigue

-- Available research shows that overtime and extended work shifts for nurses is associated with increased risk of smoking; alcohol use; risk for back, neck and shoulder disorders; vehicular accidents; and increased exposure to biological hazards.

-- A recent IOM report states that effects of fatigue include; slowed reaction time, lapses of attention to detail, errors of omission, compromised problem solving, reduced motivation, and decreased energy for successful completion of required tasks

-- Further research is needed to evaluate overtime and extended work shifts and their relationship to productivity, quality and safety provided in hospitals and the incidence of work place accidents, injuries and stress-related illnesses among nurses.

-- Further research is also needed to evaluate implications of extended/overtime work on health status of health care workers

-- Research needs to be done on reshaping federal and state policy that will limit the ability of employers to mandate overtime

Bloodborne Pathogen (BBP) Exposure

-- The EPINet data sharing network reports that in 2003 health care workers had 1,708 needlesticks or other sharps injuries, and 524 other exposures to blood or body fluids among 48 participating healthcare facilities

-- Research is needed on the human factors and work practices of RNs related to safe handling of sharp devices and compliance with other measures to protect them from BBP exposures

-- Further research is needed on facility-wide policies to promote worker compliance with safety practices

-- Further research and development of safety engineered devices is needed

Respiratory Protection

-- Research needs to be done on ensuring that federal and state pandemic planning policies include the use of N-95 filtering disposable respirators, to be annually fit-tested, rather than the use of surgical masks. Surgical masks protect the patient from the wearer. The N-95 respirator protects the wearer by providing a seal to keep the wearer from exposure to the infectious agent.

Workplace Violence

-- BLS reports that in 2004 among persons working in healthcare and social assistance there were 11,790 (or 10.7 per 10,000 full time workers) work place assaults, and 19 were killed by homicide on the job

-- Among all American workers, health care and social service workers have the highest rates of non-fatal assault injuries in the workplace

-- Further research is needed on development of preventive interventions of violence towards health care workers, and intervention effectiveness

Texas Nurses Association would like to thank you again for the opportunity to provide input into the planning for the national research agenda in workplace safety. NIOSH research continues to complement and strengthen the efforts of Texas Nurses Association in our efforts to improve the safety of care in all health care settings.

NIOSH National Occupational Research Agenda

Town Hall Meeting

University of Illinois at Chicago

School of Public Health

Chicago, Illinois

December 19, 2005

Statement of the International Brotherhood of Teamsters

Presented by Michael W. Watson, CIH

Good afternoon and thank you for the opportunity to address the committee regarding the NIOSH National Occupational Research Agenda (NORA) for construction sector issues. My name is Michael Watson and I am a representative of the Safety and Health Department, International Brotherhood of

Teamsters. The IBT represents more than 1.4 million workers in the United States of America. Our Building Material and Construction Trade Division is comprised of approximately 102,000 building material supply and construction members who may be impacted by decisions regarding the Agenda.

According to data published by the Bureau of Labor Statistics (BLS) for 2003, construction sector transportation and material moving drivers experienced 5,800 nonfatal occupational injuries and illnesses involving days away from work. These drivers perform work in highway and steel construction; water, sewer and, utility line construction; heavy construction and excavation work; ready-mixed concrete; refuse; and construction material and pipeline transportation.

With regard to fatal occupational injuries, according to the Census of Fatal Occupational Injuries (CFOI) data for 2004, the construction industry sector recorded 1,224 fatal work injuries, the most of any industry sector. A recent paper funded by NIOSH titled "Dump Truck-Related Deaths in Construction" reported that between 1992 and 2001, a total of 482 dump truck-related fatalities occurred. The Center to Protect Workers` Rights (CPWR) published a study in 2001 titled "Trends in Work-Related Death and Injury Rates among U.S. Construction Workers, 1992-98." According to the study, the fatality rate among truck drivers was consistently higher than the fatality rate for all of construction.

The Teamsters Union urges NIOSH to continue research into diesel and combustion particulate exposure. General wellness issues such as hypertension, weight-induced diabetes, and heart disease, and the use of tobacco products and caffeine is of increasing concern to the Teamsters Union. The adverse health effects of extended work cycles and chronic fatigue should be examined as well. Drivers are faced with constant monitoring using technologies such as GPS, which is an enormous change from the historical autonomy that drivers once enjoyed. NIOSH should examine the stress and other psychological effects of electronic monitoring in this industry.

The Teamsters Union is particularly concerned with injuries and fatalities resulting from highway accidents and struck-bys in the heavy and highway construction and excavation subsectors; musculoskeletal injuries and disorders among construction drivers; noise-induced hearing loss (NIHL) among construction drivers; and crystalline silica exposure among ready-mixed concrete drivers. The Teamsters Union supports the inclusion of these issues in the NIOSH Construction Program`s Draft Strategic and Intermediate Goals and Performance Measures. It is the Teamsters Union`s position that these issues should be included in the Agenda as well. The Teamsters Union is also very concerned about whole-body vibration among construction drivers. Whole-body vibration is primarily responsible for intervertebral disc degeneration, lower back pain, and muscle fatigue. The importance of addressing these issues cannot be overstated. NIOSH should continue to explore prevention strategies for highway accidents. According to data supplied by NIOSH and the National Highway Traffic Safety Administration (NHTSA) lost wages and benefits for crash victims reached \$61 billion in 2000. Costs to employers due to the loss or absence of employees from work because of highway accidents reached \$4.6 billion more. Musculoskeletal disorders and injuries and NIHL cost employers and state workers` compensation programs billions more every year.

In addition to the intermediate goals proposed by NOSH to address these issues, it is imperative that a training component be included as well. Education is a powerful tool, especially when dealing with preventable hazards. Drivers should receive better and more thorough driver education which is specifically tailored to the driving tasks that they perform. This driver education could also include components which specifically address the importance of seat belt use, proper lifting and lowering

practices, hearing conservation training, or other hazards present at the worksite. NIOSH should perform research on the most effective training techniques for educating this particular group of workers.

Of course, funding for research and education is the backbone of any initiative which seeks to implement change in an industry as dangerous and diverse as construction. Employers and Unions alike cannot and should not bear the entire cost of making sweeping changes to make our industry safer. New technologies in vehicle safety (i.e. sonar, radar, and video technologies) need to be investigated. New truck and heavy equipment design should be investigated in order to make trucks and heavy equipment more "driver friendly" and "ergonomically safe." NIOSH and other government agencies, including NIEHS, need to continue to fund this research and education if we are truly going to get at the very core of the issues.

Thank you for the opportunity to testify about these issues.

Sir:

To reduce motorists speeding in road construction work zones, would motorists drive differently (ie, slower) if the drivers were aware that hitting a worker is not just an accident, but could be a homicide? As a manner of death, such might be classified as a homicide on a death certificate.

Similarly, would drivers behave differently if drivers knew that driving while distracted (such as driving while using a cell phone) might result in a homicide, rather than just an unfortunate accident?

Thank you.

Verbal Comment 2006/12/06 (English Translation follows):

Buenas tardes. Quiero presentar específicamente tres áreas que entiendo que necesitan ser atendidas. No porque no se hayan atendido del todo, sino porque hay cosas que hay que revisar, modificar. La primera de ellas es el área de los edificios enfermos. Desde la década--desde antes de los ochenta, estamos trabajando en el área de edificios enfermos. Hay bastante investigación realizada en Estados Unidos, en Europa, sobre esto, sin embargo, la investigación en áreas tropicales es mínima.

Sabemos que el comportamiento, pues de muchos microorganismos en áreas tropicales es distinto y entendemos que hace falta mayor énfasis en este particular. Además, entendemos que en esta misma línea, el área de ácaros en--del polvo, que resultan ser más alérgenos en muchas ocasiones que los hongos, es un área que necesita mayor atención. Específicamente el área de metodologías adecuadas para poder mostrear específicamente esto, este tipo de microorganismo. Pues requiere una mayor atención ya que los métodos que existen, pues no son muy certeros, ni son, pues muy adecuados.

Dentro del área--de esta misma área, un factor que es un tanto problemático, es que desconocemos realmente los ambientes de donde viven los trabajadores. En un estudio--en un pequeño estudio que estuvimos realizando comparando las muestreos microbiológicos en los cuartos de las personas, con los muestreos microbiológicos realizados en estructuras, que encontramos que en el área de los cuartos, donde la gente duerme los conteos microbiológicos eran mucho más altos que en las áreas de edificios.

Así que eso necesita mucha atención, porque presenta el problema de dónde se está enfermando el trabajador, se enferma realmente en su área de trabajo o la enfermedad viene desde su casa. En el área de riesgos y concesiones, es un área que entendemos que está--que necesita una mayor atención. Realmente NIOSH ha estado trabajando el área en conjunto con la American Psychological Association, con énfasis mayor en el área de estrés laboral. Sin embargo entendemos que hay otras áreas como violencia en el lugar de trabajo, drogas en el lugar de trabajo. El área de discriminación en el lugar de trabajo, que se convierte en un factor difícil de manejar en muchas ocasiones. Necesita una atención mayor enfocándose desde la perspectiva del profesional de la salud ocupacional y no del psicólogo. Somos los profesionales de la salud ocupacional los que en muchas ocasiones damos la cara primero en este tipo de problemas y muchas veces no tenemos recurso para trabajarlo.

Tan es así que las escuelas graduadas de Salud y Seguridad Ocupacional, muy pocas tienen cursos que se enfocan en el área de riesgos psicosociales. Yo creo que esto es un área que en la perspectiva de la salud ocupacional necesita con urgencia una revisión, inclusive, a nivel curricular en las escuelas graduadas de Salud y Seguridad Ocupacional.

Por último, un área que no se ha atendido, ha sido el área de currículos en las escuelas. Recientemente estuvimos trabajando con el desarrollo de un currículo enfocado en la salud y seguridad ocupacional para educación pre-escolar. Y por qué para educación pre-escolar, si los niños no están trabajando, los valores comienzan desde esa edad. Y es ahí el mejor momento que tenemos para enseñarle al ser humano, en este caso los niños, sobre los valores y sobre respetar reglas, leyes que tenemos sobre salud y seguridad ocupacional. En la literatura no encontramos prácticamente nada enfocado en esta área.

Sin embargo, ya la agencia de Protección Ambiental Federal, tiene currículo completamente desarrollado sobre el área ambiental. Yo creo que esta área es una área que tenemos que trabajar y crear currículo donde se promuevan en el niño los valores en la seguridad y en la protección de la salud. Buenas tardes.

(ENGLISH TRANSLATION)

Good afternoon. I want to present three specific areas that I understand need to be addressed. Not because they haven't been attended to as a whole, but because there are things that have to be revised, modified. The first of these is the area of diseased buildings. From the decade--from before the eighties we are working in the area of diseased buildings. There is plenty investigation done in the United States, in Europe about this. Nonetheless the investigation in tropical areas is minimal.

We know that the behavior of many microorganisms in tropical areas is different and we understand that a major emphasis is needed in this particular. We also understand that in this same line, the area of dust mites which are more allergens in many occasions than the fungus, is an area that needs major attention, specifically the area of adequate methodology to demonstrate this specifically, this type of microorganism. This requires a major attention since the methods that exist are not very certain, nor are they very adequate.

Within the area--of this same area, a factor that is problematic is that we really do not know the ambients where the workers live. In a study--a small study that we made comparing the microbiological samples in the person's rooms with the microbiological made in structures, we found that in the area of the rooms where the people sleep the microbiological readings are much higher than in the areas of buildings.

Thus that needs much more attention because it presents the problem of where the worker is becoming sick. Does he really become sick in his work area or does the disease come from his house. In the area of risks and concessions this is an area that we understand is--that it needs major attention.

Categorized comment or partial comment:

Actually NIOSH has been working in the area together with the American Psychological Association with major emphasis in the area of labor stress. Nevertheless we understand that there are other areas such as violence in the work area, drugs in the work area, the area of discrimination in the work area which becomes a difficult factor to manage on many occasions needs a major attention focusing from the perspective of the occupation health professional and not of the psychologist. It is the occupational health professionals the ones who on many occasions have to first face this type of problem and many times we have no resources to work with this.

This is such that the graduate schools of Health and Occupational Safety, very few have courses that focus in the area of psychosocial risks. I believe that this is an area that from the perspective of occupational health needs urgently a revision, including a curricular level in the graduate schools of Health and Occupational Safety.

Lastly one area that has not been attended to is the area of curriculum in the schools. Recently we were working with the development of a curriculum focused in the occupational health and safety for pre-school education. And why for pre-school education if the children are not working? Our values start from that age. And that is the best moment that we have to teach the human being, in this case the children about values and about respecting rules, laws that we have about occupational health and safety. In the literature we find practically nothing focused on this area.

Nevertheless, the agency of Federal Environmental Protection has a curriculum completely developed about the environmental area. I believe that this area is one area that we have to work on and create a curriculum where it is promoted in the children the values of safety and in the protection of health.
Good afternoon.

Verbal Comment 2006/12/06: Good afternoon, everybody. I'm glad to be here, my name is Ilene Garner of the University of Virgin Islands. And I won the Safety in Paradise Program in the Virgin Islands. I'd like to spend the next few moments with you and I did have the power point presentation but I'm going to march through and keep on time. I will make it available if anyone wants to see actually the beautiful pictures of the Virgin Islands, which I brought with me.

So, I will continue on the program, the program that we have in the Virgin Islands is called "Safety in Paradise". And I would like just to spend a little bit of time talking about the U.S. Virgin Islands and where we are and why it is important that safety in paradise is a matter of place. And then I'd like to talk a little bit about some environment of challenges that I believe we have that are unique to environment. And like to finish up with our proposing some recommended research topics.

So, the U.S. Virgin Islands is located eighteen degrees North latitude between Miami and Venezuela. That presents some very interesting things for us, we're four small insular islands with a population of only a hundred and sixteen thousand. But the average temperature is eighty-five degrees Fahrenheit year round. We also have a very a corrosive kind of environment because of the salt sea and sand. The tropical climate provides us with high heat and humidity, like I said, year round.

We also have intense solar radiation all day long, because we are very close to the Ecuador. The high humidity and limited air circulation can cause some very interesting safety and health issues. We have significant historic structures that were built without air conditioning and were built with types of materials, that if you could see my pictures, you could see wall mildew.

The primary industries there are towards tourism and hospitality, construction and the marine industry. So workers are required to be outside in significant amount of time in the sun. Some of the problems that workers can--they encounter because of there's this heat stress, the effects of the heart and the risk of dehydration. In addition, intense prolonged exposure to solar rays can cause skin cancer, eye damage and further injuries. There are also very interesting things upon equipment that can happen as well, because of this environment. For example, polemic degradation which can loose the strength of safety apparadis in gear, you also have bathing in reaching a lot of sun, so you think the sun is red, because orange, if you think it's green, it becomes blue. So, those are kinds of things that you have to consider.

Also workers can have a full sense of security about the integrity of the equipment. For example, iron products corrode much faster in that kind of environment. The tense site of strength then goes down, specially in objects made of iron. Also iron objects have magnetic--that have magnetic properties, magnetic materials, can also loose their magnetic properties as a result of rust. And also their electrical conductivity, will degrade.

Workers are also exposed because of the high heat of humidity and the moist environment which causes a lot of mildew and mold in many of our buildings. So, workers are exposed to mold and mildew quite often. So we have issues surrounding mold infections, allergic reactions and obviously degraded air quality in the buildings, because of this mold and mildew. Which you cannot see often times, because in between walls and ceilings that they are just not in apparent, people start getting sick and you just don't know why.

Also mold can in very extreme instances could promote wood rote and that's another thing you need to be concerned about, specially because workers have a lot of scaffolding on our buildings. And they think that the scaffolding is working well and if you have nails, for example, in that scaffolding that are in stainless steel, guess what? They'll start to lyed.

Some of the health and safety issues that touch the perimeter, prolong the effects of high heat and humidity on workers. And it's really not established, I mean, I know we've done some research for heat stress, but I don't think we've done it enough. And I don't think we'd looked in environments such as ours, where it's hot all year round. Not just in the summer.

There is a lack of federal standards for my prospective for airborne concentrations of mold and a long term effects of mold exposure on workers. In addition and maybe again, I'm wrong, I don't see very many guidelines from workers who are close to solar rays under very long periods of time. Some of the recommended research areas vary in guidelines for worker rest regulance and solar exposure guidelines.

The relationship of material degradation due to sun, sea salt and sand is something that I think would be very good recommended area.

And the last one, are the effects of prolonged exposure to mold and mildew. And this would be done to develop guidelines for declaring a building unsafe to occupy by workers. So, Safety in Paradise, really is a matter of place. Thank you very much.

Verbal Comment 2006/12/06 (English Translation follows):

Este es Samuel Rodríguez del Recinto Universitario de Mayaguez, de la Universidad de Puerto Rico. Haré la presentación sobre una de las alianzas que tenemos, la alianza con la Puerto Rico OSHA, el departamento de Ingeniería, específicamente. Y como tenemos siete minutitos, pues voy a ir rapidito. Así que me perdonan. Primeramente, como parte de la alianza que tiene el departamento de Ingeniería Química con Puerto Rico OSHA, pues está la parte de revisión de currículo. Obviamente, queremos mantener lo fundamentos de ingeniería química, que siempre han sido importante en el departamento. También se está tratando de mejorar la comunicación de nuestros estudiantes y la ética de ingeniería también.

Y finalmente, lo que nos trae aquí hoy, la parte de incorporar los conceptos de seguridad a procesos químicos, ya la práctica de ingeniería química, especialmente con los estudiantes que se gradúan de nuestro recinto.

Entre las actividades del departamento, pues el programa de PHT comenzó en el 2000, hay aproximadamente como un total de diez millones de dólares en "research" en el departamento. Y entre la parte de innovación y en la educación, está este tipo de alianza, donde queremos llevar la salud y seguridad a través del currículo de Ingeniería Química específicamente. Estamos con la Ingeniería Química y en muchos aspectos de la seguridad, ya que los procesos químicos pueden ser sumamente peligrosos. Desde el 2003, se está trabajando en esta estrategia, la alianza fue poco después, pero ya en 2003 se comenzó a trabajar en un curso de "Chemical Process Safety", que se comenzó a dar por primera vez en el semestre--en el segundo semestre del 2004.

Y entonces se comenzaron en el 2004 las conversaciones para llegar a toda la alianza. Ya en el 2005, fue cogiendo forma y hubo aprobaciones por parte de la OSHA--Puerto Rico OSHA para perseguir este tipo de alianza. Y en octubre del 2005, finalmente, se logró la firma de la alianza entre el departamento de Ingeniería Química del colegio de Mayagüez y Puerto Rico OSHA. Como parte de las actividades que se han hecho, pues se han dado dos seminarios ya, a la comunidad en general, una fue en abril y una en noviembre.

Nos estamos reuniendos--nos hemos reunidos "quartely" y ahora estamos reuniéndonos mensualmente para llevar a cabo un plan de acción. Entre los aspectos más importantes de la alianza, pues está revisar el currículo para incluir los aspectos de salud y seguridad. Se da los cursos de "Chemical Process Safety", que ya se hizo. También se está tratando de lograr--llevar los conceptos de salud y seguridad a través de todo el currículo, de distintos cursos de ingeniería química, que van a estar estableciendo los aspectos de salud y seguridad aplicables a esa área de ingeniería química.

Se han dado--se sigue dando adiestramiento, según les mencioné. Se han dado--también se está dando--de promover la participación de los estudiantes, para ir a varios seminarios de la Puerto Rico OSHA allá en el colegio. Y no solamente de "Process Safety", sino de "Lab Safety" y otros estándares y los estudiantes han participado activamente. También uno de los propósitos es lograr diseminar esta información a través de la comunidad para que se sepa que ese tipo de alianza puede ser muy exitosa al momento de ser electa.

También conferencias como éstas y otras conferencias como la de ingeniería química, que se dio recientemente en Dorado, también hemos participado. También vamos a estar este próximo año, vamos a estar adiestrando inspectores de la Puerto Rico OSHA, en los aspectos de "Chemical Process Safety", importante para sus inspecciones en la industria química. El "expertis" del departamento se va a utilizar para que ellos entiendan mejor cómo es que se--identificar programas de "Process Safety".

De nuevo, los cursos nuevos se van a estar estableciendo, ya se estableció el de "Chemical Process Safety". Luego un curso de "safety and health" general, que también se va a establecer. Así que esta información vamos a seguir diseminándola y vamos a seguir participando del quórum como este. Las actividades futuras, para terminar, tenemos que nos vamos a estar reuniendo mensualmente, el departamento va a desarrollar cambios en el currículo. Se va a adiestrar inspectores de la OSHA y vamos a estar sometiendo una propuesta de OSHA & Science Foundation, para expandir la propuesta ocupacional y educacional. Eso es todo y muchas gracias.

(ENGLISH TRANSLATION)

This is Samuel Rodríguez from the University of Mayagüez Campus of the University of Puerto Rico. I will make a presentation about one of the alliances that we have, the alliance with the Puerto Rico OSHA, the Department of Engineering specifically. And since we have seven minutes, well I'll go a little fast. So forgive me. First of all as part of the alliance that Department of Chemical Engineering has with Puerto Rico OSHA, there is the part of revision of curriculum. Obviously we want to maintain the fundament of chemical engineering which has always been important in the department. We are also trying to improve the communication of our students and the ethics of engineering also.

Finally what brings us here today, the part of incorporating the concepts of safety and chemical processes, already the practice of chemical engineering, specially with the students who graduate from our campus.

Within the activities of the department the program of PHT started in 2000. There are approximately about a total of ten million dollars in research in the department. And between the part of innovation and in education this type of alliance where we want to take health and safety through the curriculum of Chemical Engineering specifically we are in Chemical Engineering and in many aspects with the safety, since the chemical processes can be very dangerous.

Since 2003 there has been work on this strategy, the alliance came a little after. But in 2003 there started work on the course "Chemical Process Safety" which started for the first time in the semester--in the second semester of 2004.

And then there started in 2004 the conversations to arrive at an alliance. Then in 2005 it started taking form and there were approvals on the part of OSHA--Puerto Rico OSHA to follow up on this type of alliance. And in October 2005, finally an alliance was achieved between the Department of Chemical Engineering of the Mayaguez Campus and Puerto Rico OSHA. As part of the activities carried out there have been two seminars to the community in general, one was in April and one was in November.

We are meeting--we have met quarterly and now we are meeting monthly to bring about a plan of action. Within the most important aspects of the alliance there is to revise the curriculum to include the aspects of health and safety. Courses are given of Chemical Process Safety, which was already given. Also there is work trying to achieve--take the concepts of health and safety through the whole curriculum of different courses of chemical engineering which are going to establishing the aspects of health and safety applicable to that area of chemical engineering.

There have been given--there continues to be training, as I mentioned. There have been given and also continue to be given promotion to the participation of the students to go to various seminars of the Puerto Rico OSHA there in the college. And not only of "Process Safety", but to "Lab Safety" and other standards and the students have participated actively. Also one of the purposes is to disseminate this information through the community so that it is known that this type of alliance can be successful at the moment of it being elected.

Also conferences such as these and other conferences such as the one of chemical engineering which was given recently in Dorado, we have also participated in it. We will also be this next year, we will be training inspectors of the Puerto Rico OSHA in the aspects of Chemical Process Safety which are important for the inspections in the chemical industry. The expertise of the department will be utilized so that they better understand how it is—to identify programs of Process Safety.

Again, the new courses will be established. It has already been established the one of Chemical Process Safety. Then a course of general safety and health which will also be established. Thus this information we will continue to disseminate and we will continue to participate in quorums such as this one. The future activities, we will be meeting monthly. The department will develop changes in the curriculum. Inspectors will be trained in the OSHA and we will be submitting a proposal of OSHA & Science Foundation so as to expand the occupational and educational proposal. That is all and thank you very much.

Verbal Comment 2006/12/06 (English translation follows):

Buenas tardes. Mi nombre es Carlos Guillermo Ortiz, presidente de la ILA, Local 1575. La ILA es una asociación internacional de trabajadores en el frente portuario que tenemos que ver con la carga y descarga de los barcos. Quiero también reconocer las personas que me acompañan, al señor Carlos Santiago Lugo, es director del área de distrito del departamento de Trabajo Federal, de horas y salarios. Y el señor Francisco Díaz Morales, vicepresidente de la ILA, Local 1575 y de la unión que dirijo.

Quiero dar las gracias al director de OSHA Federal aquí en Puerto Rico, al señor José Carpena, por la invitación que me extendió. Y al señor Teodoro Rovira, oficial inspector de esta agencia. Quiero darle inmensamente las gracias por la gran ayuda que nos han dado en el frente portuario. Quiero hablarle--hacer un resumen de los distintos inconvenientes que hemos tenido, pero que de alguna manera u otra pues estos dos caballeros nos han ayudado grandemente aquí en Puerto Rico.

El área de nosotros es bien compleja, es un área inmensamente grande, pero se conoce como que es tierra de nadie, ya que mientras muchos duermen, nosotros estamos trabajando en la carga y descarga de los barcos. Quiero mayormente hablarles de lo que es la seguridad y la salud en el frente portuario. Nosotros en la carga y descarga, hay veces que estamos expuestos a distintos químicos.

Queremos hacer también la recomendación de que OSHA al podernos realmente ayudar en esta carga y descarga de los barcos con químicos extraños que no nos dicen realmente que es lo que se--contienen. Se pueda también de alguna manera u otra fomentar que esas personas que han sido expuestas, pues puedan de alguna manera u otra ser atendidos o ser--se pueda someter alguna clase de estudios. Bien ligerito, me gustaría también que en las investigaciones mayormente que se hacen aquí en Puerto Rico,

entiendo que la reglamentación de alguna manera u otra se debe de esculcar y tratar de poner a tono con las necesidades regionales en sí que estamos teniendo.

Uno de los problemas bien básicos, ya que el tiempo es muy limitado, que tenemos es en el carreo de esos vagones. Esos vagones cuando bajan, no estamos hablando de libras, estamos hablando de toneladas y cuando bajan, en esa prisa de la carga y descarga, pues se intenta de que sean movidos en las áreas de los patios, como se le llama o las carreteras internas sin cerrar unos "locks". Ya que en otras áreas se permite que se puedan mover, pero se utiliza lo que se conoce los "flat bed", que son unas plataformas que nosotros aquí en esta área, pues no la tenemos para que sea de alguna manera u otra trasladado.

Quiero también que se le de seguimiento mediante a las penalidades que se encuentran, verdad. No voy a revelar el nombre de la compañía en la cual se encontraron distintas penalidades, pero sí puedo decir que fueron veinticinco penalidades que fueron serias y cuatro que fueron repetitivas. Y que actualmente esa investigación comenzó para el mes de abril y concluyó, más o menos, para octubre trece y actualmente ya el "deadline" que tenían para hacer esas mejoras o hacer esos arreglos terminaron para noviembre trece. Y actualmente, pues no se ha continuado, no se le ha dado seguimiento en sí y de alguna manera u otra, todavía seguimos siendo expuestos.

También las grúas, esas grúas que trabajan en los barcos, aquí la carga mecanizada, comenzó en 1958 y todavía tenemos grúas de los años '62, '63. Y lo que estamos en sí es solicitando de que de alguna manera u otra, esas investigaciones que se hicieron, se pueda de alguna manera u otra ser más agresivos conjunto con nosotros, porque nosotros también tenemos comité de seguridad interna en nuestro contrato. Para que de alguna manera u otra se pueda dar seguimiento a lo que estamos siendo expuestos. El tiempo es bien limitado, pues estoy haciendo un resumen porque sé que muchas de las cosas, si hubiera lo de preguntas y respuestas, pues me tendría que entonces preguntar que quiero decir con los "twin locks" o qué quiero decir cuando una persona se expone a - Distintos vocablos realmente que tenemos nosotros. Sí, me gozo de que estoy siendo partícipe y se me dio la oportunidad también de exponer los distintos riesgos que nosotros estamos pasando. Y que de alguna manera u otra yo estoy en la mejor también disposición de cooperar en todo lo que sea.

Yo llevo con la Unión ILA, treinta y tres años, así que por lo visto, pues si los dejo, pues no aparento la edad, pero comencé allí a las diecisiete años. Le agradezco mucho la oportunidad que me dieron y exhorto a que OSHA siga continuando en ese trabajo titánico. Y que le de la oportunidad también a OSHA a que aumente ese personal de inspectores, que yo sé que el señor Carpena necesita para que continúe haciendo un excelente trabajo.

Quiero decir que lo felicito, señor Carpena y en el señor Rovira tienen tremendo inspector allí, gracias.

(ENGLISH TRANSLATION)

Good afternoon. My name is Carlos Ortiz, president of the ILA Local 1575. ILA is an international association of workers in the ports that have to do with loading and unloading of ships. I want also to introduce the persons who accompany me, Mr. Carlos Santiago Lugo, director of the area of district of the Federal Labor Department, of hours and salaries. And Mr. Francisco Díaz Morales, vice president of the ILA, Local 1575 and of the union that I direct.

I want to thank the director of Federal OSHA here in Puerto Rico, to Mr. José Carpena for the invitation that he extended to me and to Mr. Teodoro Rovira, official inspector of this agency. I want to give

immense thanks for the great help they have given us in the area of the ports. I want to speak to you-- make a summary of the different inconveniences we have had, but that in one way or another these two gentlemen have greatly helped us here in Puerto Rico.

Our area is very complex, it is an immensely large area which is known that while many sleep we are working on the loading and unloading of the ships. I want to speak to you of what is the safety and health on the waterfront. We in the loading and unloading are sometimes exposed to different chemicals.

We want to also make the recommendation of OSHA to be able to really help us in this loading and unloading of the ships with strange chemicals which do not tell us really what it is they contain. It can also in some way or another encourage that those persons that have been exposed, that they can in some way or another be attended or be--that some kind of study can be submitted.

Very quickly, I would also like in the investigations that are done here in Puerto Rico--I understand that the reglamentation in one way or another should be studies and try to put in tune with the regional necessities that we are having.

One of the basic problems, since time is very limited, is the moving of those freight vans, ("vagones"). Those freight vans when they come down, we are not talking about pounds, we are talking of tonnage and when they come down in the rush of loading and unloading well, they try that they be moved in the areas of "patios" which is how it is said of the internal roads without closing some locks. Since in other areas it is permitted that they can be moved, but is used what is known as "flat bed" which are platforms that we here in this area do not have so that it be one way or another transferred.

I want also that there be followed up on the penalties that are found. I won't reveal the name of the company in which are found different penalties, but I can say that there were twenty-five penalties that were serious and four that were repetitive. And that actually that investigation started on October thirteen and actually already the deadline they had for making the improvements or make those repairs ended on November thirteen. And actually well, it has not been continued, no follow up has been done and in one way or another we still continue to be exposed.

Also the cranes, those cranes that work on the ships, here the loading is mecanized. It started in 1958 and we still have cranes from the years '62, '63. And what we are requesting is that in one way or another, those investigations that were done it can in one way or another be more aggressive along with us because we also have an internal security committee in our contract so that in one way or another it can be given follow up to what we are being exposed.

The time is very limited and I am doing a summary because I know that many of the things, if there were questions and answers then I would have to be asked what I want to say with the twin locks or what I want to say when a person is exposed to - different terms that we have. Yes, I enjoy participating and to be given the opportunity also to express the different risks that we are going through and that in one way or another I am in the best disposition of cooperating in whatever it may be.

I have been with the ILA Union thirty-three years, so I may not appear my age but I started at seventeen years old. I appreciate very much the opportunity given to me and I exhort OSHA to continue in that titanic labor. And also to give the opportunity to OSHA to increase the inspector personnel I know that Mr. Carpena needs to continue doing an excellent job.

I want to say that I congratulate you Mr. Carpena and in Mr. Rovira you have a wonderful inspector there. Thank you.

Verbal Comments 2006/12/06 (English translation follows):

Buenas tardes. Good afternoon. My name is Miguel Rubio, I'm president of the Puerto Rico Chapter of the American Society Safety Engineers, ASSE. I want to thank OSHA, the Federal Counsel and NIOSH for this opportunity to share my thoughts related to one of the biggest problems as safety professional, we're facing primarily in the construction industry.

And referring to the increase number of series accidentes, including fatalities involving excavations, scaffolding and trenching. I would start saying that probably in the last two or three years, we have seen an increase in the number of serious accidents in the construction business. Probably eight months ago, a scaffold totally collapsed killing two workers. About four or six months ago, there was a crew making an excavation, I believe in the west coast, when the same collapsed and one of the workers was buried in, dying minutes later.

It is common to listen, what or written news to find out that a worker has died or has been killed from a fall from heights. As safety professionals we have thought about potential group causes for these accidents. It is not a secret that a construction industry comprises a series of serious hazards and it's considered as a high risk industry. However, in my opinion, the increase number of these fatalities is going out of control.

Some people could say that there is not sufficient number of safety inspectors, involve the employers to watch their own people or from the government for conducting regular inspections to identify the risk. It is true that we still have a series of employers in that industry that do not spend resources and when I mean resources, we mean human and monetary for providing the necessary training for those workers to be safe at their work.

Some of these companies believe that spending resources in training goals against their benefit for at least two reasons, training cost money and also delayed projects. I want to stretch that out the efforts led by the government and some of the main companies of the Island for being offering training in this and other safety training. Some of the companies are developing curriculum, specially for the construction contract workers and are dedicating their professional to teach these courses. Some of the courses are equivalent to the ten hours course, inclusive in some cases, is the same OSHA sponsor ten hours course.

However, my concern goes beyond training. I am a believer that many of these accidents are associated with the series of shortcuts taken by employees, which in my opinion is a cultural thing. I have seen many times workers with a harness placed and with the lanyard hooked to the same bearing, rather to the light line or to the anchor point. Other occasions we have discussed with some of these workers and the answer is, it takes much time to put on or it's too complicated, excetera, etcetera.

On the other hand we can continue doing our inspections, this is like PPE, I mean, when the worker see the inspector, they follow safety rules, but once the inspector leaves the premises, they go back to the old safety behaviors. We can go even further, we can post fines and penalties to both employers and workers, but since the magnitud of the sames are so insignificants, they do not mind to pay the fine and continue following the learned behaviors.

As safety professionals we can focus on training and show the workers the standards. We can tell the workers how to raise a scaffold, how to become a competent person. Also we can explain and educate workers on the proper method for trenching an excavation. We can continue spending time and efforts in teaching the 1926 and the 1910 standards. We can spend hours and hours dedicated to let them know that whenever we work in areas with potential for falls, are six feet or higher or four feet in general industries, we need some kind of fall protection system. As a matter of fact, yesterday we were teaching a competent person course in a pharmaceutical plant. And we went out to the field and looked for some scaffolds that had been erected and so applied by a competent person. And we were surprised the amount of issues that we were able to identified, because they were not really following the proper standards.

However, there is one thing that really worried me and it's that we cannot teach these employees behaviors. This is probably a psicological issue or perhaps a sociological issue. As a matter of fact, one of the other speakers have identified these as a cultural attitude of our latin country versus, you know, imposing regulation and enforcement.

Why are workers taking risk, what motivates them to take shortcuts and miss to protect their own safety and life? Are there other things that as a technical professional, can we use and follow to ensure a better working place? This is not a mixed situation in Puerto Rico, inclusive some colleagues believe that this is a fenomenum observed in latin-american countries.

I would like to investigate the behavioral and motivational regions behind these years of unsafe acts that have caused so many serious accidents. My intention is not only to cover workers in Puerto Rico, but this increasing number of latin american workers that are rapidly occupying positions among the working population in the United States. Thank you.

Verbal Comments 2006/12/06 (English translation follows):

Buenas tardes, mi nombre es Erlinda González. Y hoy me encuentro aquí representando al Colegio de Ingenieros y Agrimensores de Puerto Rico. A pesar de que también soy una empleada de la industria farmacéutica por los últimos veinticinco años. Y quisiera compartir con ustedes una situación que entiendo yo que nuestra cultura en cierta manera nos está imponiendo al patrono. Y que de alguna manera necesitamos ayuda para poderla manejar.

Actualmente en Puerto Rico, el sesenta y dos por ciento de nuestra población está sobrepeso. Y el sobrepeso trae un montón de problemas musculo-esqueletal, que nada tiene que ver con el ambiente ocupacional. Pero que lamentablemente nuestro ambiente de trabajo, con los requerimientos del registro en los 'logs' de enfermedades ocupacionales, en la manera en que están definidas, nos ataca y básicamente nos obliga a reportarla como ocupacional cuando entendemos que la mayoría de los casos, no tiene nada que ver con el ambiente de trabajo.

En la industria hacemos 'N' gestiones con los doctores y las enfermeras y el personal de seguridad para ayudar a los empleados en programas de manejo de peso. En programas de ejercicio, se le paga el gimnasio, se le provee el gimnasio, se le proveen un montón de facilidades para ayudar a bajar de peso, porque entendemos que ese sobrepeso es una de las razones principales por sus lesiones. Pero no hay manera de obligarlos, es algo voluntario y al no poder obligar al empleado a hacer este programa para mejorar su salud personal, nos está impactando grandemente en las lesiones musculo-esqueletales y en el ausentismo en el ambiente de trabajo.

Y de alguna manera, nos gustaría ver cómo nos podemos ayudar o estableciendo criterios o maneras de cómo el patrono puede establecer programas de auto-ayuda con el personal para el manejo de peso. O

como podemos revisar estos requerimientos de registros de lesiones musculo-esqueletales en el 'log' de OSHA. Muchas gracias.

(ENGLISH TRANSLATION)

Good afternoon. My name is Erlinda González. And today I am here representing the College of Engineers and Agronomists of Puerto Rico, despite the fact I am also an employee of the pharmaceutical industry for the last twenty-five years. I would like to share with you a situation that I understand our culture in a certain manner is imposing on the employer and in some way we need to help in order to manage this.

Actually in Puerto Rico sixty-two percent of our population is overweight. And this overweight brings many muscular skeletal problems that have nothing to do with occupational environment. But unfortunately our work environment with the requirements of register in logs of occupation disease in the way they are defined does attack and basically it obliges us to report as occupational when we understand that the majority of the cases have nothing to do with work environment.

In the industry we make "N" gestures with the doctors and nurses and the safety personnel to help the employees in programs of weight management. In exercise programs the gym is paid for, the gym is provided, many facilities are provided to help in losing weight because we understand that obesity is one of the principal reasons for injuries. But there is no way to obligate them, it is something voluntary and in not obligating the employee do do this program and improve personal health, we are being greatly impacted in the muscular skeletal injuries and in absenteeism in the work place.

Thus in some way we would like to see how we can help each other establishing criteria or ways of how the employer can establish programs of self-help with the personnel for the management of weight. Or how we can revise these requirements of registry of muscular skeletal injuries in the OSHA log. Thank you very much.

Verbal Comments 2006/12/06:

Good afternoon. I come in representation of the Society of Professionals of Prevention of Accidents of Puerto Rico, specifically as part of an alliance that we have with OSHA. I wish to indicate that with me is also our president, Ms. Carmen Vázquez.

We have a very interesting subject which is a preoccupation we have and our board as well has been evaluating this and it is the following: the importance of having good industrial hygienists able to analyze the process and knowledge of developing good strategies of sampling and evaluation of qualitative and quantitative in the health area of occupational health for the effective protection of our workers. We have been noticing that the university curriculum are graduating students that go to the field to jobs of industrial engineers and they really do not have the knowledge that is required to be able to execute this profession.

We should be giving them the necessary tools so that these professionals of industrial engineering can execute these strategies in an effective manner. In a manner that they avoid their employers and monetary penalties be imposed. And not only that, but that they also be the effective form so they can protect those workers. In the case, you all know for example, I worked with Puerto Rico OSHA, what is now known as Puerto Rico OSHA since it was OSHO. And I am also an industrial engineer.

There things are different because of course there are a number of strategies that are studied in the OSHA Institute. And if we go to Sal Lake City to the laboratories they do teach there about these three strategies. And we are in the field, in the practice, but not with these industrial engineers that we know are being recruited and only with a short course or they don't really have the strategies at all.

In Puerto Rico right now there does not exist in the universities that they have this type of competition. Yes, there are many masters which our curriculum recommends that they be realized. I am also a professor of various universities and we understand that we are seeing these failures. We are

recommending that these curriculum be revised and enlarged so that there be included good practices for them to make their effective analysis of the process and proper and adequate action be taken so that the final plan of action be an effective one.

We are also recommending and we support that these industries that are not listening here today can promote that students be recruited in their work place so that the practice be a real one, that they have a real work place.

We as an organization and a society are also asking those companies--we think we can prepare a campaign for those companies that are going to scrap some type of equipment, technical, monitoring and the rest that they remember we are a non-profit entity. We want to be involved in some way to also take this education and we want to know if there is anyone that can help us to develop a campaign to ask that those equipments that can be donated we are available to accept them.

We are going to do as the Banco Popular campaign is doing which solicits musical instruments so that music can be continued and encouraged. We want this profession be one that the person can really practice in an effective manner.

Thus we say thanks in the name of the Society of Professionals of Prevention of Accidents and to the Puerto Rico Federal Safety and Health Council for allowing us to be here. And to NORA, thank you.

Verbal comments 2006/12/06:

Good afternoon. In representation of the Aqueducts & Sewers Authority and the executive president, Mr. Jorge Rodríguez, we are very thankful for the invitation to this conference.

I wish to make a brief introduction which concurs with Professor Jorge Ramos in that many of the accidents had by the employees do not occur in the work area and I will bring two examples. Number one arises--I receive a case of a co-worker who registers a condition of allergies in contact with the asphalt fumes. And I investigate and this employee had previously been declared totally disabled by the State Insurance Fund and the employer had not been informed of his condition. The case was not in the work place and he still alleged it.

Number two, an employee who alleges an emotional condition due to a problem with the supervisor. It is investigated and it was in another place that the alleged emotional condition occurred and it was not in the work place. But what bring us here are two points, first the cases of alumina in the Aqueducts & Sewers Authority. Now we have a case for obvious reasons the name is not mentioned, that has been incurring around four hundred thousand to five hundred thousand dollars in the State Insurance Fund in costs for this employee.

It was investigated in the Department of Health and various agencies and I also did an investigation and it results that he was working with another employer exposed to toxic materials, alleged toxins. And the Authority never worked with this type of toxins. In the first place, the Fund does not relate the case but as we all know there is another, the Industrial Commission. It is appealed in the Commission and there the Commission gives total protection of the law to these employees.

But the situation of alumina by the year 2005 there had been thirty cases registered for which we requested professional advice to the Medical Sciences Campus for evaluation. This was requested based on analysis data from laboratories that the employees took from their private doctors, which are over the levels of exceeding ten miligrams.

One curious data was that all indicated having the supposed exposure between 1989 and 2000, but it was not until 2004 that they all decided to report the State Insurance Fund which originates this chain of claims from a subscriber of the Authority. Another curious data was that three employees indicated they had taken Maalox, an antacid with a high content of alumina. And before going to the Fund they drank a bottle of alumina and when the analysis were made obviously the volumen was high.

It is indicated that during a visit to the clinic of the State Insurance Fund it was heard when one patient said to another to drink a lot of antacid so that the level of alumina would be high in the tests. On verifying who they were it resulted to be an employee of the group from Cayay. And only in the regions of the Authority where they only indicated contamination with alumina it was in the region of Cayey, not in any other region of the Aqueducts & Sewers Authority.

The aluminium is excreted through the body through the urine in an average time of ninety days. Thus, the hypothesis that there could be an exposure through the use of the urine is discarded. It is indicated that they have said there exists the possibility that they are contaminated on having tanks of chlorine in the truck and tied with chains, since the paint of aluminum of the tank comes off and it forms an aerosol of aluminum. They made and there have been made all investigations since the Authority is not authorizing the alumina and we are receiving other cases.

That is why in my hypothesis that there are many, but not to say all, many of the cases that are alleging contamination are from other places or from their house and not from the Aqueducts & Sewers Authority.

Another petition that is being made is of Hepatitis C. There are some other co-workers that are alleging contamination with Hepatitis C and the contamination is through sex or blood transfusions. And they are alleging that the contact with dirty waters from sewers they are being contaminated with Hepatitis C, for which we are asking also some help on this point.

There is another situation also that is very important that obviously is a risk that cannot be corrected, it is a matter of negotiation and it is that the employees of Aqueducts & Sewers Authority have two years when they can be reported to the Fund, collecting full pay for each case. There are employees that have three, four and five cases which multiplied by two can be ten years without working collecting their salary. And this is one of the situations that I have been pointing out to correct that to bring down the work related accidents.

And the risk, one of the major risks that we have is this negotiation that was done, that we have one employee who registers one case, he is discharged from treatment today and the following week he registers another one.

And once again, congratulations, many thanks for the attention and God Bless. Good afternoon, very many thanks.

Note: Verbal testimony provided to NORA Town Hall meeting in Isla Verde, PR, 2006/12/06.

Verbal Comment 2006/12/06 (English translation follows):

Muy buenas tardes. Muchas gracias por esta oportunidad. Con el propósito de contribuir en la anticipación, prevención, litigación de condiciones y situaciones que afectan áreas ocupacionales. Y la distinción entre condiciones ambientales y lo que se atribuye como error humano. Y para un mejor entendimiento en relación a los aspectos antes mencionados, propongo la investigación, utilizando un modelo estocástico dinámico, basado en el estudio y análisis de patrones obtenidos de datos, como estadísticas de histogramas.

El objetivo es el diseño de estrategias para anticipar eventos y proyectar situaciones futuras. En otras palabras, estar preparados. Si dentro de la--por ejemplo, si dentro de la teoría del caos, se puede encontrar el punto donde se detectan patrones, así mismo con este evaluo se espera que se faciliten esos patrones para un desarrollo dinámico en la conceptualización de programas educacionales y entrenamientos acertijos en la búsqueda de un estado de excelencia en salud y seguridad ocupacional. Por ejemplo, este tipo de modelo se podría utilizar en diferentes situaciones y preocupaciones que se han planteado hoy en la tarde. Por ejemplo, yo traigo a colación, que se puede investigar igualmente la relación entre los niveles de ansiedad y afecto en propensión de accidentes y productividad, luego del 911.

Eso es un área que sí afecta por todo lo que es el área ocupacional. Eso es todo lo que tengo que decir por hoy, muchas gracias por su atención.

(ENGLISH TRANSLATION)

Good afternoon. Many thanks for this opportunity. With the purpose of contributing in the anticipation, prevention, litigation of conditions and situations that affect occupational areas and the distinction between environment conditions and what is attributed to human error. And for a better

understanding with relation to the aspects mentioned before I propose the investigation utilizing a model of dynamic estocastic based on the study and analysis of patterns obtained from data like statistics and histograms.

The objective is to design strategies to anticipate events and project future situations. In other words, to be prepared. For example, if in the theory of chaos it can be found the point from where to detect patterns the same as in this evaluation it is expected that other patterns are facilitated for a dynamic development in the conceptualization of educational programs and trainings in the search for a state of excellence in occupational health and safety.

For example, this type of model could be used in different situations and preoccupations that have been presented this afternoon. For example, I bring that it can be investigated the relation between the levels of anxiety and affect in propensity of accidents and productivity after 9/11.

That is an area that does affect in the whole occupational area. That is all that I have to say today. Many thanks for your attention.

Verbal Comment 2006/12/06 (English translation follows):

Buenas tardes. Mi nombre es Rosa Rosario, Ingeniero Ocupacional e Investigadora Social de la Universidad de Puerto Rico, Recinto de Cayey. Gracias por invitarnos a esta actividad.

Durante la tarde de hoy nuestro equipo de trabajo, compuesto por el doctor Enríque López, que es Geógrafo y Estadístico y la profesora Iris Figueroa, Ingeniero Industrial y ésta servidora, estaremos presentando unos temas de investigación que son de principal interés dada a la población que sirve nuestra institución.

Como pueden ver la Universidad de Puerto Rico en Cayey, sirve a once municipios de la Isla, para una población estimada de cuatrocientos sesenta y siete mil trescientos treinta y nueve habitantes. A través del instituto de investigaciones intra-disciplinarias, se ha logrado un 'Grant', que es está permitiendo el desarrollo de la infraestructura de investigación de la universidad. Uno de los temas de particular interés para los investigadores del instituto, es el estado de salud de la población trabajadora que reside en esta región, obviamente, a los once municipios.

Según el censo del año 2000, se estima que la población empleada de dieciseis años o más, residente en la región, asciende a ciento seis mil ciento ochenta y cuatro trabajadores. La mayoría de ellos trabaja para la industria privada o el gobierno. Sin embargo, hay un número importante de trabajadores con negocio propio o trabajando sin paga para familiares, que es de particular interés para nuestros investigadores. Las industrias de la manufactura y el comercio, son las principales fuentes de empleo en la región. Esto coincide, verdad, con lo que había presentado OSHA, en término de las industrias de particular interés para la agenda nacional.

Dado que no tenemos datos que evidencien cual es el estado de salud, ni cuales son las necesidades de los trabajadores residentes de la zona, proponemos en primera instancia un estudio socio-demográfico y de salud de nuestros trabajadores. Y el propósito de este estudio sería explorar que existen diferencias con género e industria en el perfil de nuestra fuerza trabajadora. Los tópicos de interés para el estudio incluyen, características socio-demográficas, datos relacionado a la ocupación, como por ejemplo, industria ocupación actual y/o ocupación usual, necesidad de y uso de equipo de protección personal. Enfermedades y lesiones de mayor prevalencia, uso de sustancias como por ejemplo, alcohol, tabaco y otras drogas.

Acceso a servicios preventivos y de salud y productividad aceptada por el estado de salud del trabajador, incluyendo el componente sico-social. Porque es importante este tipo de estudio, bueno, información obtenida a través del estudio, nos serviría para monitorear el estado de salud de nuestros trabajadores. A la misma vez que proveerá evidencia científica necesaria en la formulación de preguntas de investigación. Y en la documentación de propuestas y agendas de investigaciones.

(ENGLISH TRANSLATION)

Good afternoon. My name is Rosa Rosario, Occupational Engineer and Social Investigador of the University of Puerto Rico, Cayey Campus. Thank you for inviting us to this activity.

During this afternoon our staff composed by Dr. Enrique López, Geologist and Statistical and Professor Iris Figueroa, Industrial Engineer and myself will be presenting some subjects of investigation that are of principal interest to the population that our institute serves.

As can be seen the University of Puerto Rico in Cayey serves eleven municipalities on the island for an estimated population of four hundred sixty seven thousand three hundred thirty nine inhabitants. Through the institute of investigations intra disciplinary there has been achieved a Grant that is permitting the development of the infrastructure of investigation of the university. One of the subjects of particular interest for the investigators of the institute is the health condition of the population of workers that resides in this region, obviously of the eleven municipalities.

According to the census of the year 2000 it is estimated that the population employed of sixteen years old or more residing in the region comes to one hundred six thousand one hundred eighty four workers. The majority of them work for the private industry or the government. But there are an important number of workers with privately owned enterprise working without pay for family members which is of great interest for our investigators. The manufacturing industry and commerce are principal employers in the region. This coincides with what has been presented by OSHA in terms of the industries of particular interest for the national agenda.

Due that we do not have data evidencing what is the health condition nor which are the needs of the workers residing in the zone, we propose in first place a socio-demographic study and of the health of our workers. And the purpose of this study would be to explore if there exists differences with manner and industry in the profile of our work force. The topics of interest for the study include socio-demographic characteristics, data related to occupation, like for example the actual occupational industry and/or usual occupation, the need for use of equipment for personal protection, diseases and injuries of prevalence, use of substances like for example, alcohol, tobacco and other drugs.

Also access to preventive services and for health and accepted productivity for the health condition of the worker, including the psycho-social component. Because it is important this type of study,

information obtained through the study, it would serve to monitor the health condition of our workers. At the same time it would provide scientific evidence necessary for the formulation of questions of investigation and in the documentation of proposals and agendas of investigations.

(English translation follows)

Un sub-grupo de interés dentro de la fuerza trabajadora, residentes en la región servida por UPR Cayey, son las trabajadoras de los salones de bellezas. Estas son las mujeres, verdad, que pintan cabello, arreglan cabello, pero particularmente las mujeres que trabajan las uñas de acrílico. Como parte de su trabajo, estas mujeres pueden estar expuestas a sustancias que pudieran estar relacionadas a un incremento en el riesgo de asma y otras enfermedades respiratorias.

Como pueden ver en esta gráfica, en Puerto Rico, el asma es una de las enfermedades de mayor prevalencia entre los adultos. Aquí podemos ver que ocupa la quinta posición en el grupo de cuarenta y cinco a sesenta y cuatro años. Según la literatura científica, la ocurrencia de asma puede estar relacionada a o agravada por exposiciones en el área de trabajo. De hecho, las exposiciones en el área de trabajo han sido implicada en la búsqueda de explicaciones a elevadas frecuencias de casos de asma entre adultos. Existen sobre trescientos cincuenta agentes asociados al comienzo y/o exacerbación del asma.

Porque es importante este tipo de estudios, bueno, las trabajadoras de salones de bellezas están expuestas a diferentes agentes asociados al asma. Este estudio nos permitiría alcanzar una población y en su mayoría auto-empleadas y que no ha sido estudiada previamente. De hecho, no se recopilan datos, verdad, en términos de salud de estas poblaciones que son auto-empleadas.

Y los objetivos de este estudio serían describir las condiciones de trabajo en los salones de bellezas, evaluar la prevalencia y los factores de riesgos para asma entre las trabajadoras de salones de belleza y

evaluar las exposiciones a productos como parte del trabajo. Como ya les mencioné, el Instituto de Investigaciones Interdisciplinarias está desarrollando una infraestructura de investigación en una región de Puerto Rico, que no ha sido estudiada debidamente.

Así que nosotros, epidemiólogos, estadísticos, profesionales de la salud pública, psicología, etcétera, nos estamos dando a la tarea de documentar y desarrollar unas agendas de investigación que nos permita servir a aquella población, verdad, que es nuestra razón de ser. Y es la región servida por la Universidad de Puerto Rico en Cayey, muchas gracias.

(ENGLISH TRANSLATION)

A sub-group of interest within the work force are residents in the region served by UPR Cayey are the workers in beauty salons. These are the women who dye hair, style hair but particularly the women who work with acrylic nails. As part of their work these women can be exposed to substances that could be related to an increment in the risk of asthma and other respiratory diseases.

As can be seen in this graphic, in Puerto Rico asthma is one of the diseases of major prevalence in adults. Here we can see that it occupies the fifth position in the group of forty-five and sixty-four years of age. According to the scientific literature the occurrence of asthma can be related to or aggravated by exposition in the work area. The expositions in the work area have been implicated in the search of explanations of elevated frequencies of cases of asthma in adults. There exist over three hundred agents associated to the beginning and/or exacerbation of asthma.

Why is this type of study important? Well, the beauty salon workers are exposed to different agents associated with asthma. This study would allow us to reach the population and in its majority self-employed that have not been studied previously. In fact, there are no data in terms of the health of this population that are self-employed.

And the objectives of this study would be to describe the work conditions in the beauty salons, evaluate the prevalence and the risk factors for asthma among the workers of beauty salons and evaluate the exposure to products as part of their work. As I already mentioned the Institute of Interdisciplinary Investigations is developing an infrastructure of investigation in one region of Puerto Rico that has not been studied properly.

So that we, epidemiologists, statisticals, public health professionals, psychologists, etcetera, are working towards documenting and developing agendas of investigation that will permit us to serve that population which is our reason for being. And it is the region served by the University of Puerto Rico in Cayey. Many thanks.

Verbal Comment 2006/12/06 (English translation follows):

Mi nombre es Roland González, ex-inspector del programa estatal de OSHA y soy Gerente de Proyecto y de Recursos Humanos de la Autoridad del Distrito del Centro de Convenciones. Lo que voy a compartir con ustedes mayormente lo que pasó allí en el Centro de Convenciones, donde tengo unas preocupaciones o 'concerns' con referencia a lo que como está escrito, los 'steel erection', donde tuve mis dificultades, tuve que trabajarlo de una forma en pro del empleado y tuve que más o menos que inventármela. Y es con referencia de que el estándar establece como una persona competente aquella persona que tiene los conocimientos para reconocer los riesgos. Y que tenga la autoridad para corregirlo. Pero dentro del estándar establece de que la persona competente va a ser la persona que va a evaluar si se requiere estabilizar o no se quiere estabilizar una columna o una viga.

Realmente, yo como ingeniero industrial y maestría en Recursos Humanos, jamás y nunca me voy a tomar esa decisión de si se requiere o no se requiere estabilizar una columna de vigas. Qué yo hice, utilicé a mis inspectores y utilicé a mi gente que saben de esto. Ellos me tienen que certificar a mí, si se requería o no se requería entonces estabilizar esa columna, pero como está escrito aquí en el estándar, dice que es la persona competente. En mi opinión, debería ser 'a qualified person', la persona cualificada.

Porque sí dice, que una persona cualificada tiene que tener ese conocimiento, ya sea por su grado de universitario, por su experiencia, que sabe sobre lo que se puede hacer o sobre la montura de una estructura de acero. Más adelante el estándar establece sobre otras responsabilidades a la persona

competente con referencia a la montura del acero, si se requiere o no se requiere dos pernos o más y muchas otras cosas con referencia a la estabilidad de la estructura. 'Hello', yo no soy ingeniero de estructura, jamás yo iba a tomar esa decisión y sí era la persona competente del proyecto. Era el 'safety officer' del proyecto.

Por lo tanto, qué yo hice, me la tuve que arreglar con los verdaderos inspectores, la gente que saben de esto para que ellos me certificaran a mí que sí entraba, que estaba estable, estabilizada, las columnas y las vigas. Sin embargo, más adelante se dice de que se tiene que hacer acorde con el ingeniero del proyecto estructural. Pues mi gente, si hay que hacerlo de esa forma, quien es la mejor persona para poder hacer esto así, el ingeniero estructural del proyecto, que está ahí día a día verificando y chequeando que se hagan las cosas bien.

Gracias a Dios, el Centro de Convenciones se hizo y ninguna columna, ninguna viga se ha caído, no pasó nada de eso. Más sin embargo, recientemente tuvimos un accidente, una fatalidad en el Natatorio a causa de que una viga se cayó sobre una persona. Y el caso tuve que trabajarlo. Donde hubo una discreción--discrepancia entre dos ingenieros estructurales profesionales, donde uno decía, uno así y uno así no, de que no se caía y el otro decía, que sí, que sí se caía. En cual de los dos creemos, son dos profesionales de esto.

Por lo tanto, la estabilidad de una estructura de acero no debería de depender de una persona competente, sino una persona cualificada para que se sepa como se va a trabajar esto. Adicional a esto, otro 'concern' u otra preocupación que tengo, es con referencia a lo de 'fall protection', la protección contra caídas. Dice aquí que después de quince pies, usted va a proteger todos los empleados, pero si es conector va a ser después de los treinta pies. Se requiere, sí, que lo utilicen después de quince pies, pero tiene que entonces amarrarse después de los treinta pies. No puedo hacer--aceptar esto, porque significa que un conector se cae de veintiocho pies, va a rebotar o va a ser algo y no va a pasar nada. No creo, si se cae de veintiocho pies o veintinueve pies, puede ocurrir una muerte fácilmente.

Por lo tanto, yo sé que es difícil la estructura de acero, es difícil moverse a través de las vigas, se requiere cierta libertad de movimiento, pero ese momento se restringe a cuarenta, cincuenta pies, porque no a quince, porque no a veinte. Eso era una de mis preocupaciones referente a esto. Y otra cosa es que un estudiante cuando doy clases en la Universidad Interamericana y en Mayagüez, veo a que muchas veces el estudiante pregunta, porque hay tantas medidas para la protección contra caídas. Cuatro pies con dos plataformas, seis pies con doble "E", que la superficie de construcción, diez pies con los andamios, quince pies, pie derecho, como acabo de decir los conectores. Estas medidas y estas cosas, como quiera es 'fall protection'. Es como quiere protección contra caídas, porque vamos a complicarle las cosas, simplifiquémoslo. Yo cojo una recomendación y tú me dices quizás que ponga de cuatro a ocho, si son--o un equipo de control de ingeniería. Y después de ocho pies se utiliza algún sistema de protección contra caídas.

Porque he visto que han obligado a empleados dentro de una farmacéutica y eso, hacer que se pongan un arnez, pero se cae, se fastidia. Por lo tanto, yo entiendo de que debe darse más simple, más fácil. Es más fácil memorizar las cosas y tener una medida estándar para cualquier tipo de protección contra caídas, porque es caídas. Si tú me dices que de quince pies o mejor dicho, me dices de seis pies tengo que proteger y a diez pies no tengo que proteger, no me hace sentido, de verdad. Debemos de proteger a estos empleados, debemos de simplificar esto, de que no importa de qué alto se encuentre, si está sobre cuatro, ocho, debemos establecer que hay que proteger al empleado. Eso es todo, gracias.

(ENGLISH TRANSLATION)

My name is Roland González, ex-inspector of the state program of OSHA and I am Project and Human Resources Manager of the District Authority of the Convention Center. What I am going to share with you mainly is what happened in the Convention Center where I have some concerns with reference to what is written, the steel erection where I had some difficulties. I had to work them in a way in pro of the employee and I had to more or less intervene. And it is with reference that the standard establishes how a competent person, that person that has knowledge to recognize the risks and that has the authority to correct it. But the standard establishes that the competent person will be the person who will evaluate if we want to stabilize or not to stabilize a column or beam.

Really, I as an industrial engineer with master in Human Resources and will never take that decision of if it's required or not required to stabilize a column of beams. What did I do? I used my inspectors and utilized my people who know about that. They have to certify to me if it is required or not to stabilize that column. But as it is written here in the standard it says that it has to be the competent person. In my opinion, it should be a qualified person, the qualified person.

Because it says that a qualified person has to have that knowledge be it by university grade, by experience, that knows about what can be done or about the building of a steel structure. Further on the standard establishes about other responsibilities to the competent person with reference to the building of the steel, if it is required or not two bolts or much more things with reference to the stability of the structure. Hello, I am not a structural engineer, I would never take that decision and yes the competent person of the project, it was the safety officer of the project.

Thus, what did I do? I had to arrange with the real inspectors, the people who know about this that they certify to me that it would go in, that it was stable, stabilized the columns and the beams. Nevertheless, further on it says that it has to be done in accord with the structural project engineer. So my people yes it has to be done that way. Who is the best person to do this that way, the structural project engineer who is there day by day verifying and checking that things be done well.

Thank God, the Convention Center was built and no column, no beam has fallen, nothing like that happened. Nevertheless, we recently had an accident, a fatality in the Natatory caused by a beam that fell on a person. And I had to deal with the case. Where there was a discrepancy between two professional structural engineers where one said one this way and one this way not that it would not fall and the other one said yes that it would fall, which of the two do we believe, they are two professionals about this.

Thus, the stability of a structure of steel should not depend on one competent person, but on a qualified person so that we know how this is going to be worked. In addition another concern or preoccupation that I have is in reference to fall protection. It says here that after fifteen feet you will protect all employees but if it is connecting it will be after thirty feet. It is required yes, that it be utilized after fifteen feet but it has to be tied after thirty feet. I cannot accept this because it signifies that a connector falls from twenty-eight feet it will rebound, it will do something or nothing will happen. I don't believe--if it falls from twenty-eight feet or twenty-nine feet there can be a death easily.

Thus, I know it is difficult with a steel structure, it is difficult to move within the beams, a certain liberty of movement is required. But that moment is restricted to forty, fifty feet, why not at fifteen, why not at twenty. That was one of my concerns regarding this. And another thing is that a student when I give

class in the Inter-American University and at Mayaguez, I see that many times the student asks why there are so many measures for the protection against falls. Four feet with two platforms, six feet with double E, that the construction surface, ten feet with the scaffolding, fifteen feet, right foot as I just said, the connectors. These measures and these things is fall protection. It is a protection against falls, why are we going to complicate things, let's simplify. I take a recommendation and you tell me perhaps to put four to eight if it is an engineering equipment control. And after eight feet use some system of protection against falls.

I have seen that employees have been forced within the pharmaceuticals that make them wear a harness but they fall, they are hurt. Thus I understand it should be more simple, easier. It is easier to memorize things and have a standard measure for any type of protection against falls, because it is falls. If you tell me that from fifteen feet or more, you tell me from six feet I have to protect and at ten feet I don't have to protect it doesn't make sense to me. We should protect those employees, we should simplify this that it is not important from what height it is found, if it is over four, eight, we should establish that there must be protection of the employee. That is all, thank you.

Verbal Comment 2006/12/06 (English translation follows):

Buenas tardes, Roberto Rosado. Estudiante de Maestría de la Universidad del Sagrado Corazón. En el proceso de trabajo, de que soy presidente de los Enfermeros Ocupacionales del Colegio Profesional de la Enfermería. Especialista en manejo de incapacidad y representante de reclamaciones de incapacidad para el Seguro Social en forma independiente.

Consciente en el aumento de casos de reclamaciones por incapacidad permanente y solicitud del Seguro Social, es mi presentación. El cual se menciona como intervención de profesionales de la Enfermería ante el manejo de casos de incapacidad del Seguro Social. Reconociendo que el éxito de los programas de rehabilitación e incapacidad depende de programas estructurados en compromiso gerencial, objetivos específicos y compromisos del equipo de salud y seguridad. Quiero mencionar que los procesos de reclamación del Seguro Social en su etapa inicial tardan de seis a ocho meses, una decisión. Si el caso es denegado, pues se considera de cuatro a seis meses en espera y de no ser aprobado, pues el caso se ve ante una vista ante un juez, dieciocho meses después de haber solicitado la reclamación.

En análisis del caso, investigamos posibles causas, identificamos causa, establecemos un compromiso del empleado o reclamante de la reclamación, o sea, valga la renundancia. El equipo de trabajo en el área ocupacional, pues está enfermería, médicos, el gerente de producción y supervisor en Recursos Humanos trabajando en equipo. En la parte ocupacional, Seguro Social, el representante va enfocado a analizar el caso, establecer si este caso es posible para un programa de rehabilitación y regresarlo al ambiente laboral. De lo contrario, establecer un nivel de incapacidad y llevarlo a una solicitud de Seguro Social por incapacidad. La clave para el manejo de incapacidad es analisis del caso, la entrevista del reclamante, reconocer las necesidades. Referir o recomendar, clarificar derechos del empleado para referirlo al Fondo del Seguro del Estado, Sinot, programas de vales o incapacidad a largo plazo.

Seguimiento frecuente de los casos, asuntos pendientes, evaluaciones por médicos especialistas en las condiciones. Evaluación de incapacidad funcional, emocional, determinar la incapacidad, que sea permanente. Las limitaciones tienen que estar por escrito, se evalúa si el empleado puede hacer el mismo trabajo, pudiera hacer otro tipo de trabajo. Para que tengan una idea, en el caso de las mujeres, se establece si no puede hacer sus ocho horas que hacía anteriormente, si pudiese hacer cuatro horas sentada en un escritorio contestando un teléfono. En el caso del hombre, estar cuatro horas en un garaje de gasolina, teniendo empleo mientras hay clientes y si no hay clientes, pues solamente se va a limitar a observar.

Además se evalúan las consecuencias y otras condiciones que se tienen, se hace unas comunicaciones con los profesionales de la salud de la comunidad, de manera de tener un banco de recurso o referido. Las limitaciones tienen que estar en un documento adecuado, detallada, que no se contradiga, que el empleado no pueda hacer su trabajo, pero puede hacer uno distinto. O que pueda ser en términos de limitaciones más de tres horas, si puede hacer cuatro horas, pues puede hacer un part-time.

Se clarifican las dudas con el médico, de información que ha documentado. Si son permanentes, pues se procede a hacer la reclamación por incapacidad o si son temporeras, pues entonces se refiere a un programa de rehabilitación. Los referidos a los médicos para seguimiento, la importancia de los estudios de radiología y especializados, pues van a obviamente, a validar el diagnóstico, a validar la queja del paciente. Recertificar una condición, si hay una mejoría o la condición es progresiva. La entrevista va a reconocer la realidad del caso, conocer las emociones de la persona y conocer los intereses del cliente. Que es lo que él quiere, regresar al ambiente laboral o quiere unas comisiones que va a una incapacidad.

Reconocer si es candidato a rehabilitarse, obviamente, y la rehabilitación nos va a ayudar en la posición de ocupaciones por su referencia, en el caso del Fondo. Las no ocupacionales, pues referidas a médicos o médicos especialistas. En la rehabilitación hay que promover la integración familiar en este proceso y en el lugar de trabajo. Se evalúa la condición de acuerdo a la evidencia médica, además se discuten las probabilidades del caso. Un caso que no tiene probabilidad de aprobación, pues entonces se le menciona que su oportunidad para el área de la rehabilitación.

La realidad actual, casos que con condiciones limitantes, pueden ser delegados por un manejo inadecuado. Las condiciones pueden existir, pero si no existe una evidencia de tratamiento en el caso, es denegado. La intervención tardía en manejo de casos en el lugar de trabajo, genera más reclamaciones. La integración de los servicios por referidos en ocasiones es controlada. Se reclama una incapacidad u orientación en la etapa de crisis limitando las oportunidades de regreso al trabajo.

En mi trabajo, mi aportación a estos programas, pues soy el primer representante con experiencia en Enfermería Ocupacional. Se representa el caso ante un juez administrativo del Seguro Social, al cliente se le ayuda en el proceso de rehabilitación y por lo regular, si está en etapas tempranas, pues regresa al ambiente laboral. En mi experiencia, un noventa por ciento de los casos sometidos ante el tribunal del Seguro Social, han sido aprobados en los cinco años de práctica que tengo como agente independiente.

El conocimiento clínico y ocupacional permite tener empatía con los reclamantes. Se realizan referidos para llenar las necesidades del mismo. Cual es el beneficio de estos servicios de la comunidad, pues recomendación a tratamiento, regreso al trabajo, dependiendo del caso. Evaluación objetiva aplicando conocimientos del área ocupacional, la medicina tradicional y concepto de mediación durante el proceso. Condiciones o problemas frecuentes para reclamaciones de incapacidad, pues son las

musculares o el trauma de trabajo repetitivo, trastornos emocionales secundarios a condiciones físicas y los respiratorios, los casos de asma. Condiciones secundarias a la--como consecuencia de una primaria, pues disfunciones sexuales en ambos sexos, más reconocido en la mujer, dado el caso de que el hombre inventa otros argumentos para este tipo de problemas que tiene.

En términos de aportación, las expectativas profesionales mediante el ofrecimiento de educación continua, motivar a otros profesionales a desarrollar programas como el que yo trabajo, que sean efectivos. Ayudar en los casos posibles con la intervención en una etapa temprana, transcribir al reclamante una evaluación justa y razonable. Aportar conocimiento en el área de manejo de casos de incapacidad a profesional de la salud en el área ocupacional. Gracias por su atención, pasen buen día, feliz Navidad.

(ENGLISH TRANSLATION)

Good afternoon. Roberto Rosado, a masters student of the Sacred Heart University. In the work process I am president of Occupational Nurses of the Professional College of Nursing, specialists in the management of disability and representative of claims of disability for the Social Security in the independent form.

Conscious of the increase of cases of claims for permanent disability and requests for Social Security this is my presentation, which is mentioned as intervention of professionals of Nursing before the management of cases of disability of Social Security. Recognizing that the success of the programs of rehabilitation and incapacity depends on the structured programs in management commitment, specific objectives and commitment of the health and safety staff.

I want to mention that the process of claims of Social Security in its initial stage are delayed from six to eight months for a decision. If the case is denied then consider that four to six months waiting and if not approved, then the case is seen before a hearing before a judge, eighteen months after having requested this claim.

In analysis of the case we investigate possible causes, we identify cause, we establish a commitment of the employee or claimant of the claim, thus the redundancy. The work staff in the occupational area, there is nursing, doctors, the production manager and supervisor in Human Resources working in a group. In the occupational part, Social Security, the representative focuses on analyzing the case, establish if the case is possible for a program of rehabilitation and return him to the work environment. On the contrary it establishes a level of incapacity and take him to a request for Social Security due to disability. The code for management of disability is analysis of the case, the claimant's interview, recognize the needs. Refer or recommend, clarify employee rights to refer him to Fondo Del Seguro Del Estado, SINOT, value programs or incapacity in the long run.

Frequent follow up of the cases, pending matters, evaluations of specialist doctors in the conditions. Evaluation of functional incapacity, emotional, determine the incapacity, if it is permanent. The limitations have to be in written form. It is evaluated if the employee can do the same work, could do other type of work.

So that you have an idea, in the case of women it is established if they cannot do the eight hours that they did previously, if they could do four hours sitting at a desk answering the phone. In the case of men, to be four hours in a gasoline station having employment while there are clients or not any clients, he would only be limited to observing.

Also evaluated are the consequences and other conditions that are present, communications are made with the professionals of the health in the community, so that to have a bank of resources or referrals. The limitations have to be in an adequate document in detail, that do not contradict, that the employee cannot do his work, but can do another different one. Or that it can be in terms of limitations of more than three hours, if he can do four hours, then he can do a part-time.

These doubts are clarified with the doctor, from information documented by him. If they are permanent then they proceed to make the claim due to disability or if they are temporary then they are referred to programs of rehabilitation. The referrals to the doctors for follow up, the importance of the studies of radiology and specialists will obviously validate the the diagnosis, validate the patient's complaint. Recertify a condition if there is an improvement or the condition is progressive. The interview will recognize the reality of the case, recognize the emotions of the person and recognize the interests of the client. What is it that he wants, return to the work environment or does he want a commission that lead to an incapacity.

To recognize if he is a candidate for rehabilitation obviously and the rehabilitation will help us in the position of occupations by reference in the case of the Fund. The non-occupational referred to doctors or specialists. In the rehabilitation there has to be a family integration in this process and in the work place. The condition is evaluated according to the medical evidence, also probabilities are discussed of the case. One case that does not have probability of being approved, then it is mentioned about the opportunity in the area of rehabilitation.

The actual reality of cases with limiting conditions can be delegated by an inadequate management. The conditions can exist but if there does not exist an evidence of treatment in the case, it is denied. The delayed intervention in management of cases in the work place generates more claims. The integration of services by referrals on occasion is controlled. An incapacity is claimed or orientation in the critical stage limiting and opportunities of returning to work.

In my work, my contribution in these programs is I am the first representative with experience in Occupational Nursing. The case is represented before an administrative judge of Social Security. The client is helped in the process of rehabilitation and usually if he is in an early stage he returns to the work environment. In my experience ninety percent of the cases submitted before the tribunal of Social Security have been approved en the five years of practice that I have as indepent agent.

The clinical and occupational knowledge permits us to have empathy with the claimants. Referrals are made to fill the needs of the same. What is the benefit of these services of the community? Well, recommendation to treatment, return to work, depending on the case. Objective evaluation applying knowledge and concept of mediation during the process. Conditions or frequent problems for claims of incapacity are the muscular or the trauma of repetitive work, secondary emotional problems to physical conditions and the respiratory ones, the cases of asthma. And secondary conditions as a consequence of the primary well, sexual dysfunction in both sexes mostly recognized in the woman given the case that the man invents other arguments for this type of problem that he has.

In terms of contribution the professional expectations through the offers of continued education motivates other professionals to develop programs like the one that I work, that can be effective. To help in the possible cases with the intervention in an early stage to transact to the claimant a just and reasonable evaluation and to contribute knowledge in the area of management of cases of disability to health professionals in the occupational area. Thank you for your attention, have a happy Christmas.

Verbal Comments 2006/12/06:

Good afternoon. My name is Madeline Jordan and I work at the San Juan National Historic Site. The site covers Fort San Felipe del Morro, approximately three miles of wall and Fort San Cristobal and El Cañuelo. In the National Park Service safety for visitors and employees cover under directors orders Fifty--"A", OWCP, "B", employee safety and, "C", risk management for the public.

The safety of the visitor as you can see, historically has been mainly at the operating unit in response to it. Directors are over fifty-six steps in any direction, emphasize on prevention this still related, while ensure a proper response capability. While recognizing the computing concerns of the cause and the safety, it restricts the services ability to eliminate hazards. The service will be trying to protect human lifes which is a major and provides an injury free visit, doing so as in the concentrate of the organic act resources.

Park resources are not only a visitor attraction, but they are potentially hazards. Within the San Juan National Historic Site, well, lightly represent a hazard for visitors and employees safety, through statistics. We have changed the scene which is the little top at the center box that we have adjusted them and we have complied. Tripping hazards are eloged for our visitors and our employees, these areas we cannot change, however, we have ramps all over the ports, they do represents hazards for visitors, specially where is deep, they become very--on this particular one, we had one suit that went on to the District Court and it was in failure of the National Park Service. This specific one, we had so many falls that we had--actually we had all integrity of the Culture Patrimone and we had--just in this area. We also had tripping hazard on falling steps, visitors climbed on the fence which are instructions that you can see on your right hand and your left side. On the cannon and bridges I think we haven't had any visitors falling from them, they are forty feet down.

The means of public safety concerns have to be made in the discriptions of the superintendent and, acomplished the following nine areas to address. Public safety, where we have all of them except the San Juan National Historic Site. MPS cleaning of the sections of the histories of structures done with cannons and specifically in this area between Fort San Cristobal and Fort El Morro, we have a specific concern about the scaffolding on the regulations and we have opted to stop using hanging scaffolding on these areas. And we use machines on the other areas. This is a very dangerous and hazard, the historic structures that they- - So, remember that when you go to the National Park, they have--are in hazards not only for the visitors, but for our employees. Thanks.

Verbal Comment 2006/12/06 (English translation follows):

Hola, buenas tardes a todos y a todas. Y gracias por la oportunidad de podernos expresar acerca de algo que nos preocupa bastante con relación a la formación de seguridad ocupacional concretamente en el campo no formal, en el campo del 'Outreach Program'. Recientemente nos hemos estado dando cuenta de que llegan personas que aspiran a tomar los cursos de 'trainer' con nosotros. Que revelan una falta de formación básica, no solamente ya en los estándares, sino incluso en el dominio básico de los conceptos de OSHA.

Por ejemplo, tenemos personas que llegan y nos piden que quieren tomar las quinientas horas de OSHA. O sea, eso se le puede perdonar, por ejemplo, a una persona que se está iniciando, pero una persona que--no es una persona que aspira ser un increíble 'trainer', después de cuatro días. También nos preocupa, por ejemplo, el uso que hacen algunas empresas de formación, que incorporan el tema de la seguridad y la salud ocupacional a su ofrecimiento, con frases como por ejemplo, que el curso es certificado por OSHA. Como puede certificar un curso que no le corresponde, que no es de OSHA.

También sabemos que algunos documentos que nos presentan algunos aspirantes al 'training' de 'trainer', son dudosos. Por ejemplo, en el nombre donde supuestamente va la persona acreedora de esa tarjeta de OSHA, pues vemos que ha sido manipulada, que ha sido quizás removido el nombre y ha sido puesto otro nombre encima. También en los documentos que por ejemplo se nos presentan, como prueba de que esa persona tiene una experiencia mínima de cinco años como oficial de seguridad y salud ocupacional de una empresa, cuando nos revela cosas en el dialogo que establecemos con ellos, que se delatan así mismo, de que en realidad no tienen mucha experiencia.

En fin, yo creo que es muy importante que desde OSHA, en NIOSH, nos ayuden a aclarar un poco del ambiente enrarecido que se ha formado recientemente. O sea, por lo menos a nosotros no nos lo--lo estabamos detectando recientemente en todo lo que es un programa de 'outreach'. También hemos sabido, por ejemplo, de instructores autorizados por OSHA para el programa de 'outreach', que firman

tarjetas y sabemos porque las personas que han asistido a esos cursos, nos dice que los que firman las tarjetas no han sido los que lo han instruido. Luego aquí estamos empezando a ver que hay gente que son instructores autorizados, que subcontratan la formación, su trabajo a otras personas que no están autorizadas, que hacen la formación, que ve tú a ver cómo la hacen. Y luego un instructor autorizado firma esas tarjetas.

En fin, yo creo que para muchas personas empresarias han descubierto el tema de la seguridad y la salud ocupacional como otra fuente de ingresos. Y se están simplemente haciendo una 'chapuza', como decimos aquí vulgarmente. Y creo que esto repercute, bueno, en la imagen de OSHA, en la imagen de todas las personas que seriamente estamos involucradas en este quehacer. Y más trágicamente en la salud y la seguridad de nuestros trabajadores en Puerto Rico.

Les quiero anunciar que también en OSHA Training Center, que tenemos un programa de radio que está a la disposición de todos. Que tiene un consejo asesor, que están invitados todos, que nos reunimos con relativa frecuencia, cada tres o cuatro meses para sugerir temas. Y recursos para esos programas y que estamos siempre reclutando porque nos gustaría tener la mayor participación de todos los concernidos. Eso es todo, muchas gracias a los representantes de NIOSH, que han venido aquí para escuchar nuestras opiniones.

(ENGLISH TRANSLATION)

Hello, good afternoon to everyone and thanks for the opportunity to express ourselves about something that worries us with relation to the formation of occupation safety concretely in the informal area, in the area of the Outreach Program. Recently we have been noticing that people arrive who aspire to take the trainer courses with us who reveal a lack of basic formation not only in the standards but also in the basic understanding of the concepts of OSHA.

We also know that some documents that are presented to us by those aspiring to the training of trainer are doubtful. For example, in the name where the person of that card from OSHA should be, well we see that it has been manipulated, that the name has been possibly removed and there has been put another name on top. Also in the documents that are presented to us for example, as proof that the person has a minimum experience of five years as safety official and occupational health of a company, they reveal things in the dialogue that we have with them, they reveal themselves that in reality they do not have much experience.

Finally, I believe it is very important that OSHA, in NIOSH they help us to clear up the environment that has been formed recently. At least to us we do not like--we were detecting this recently in all the program of outreach that they sign cards and we know that the persons who have attended those courses, they tell us that the ones who sign the cards have not been the ones who have instructed them. Then we are starting to see that the persons who are authorized instructors that they sub-contract the formation, their work to other persons who are not authorized, who do the formation, and let's see how it is that they do it. And later an authorized instructor signs those cards.

Finally I believe that many company persons have discovered the subject of safety and occupational health as another form of income. And they are simply making a "chapuza" as we say here. And I believe this reflects on the image of OSHA, on the image of all the persons who are seriously involved in this and more tragically in the health and safety of our workers in Puerto Rico.

I want to announce that also in OSHA Training Center we have a radio program which is at the disposition of everyone. That it has an advising council, that you are all invited, that we meet with relative frequency every three or four months to follow up on subjects. And there are resources for those programs and we are always recruiting because we would like to have a major participation from all concerned. That is all and many thanks to the representatives of NIOSH who have come here to listen to our opinions.

Verbal Comments 2006/12/06 (English translation follows):

Buenas tardes a todos. Nosotros como parte del Recinto de Ciencias Médicas, la Escuela Graduada de Salud Pública, en particular el departamento de Salud Ambiental, trajimos algunas inquietudes e ideas y algunos tópicos potenciales para investigación, tanto de laboratorio como aplicada que entendemos sea de trascendencia para nuestra Isla.

Entrando de frente a ellos es que una de las cosas bastante importantes o temas bien importantes sería la caracterización de la interacción entre ruido y químicos ototóxicos, es decir químicos que interactúan con el ruido, aumentando la probabilidad de desarrollo de pérdida auditiva. En el aspecto ocupacional en particular, estaríamos hablando de exposición a solventes orgánicos como en las imprentas, en las empresas que hacen lavado a seco de ropa.

Y un problema mayor que nos afecta es cuando tenemos monóxido de carbono presente en el ambiente. Todos acá, que vivimos en Puerto Rico conocemos la palabra tapón. Ese congestionamiento viene de una densidad vehicular altísima en el área Metropolitana. Las personas que están expuestas a ruido ambiental, pero están trabajando, léase aquellos que trabajan en los peajes, policías de tránsito, personas que trabajan cortando grama con los 'trimmers'. En las carreteras cercanas al área Metropolitana, están expuestas a ambos riesgos, el ruido como también el monóxido de carbono. O sea, que eso es un tópico que nosotros estamos estudiando en función de diferentes propuestas y diferentes proyectos. Y que creemos que es de trascendencia para nuestra Isla.

Problemas del ambiente construido o por su nombre en inglés, 'built environment'. También el problema del ruido es un problema que nos afecta a todos. Cuando hablamos de las escuelas, por

ejemplo y estándares de ruido dentro de las escuelas para que la integibilidad de la voz del maestro sea la apropiada. Los niveles recomendados en la literatura, son niveles significativamente inferiores a los niveles que podemos tener acá con el ruido ambiental existente. Material particular en el ambiente por las emisiones de los vehículos movidos a diesel y otras generaciones de materias particulados y químicos ototóxicos.

(ENGLISH TRANSLATION)

Good afternoon to all. We as part of the Medical Sciences Campus , the Graduate School of Public Health in particular the Department of Environmental Health, bring some concerns and ideas and some potential topics for investigation, from laboratories as we understand that is of transcendence for our island.

Facing them is that one of the important things or important subjects would be the characterization of the interaction between noise and ototoxic chemicals, to say chemicals that interact with the noise, increasing the probability of developing the loss of hearing. In the occupational aspect in particular we would be talking of exposition to organic solvents as in the print shops, in the company that does washing and drying of clothes.

And a major problem that affects us is when we have carbon monoxide present in the environment. All of us here who live in Puerto Rico know the word traffic jamb. That congestion comes in an automobile density in the metropolitan area, the persons who are exposed to environmental noise but are working meaning those who work in the toll roads, transit police, people who work cutting grass with the trimmers. In the roads near the metropolitan area those people are exposed to both risks, the noise and also carbon monoxide. Thus this is a topic that we are studying in different proposals and different projects. And we believe that it is of great transcendence for our island.

Problems of the built environment as it is called in English and also the problem of noise is a problem that affects us all. When we talk about the schools for example and noise standards of the schools in order that the intelligibility of the teacher's voice can be the appropriate one. The recommended levels in the literature are significant levels inferior to the levels that we can have here in the existing environmental noise. And particular material in the environment because of the emissions of the vehicles moving with diesel and other emissions of particular materials and otototoxic chemicals.

También entendemos que es bien importante hablar de la investigación de problemas típicos de Puerto Rico. Que no necesariamente se generalizan a otros estados de la unión, estamos hablando de estrellas de calor. Si hablamos de problemas asociados a la exposición a alta temperatura y altos grados de humedad, pues Puerto Rico es un laboratorio de estudio tremendo. Acá, cualquiera que haya tratado de cortar grama a las doce del día, siente ese problema, imagínese aquellos trabajadores de construcción civil, que trabajan afuera en días ensolados durante el verano.

(ENGLISH TRANSLATION)

We also understand that it is very important to speak of the investigation of problems typical to Puerto Rico which do not necessarily are generalized in other states of the union, we are speaking of grades of heat, 'estrellas de calor'. If we speak of the problems associated to the exposition of high temperature and high grades of humidity then Puerto Rico is a tremendous laboratory of study. Here anyone who has tried to cut grass at twelve noon can feel that problem. Imagine those workers in civil construction that work outside on sunny days during the summer.

Uno de los temas más importantes, principalmente para la pequeña industria es el desarrollo de soluciones que sean económicamente factibles de implementar. Que sean a su vez eficaces, en el sentido de que resuelvan el problema y eficientes de tal forma que sean económicamente factibles de hacer. Nuestros pequeños empresarios no tienen capacidad económica para implementar aquellas soluciones que compramos de las revistas. Que por su propio nombre tienen un precio bastante alto para la capacidad económica de esas pequeñas empresas.

(ENGLISH TRANSLATION)

One of the most important subjects principally for the small industry is the development of solutions that are economically feasible to implement. That they should be at the same time efficient in the sense of resolving the problem and efficient in such a way as to be economically feasible to bring about. Our small businesses do not have the economic capacity to implement those solutions that we find in magazines which by their name have a high price for the economic capacity of those small businesses.

Nosotros tenemos una actitud hacia la seguridad como cultura, que es desde varios puntos de vista diferentes a la cultura de San Juan. El otro día estaba pasando--guiando por la calle y encontré una 'van' con la puerta abierta y cuatro pasajeros en la parte de atrás de la 'van'. Bajé la ventana y dije, 'oiga, cierre la puerta, es peligroso' y me terminaron insultando. Como yo me estoy metiendo en su espacio. O sea, nosotros tenemos una cultura hacia la seguridad, que debe de ser estudiado. Dado que los métodos de atacar ese problema son diferentes. Es una actitud cultural que no necesariamente como sistema de ventilación o con tapones de oídos lo vamos a resolver.

Nuestras organizaciones están cada vez más apretadas de tiempo y eso afecta la estabilidad y sostenibilidad humana y económica del negocio. Desafortunadamente, algunos de los costos más importantes en el salario no se contabilizan a nivel empresarial. Cuando nosotros presionamos al trabajador, al ingeniero o al administrador que trabaje doce, diez, catorce horas al día, esa situación no es una situación sostenible. Hablamos tanto de sostenibilidad desde el punto de vista ambiental y sostenibilidad desde el punto de vista humano, nunca se menciona. Eso tiene un costo altísimo a la industria y eso es bastante importante.

(ENGLISH TRANSLATION)

We have an attitude towards safety as a culture that is from various points different than the culture of San Juan. The other day I was passing--driving along a street and I found a van with the door open and four passengers in the back of the van. I lowered my window and said, 'listen close the door, it's

dangerous' and they ended up insulting me. How do I dare get into their space? We have a culture towards safety that should be studied since the methods of attacking that problem are different. It is a cultural attitude that is not necessarily a ventilating system or with ear plugs it is going to be solved.

Our organizations are more and more short of time and that affects the human stability and sustainability and also the economics of business. Unfortunately some of the most important costs in salaries are not calculated at the business level. When we pressure the worker, the engineer or the administrator to work twelve, ten, fourteen hours a day that situation is not a sustainable situation. We speak so much of sustainability from the point of view of environment and sustainability from the human point of view is never mentioned. That has a high cost to the industry and that is also important.

Verbal Comments 2006/12/06 (English translation follows):

Buenas tardes. Mi nombre es Cruz María Nazario. Yo soy epidemióloga y soy profesora de la Escuela Graduada de Salud Pública y enseño un curso de Epidemiología Ocupacional. Tenemos un programa graduado en Higiene Industrial en la Escuela, que prepara y capacita muy bien a personas que van a dedicar sus carreras profesionales en este campo.

Durante la tarde, agradezco la oportunidad de hablar con ustedes un poco y presentarles mi preocupación sobre algunos asuntos relacionados con la salud y la seguridad de nuestros trabajadores. Primero, todos los años vemos en Puerto Rico la foto en el periódico donde se presenta este trabajador que murió en una construcción porque se derrumbó un talúd de tierra. Y la descripción que se hace de ese evento, es un accidente ocupacional. Lo que sucede es que si le llamamos accidente ocupacional, como buen salubrista sabemos que entonces no tenemos nada que hacer para resolverlo.

Durante mi investigación en los documentos que se presentan de las estadísticas del Departamento del Trabajo, uno encuentra la utilización de la palabra 'accidente' y también la palabra 'incidente'. Y yo creo que un esfuerzo muy importante que podría hacerse de este grupo de personas interesadas en este campo, es nombrar las enfermedades por su nombre. No son accidentes, son actos de negligencia. Y cuando lo llamamos correctamente, adjudicamos responsabilidad.

Y mi preocupación en cuanto a los alegados eventos que ocurren de esta forma, en la industria de la construcción, tiene que ver porque muchos de estos empleados, son empleados inmigrantes y en

ocasiones son ilegales. Así que solamente vemos cuando ha ocurrido un incidente de tal magnitud que ese trabajador muere. Pero hay muchos eventos que tenemos conocimiento, que no se registran en las estadísticas, por el hecho de que estamos hablando de trabajadores ilegales en donde se les dice que no pueden informar el hecho de que han sido lesionados o han recibido algún trauma, algún problema de salud.

Como epidemióloga, me interesa mucho conocer en el análisis de la tendencia de los eventos, los incidentes, los traumas y las lesiones en los trabajadores, que en términos generales podemos demostrar que desde 1980 al 2000, hay una disminución en las tasas de incidencias de lesiones. Pero no es parejo para todas las industrias. Y vemos como en la industria clasificada como gobierno, hay un descenso de un seis por ciento por año en esos últimos veintidos años.

Pero sin embargo, en las otras industrias, lo que vemos es un aumento, pero matemáticamente al hacer la suma, esta disminución aparece como que estamos haciendo algo positivo para disminuir las lesiones ocupacionales. Cuando en realidad no sabemos si esos datos estadísticos por la forma en que se recogen, puedan estar ocultando algún problema que amerite y que tenga solución con intervención temprana.

Hay que nombrar a las enfermedades como enfermedad, hay que nombrar a los incidentes como problemas de salud, tenemos que analizar y ver porque está disminuyendo la tasa de incidencia en una industria y ver cuales son los factores que han promovido ese descenso. Porque podemos ver en términos positivos, si funciona en una industria podemos entonces aplicar, modificando esas estrategias que verdaderamente ha sido efectivas para disminuir los riesgos en las otras, en donde no hemos sido efectivos.

Mi propuesta en el día de hoy es que le llamemos a los eventos como problemas de salud, que identifiquemos los factores de riesgos que los promueven. Y que también podamos hacer comparaciones y evaluar en donde hemos sido efectivos, identificando cuales son las estrategias e intervención que protegen a nuestros trabajadores de esos eventos que le causan lesiones y trauma. Gracias.

(ENGLISH TRANSLATION)

Good afternoon. My name is Cruz María Nazario. I am professor of the Graduate School of Public Health. We have a graduate program in Industrial Hygiene in this school that prepares and makes competent the persons who are going to dedicate their professional careers in this field.

During this afternoon I appreciate the opportunity to speak with you and present my preoccupation about some things related to health and safety among our workers. First, every year we see in Puerto Rico photos in newspapers where is presented this worker who died in a construction project because there was a landslide in the "talud" of the soil. And the description made of that event is an occupational accident. What happens is if we call it occupational accident, as good health people that we are, we know that we have nothing to do to resolve this.

During my investigation in the documents that are presented of the statistics of the Department of Labor one finds the utilization of the word 'accident' and also the word 'incident'. And I believe that an important effort from this group of interested persons in this field would be to give the proper name to this. They are not accidents, they are acts of negligence. And when we name them correctly, we adjudicate responsibility.

And my preoccupation as to the alleged events that occur in this manner in the construction industry has to do with the fact that many of these employees are immigrants and on occasion they are illegal, so that we only see when an incident has occurred of this magnitude when the worker dies. But there are many events that we know of that do not register statistics by the fact that we are speaking of illegal workers where they are told they cannot inform about being injured or have had some trauma, some health problem.

As epidemiologist I am very much interested in knowing the analysis of the tendency of the events, the incidents, the traumas and the injuries in workers which in general terms we can demonstrate that from 1980 to 2000 there is a decrease in the lists of incidents of injuries. But it is not equal for all the industries. And we see how in the industry classified as government, there is a decrease of six percent per year in those last twenty-two years.

But nevertheless in the other industries what we see is an increase mathematically on doing the numbers this decrease appears as if we are doing something positive to decrease the occupational injuries when in reality we don't know if those statistical data by the way they are compiled, can be hiding some problem that merits and has a solution with early intervention.

The illness has to be named as illness, the incidents have to be named as health problems, we have to analyze and see why there is a decrease in the numbers of incidents in an industry and see which are the factors that have made that decrease. Because we can see in positive terms if it functions in an industry and then apply it, modifying that strategy that really has been effective to reduce the risks in others where we have not been effective.

My proposal on this day is that we name the events as health problems, that we identify the risk factors that promote them. And that we could also make comparisons and evaluate where we have been effective, identifying which are the strategies and intervention that protect our workers from those events that cause injuries and trauma. Thank you.

Verbal Comments 2006/12/06:

Good afternoon. I would like to appreciate the opportunity to present what I think is one of the various characteristics of the situation of injury and illness in Puerto Rico. Because "latinos" are just the second largest group, in terms of incidents and severity of this, so I congratulate NIOSH and NORA, specifically in their vision of including us in this activity.

I'm an associate professor at the University of Puerto Rico, the Medical Science Campus. And I am also the president of the local section of the Industrial Hygiene Association. I'm going to skip the background on the association, but I would like to say that in Puerto Rico, the local section represents around two hundred and fifteen members, that belongs to this organization. The majority of them are alumni of the Industrial Hygiene Program and others are professionals that have very direct intervention in terms of industrial hygiene.

Our objective is to promote study and evaluation of environmental stresses in organizations and its surrounding communities. I have developed the presentation in different topics, some of them are very-do have a sectorial approach to them. I would like to know--I would like to mention that some of these topics, are topics that have already been intervened by NIOSH and the scientific community. But some of those findings have not been translated into practice. And my intention is to actually motivate--those are going to be developing these resources agenda to move into the RTP [editor: "r2p") section that NORA stands for.

In terms of the general concerns, we have interest in the epidemiology post-studies that look at sico-social [editor: "psycho-social"] nature of cumulative trauma disorders, specifically among "latinos" employees. As well as a epidemiology study that look at the impact of the change into the new record keeping standard that went on, on 2001. We believe that these changes actually perclude us from getting real intelgence in terms of where and what type of injuries we are actually looking in the work place.

We have several issues regarding indoor air quality and some of these issues came directly from our practicing members. Evaluation of the actual guidelines for indoor air quality, specifically those internal environment that are depending on air conditioning. We have an issue with the electricity here in Puerto Rico and when we don't have electricity, most of our systems just go down.

Evaluation of the indoor air quality guidelines for spaces specifically in tropical weather that depend on air conditioning. We need--we believe we need action for contaminants measuring technologies and control interventions. Action leadings like some allergens that cause occupational asma. Action limits that--pest control chemicals under using indoor air that are dependant on air conditioning.

Submitted written statement:

COMMENTS ON BEHALF OF THE INTERNATIONAL LONGSHORE AND WAREHOUSE UNION REGARDING
THE NATIONAL OCCUPATIONAL RESEARCH AGENDA

Submitted by:

John M. Castanho

Chairman, IL WU Coast Safety Committee

This is submitted in writing as the official position of the ILWU regarding what needs to be done to improve workplace health and safety conditions of shipping terminals up and down the west coast. These comments will reflect our historic and current position on this matter, as well as a synopsis on what we feel needs to be done in the near, as well as distant future. We ask that the National Institute of Occupational Safety and Health (NIOSH) give this their full consideration when developing their National Occupational Research Agenda (NORA) for the next ten years.

Historically, longshore work on the docks consisted of many hazards, most of which have evolved over time. Years ago, the work was so dangerous that it was not only common, but also an accepted fact that longshore workers were either killed or maimed with alarming regularity. Work shifts that lasted twelve hours or more were common, adding to the already unsafe conditions that were prevalent. The work was arduous, sweat-filled and backbreaking. There were very few safety provisions covering longshore workers at that time. If someone were injured or even killed, they would simply be carted off and replaced by someone else eager to earn a day's wage. These were the dark days of working on the docks.

With the advent of mechanization in the 1960's, it became readily apparent that a need existed for safety regulations to be instituted and implemented in the workplace on the waterfront. There were two reasons for this. The first was obvious; the introduction of labor-saving machinery brought with it a new set of hazards that led to even more unsafe conditions. Trucks, huge forklifts, cranes, and other container-handling equipment took the place of hundreds of men handling cargo by hand. The more machinery that was present, the greater the risk was of someone getting crushed or run over by it. The second reason proving the need for more safety regulations was more subtle, but just as prevalent. Longshore workers who had been working twenty, even thirty years on the waterfront became diagnosed with asbestosis and asbestos-related cancer. This was due to fact that there were no basic safety provisions governing the safe handling of asbestos in bulk form, and these workers had been exposed to it over the course of many years.

Over the next three decades, the ILWU was successful in negotiating safety regulations with the Pacific Maritime Association. These negotiations took place every three years, and were aimed at addressing safety issues that were of concern to workers who endured an ever-changing work environment. As new machinery and modes of work operations came about, so to did the need to incorporate basic safety rules to govern them. For years, the ILWU and the PMA recognized that a safe work environment was in the best interest of everyone involved with working on the waterfront. Based upon the principle of a safe work environment, there was a mutual respect that was forged between labor and the employers. A safe workplace not only decreased the chances of an industrial accident, it also provided safeguards to the environment and the communities that were adjacent to waterfront terminals.

In the late 1990's, this mutual respect was replaced with skepticism and mistrust. The employers complained that the safety rules that had been negotiated were limiting the ability to have their ships loaded unloaded in a "timely" manner. The union did not agree with this assessment. Accidents and fatalities were on the rise. This was due to a disregard of the safety standards that had been adhered to for years, and a "speedup", or an unsafe, increased rate of work was demanded by employers.

Reports of illnesses have also increased in the last ten years, particularly respiratory-related types. Asthma, bronchitis, lung and throat cancers, heart disease, and a host of other ailments are becoming more and more commonplace. Unfortunately, this situation is not confined to the docks, but has spread to the communities that surround these ports. The biggest culprits that can be readily targeted as a problem are diesel exhaust and ship's stack-gas emissions. Each year, tens-of-thousands of trucks drive to and from the ports, hauling containerized cargo through our communities to their final destination. Thousands of ships enter U.S. ports each year as well, their stacks emitting thousands of tons of carcinogenic smoke. Both sets of emissions not only find their way into the bodies of the longshore workers, but also to the adults and children who live, work, and attend schools nearby. This condition adversely affects thousands of people, creating "cancer-clusters" in different regions. Separate studies

recently conducted by the University of Southern California suggest that communities located many miles inland, away from the ports of Los Angeles and Long Beach are incurring these clusters as a direct result of the pollution created by the ships and truck traffic in these ports.

The ILWU has long held the position that cleaner-burning fuels are needed on port terminals, and that the ships that call here need to use low-sulfur, or even “ultra-low”-sulfur bunker fuel. During the 2002 Safety Negotiations, the union bargained for weeks, unsuccessfully, to negotiate the use of biodiesel for use on all waterfront equipment that ran on diesel fuel. We argued that it was technology that could be implemented immediately, that could almost eliminate most harmful emissions. There was lengthy discussion on the viability of liquefied natural gas and compressed natural gas. The employers pointed that the federal government does not have a permissible exposure limit (PEL) established for diesel emissions. Rather, they have a “recommendation” of 20-micrograms/cubic meter of air (which is actually the PEL in the state of California). They did not feel the need to spend money on something that would clean up the air and make it safer for longshore workers, as well as all who live nearby and beyond.

NIOSH needs to begin a long-term analysis of the air quality problems plaguing our nation’s ports and their surrounding areas. Short-term studies are only good for generating data to solve short-term problems. What the industry is creating are long and permanent problem. What the industry is creating are long and permanent problems. There is a need to have funding made available through the federal government to ensure that a long-term commitment can be realized. Further studies into the health hazards of air contaminants also need to be continued. This problem will only worsen over time. As shipping volumes continue to increase, so too will the current problems that it causes. The sooner that NIOSH takes steps towards eliminating this problem, the sooner our workers and citizens will realize fewer health problems associated with the pollution generated by these ports.

Submitted written statement:

R. ERIC LEBER, Ph.D
4411 King Drive
West Richland, Washington 99353

January 15, 2006

To Whom It May Concern:

I am writing as a Chemistry professor at Heritage University (Toppenish, Washington), a researcher focusing on alternative (primarily non-food) uses of agriculture, and a member of El Proyecto Bienestar (a partnership among the University of Washington, the Yakima Valley Farm Workers Clinic, the Northwest Communities' Education Center, and Heritage University dedicated to protecting the health and well-being of local agricultural workers and their families).

For several years, my students (90-percent of whom are Hispanic or Native American) and I have been making and testing biodiesel fuels, ethanol, producer gas, palletized solid fuels, biolubricants, polymer, composite materials, specialty papers, inks and wood stains, skin creams and cosmetics, nutritional

supplements, baking ingredients, animal feeds, soil amendments, and other products (more than two-dozen items in all) derived from agricultural byproducts discharged from local industrial operations.

To date, we have been accident-and injury free during the conduct of this work; since we observe the proper safety and environmental procedures.

My concern regards the implications of scaling-up these technologies and moving them out of the laboratory environment (where skilled students and faculty use proper protective gear and training to ensure the safe handling and management of chemically and biologically active materials and equipment) into the field.

I am supportive of efforts to expand the scope of agriculture to address our nation's energy, materials, chemical, nutritional, and pharmaceutical needs. These measures could lead to a substantial improvement in the availability and affordability of these items and create related jobs and businesses in economically depressed areas while reducing our dependence on foreign sources and minimizing the adverse environmental impacts of current practices.

These measures could also lead to a substantial increase in the number of chemical, biological, electrical, mechanical, and perhaps radiological risks faced by agricultural workers and their communities, to the extent that the commercial deployment of these new technologies proceeds in a modular, distributed fashion (i.e., close to the farm in order to reduce the costs of transporting low-value materials).

Among these risks are toxic substances (e.g., methanol, carbon monoxide, methoxides), flammable substances (e.g., methane, ethanol, hexanes), biological substances (e.g., many micro-organisms, plants, and their substances that are new to commercial agriculture and have different characteristics and properties), electrical components (e.g., inverters, switch gear, transformers, network interconnects), mechanical components (e.g., shredders, mixers, pelletizers, gasifiers), and possibly radiation sources (e.g., gamma-rays and e-beams for sterilizing, pre-conditioning, or reacting biomaterials).

Accordingly, I urge that - in anticipation of these new directions in agriculture - communication, education, and training programs (in English and Spanish) be developed, based on the best available research and understanding of these risks and incorporating the best available detection and control technologies, and disseminated to ensure that these enterprises can proceed without exacerbating the risks of injury and illness already faced by our agricultural workers and their families.

Thank you for your consideration of this important matter. I would be pleased to respond to any related comments or questions.

Sincerely,

Eric Leber

Washington State Department of
Natural Resources

17 Jan 2006

To: Members of the National Institute of Occupational Safety & Health (NIOSH), and Members of the National Occupational Research Agenda (NORA)

From: Jim Sedore, WA State Dept of Natural Resources Safety & Health Manager
Box 47033

Olympia WA 98504-7033

Email: Jim.Sedore@WA.DNR.gov

Phone: 360-902-1133

Subject: Input on future research related to Agriculture, Forestry and Fisheries Sector

Members of NIOSH & NORA

Thank you for the opportunity to provide input about future research on reducing work-related injury and illness in to employees in Agriculture, Forestry and Fishing.

For the past 20 years, I have served as the Safety & Health Manager for the WA State Dept of Natural Resources. This state agency manages 5 million acres of land and protects 12.7 million private and state-owned forested acres from wildfire. Approximately 1,200 permanent employees, 400 summer wildland fire fighters, and 400 inmates staff the agency.

Employees file approximately 180 work-related injuries per year requiring medical care beyond first aid. Despite the exposures to wildfires, scuba diving, mine inspection and timber harvesting, the DNR has one of the lowest rates of claims/hr of any state agency. At your request, I can provide statistics on accident severity and frequency for that last 6 years.

However, critical safety and health research is needed in the following areas:

1. Age related injuries:

As retirement parameters result in older employees in the field, what can employees and employers do to reduce the number and severity of age-related injuries. I'll give 2 examples:

-- a. Injuries to load bearing joints. The number and seriousness of knee injuries are increasing significantly in field employees over 45. What can be done to improve conditioning, footwear and medical treatment for knee injuries? In the last 5 years, DNR employees have suffered 127 knee injuries costing \$321,520 including \$49,000 in time loss for an average of \$2,531/injury.

2. Creating and maintaining physical fitness in wildland fire fighters and natural resource workers:

While vehicles and equipment are great, there are many places where the fire engine or bulldozer can't go. In government, managers don't know if they can justify fitness programs and gym memberships to the taxpayer. However, many tasks in the natural resource environment require high levels of physical fitness. Objective research is needed showing if there is a value of on-the-job fitness programs on injury prevention, productivity and sick leave reduction. Ideally this research would identify the most effective fitness and conditioning programs.

This research would follow up on the current NORA research projects on "Aging Effects on Intermittent Work Capacity," "Effects of Physical Conditioning on Lifting Biomechanics," and "Evaluating the Effectiveness of a Logger Safety Training Program."

3. The upcoming work force-weak, fat and electronic

In years past, natural resource employers often hired the children of loggers, farmers and fishermen. This young population is shrinking and being replaced by young adults who are great with a joystick but have never used a chainsaw. They can operate an ipod but not a manual transmission. And, more and more of them are overweight with asthma or diabetes.

What medical exams or fitness tests are best at identifying the fittest applicants? As much of our young culture becomes more high tech, how do we teach arduous hand labor skills like digging a fire trail or operating a chainsaw to remove downed trees?

Written expansion of verbal comment 2006/01/17:

Opportunities for Reducing Injuries and Illnesses in Agriculture

Comments on the National Occupational Research Agenda for Agriculture, Forestry and Fishing.

Mitch Ricketts, MS, CSP

K-State Research and Extension

105D Walters Hall

Kansas State University

Manhattan, KS 66506

785-532-7068

mrickett@ksu.edu

The National Occupational Research Agenda (NORA) is an effective framework for guiding research in occupational safety and health. The new sector-based approach will further improve NORA by identifying the unique needs of particular industry sectors, such as agriculture, forestry and fishing. My comments on NORA today will be limited to agriculture.

Effective Partners for Safety and Health Research in Agriculture.

The Agriculture NORA will have its greatest impact if it encourages partnerships with agencies and organizations that already have trusted relationships with farmers and ranchers. Farmers cannot adopt

new methods unless they know about them. Furthermore, farmers will not adopt new methods for improving safety unless those methods are efficient, profitable, and realistic in relation to the goals and resources of the farmer. For research to have a measurable impact on safety and health, the agricultural community must be engaged to provide meaningful input at every stage of the process from research to practice.

In this regard, the Agricultural NORA should encourage more partnerships with the research and outreach programs supported by the U.S. Department of Agriculture and the nation's Land-Grant University system. The Cooperative State Research, Education, and Extension Service (CSREES) is the primary agency by which the U.S. Department of Agriculture makes programs accessible to the agricultural community. Through a network of state and local Extension Offices, Experiment Stations, and Land-Grant Universities, CSREES helps provide information, training, and assistance to farmers and agribusinesses throughout the nation. State and local employees of these programs are in constant contact with the agricultural community. When farmers and ranchers need information or solutions to difficult problems, their first call is usually to an Extension Office, Experiment Station, or Land-Grant University.

CSREES and the Land-Grant system have built close and lasting partnerships with the agricultural community throughout the U.S. These partnerships have facilitated a long history of successful interventions on America's farm. The Agricultural NORA can ensure that future agricultural safety and health efforts have a direct impact on farmers, laborers, and farm families by encouraging more projects through the state and local research and outreach programs associated with CSREES and the Land-Grant system.

Priority Safety and Health Issues and Approaches.

The Agricultural NORA will be most effective if it targets important categories of research issues, rather than specific hazards and particular methodologies. This approach will permit researchers to use current data, literature, and professional judgment to identify significant topics within the broader categories of emphasis. Some examples of important categories are listed below. These examples are not meant as a comprehensive listing. Instead, they are offered as illustrations of how research categories might be constructed.

Cooperative State Research, Education, and Extension Service (CSREES) through the U.S.

Department of Agriculture

Categorized comment or partial comment:

Category 1: Leading classes of injury and illness. To have a substantial impact on overall agricultural safety and health, NORA must target those issues that are associated with the greatest number of injuries and illnesses in agriculture. For instance:

- Transportation incidents account for the largest share of fatal injuries in agriculture. A large proportion of these are non-highway incidents (Bureau of Labor Statistics, n.d., Table R1; Myers, 1997, 1998, 2001).
- Sprains and strains comprise the most common nature of nonfatal injuries and illnesses, accounting for about one-third of incidents agriculture (Bureau of Labor Stastics, n.d., Tables A-1 and R8).
- The back is the part of the body most often injured, accounting for almost one-fifth of all non-fatal injuries and illnesses in agriculture (Bureau of Labor Statistics, n.d., Table R2).
- The most common events or exposures leading to nonfatal injuries and illnesses in agriculture are contact with objects, slips/trips/falls, and overexertion. Together, these events or exposures account for about three-fourths of all nonfatal incidents (Bureau of Labor Statistics, n.d., Table R4).

Category 2: Region- and operation-specific issues. To have substantial impact in individual workplaces, the Agricultural NORA must also place an emphasis on issues that affect particular sub-sectors and regions within agriculture. For instance:

- Assaults by beef and dairy cattle account for a disproportionately large share of fatal and nonfatal injuries in animal production (Bureau of Labor Statistics, n.d., Tables A-1 and R8.)

- In crop production, the incidence rate for amputations is more than three times the average for private industry, and the incidence rate for machinery-related injuries is more than double the average for private industry (Bureau of Labor Statistics, n.d., Tables R5 and R7).

- The Midwest tends to have a particularly high rate of injuries related to beef, hogs, and sheep (Myers, 1997, 1998, 2001.)

Categorized comment or partial comment:

Category 3: Issues that distinguish agriculture from other industries. Although this category may account for fewer injuries and illnesses than those mentioned above, research should be supported because these issues are not likely to be addressed by other research agendas. For instance:

- Pesticide exposure.
- Confined space issues in silos, manure pits, and other agricultural facilities.

Categorized comment or partial comment:

Category 4: Issues relating to the changing nature of agriculture. Research on these issues should be supported in order to address emerging trends in agricultural safety and health. For instance:

- The increasing number of "hobby farmers" in some regions means that people with little or no agricultural experience are operating machinery and handling livestock.
- The increasing number of producers engaging in "value-added agriculture" means that many producers with little manufacturing experience are hiring employees and operating small scale food processing facilities on their own farms.

Department of Agriculture

Categorized comment or partial comment:

Category 5: Vulnerable populations. Research on these issues is needed in order to address the special needs of workers in agriculture.

- For agricultural employers with 11 or more employees, Hispanic and Latino workers comprised the most common race or ethnic origin of workers suffering injuries and illnesses in 2004 (Bureau of Labor Statistics, n.d., Table R38).
- For agricultural employers with 11 or more employees, females account for about one-fifth of the injuries and illnesses (Bureau of Labor Statistics, n.d., Table R39).
- Most farm operations are small businesses. Like other small business owners, most farmers do not have effective safety programs, nor do they have easy access to resources for developing safety programs.

Department of Agriculture

Categorized comment or partial comment:

Category 6: Research approaches. Research approaches should be selected according to their potential to increase the effectiveness of safety and health interventions and to ensure the results of research are actually implemented on farms.

- All projects should include meaningful partnerships with affected populations whenever possible. Many farmers do little to prevent injuries because traditional safety approaches are often impractical to implement on farms. The best way change the safety culture is to enlist farmers and laborers to help develop approaches that are practical and profitable in their own workplaces.

- Education/translation projects should employ effective methods of communication and persuasion. Many education projects fail because they present safety information in an abstract and unconvincing manner. The effectiveness of safety training depends as much on communication strategies as it does on content.

Clean Air Filter

Categorized comment or partial comment:

Clean Air Filter is a small filter manufacturing company in Defiance, Iowa. Clean Air Filter also tests, evaluates (lab and field) and completely characterizes enclosed environmental cabs used to protect workers from hazardous air contaminants (aerosol and gas/vapor).

Clean Air Filter has partnered with NIOSH researchers at PRL and NIOSH Morgantown. These efforts concentrated on improving the testing and quality of the protection workers are receiving when working in environmental cabs. Clean Air Filter is particularly concerned because effective standards do not exist to routinely test environmental cabs to make sure they are providing acceptable worker protection. Therefore, numerous workers are being exposed to hazardous contaminants (chemicals, silica, aerosols, gas/vapor) and only have a false sense of security concerning the protection they are receiving.

Environmental cabs essentially function as large powered air-purifying respirators. Respirators have established federal criteria that must be met to be certified as giving an APF value. No critical criteria exists for enclosed environmental cabs. Clean Air Filter knows the importance of performance standards, maintenance, and recertification to continually assure cab routine performance.

Clean Air Filter is committed to this effort and will continue to partner with NIOSH to make these efforts become a reality so that workers are receiving the protection they need.

Categorized comment or partial comment:

I have been working on coal mine safety and health issues for many years. In the past, I received funding from NORA sponsored research programs. I have two comments for the mining council to consider:

1) MINER Act of 2006 mainly focuses on safety. NORA should focus on safety and health. NORA should encourage basic sciences with inter-disciplines addressing multiple coal mining problems or differences in coals among various coal mine regions. An example is that pyrite (FeS_2)-containing coal is known to cause spontaneous coal combustion, acid mine drainage, and acid rain. We have found that oxidation products from the same pyrite can cause pulmonary diseases in coal workers. However, products from Eastern coal mines (e.g. PA and WV) are stable and bioavailable, which can lead to lung damage. On the other hand, the formed products are not stable in the Western coal mines (e.g. CO and UT) because of the presence of calcite (CaCO_3). This may explain why the incidence of lung disease or accident is higher in the east coal miners than in the west coal miners. This type of studies should receive funding. To make my point clear, I have attached a paper that was published in Environmental Health Perspectives.

2) NORA should also encourage studies on prevention of safety and health problems in relation to the development of new methodology for mining. Again, basic sciences on physico-chemical characteristics of coals among different regions are important. For example, we have found that addition of calcite into the PA coals can attenuate some of the PA coals' toxicities (see attached paper published in Journal of Toxicology and Environmental Health). We would propose to add calcite into the water spray when mining. This would reduce lung disease incidence, acid mine and acid rain problems. However, we could

not find a collaborator to do a feasibility study. The mining council should encourage this type of collaboration.

It may seem that my comments are self serving but I do think that they are important for the council to consider. Thank you for your time in this matter. If you have any questions, please let me know.

Written expansion of verbal comments 2006/01/23:

National Institute of Occupational Safety and Health

National Occupational Research Agenda

Presentation on Safety and Health Issues in Healthcare

Houston, Texas

1/23/06

Kaiser Permanente Introduction

The following comments are submitted on behalf of Kaiser Foundation Health Plan, Inc., Kaiser Foundation Hospitals, and the Permanente Medical Groups, collectively known as the Kaiser Permanente Medical Care Program ("Kaiser Permanente" or "the Program"). The Program provides health care services on an inpatient and outpatient basis to over 8.3 million members in 9 states and the District of Columbia. Kaiser Permanente includes over 12,000 physicians and more than 148,000 non-physician employees and operates 30 medical centers and more than 430 medical office buildings.

Healthcare's Issues

In 2004, hospitals reported more non-fatal illnesses and injuries than any other industry and healthcare retained the fourth largest non-fatal incident rate compared to other industrial sectors. Healthcare has

3 issues, cultural, ergonomic and hazardous exposures. These issues cut across all aspects of healthcare systems that include hospital, medical office buildings, laboratories, pharmacies, and radiology.

The Cultural Challenges of Healthcare

While the healthcare industry has a good picture of what the current injury risks are, unique cultural challenges make reducing workplace injuries extremely challenging.

The biggest challenge that the healthcare industry faces is creating a culture of safety within the complex hierarchical structure. The practice of medicine, while moving more toward team-based care, is still predominantly practiced by individuals with a high degree of autonomy. Autonomy, coupled with a significant hierarchical infrastructure, makes it very difficult to adopt performance improvement mechanisms like behavior-based safety which requires a degree of "psychological safety" that doesn't presently exist, including a willingness and openness to give and receive feedback. In addition, there is a history of "blame and shame" following adverse outcomes which has created a fear of reporting. Implementing an Ombudsman program is one way to support physicians and other caregivers when the report.

Creating a culture of safety in healthcare is also challenging because of a rapid and constantly changing environment. New health and safety issues arise regularly with the creation of new practices, technology, and the changing demographics of the population.

New priorities always arise in healthcare and often take the spotlight off workplace safety. New regulation that affects the industry is quite frequent and can consume the organization's efforts. The escalating cost of healthcare has put a new emphasis on efficiency and decreasing cost. In addition, healthcare workers must work long hours with declining numbers of nurses in the profession juggling more responsibilities than before.

Recent revelations about the prevalence of medical errors have shifted more focus on patient safety which may directly compete with worker safety. The link between healthcare occupational safety and patient safety will be a critical component of moving the two fields forward together instead of in opposition. One example is using lifting equipment which eliminates worker injury during assisted patient transfers and is also safer for the patient because there is little chance of being dropped.

The ability of an organization to maintain a productive and healthy workforce is becoming exceedingly difficult in the United States. The prevalence of chronic diseases such as obesity, diabetes, and asthma is increasing rapidly resulting in lost productivity and higher costs to America's workforce. The healthcare industry is learning that promoting employee wellness and integrated disability management within the workplace is not only the right thing to do, but can

Ergonomics

Ergonomic related injuries are a primary contributor to the overall injury rate in healthcare. Sixty percent of Kaiser Permanente's workplace injuries are related to strains and sprains and ten percent are attributed to work-related musculoskeletal disorders. The ergonomic risks that healthcare workers are exposed to vary greatly. Slips, trips, and falls may result in acute injuries while workers who do material handling, patient handling, or work with computers and diagnostic or screening equipment are at risk for developing work-related musculoskeletal disorders.

In addition to existing ergonomic risks, new medical technology and electronic data systems are being introduced at a faster rate than ever before creating new and more numerous exposures. The electronic medical record is becoming a standard in healthcare and it is important to build good ergonomic practices into the implementation of electronic medical records systems.

The changing demographics of the U.S. population introduce new ergonomic concerns as well. More chronically ill and obese patients who may not be able to assist themselves need assisted transfers in greater numbers than before. As medicine treats more patients in the outpatient setting, there is greater potential for injury to workers who must assist patients who could have previously walking in and out on their own.

Hazardous Exposure and Unknown Hazards

Healthcare is unique in that not only are workers exposed to known hazards like chemical disinfectants and waste anesthetic gases, but there is also a possibility that exposure to an unknown biological respiratory hazard could occur at anytime. Implementing a system to effectively evaluate and control exposure to an unknown respiratory disease is extremely difficult. The issue is exacerbated by the need for care providers to continue to treat patients in an effective manner which limits the ability to eliminate exposures. Patients do not expect their healthcare worker to be wearing certain types of respiratory and protective gear during regular appointments. In addition, respiratory protection against biological hazards continues to be one of the most difficult safety programs to implement in the healthcare industry. Healthcare-specific evidence-based science is needed.

There are challenges in evaluating exposures to known hazards as well. Exposure monitoring and modeling for chemicals are constantly becoming more refined. Historical monitoring continues to lose validity as time moves on and technology evolves making it even more difficult to get a true picture of what healthcare workers' exposures are. The research on exposure and health effects does not always move quickly so in some cases, we do not truly understand what the exposures actually mean to our employees.

Hazardous drugs is one example. There is substantial evidence that hazardous drug exposures during preparation and administration may be more prevalent than previously thought. However there are few established methodologies available to measure airborne or surface concentrations of hazardous drugs and very little dose-response information available to evaluate exposure data.

High level disinfectants pose similar exposure concerns. New products are frequently introduced with little or no exposure data or sampling methodologies available to assist in evaluating potential health risks to healthcare workers.

Conclusion

Healthcare currently faces many challenges in maintaining a safe and healthy workplace. The biggest challenge is creating a safety culture that is adaptable to the complex hierarchical structure and multiple priorities of healthcare. In addition, the industry needs to create new ways of reducing ergonomics risks and assessing hazardous biological and chemical exposures.

We appreciate this opportunity to comment on the National Occupational Research Agenda and offer to partner with NIOSH to refine the agenda for healthcare research for the next ten years. If there are questions regarding any of Kaiser Permanente's comments, please do not hesitate to contact me.

Sincerely

Barbara Smisko

Alternatives to the Regulatory Witch Hunt

Barbara Kanegsberg

BFK Solutions, LLC

We regulate chemicals based on what I can best describe as a regulatory witch hunt. Regulatory agencies address safety and environmental problems based on management of individual chemicals or classes of chemicals. As a chemical proves efficacious in various processes, the usage increases. The chemical then comes under increasing regulatory scrutiny. Based on environmental or worker safety profiles, it is placed on a list of restricted or even banned materials. Industry then substitutes one or

more chemicals that then in turn come under scrutiny, and the cycle continues. The chemical witch hunt automatically targets high performance chemicals, with the unintended consequences of development of mystery mix formulations, an increase in the use of multiple chemicals where the toxicological and environmental impacts are not well understood, and secrecy on the part of chemical producers. To compound the situation, the various regulatory agencies publish lists of chemicals indicating safety and environmental attributes that are contradictory and confusing to industry, to community activists, and to regulators themselves.

This approach is damaging to industry, workers, communities impacted by industry, and the overall environment. We need a paradigm shift. Examples of better approaches include:

- Process management, not product bans
- Simplification, Nationalization, and Globalization of standards and regulations
- Holistic regulatory approach, combining safety and environmental
- True sustainable regulations

My background

I am an independent consultant in cleaning, surface preparation, and surface attributes with over 30 years of industrial experience. My background includes biology, biochemistry, clinical chemistry, and industrial process development.

My for-profit consultancy is BFK Solutions, LLC. As independent advisors to the manufacturing community, we do not accept commissions or referral fees for chemicals or equipment. My comments do not reflect the promotion of a chemistry or technology.

I also have a separate non-profit organization, Surface Quality Resource Center. Activities include education and outreach to industry and to communities impacted by industrial operations.

They call me the cleaning lady, because my expertise is in precision cleaning or critical cleaning. I don't do windows. I do help manufacturers develop processes to clean and manufacture optics, as well as many other products.

About critical cleaning

The field of critical cleaning encompasses far more than optics fabrication. Virtually all manufactured objects require cleaning (removal of lubricants, lapping compounds, etc.) to achieve the appropriate surface characteristics and to assure product reliability. Cleaning involves not only chemicals but also the process, including cleaning agents, cleaning force, heat, and time.

The demand for effective cleaning chemicals and cleaning processes will increase. As medical devices become smaller and with an expected product life of decades, cleaning becomes more critical, not less. As devices and products approach the micro and nano level, the ratio of surface to volume increases. As an end-point, the surface becomes the product. Without appropriate surface preparation, the health and well-being of all individuals will be compromised.

Traditional approach

Traditionally, agencies have regulated the chemical. Beginning in the mid-1980's, there was program to eliminate ozone depleting substances (ODS). In manufacturing this meant not only replacing common

refrigerants. I headed a team involved in ambitious programs to revise critical manufacturing processes that depended on CFC-113 (a Freon) and 1,1,1-trichloroethane (a chlorinated solvent). We successfully eliminated ODS in aerospace applications; and in 1996, I received a U.S. EPA Stratospheric Ozone Protection Award.

A plethora of lists

I treasure my EPA award. However, I have come to the conclusion that eliminating chemicals of utility to industry is not the answer. The chemicals that were adopted as replacements for eliminated ODS chemicals have their own safety and environmental baggage. As we learn more and more about the safety and environmental consequences of industrial chemicals, increasing alarms are raised.

Over the past 20 years, regulatory agencies at the International, Federal, State, and Local levels have published list upon list of chemicals that are banned, regulated, or determined to be what might be thought of as “environmentally challenged” or “politically incorrect.”

Confusion Demotivation

The various “no-no” lists are counterproductive for communities and for industry. Given the number of chemicals of potential industrial utility, the lists are likely to grow.

SQRC, our non-profit organization, works with the Willits Community Action Council. Willits, a small town in Northern California, has been adversely impacted by industrial chemicals. While many of the activists have become potentially and technically savvy, they continue to be frustrated by conflicting environmental regulations, by incomprehensible lists, and by the definitions of what constitutes “dangerous” levels of particular compounds that may vary among lists by orders of magnitude. Achieving successful remediation and meaningful medical monitoring are daunting tasks; the regulatory information has added to the confusion. These conflicts also provide ammunition to legal advisors of those seeking to avoid dealing with the problems of site cleanup and medical monitoring. The community is left to struggle with severe health and environmental impacts.

As part of my consultancy, I am a member of the Joint Solvent Substitution Working Group (JS3WG), a consortium of the military services and of NASA with the laudable goals of streamlining implementation of non-HAP and low or no-VOC chemicals throughout the military and of normalizing processes. Discussion of the relative merits of lists and of lists of lists occupies a great deal of time and effort. Progress would be faster if it were fewer, more consistent safety and environmental regulations.

Similarly, in industry, workers struggle to understand the toxicity of industrial chemicals. Some naively accept statements by vendors; or, they assume that any chemical that is not on a safety or environmental regulatory list of restricted or banned chemicals must be safe. Managers and their advisers navigate complex lists and requirements, struggling to keep their production lines running.

Particularly, in Southern California, industry is left with a very short list of chemicals that can be readily used. Some use inefficient processes that because they must be repeated and because of increases in process time, effectively increases exposure of workers to potentially dangerous chemicals. These same processes subject nearby communities to chemical soups with virtually unknown toxicity and environmental profiles.

Despite hopeful phrases like “cross media implications,” regulatory agencies often have little to no understanding of regulations being promulgated in an office down the hall, let alone those that are

developed by another agency. I recently spoke at one local agency; the attendees all wanted to understand the regulations at a second local agency; and they commented about complex, ambiguous, and conflicting rules. If regulatory personnel have problems understanding the rules, imagine the problems for people who are trying to run their business or keep their communities and children safe.

Creative Foundations

Make no mistake, all industrial process formulations use chemicals; and this is true for both solvent based and water based products. Manufacturers of cleaning agents and coatings often formulate around lists of restricted chemicals. If one chemical is on "the list," they find another one that is sort of like it. Perhaps they use five compounds, where one would have previously sufficed. We have seen an increase in chemical blends, or "mystery mixes."

The trend also leads to use of a greater assortment of chemicals with poorly-established toxicological and environmental characteristics. It also increases the opportunity of chemical synergy, and that synergy may mean enhanced safety or environmental issues.

The cleaning market is fragmented. Given increased regulatory restrictions and diverse process requirements, it is likely to become more fragmented. In many cases, there is little or no economic incentive to develop new products.

No Miracle Chemical

A new, miracle chemical is unlikely. There are technical and physical constraints, so while it is desirable to think outside the box, thinking outside the periodic table of the elements is more difficult. A safe, environmentally-preferred, and effective chemical is counterintuitive. Human beings, the environment, and industrial process agents all contain compounds that are chemically-related. Therefore, if a cleaning chemistry is effective against major soils of interest, there is the potential for interaction with people and/or with the environment.

Some companies have also elected to engage in what I term "political chemistry." That is, they approach regulatory agencies using scare tactics to warn them of potential safety and environmental disasters if the products of the competition are allowed to remain on the market. This has led to regulatory hold-ups and a disincentive to introduce new, potentially useful products.

Finally, fear of the regulatory with hunt leads some of these same companies to be less than transparent to their customer and to the public about the toxicity profile of their own products.

A more productive approach

The generation of ever-growing lists of undesirable chemicals produced by multiple agencies is counterproductive. We need a more proactive, sustainable approach. I do not have all of the answers. I do have a few ideas.

Process management, not product bans

We need aggressive, targeted cleaning agents and aggressive cleaning processes. Restricting cleaning chemistries to benign products that do not do the job efficiently is dangerous and probably damaging to the environment. Such an approach is like attempting to protect surgeons from cutting themselves by restricting them to blunt, plastic knives instead of scalpels. Instead, we regulate the process; and we have standards for doctors.

By analogy, industrial processes, not individual chemicals must be addressed.

Simplification; Nationalization; Globalization

Right now, air and water standards in California are different from those in New Jersey. This is an unproductive situation. Because industry may dispute the more stringent regulations, neither the citizens of New Jersey nor those in California stand to benefit.

The simplified worksheets developed by ATSDR are helpful. Standardization is necessary to achieve true understanding of safety and the environment.

Holistic regulatory approach, combining safety and environmental

Safety and environmental regulations should be normalized and made consistent.

Yes, there are different requirements for those using a chemical in the workplace versus those in communities being exposed to air and water contamination. However, it is unreasonable that the standards are not coordinated. There are instances where a chemical is environmentally-preferred; but it may have a less than optimal worker safety profile. Environmental regulations may compel industries to use such unsafe chemicals rather than to develop overall less emissive processes.

Sustainable regulations

We ask manufacturers to develop sustainable processes. We need sustainable regulations. Restricting industry to ineffective chemicals is incorrect, short-sighted, and counter-productive. An inefficient or ineffective manufacturing process, a process that results in rework or waste is, by definition, wasteful. Such a process does not promote pollution prevention.

Written expansion of verbal comment 2005/12/05:

Comments of

Brenda Cantrell, Director
Railway Workers Hazardous Materials Training Program
National Labor College

Before Town Hall Meeting

Input for the National Occupational Research Agenda
National Institute for Occupational Safety and Health
College Park, Maryland

December 5, 2005

Thank you for the opportunity to address this meeting and share with you the very important research needs associated with the occupational safety and health of railroad workers. Over the next decade, we urge NIOSH to continue its intervention-oriented research, research that saves the lives and health of workers. Research associated with rail worker safety and health is sorely needed.

My name is Brenda Cantrell. I come to you as director of the Railway Workers Hazardous Materials Training Programs, a program that over the last 15 years has formally trained approximately 20,000 railroad workers in every state across the country (except Hawaii which has no railroads). Because of the active peer trainers teaching in the program, there are also hundreds, perhaps thousands, of additional contacts a year when these trainers are on-the-job and over lunch, or a break, they teach about hazards or about how to use resources to understand chemical exposures; where they discuss the importance of personal protective equipment, etc. Funded by the National Institute of Environmental Health Sciences, and run by the National Labor College, the Rail Program is also associated with the AFL-CIO Departments of Occupational Safety and Health and of Transportation Trades, the North American Railway Foundation, and 7 rail unions: The Brotherhood of Locomotive Engineers and Trainmen, International Brotherhood of Teamsters; the Brotherhood of Railroad Signalmen; International Brotherhood of Boilermakers; National Conference of Fireman and Oilers, SEIU; Transportation-Communication Workers International Union, Brotherhood of Railway Carmen; and the Transport Workers Union. The Program also works in conjunction with ERC faculty from John Hopkins, to do medical testing before trainees don self-contained breathing apparatus and chemical protective clothing and to teach toxicology. Our trainees work on the major railroads as well as commuter and short-line railroads.

There are approximately 160,000 railroad workers in the United States. Freight revenue alone, in 2004, was \$40 billion. With approximately 500,000 rail freight cars, there were 30 million carloads annually. Each car weighs approximately 60 tons, with the average train carrying well over 3000 tons. In 2004, railroads carried 1.8 billion tons of freight, totaling 1.7 trillion ton miles.

The health risks facing rail workers are among the most significant of any workers. According to the International Labour Organization, "50 percent of transported goods are dangerous...85 percent of chlorine, which is one of the very dangerous chemicals, is transported by rail." Other highly dangerous materials transported regularly and in large quantity by rail include anhydrous ammonia, sulfuric acid, nitric acid, methanol, and phenol. During course sessions, trainees share information with the class about work colleagues who have become ill, and sometimes died, from diseases that they assume were work-related. Sometimes it is only when they hear the health risks of some of the materials they work with, like silica or benzene, that they begin to make the links between exposure and possible illnesses. Among listed health problems are: asbestos-related diseases, asthma, brain damage, brain cancer, chest pain/tightness, colon cancer, dermatitis, dizziness, equilibrium disabilities, headaches, kidney cancer, leukemia, liver diseases, lung cancer and other severe lung diseases, lymphoma, multiple myeloma, pancreatic cancer, silicosis, stomach cancer, skin cancer, testicular cancer, and throat cancer. They report many people in their shops or on their track gangs who have gotten cancer and died at early ages-in their thirties or forties-as well as the fear that many live with, of getting cancer from work place exposure. Trainees have listed over 200 hazardous materials to which they have been exposed. It is an area begging for NIOSH research. Track workers, for example, come in contact with every hazardous material that travels by rail and drips along the track, and are thus exposed to a very complex "soup" of

chemicals. Their union, BMWED, has limited number of retirees because so many people die before retirement age.

The injury risks to rail workers are also high. In 2004, in Ohio alone there were more than 100 accidents and more than one-quarter of involved hazardous cargo. In 2005, there were, in the U.S., 2 major rail accidents involving Hazmats, each of which left rail workers and residents dead. In January of this year the puncture of rail car carrying chlorine through Spartanville, South Carolina killed the engineer and 8 other people. In June a train accident in Bexar County, Texas left three dead from chlorine. The rail sector of the transportation industry is a sector with accidents and disease, where NIOSH focus could make a vital contribution.

Evaluation research has consistently led to intervention strategies to improve the health and safety of rail workers, their families, and those in the communities near rail tracks and rail yards. Over the years, the Rail Program has adapted its programs to emerging needs and priorities. I would like to relate just three examples. First, when a derailment in Bexar County, Texas led to fatalities from chlorine leaks, analysis showed that emergency dispatchers should have known more about chemical hazards when doing their work during the incident. The Railway Workers Hazardous Materials Training Program offered all of these San Antonio area dispatchers the on-line hazardous chemical awareness course that is available to rail workers. The County required that its dispatchers take the course.

A second example was after Dine (Navajo) track workers received the four-day hazardous waste and chemical emergency response course. They became concerned not only about their own exposures at work, but the vulnerabilities of their communities, many of which have rail traveling across the Dine Nation with radioactive as well as other hazardous materials. They asked if the Rail Program could jointly train community emergency responders along with rail workers-and the Rail Program delivered two 4-day training sessions in Chinle, Arizona. Similarly, several 8-hour awareness classes have been held in New Jersey, also bringing together emergency responders with rail workers-a way to maximize coordination of responders in a rail emergency.

A third example is the increasing amount of class curriculum relating to issues of security and possible terrorist events. The dress-out simulation, that teaches about level A chemical protective clothing, was broadened into a full emergency response simulation, also teaching rail workers about incident command and the roles of skilled support in an emergency.

Rail workers face many workplace dangers, including exposure to hazardous materials routinely on a daily basis—be it in the yards, the shops, on the trains, or along the track. Training is critical, and so too is research aimed at designing life-saving interventions. NIOSH research findings, widely disseminated, often through training programs, pave the way for safer and more healthful work places.

donfarm@comcast.net

Comments of Don Villarejo, NIOSH/NORA Town Meeting, Seattle, January 17, 2006

Perhaps the most important change in U.S. agriculture during the past thirty years is the dramatic increase in the importance of labor-intensive agricultural production and the associated greater reliance on hired workers.

Three major factors account for the greater utilization of hired workers in U.S. agriculture. First, over twenty years, there has been a steady increase in the proportion of U.S. crop farm cash receipts derived from the sale of fruits and nuts, vegetables, and nursery and greenhouse products. In 1974, fruits, vegetables and nursery products were 17% of farm cash receipts from crop sales. By 2002, that share had increased more than two-fold to 40%. The physical output of U.S. fruits and vegetables, in tons harvested, nearly doubled between the years 1970 and 2000.

Second, sharply increased farm-size usually requires supplementing farm and family labor with hired labor. Among fruit and vegetable producers, the increase of size concentration is particularly dramatic. Between 1974 and 2002, the number of U.S. farms reporting 500 or more acres of harvested vegetables increased by half (from 919 to 1,416), and their corresponding aggregate acreage of vegetables harvested nearly doubled. For land in orchards, the number of U.S. farms with at least 500 acres of trees and/or vines grew by more than half (972 to 1,522), and their corresponding aggregate acres in orchards increased by two-thirds.

Third, the labor supplied by hired workers on U.S. farms now exceeds the total labor provided by farmers and unpaid family members. In the Census of Population, the number of persons who indicated their occupation was Farmer (or Rancher) declined from 830,000 in 1990 to just 587,000 in 2000. In contrast, the number of persons working 150 days or more for farmers, 'regular' hired workers, was 928,000. In the last twenty-eight years, the share of U.S. farms hiring workers for at least 150 days increased, and the number of such workers climbed by 30%.

Of course, the above discussion excludes the one million or more short-term, temporary hired farmworkers who are directly employed by farm operators or who work for labor market intermediaries, such as farm labor contractors.

Characteristics of the farm labor population

What do we know about this population? The most comprehensive, large-scale, on-going national survey of workers employed in seasonal agricultural crop services is the National Agricultural Workers Survey (NAWS). Hired livestock laborers and certain other hired farmworkers are excluded from the survey.

The most recent published report of national findings from the NAWS is based on 6,500 personal interviews conducted between October 1, 2000 and September 30, 2002, in 80 or more randomly selected counties throughout the United States. The NAWS finds that the typical hired crop farm laborer is a young, low-income, foreign-born (mostly Mexican) male with low educational attainment and who has only recently migrated to the United States. Most U.S. hired farmworkers are characterized by low socio-economic status (SES), long associated with adverse health outcomes.

The most significant development within the California farm labor market in recent times is the sharply increased flow of indigenous migrants from the southern Mexican states of Chiapas, Oaxaca, Guerrero, Puebla (Northern Sierra region) and Veracruz. A particularly useful contribution of very recent NAWS report on California farm labor is the highlighting of findings that inform aspects of this migration.

All observers agree that indigenous migrants are the fastest growing component of the state's farm labor force. According to the NAWS report on California, "Workers from (Mexican) states with high indigenous populations have characteristics that differ from other farmworkers, including a higher percentage of newcomers, migrants and with lack of authorization to work in the U.S."

Estimating the size of the indigenous migrant population within the hired farm labor force is difficult because only a relatively few choose to self-identify as 'indigenous' for reasons likely associated with their experience of discrimination within Mexico. Thus, while NAWS finds that 16% of hired crop farm workers in California are indigenous migrants, this estimate is based only on individuals' self-reported origin within one of the Mexican states with large numbers of persons of indigenous ethnicity.

Occupational safety and health among farm laborers-the California experience

The seriousness of farm labor occupational hazards was underscored in California during the Summer 2005 heat wave when statewide attention was drawn to four deaths among the state's hired crop farm workers who suffered heat illness while hurrying to pick crops.

There is persuasive evidence that vigorous enforcement of occupational safety laws reduces workplace injuries and illnesses throughout industry. Within California agriculture, the CalOSHA Agricultural Safety and Health Project (ASHIP) initiative clearly played a positive role in improving field sanitation for hired farm laborers. In the new NAWS report, nearly all workers (99%) say their employer provides both toilets and water for hand-washing. Similarly, some 96% of workers report their employer provides drinking water and cups everyday. These findings represent a substantial improvement above the levels of compliance with Cal/OSHA field sanitation regulations (83%-91%) found by NAWS in 1980-90.

Similarly, following the horrific deaths in August 1999 of 13 Fresno County farms laborers when the unsafe labor van in which they were riding was demolished in a collision with a tomato truck, the Legislature and the Highway Patrol developed a new licensing and inspection program for farm labor vehicles. The program included, for the first time, a seat belt requirement, and that vans with more than 10 passenger seats be inspected on a regular basis. Most importantly, funds were specifically earmarked for enforcement and inspection of such vehicles. The fall-off in farm labor vehicle accidents in subsequent years demonstrates once again the importance of enforcement as an injury prevention tool.

An econometric multi-variate analysis of non-cumulative injury workers compensation claim frequency for all industries in the state, conducted by the Workers Compensation Insurance Rating Bureau of California, that examined all such claims for the ten year period 1989-1998, finds CalOSHA enforcement and education was the single largest factor contributing to reductions in claims resulting from non-cumulative injury.

The available evidence indicates there has been little progress in the recent past in reducing the prevalence of both fatal and nonfatal work-related injuries to California's hired farm workers. The annual number of fatal occupational injuries or illnesses to hired farm workers varies from year-to-year. However, the Workers Compensation Insurance Rating Bureau finds the number of California farm production workers who lost their lives to occupational injuries or illnesses was relatively constant in successive five-year periods starting in 1988. The number of such occupational fatalities was 221 during the interval 1988-92, 237 during 1993-1997, and 203 during 1998-2002.

The health of U.S. hired farm workers

The health of U.S. hired farmworkers is affected by several factors, each having an influence on acute and chronic conditions in the population. A major factor is the extent of poverty affecting this group. This has its impact in diverse ways, including lack access to health care; limited nutritional choices; decrease in preventive health services (e.g., dental, vision care, vaccinations); and poor housing conditions. Some health outcomes, such as poor dentition, infectious disease, obesity and diabetes directly reflect the low socioeconomic status of the population.

A second major influence is the hazards of agricultural work. Agricultural hazards cover a broad spectrum that includes physical stresses (e.g., trauma, heat, and cold), infectious agents, chemicals hazards, psychosocial stresses and the effects of repetitive trauma. The effects of agricultural work on numerous health outcomes have been documented, although studies among hired farmworkers are

relatively few in number. Data on this population is further limited by the lack of effective surveillance systems, a paucity of studies on chronic health effects, and the mobility of the population. Health status is further limited by inadequate medical care, lack of worker's compensation for occupational injuries in many states, and the lack of legal rights owing to unlawful immigration status. As regards the latter, many social service benefits that are designed to assist low-income workers, including non-emergency health services, are denied to most unauthorized immigrants, even though they would otherwise qualify.

Third, the low educational attainment of adults in this population presents a major challenge to health educators and health care providers. Written information may be inaccessible to many in the population. The lack of English language skills among native speakers of Spanish can, in principle, be overcome with suitable bi-lingual/bi-cultural staff, but a large and increasing fraction of the population is comprised of indigenous migrants from southern Mexico and Central America for whom Spanish is as foreign a language as English. For the latter segment of the hired farm workforce, language and cultural barriers are even greater.

Fourth, many workers are uninformed or ill-informed about their rights in the U.S. workplace. The variation in legal protections from state-to-state, the pervasive "agricultural exceptionalism" in much of federal labor law, and the apparent lack of recourse to resolve workplace disputes leaves many workers with the feeling that their situation must be accepted, even if there are genuine violations of labor or safety law involved.

Finally, behavioral and other exchanges associated with acculturation, disruption of families, and migration have an important impact on the health of hired farmworkers. Many of the behavioral changes associated with acculturation, particularly among women, are reflected in worsening of health status after longer residence in U.S. Improvement in the health of hired farmworkers and farm family members, but specific attention to the health status of hired farmworkers is needed because of the unique conditions under which they labor.

Recommendations to NIOSH

An agenda for farm labor safety and health research:

- Prospective cohort studies of hired farmworkers, including surveillance of occupational and environmental exposures, acculturation, and risk behaviors.
- Cross-sectional studies should include comprehensive physical examination, such as BCD blood panels and screening for STDs.
- NIOSH should add a periodic occupational supplements to the NAWS, perhaps every three or four years, such as is standard practice in the Current Population Survey.
- NIOSH should immediately provide public access to raw data files already collected, subject to privacy protection, as is standard practice by the Census of Population and Housing (PUMS) and by the NAWS.
- Restore Environmental Justice program to address the disparities of risk faced by some ethnic minority populations.
- Retrospective analysis of the impact of CalOSHA enforcement, and of the heightened regulation of farm labor vehicles.

National Occupational Research Agenda (NORA)

February 21,2006, Los Angeles

Submitted by Linda Delp, Director

UCLA Labor Occupational Safety & Health Program (UCLA-LOSH)

UCLA-LOSH develops programs for a variety of workers from the public and private sectors, the formal and the informal economy. Our goal is to improve workplace health

and safety conditions by developing leadership skills among workers so they can participate actively in workplace health and safety programs and in the policy arena. We do so through participatory education, collaborative research and promoting policy change.

Southern California has a large immigrant workforce; today you've heard about issues affecting immigrant workers in the garment, restaurant, hotel, janitorial and construction

industries. Workers in these industries are often invisible - as a society, we tend to ignore the fact that a large segment of the population works in hazardous conditions for low wages with limited access to health care.

I want to highlight another sector of the often invisible workforce - the growing number of home care workers who provide essential personal care services to the elderly and disabled - over 100,000 In-Home Supportive Services workers in Los Angeles County alone. They are predominantly middle aged women (86%), ethnically diverse and half are immigrants. And their workplace is the home.

For the last year, I have been analyzing data from over 1600 questionnaires and from six focus group discussions conducted with home care workers, a research project undertaken with SEIU Local 434B, the union that represents the workers in Los Angeles.

It is clear that stressors related to direct care work and to inadequate home care policies are significantly associated with workers' health and job satisfaction. It is also clear that home care policies and union activities that support workers - through classes and other benefits - have a positive effect. What is not completely clear are the all the mechanisms through which these different factors operate.

I want to highlight a few issues that have emerged in the course of this research:

First, the occupational health needs of this workforce warrant concerted research efforts to better understand how to support a workforce that provides critical

services for the growing elderly population in our society. These research needs include the traditional hazards of care work such as lifting and blood-borne pathogen exposure. Even more important are the stressors associated with direct care and the organization of the work - the schedule demands, the lack of back-up support, etc.

Second, the research approach must fundamentally change. If a research goal is to collect valid data that can be relied on as the foundation for making policy

changes, which I believe it should be, researchers cannot use a traditional approach, It is critical that research be conducted through collaborative partnerships with the organizations that represent or advocate for workers; in this case, the union that represents home care workers, in other cases, public authorities, community based organizations or worker centers. Only by working in collaboration can the important research questions be identified and a relationship of trust developed that is critical to collecting accurate data, This is, in essence, what is commonly referred to as a community-based or participatory action research approach.

For example, I was involved in a study that included home care workers and union staff in developing the questionnaire that was used. We also trained home care workers to conduct the interviews in four different languages. With training and supervision, I believe workers can collect data that is as valid as that collected by traditional researchers and they may have better access to workers. One Chinese worker interviewer unable to reach Chinese home care workers insisted on making phone calls at 11:30 at night, asserting that many workers had restaurant jobs to supplement the low wages of home care work and that the late evening was the only viable time to reach them. She was right - she ultimately achieved the highest response rate of anyone on the team.

Third, data collected from workers must include both quantitative and qualitative methods. For example, unless in-depth interviews and focus group discussions are conducted, questions developed for use in a survey will be meaningless and quantitative results cannot be interpreted.

Finally, worker education is a critical component of research. Results of research must be disseminated to those most affected -the workers themselves. A collaborative approach to research that includes worker education will enhance the ability to disseminate results and to use them to improve working conditions, ultimately the goal of any occupational health research.

Farm Worker Pesticide Project

Room NB3, 5031 University Way NE Seattle, WA 98105; 206-729-0498

Statement of Carol Dansereau'

Director, Farm Worker Pesticide Project

Town Hall Meeting, The National Occupational Research Agenda

January 17, 2006; Seattle, Washington

Thank you for this opportunity to provide input. I am Carol Dansereau of the Farm Worker Pesticide Project, a non-profit organization directed by farm workers.

We urge that high priority be given to research on farm worker pesticide issues. Given the huge numbers of workers affected, the high toxicity of chemicals involved, and the documentation of widespread exposures, priority for these issues is clearly warranted. Documentation of exposures comes from many sources: extensive urine and dust sampling, air monitoring in California, Pesticide Incident Reporting and Tracking (PIRT) reports, focus groups by Washington State's Department of Health in which three of four workers recounted pesticide-induced illness at work (with almost none of these cases reported to authorities), and our new cutting edge medical monitoring program here. As you may have heard, one in five workers in the first year of the program had cholinesterase depressions after handling pesticides which triggered protective action under the program. One in ten of a broader pool of workers in the second year of the program experienced these significant depressions, and the majority of workers had depressions of some level after handling pesticides.

There are two specific research needs that I want to highlight today.

First, we call for Exposure Monitoring research. We have extensive general documentation of exposures. We have measured physiological changes in workers' nervous systems in the medical monitoring program. But we have done almost no monitoring to determine the concentrations and types of exposures workers are experiencing in general in their agricultural workplaces.

The need for such monitoring is made clear by ambient air monitoring in California. We urge NIOSH and others to read the California studies carefully. They reveal that high percentages of the general population inhale common agricultural pesticides at levels exceeding health guidelines. Researchers warn that farm workers probably experience much higher exposures because of where they work and live.

It is ironic that monitoring the air and workers' exposures is a given in other workplaces such as facilities where toxic chemicals are unintentional byproducts released in comparatively small amounts from manufacturing processes. By contrast in the farm workers' workplace massive quantities of highly toxic chemicals are intentionally released directly to the worker's immediate environment, and yet there is not exposure monitoring.

We call for exposure monitoring studies both: 1) to gather much-needed data which is currently completely missing about exposures. This data is essential for informed policy discussions, and 2) to identify the best exposure monitoring techniques which other researchers and government agencies can employ in order to monitor workplace exposures.

Categorized comment or partial comment:

The second research need that we would like to highlight is research related to pregnant farm workers and worker's children. The sad cases of farm worker children with severe birth defects in Immokalee, Florida and related media coverage have elevated this issue in the past year. Our organization is working with farm workers in Mattawa who are deeply concerned about high rates of cancer among their children. We have asked the Washington State Department of Health to investigate.

It cannot be stated with any certainty that pesticides caused children's health problems in Immokalee or in Mattawa. However, there is every reason to believe that some farm worker children in our country are experiencing birth defects, cancers or other problems are the result of exposures. Extensive laboratory and other data strongly implicate chlorpyrifos with major impairment of neurological development, for example. Farm worker children are being exposed to this chemical parentally and at home through take-home pesticides and drift.

We call for research that identifies the numbers of pregnant workers in the fields and monitors their exposures and the resulting exposures for their unborn children. We need to see tracking of birth defects and other health effects. (There needs to be increased tracking of health effects in adults, too.) It is important that researchers meet with workers in settings where they can talk, such as focus groups. It will also be important to talk to medical care providers and community groups.

Before closing, I would like to also urge research institutions and individual researchers to take on a role beyond research. Please encourage appropriate agencies and other policymakers to collect essential data such as through exposure monitoring, pesticide use reporting, and notice prior to applications.

Please, also speak about the precautionary principle and call for its application here. If ever there was a time to break the silence and speak for precaution it is on these issues. They involve highly toxic chemicals and documented exposures of not only workers, but also their vulnerable children.

Written expansion of verbal comment 2006/12/05:

December 5, 2005

Good Morning. My name is Michael Feurstein, PhD, MPH. I am a professor in Medical and Clinical Psychology and Preventive Medicine and Biometrics at the Uniformed Services University in Bethesda, Maryland. I am here today to propose that problems faced by cancer survivors in the workplace be added to the NORA research agenda. The problems that cancer survivors experience at work represent a national burden in the American workplace. As the number of cancer survivors' increase, a result of earlier detection and improved interventions, the number of cancer survivors who desire or need to return to productive work will increase. Currently, there are approximately 3.8 million working aged adults with cancer in the U.S. This workplace public health problem will escalate over the next decade as treatment becomes more successful and the workforce ages (IOM/NRC, 2005).

Public health burden. So what are some of the data on cancer survivors and the American workplace that signal a problem?

1. One out of five cancer survivors who are 1-5 years post diagnosis report cancer related limitations in their ability to work. Nine percent were actually unable to work. Research indicates that labor force participation declines 12 percent immediately following diagnosis to follow-up. (Short et al 2005).
2. Using another national database, the National Health Interview Survey between 1998 and 2000 research indicates that 17 percent or approximately 1 in 6 workers with a history of cancer report they are unable to work. These employees attributed this work disability to physical, cognitive or emotional challenges. An additional 7 percent indicated they were limited in the amount and type of work they could perform (Hewitt et al 2003).
3. This burden does not rest solely on the cancer survivor or his or her family. As with any health problem that impacts works productivity, there is a cost to employers. Of course, there are medical costs, of which a large portion are often covered by the employer, but there are also real costs related to lost productivity, turnover, family medical leave and potential effects on coworker.
4. Our culture continues to perpetuate the view that an individual with cancer is somehow now defective. While at this point limitations in function often represent the sequelae of cancer and its treatment, the question we need to be asking is not can he or she do the work, but rather can the cancer survivor perform the essential tasks of his or her job and, if not, can he or she be reasonably accommodated to minimize the impact of the illness on work productivity? Yet employers and supervisors continue to perceive cancer survivors as poor risk for job loss. The outcomes can regrettably lead to a cascade of problems for the survivor, the workplace and society.
5. Accommodating workers with other medical conditions have been on the rise; however, a study completed by my research group using litigation data from 1990-1996 indicated that cancer accounted for 7% of all impairments involved in EEOC litigation related to failure to accommodate (Huang and Feuerstein, 1998).

Case Example. I am a 55 year old tenured full professor. I was brought to the Uniformed Services University to develop and direct the first and only clinical psychology PhD program for the military in the US 10 years ago at the request of Congress. I never had any problems at work. Work was and still is a major aspect of my life. I was a high achiever. In the summer of 2002, I was diagnosed with a malignant brain tumor. I had surgery to biopsy the tumor the maximum radiation tolerable and 12 months of chemotherapy. I now receive MRIs every 4 months. I am a cancer survivor.

I return to work two weeks after brain surgery and worked throughout my radiation and chemotherapy. I myself experienced problems reintegrating into the workplace. The unexpected problem was my supervisor's reaction to me, not my health. I returned to work to find out from a secretary that some research space and a part-time research assistant were no longer available. I went into my supervisor's office and asked why? He told me that I did not need these anymore because I was no longer normal. Fortunately, I was able to resolve this matter through frank discussion and support of colleagues. I also experienced a number of other workplace challenges following my diagnosis including the denial of my request for an accommodation that I sincerely believe was reasonable.

Future Needs Related to NORA. Given the challenges that I and other cancer survivors experience at work I recommend NORA add cancer survivorship and work to its agenda over the next decade. Specifically, research in the following areas should be seriously considered:

1. Epidemiological studies of this burden at a population health level.

2. Identification of modifiable risk factors.
3. Detection and long-term surveillance of problems in affected workers.
4. Evidence based cost effective approaches that address the problems cancer survivors experience in returning to work, work retention and work productivity.
5. National and state policy on more effective ways to address this problem at a system level.

Thank you.

Brominated Flame Retardants (BFRs) and Worker Safety and Health

Brominated flame retardants (BFRs), especially polybrominated diphenyl ethers (PBDEs) are widely used in the U.S.A. to reduce fire injuries. They are found in television sets, computers, fax machines, in some

textiles, in Styrofoam in chairs and mattresses, and in carpet padding (Birnbaum and Staskal 2004). These brominated flame retardants are currently found in all persons studied to date in the USA, whether in blood or milk, fat tissue or in fetal liver (Hites 2004; Schechter et al 2006; Schechter et al. 2005b; Schechter et al. 2003; She et al. 2002).

Levels of one type of these, polybrominated diphenyl ethers of PBDEs, are orders of magnitude higher in the U.S.A. than found elsewhere worldwide (Schechter et al. 2005b; Siodin et al. 2004). High levels have been reported in U.S. household vacuum sweepings and on office computer and computer monitor wipes (Schechter et al. 2005a).

There is both structural and toxicological similarity of PBDEs to PCBs. Animal studies with PBDEs show similar health outcomes, cancer, reproductive and developmental toxicity, endocrine disruption and central nervous system alterations (Birnbaum and Staskal 2004). No human health studies have been published at this time.

The only occupational study is from Sweden. Worker studies in Swedish electrical recycling workers showed elevated PBDEs in blood of workers. After worker protective measures were instituted, levels decreased (Sjodin et al. 1999; Thuresdson et al. 2004). The elevated PBDEs levels reported in exposed Swedish workers were lower than the general population levels in persons living in the U.S.A.

It is believed that some US workers are at risk from PBDE and other BFR exposure. Exposure and health studies are urgently needed to document exposure and also possible adverse health consequences from such exposures.

Workers at risk include those involved in manufacture of brominated flame retardants, those involved in putting BFRs on or into electronics, textiles, or Styrofoam, those involved recycling such materials, first responders such as firefighters, police and emergency medical specialists, as well as garbage disposal workers, among others.

Since PBDE levels in humans have gone from not detectable in the 1970's in the USA to the highest in the world in the early 2000s (while dioxins, dibenzofurans and PCBs have declined) (Schechter et al. 2005b) it is of considerable urgency to determine which workers are exposed, how such exposure can be decreased, and what the health consequences are of worker and general population exposure.

Written expansion of verbal comment 2006/01/17:

Thank you for the opportunity to provide comments to NORA about the future areas of research in order to reduce the incidence of WMSDs. My name is Janet Peterson and I am a physical therapist and ergonomist in the Seattle area. I also am a current board member of the American Physical Therapy Association [APTA] and a past president of the Physical Therapy Association of Washington [PTWA].

In looking at future research directions, I'd like to encourage NORA to consider an interdisciplinary model when creating research teams. The various disciplines of engineering, epidemiology, medicine, psychology, physical therapy, and basic scientists working together with "end user" businesses and industry can produce a more comprehensive outcome than a single discipline working alone.

One example of this is the upcoming collaboration between APTA, the Association of Rehabilitation Nurses (ARN) and the American Occupational Therapy Association (AOTA) on a project entitled "Therapeutic Use of Patient Handling Equipment". This is a continuation of a very successful collaboration with the ARN last year when we developed and published a white paper on safe patient handling. The purpose of the upcoming program is to develop clinical tools that will assist the clinician in the selection, implementation and assessment of safe patient handling technologies to reduce the risk of injury for both caregivers and patients.

Physical therapists are well-suited to assisting in the research of work-related musculoskeletal disorders. The knowledge base of physical therapists includes:

- Anatomy
- Biomechanics and mechanics
- Kinesiology
- Pathokinesiology
- Motor Control
- Statistics
- Epidemiology
- Ergonomic Processes

Physical therapists are educated at the doctoral (70% of physical therapy programs) or the master's degree level, are licensed in all 50 states, and work in a wide variety of settings including research and industry.

There is evidence that repetitive motion, stressful postures and forceful exertions are associated with a variety of musculoskeletal disorders (MSDs):

- Silverstein, MA, Silverstein BA, Franklin GM. Evidence for work-related musculoskeletal disorder: a scientific counterargument. *J Occup Environ Med.* 1996;38:477-484.
- Waddell, G and Burton, AK. Occupational health guidelines for the management of low back pain at work: evidence review. *Occup. Med.* 2001; 51(2) 124-135.

There is evidence that exposure to computer workstation job tasks increases the incidence of musculoskeletal disorders (MSDs):

- Gerr F, Marcus M et al, A Prospective Study of Computer Users: I. Study Design and Incidence of Musculoskeletal Symptoms and Disorders. *Am J of Indus Med* 2002: 41:221-235 and Marcus M, Gerr et al, et al, A Prospective Study of Computer Users: II. Postural Risk Factors for Musculoskeletal Symptoms and Disorders. *Am J of Indus Med* 2002: 41:236-249.

There is evidence that return to work depends on an increase in functional abilities:

- Lindstrom I, Ohlund C, Nachemson A. Physical performance, pain, pain behavior and subjective disability in patients with subacute low back pain. *Scan J Rehabil Med.* 1995; 27:153-160.
- Waddell, G and Burton, AK. Occupational health guidelines for the management of low back pain at work: evidence review. *Occup. Med.* 2001; 51(2) 124-135.

APTA applauds NORA's efforts to seek further evidence to assess the most effective interventions for decreasing the risk for work-related injuries; we invite you to include physical therapists in those efforts.

Sincerely,

Janet Maines Paeterson, PT, MA

Physical Therapist and Ergonomic Consultant

NORA II Testimony

Author: Kathleen M. McPhaul, PhD, MPH, RN, Assistant Professor

Affiliation: University of Maryland School of Nursing, Baltimore, Maryland

Co-Investigator/Investigator NIOSH supported workplace violence intervention research studies involving mixed methods such as qualitative injury and participatory action research.

Planning Committee Member: Partnering in Workplace Violence Prevention: Translating Research to Practice: National Workplace Violence Conference sponsored by NIOSH (2004)

Industry sub sector: Cross Sector- Healthcare and social services; Services, Retail, and Transportation

Occupational Exposure: In each year from 1993-1999 1.7 million incidents of violence occurred in the workplace. Twelve percent of all victims reported physical injuries. Six percent of the workplace crimes resulted in injury that required medical treatment. Only 46 percent of all incidents were reported to the police. Mental health professional had an incidence rate of 68 per 1,000 workers compared with an overall rate of 12 per 1,000 workers. Nurses had an incidence rate of 22 per 1,000 workers, the highest rate in the "medical" category.ⁱ In a Washington State psychiatric facility, 73 percent of staff surveyed had reported at least a minor injury related to an assault by a patient during the past year; only 43 percent of those reporting moderate, severe, or disabling injuries related to such assaults had filed for workers' compensation. The survey found an assault incidence rate of 437 per 100 employees per year, whereas the hospital incident reports indicated a rate of only 35 per 100.ⁱⁱ

Jobs and/or occupations involved: Multiple transportation and retail jobs. Professional and para-professional healthcare providers and support staff including (but not limited to) nurses, community, mental health case workers, nurse's aides, mental health technicians, addictions counselors, psychologists, social workers, physicians, security workers in healthcare

Barriers and Challenges to Implementation of Workplace Violence Prevention Efforts

The lack of effectiveness data and the overall culture of violence within society present formidable challenges to the workplace violence prevention community. Unless there is a tragedy, most employers are willing to allow competing demands to take precedence over workplace violence. In many industry sub-sectors such as healthcare, violence is embedded in the workplace culture and considered "part of the job". Regulatory solutions, such as an OSHA standard requiring workplaces to institute effective workplace violence programming depend on solid cost and effectiveness data.

Type of new information or action that is needed (for example, data to describe the problem, research to obtain new knowledge, evaluation of existing solutions, or moving known solutions into widespread practice)

The workplace violence base has broadened considerably in the last decade, however, basic information about situational and environmental triggers, characteristics of both perpetrators and victims, and most, importantly, conclusive data on effective preventive strategies are lacking. For example, the true frequency of workplace violence, especially, verbal violence is not known. We cannot estimate the true risk of violence directed toward staff by job title, service setting, client type, time of day, staffing levels, or by situational or environmental variables. Motivating employers, workers, and policy-makers to devote time and resources is made more difficult without firm prevalence figures.

A related gap is the absence of data on the cost of workplace violence and the cost-effectiveness of prevention strategies. While cost is not the only measure of success of workplace violence prevention, employers and regulators respond to empiric cost studies. Employers are particularly interested in data that allows them to determine the "return on their investment". Employers may not need every intervention to pay for itself, but they want to understand the cost relative to the benefit. Creative

approaches to cost research include establishing the cost effectiveness of a “non-event” or assault that has been prevented. Other costs that should be considered are the costs of staff turnover such as training new personnel and the indirect costs to employers and employees of reduced morale secondary to a violent workplace.

There is a need to identify and describe successful management systems for tracking workplace violence and related follow-up actions. These systems may be in place in private workplaces, but considered propriety information thus not shared by employers to the field. NIOSH, however, can include the development and testing of such systems in its research grant programs.

Workplace violence prevention training is a critical and powerful preventive strategy when effective. There are a myriad of gaps, however, in our understanding of the most effective training. For example, the training evidence base, including content, effective teaching methods, and intervals between sessions, is currently insufficient to guide the field.

Not all information gaps represent gaps in basic research. Many elements of the workplace violence prevention evidence base are available, but not widely or appropriately disseminated. For example, the definition of workplace violence is not universally understood by employers and workers, even though it has been published. Specifically, there seems to be widespread misunderstanding of the nature of Type II violence in hospitals, schools, and social services. The employer and worker communities appear to focus on and be more concerned about worker on worker violence (Type III). Strategies for timely translation of workplace violence research into occupational health practice must be better understood.

Partners that need to work together to address the problem

Yet perhaps unlike regulating other hazards, violence prevention in healthcare and human services will require the involvement of the patient care quality community such as the Joint Commission for Accreditation of Healthcare Organizations (JCAHO) and healthcare regulatory bodies within the Department of Health and Human Services. The patient safety and worker safety communities must work together. Crucial agencies include the National Institute of Mental Health (NIMH), the Centers for Medicaid and Medicare (CMS), American Psychological Association (APA), American Hospital Association, Joint Commission for the Accreditation of Healthcare Organizations (JCAHO), Occupational Safety and Health Administration (OSHA), NIOSH, professional societies, law enforcement and legal experts, and worker and patient advocate groups. NIOSH must also prioritize workplace violence by making the issue more visible via public information campaigns.

Summary and Recommendations

In summary, prevention of Workplace Violence is hampered by public ignorance and misunderstanding of the problem (especially in healthcare), underreporting of low level and verbal violence, and an inadequate understanding of effective prevention strategies. Furthermore, workplace violence is highly complex and requires the commitment and involvement of management, employees, and customer/clients. Additionally healthcare and social services industry accreditation efforts and government patient and worker safety regulations must be coordinated in order to develop meaningful regulation and avoid burdensome and futile regulatory requirements.

The following questions should guide the research agenda for workplace violence:

1. How prevalent is the full continuum of workplace violence including verbal abuse, verbal threats, and non-fatal assaults with and without injury?

2. What are the organizational attributes that contribute to successful workplace violence prevention?
3. What training content, methodologies, and intervals result in optimal staff and management knowledge and behaviors to prevent workplace violence?
4. What are the direct and indirect costs of not implementing a successful workplace violence prevention strategy?
5. How can private industry provide and share prevalence and “best practices” data to accelerate intervention effectiveness research and still meet rigorous scientific and peer review standards?
6. How can basic workplace violence research be translated in a timely manner to occupational health practitioners, employers, and workers?

Ergonomics in Healthcare

I. Thank you for the opportunity to present some of the challenges and research opportunities for addressing the incidence of illness and injury in the healthcare industry. As a nurse who has worked in hospital, home care and nursing homes and a health and safety professional, this is a topic of personal and professional concern. For the purpose of this presentation, I focus my remarks on NACS code 623000 and 622000 Nursing and Residential Care Facilities and Hospitals, respectively.

II. Employment in Hospitals and Nursing Homes is estimated to exceed 7 million. While this number is impressive, it is far below the number necessary to serve the needs of our aging population. The U.S. Department of Labor estimates that we have over 100,000 vacant healthcare positions, as we anticipate the beginning of retirement for 78 million "baby boomers" in the year 2010. At the same time our nurses are aging, with an average age approaching 50. Estimates of the lack of availability of nursing care are astounding. The Department of Health and Human Services has reported that by 2020 we will need 2.8million nurses, 1 million more than the projected supply. Our healthcare workforce crisis is not limited to nurses. The American Hospital Association projects severe workforce shortages in clinical and non-clinical workers, including: nurses, radiology technicians, pharmacists, medical records personnel,

housekeepers and food service personnel. It is most disturbing to recognize that the Joint Commission on Accreditation of Hospitals (JCAHO) has identified thousands of hospital deaths each year related to the nationwide nursing shortage.

III. What does our healthcare workforce crisis have to do with ergonomics and injury prevention? The connection becomes quite clear when we acknowledge that healthcare workers are leaving the profession at an alarming rate, partly due to health and safety concerns and continue to be injured at rates that far exceed our rate of injury in private industry. A 2001 American Nurses Association survey confirmed that nurses are concerned about their health and safety at work. 88% of the responding nurses reported that health and safety concerns influenced their decision to stay (or leave) nursing. 60% identified disabling back injury within their top 3 health and safety concerns.

Bureau of Labor Statistics data support the extent of our healthcare worker injury crisis. The rate of non-fatal occupational injuries and illnesses in the private sector in 2004 was 4.8 per 100 full-time equivalent workers, while hospitals reported a rate of 9.7 and nursing homes, 8.3. Of particular note is the rate for "all other illness cases", where the OSHA recordkeeping standard directs us to record our cumulative workplace injuries. The private industry rate per 10,000 full-time workers is 18.0 versus 54.3 in hospitals and 26.4 in nursing homes.

IV. The Maryland Center for Environmental Training recently completed an Ergonomics Train-the-Trainer program funded by an OSHA Susan Harwood grant, in cooperation with the Johns Hopkins Bloomberg School of Public Health Education and Research Center and the Institute for Johns Hopkins Nursing. Development and delivery of the train-the-trainer curriculum allowed us entrance into 13 Maryland-based nursing homes. Delivery of the curriculum with the support of Maryland Occupational Safety and Health, facilitated our interaction with representatives of an additional 27 Maryland-based healthcare facilities. Anecdotal data collected through the delivery of this training is indicative of how far we have to go to improve the health and safety of this critical working population.

-- Of the 195 attendees from our on site program, only 1 had read or reviewed OSHA's Ergonomics Guideline for Nursing Homes prior to attending our training session.

-- Pre-planning site visits to facilities identified care-givers working without the benefit of electric beds and assistive resident handling devices, while we are preaching and teaching concepts of neutral body postures and zero lifting policies.

-- Ancillary department staff, including laundry, housekeeping and food service is consistently left out of injury prevention initiatives, while being exposed to significant risk for injury, especially in manual material handling.

-- Certified nursing assistants and nurses that teach nursing assistants, when asked, admit that prevention of work-related injury is not currently included in their training.

-- Registered nurses describe working in a "patient-focused" environment with little room for "workers-focus" and the prevention of worker injury.

V. We strongly urge NIOSH and other partners to address the question of how we will prevent work-related injury within our healthcare workforce. The answer to our healthcare staffing crisis is not in recruitment and training alone but should incorporate strategies for keeping our existing workers at work and those entering the healthcare workforce safe and injury-free in the future.

Areas for future research may include:

- Injury prevention strategies for an aging workforce;
- Economic models for justification of patient handling and material handling equipment;
- Exploration of our educational system for certified and licensed healthcare professionals with consideration of opportunities to incorporate concepts of injury prevention and ergonomics;
- Methods of evaluation of current injury prevention training and
- Effective means for dissemination of injury prevention information within the healthcare industry.

Written expansion of verbal comment 2005/12/05:

Good morning, my name is Cherise Baldwin Harrington. I am speaking on behalf of Dr. Michael Feuerstein from the Uniformed Services University in Bethesda, Maryland. I am a graduate student and a member of his research group here to discuss areas of importance to work disability.

Work disability is a source of significant cost to the worker, workplace, and society. As result of these problems a worker can find it hard to cope with persistent pain and changes in function that accompany these disorders while attempting to return to work or remain at work. This change in function and productivity can also exert a substantial financial burden (IOM, 2001). Costs to society derive from lost-time wage replacement, disability settlements and healthcare. In addition, there are indirect costs associated with training of replacement workers and lost tax revenues. Also it is interesting to note that when Dr. Feuerstein developed the Journal of Occupational Rehabilitation over 15 years ago he thought that perhaps the journal would gradually loose is popularity as the problem of work disability was solved yet almost two decades later it is stronger than ever with citations of research at its highest levels and

submissions from around the world continuing to increase. Clearly, work disability continues to be an important public health concern.

A major source of work disability continues to be musculoskeletal disorders of the back and upper limb. While most workers return to work within a month from a claim for a musculoskeletal disorder many who actually return to work continue to experience pain and disability. It is well known at this point that a small percent of these workers transition into prolonged disability and account for a disproportionate share of the health care burden. Also, in some cases back and upper limb pain can be recurrent and those returning to work with pain are at increased risk for future problems. Research from our group and groups from around the world strongly indicate that recurrent and prolonged work disability are influenced by a number of factors including the medical status of the individual, their physical condition in relation to work demands, various workplace and individual psychosocial factors and systems level variables (Feuerstein, 1991; IOM, 2001).

Data also suggests that by identifying workers at high risk for disability and intervening within a few months from the time of first report of pain or injury, disability can be prevented (Gatchel et al., 1995; Linton & Bradley, 1996). Our group has also investigated such outcomes as function, patient satisfaction, perceived health and costs related to health care in acute low back pain and have also identified a possible pathway for this prolonged pain and disability. We first observed in over 10,000 cases that provider adherence to clinical practice guidelines suggested workplace ergonomic evaluation and intervention as well as psychosocial intervention was associated with better outcomes and lower costs (Feuerstein et al., in press; IOM, 2001). In an prospective study on n=368 participants, to be published soon, we found that workers exposed to ergonomic risks reported greater job stress which in turn was related to higher levels of emotional distress and increases likelihood of returning to the clinic with persistent back pain (Feuerstein et., in press). Future efforts need to investigate these relationships more closely and develop innovative approaches at the workplace to address these areas realistically and head on. Currently, this pathway is either ignored or held out as possible explanation only months after persistent pain leads to prolonged disability and a series of other problems for the worker and workplace emerge. It is time the integrative role of these factors is studied more seriously and cost effective approaches are developed to mitigate them.

Another important concern is the risk of recurrent disability following return to work (Butler et al., 1995). In preventing reinjury, accommodations are often helpful (Hogg-Johnson & Cole, 1998). Work disability is further impacted by the complexities often involved in truly implementing these accommodations over the long run and assessing their impact. Research done by our group some years ago indicated that musculoskeletal disorders accounted for 23% of all impairments involved in litigation for failure to accommodate under the Americans with Disabilities Act (Huang & Feuerstein, 1998). Have things changed?

The concerns associated with work disability do not discriminate in job type or setting. The prevalence of these problems emphasize that more attention be placed on identifying the relevant risk factors for onset, progression, maintenance, and the effects of innovative interventions. Also, it is important to note that BLS data indicate that more workers return to work with pain than ever before (IOM, 2001). Is that the solution? Probably, not.

It is recommended that NORA reconsider what needs to be done about work related musculoskeletal problems and work disability in the following areas:

1. Well-controlled epidemiology studies on the interactions and pathways among multiple risk factors and their relationship to work disability.
2. Randomized controlled trials (RCTs) based on work from recommendation number 1 to identify effective long-term interventions for work disability.
3. Research on policy that helps facilitate the recognition and need for approaches that address the multiple factors involved in world disability that maximize the application of evidenced based policy. There needs to greater awareness that by focusing on multiple factors we are not blaming workers or labeling workers with psychological problems. Workers experience natural reactions to injury, pain and workplace stress that combine to create a situation that is often fueled by the way we look at this process and manage it. Armed with new data it is time to seriously tackle the problem from a broader perspective.

NIOSH DOCKET 047

NATIONAL OCCUPATIONAL RESEARCH AGENDA

PROPOSED RESEARCH PRIORITIES FOR THE AIR TRANSPORTATION SECTOR

Judith Murawski, Industrial Hygienist

Association of Flight Attendants-CWA, AFL-CIO

December 14, 2005

What follows are comments for NIOSH and its NORA partners to consider as they develop research agendas and action plans for workers in the air transportation sector (NAICS code 481) in the next decade. While the research agenda described here has an obvious benefit to the 115,000 flight attendants and 80,000 pilots employed in the aviation industry, it would also benefit any workers exposed to tricresylphosphates (TCPs), including mechanics, oil rig workers, and machinists that use cutting oils.

In the past ten years, NIOSH has funded a series of studies on flight attendant health, although for the most part, this is a research area that has largely been ignored, perhaps partly because OSHA has no jurisdiction over flight attendants when they are working on an aircraft in operation, and partly because in many people's minds, flight attendants are just waitresses that fly, so what could be hazardous about that?

Thanks to the 4(b)(1) clause in the Occupational Safety and Health Act, the Federal Aviation Administration (FAA) assumed jurisdiction over the health and safety of crewmembers in 1975. Unfortunately though, the FAA has not yet exercised that jurisdiction and does not have the expertise to do so. In short, crewmembers are an occupational cohort in serious need of attention.

The three research gaps described here all relate to the hazards posed by exposure to partly combusted and aerosolized engine oil. As such, they are presented together. Exposure to partly combusted engine oil may sound more like a hazard that would only apply to maintenance workers but it is not: We know that the aircraft air supply gets contaminated because the aircraft mechanical records confirm it and the ventilation ducts are coated with oil afterwards. We know all aircraft engine oils contain up to 3% of the neurotoxic TCPs, and that carbon monoxide gas can be generated upon heating. We know that TCPs get distributed to the cabin because they have been identified on aircraft recirculation filters. We know that many crewmembers around the world have reported severe neurological symptoms that are consistent with exposure to organophosphates and carbon monoxide during and after these events. We know that these events happen approximately 1 per 1000 flights on the more problematic aircraft types, and we certainly know that even for a single event, the impact on workers can be devastating. Supporting documentation for all of these statements is available upon request.

The best way to put the specific research gaps in context and emphasize the importance of filling them is to provide an example: On October 8, 2005, three flight attendants flying on a major US airline on a domestic flight noticed a strong smell like dirty socks in the aircraft cabin upon descent. The smell was that of carboxylic acids, a component of heated engine oil. The flight attendants all felt disoriented and sick to their stomachs. They were having difficulty breathing. They called up to the cockpit to find out that the pilot and copilot were aware of the situation and had both been feeling faint and were both on oxygen but would not deploy the masks in the cabin because it “wouldn’t be cost effective.” Emergency vehicles met the aircraft upon landing and the mechanics confirmed that heated oil had leaked into their air supply system. The three flight attendants had sore throats, bad headaches, weak muscles, and felt unusually fatigued. When they felt worse the next day, they reported to the local Emergency Room, although the staff had no idea what to do with them. Since then, these crewmembers have developed problems with memory and concentration; they are regularly weak and fatigued; they have tingling and pain in their hands and feet; they have periods of lightheadedness and confusion. One has been told that she may have Multiple Sclerosis; the second has been told that TCPs are not toxic and that she should see a therapist; and the third was told that her abnormal liver test results are likely due to Hepatitis, despite the fact that she was vaccinated two years ago.

Clearly, these crew members would have benefited from air monitoring in the air supply system during the flight. A simple blood test that would either confirm or deny TCP exposure would have saved them countless hours and doctor visits and unnecessary tests. Such a blood test would also save the airlines the expense of sending crewmembers to countless doctors, once they are made to pay the worker’s compensation costs. Finally, the physicians that these crewmembers are meeting with for diagnosis and relief would clearly benefit from a published paper that describes the relationship between inhalation exposure and neurological illness. These are the research gaps that need to be filled.

The first two research gaps concern exposure assessment: what level of exposure to TCPs are workers exposed to during one these events and what biomarkers are available to identify and quantify what crewmembers are exposed to during a flight?

The third research gap addresses health effects: what systematic scientific studies have been published on the chronic, central nervous system effects of inhalation exposure?

Exposure assessment:

On the subject of exposure, there is currently no requirement for airlines to install air monitoring equipment on commercial aircraft. It is of interest to note, however, that a draft aircraft air quality standard recently released by the American Society of Heating, Refrigerating, and Air Conditioning Engineers (ASHRAE) does require continuous monitoring of appropriate chemical contaminants in the aircraft supply systems to enable crewmembers to respond to a contamination event and to provide proof of exposure. The draft ASHRAE standard echoes the recommendations of the 2002 National Research Council (NRC) Committee on Air Quality in Passenger Cabins of Commercial Aircraft for the FAA to require air supply monitoring in ducts that supply the passenger cabin and establish standard operating procedures for responding to elevated concentrations. Exposure monitoring would also respond to the following specific research question that the NRC Committee posed in their final report: "How are these oils, fluids, and degradation products distributed from the engines into the ECS and throughout the cabin environment?"

Currently, there is no commercially available technology to continuously monitor for ambient TCPs at low concentrations in real time. NIOSH could address this research gap by funding a one-year biosensor research project to apply technology that has been developed and applied for the military to commercial aircraft. To date, biosensor research has identified and isolated animal antibodies that only react to particular chemical agents (such as ricin and anthrax). These antibodies are housed in sensor equipment and, upon exposure, they bind to the specific airborne chemical agent at a rate that can be quantified and converted into a concentration at ppb level in real time on a continuous monitoring basis. The sensor unit now being developed is likely to cost less than \$25K and is the size of a child's lunch box. TCP-specific animal antibodies exist but need to be identified and isolated so that this technology could be applied to quantify ambient TCP levels on a real time basis in the cabin and cockpit.

Another research gap with serious implications for exposed workers is that there is no TCP-specific blood test, such that these workers are without direct proof of exposure and absorption. It is of great interest that TCP has been demonstrated to modify a commercially available pig liver enzyme in a way that is not only detectable but is quantifiable. Research funds for a one to two-year project are needed to apply these findings to develop a TCP-specific test for human blood. The need for a diagnostic tool that would confirm exposure is also supported by the 2002 NRC report per the Committee's recommendation for health surveillance program that would "allow [for the] analysis of the suggested relationship between health effects or complaints and cabin air quality."

Health effects:

There are published studies that report that when test animals ingest these oils or individual isomers of TCP they show delayed effects, largely to the peripheral nervous system and partly to the central nervous system. However, the studies conducted to date are inadequate for the following four reasons:

First, workers are not ingesting these oils and there is evidence that inhalation may have very different toxic effects than ingestion. Second, these studies have not included postmortem analyses to identify damage to parts of the brain involved in cognitive functioning, Third, TCP isomers vary in their neurotoxic effect, but there is no guarantee that the mixtures of TCP isomers that have been tested

reflect the mixtures that workers are inadvertently inhaling on the job. Finally, the engine oil manufacturers paid for the inhalation studies, so there is an inherent conflict of interest.

Crewmembers need NIOSH to take the lead in funding inhalation studies of these engine oils with a focus on damage to the parts of the brain involved in cognition. Such research would respond to the following specific research questions raised in the 2002 NRC Committee report: "What is toxicity of the constituents or degrading products of engine lubricating oils, hydraulic fluids, and deicing fluids, and is there a relationship between exposures to them and reported health effects on cabin crew?"

Dr. Mohamed Abou-Donia at Duke University and Dr. Christian van Netten at the University of British Columbia are experts in this field and could readily fill this research gap.

Conclusion:

Each of these three projects-the biosensor to detect TCPs in real time, the TCP-specific blood test, and the engine oil inhalation research-could be funded well within typical NIOSH grant levels and are estimated to take one to two years to complete, depending on the available funding. NIOSH would be filling major research gaps by answering questions that have been left unanswered for decades with obvious benefits for workers in the transportation sector and beyond.

Sincere thanks to NIOSH and its NORA partners for taking the time to learn about this workplace hazard that affects so many transportation sector workers. We hope that NIOSH will elect to fund the research described here in order to fill the knowledge gaps and develop the practical tools that are sorely needed by flight attendants and pilots alike.

MARYLAND COLLEGE OF OCCUPATIONAL AND ENVIRONMENTAL MEDICINE
A COMPONENT SOCIETY OF
AMERICAN COLLEGE OF
OCCUPATIONAL AND
ENVIRONMENTAL MEDICINE

December 2, 2005

Docket NIOSH-047

Robert A. Taft Laboratories (C-34)

4676 Columbia Parkway

Cincinnati, OH 45226

Dear Sir or Madam:

The Maryland College of Occupational & Environmental Medicine (MCOEM) is pleased to submit these comments on NIOSH's National Occupational Research Agenda (NORA). MCOEM is a voluntary non-profit association of over one hundred physicians and allied health care providers in the state of Maryland. Our members practice occupational medicine in factories, clinics, hospitals, military bases, and academic centers from the shores to the mountains. We, collectively, care for tens of thousands of Maryland workers who directly benefit from our professional efforts and the efforts at NIOSH to produce quality occupational research.

We applaud NIOSH's solicitation of comments on such a significant pathway for guiding the agency for the next decade and beyond. We recognize the accomplishments from the first decade of NORA and like the aspiring athlete we encourage NIOSH to excel further. We fully subscribe to the proposition that NORA is setting an agenda not only for NIOSH but for Occupational & Environmental evidence based medicine.

While there are many issues that deserve attention from researchers, given the ongoing changes in the U.S. workplace and the field of occupational/environmental health, we have identified several areas that we feel should be priorities for occupational health research in the coming years:

- Mental health and organizational psychology
- Indoor environments
- Emerging diseases
- Emergency preparedness
- Delivery of occupational health services to small-and medium-sized employers
- Cost-effectiveness of occupational health services
- Vulnerable populations
- Effects of chronic disease on work and working populations

The issue of mental health in organizations is large. We know that the combination of affective and other disorders in the workplace has imposed huge direct and indirect costs on many employers. In addition, the role of mental health in productivity is only just beginning to be appreciated. NIOSH should seek opportunities to partner with other Federal and private research intuitions to foster research in this area.

Similarly, we know that workers spend a sizable amount of time indoors, yet the science of indoor environments is still fairly young and at times chaotic. Much more work is needed to understand the complex interplay between indoor environments, work, physical and mental health, quality of life and productivity. We applaud NIOSH's efforts in this area to date, but would still regard it as in need of further emphasis.

As demonstrated so sadly following 9/11/2001 and the anthrax exposures, the nation looked long and hard for expertise in safe remediation measures. This is an area where NIOSH has particular expertise and could identify and demonstrate appropriate remediation techniques, including worker protection.

MCOEM urges NIOSH to consider that the threat of emerging infectious diseases requires a reserve of resources and their preparedness while the nation's improvement in hearing conversation warrants applause more than further basic science research. Likewise, finding effective personal protective equipment, e.g. respirators and gloves, warrants more investigation than the association of cigarette smoking with chronic obstructive disease.

The delivery of occupational health services to small and medium-size employers is a critical issue. NIOSH has an opportunity to demonstrate through research and effectiveness of different models of occupational safety and health and occupational health care delivery.

Similarly, there are many practices in occupational safety and health that have been used for years for which there are few, if any, data demonstrating their effectiveness. In this time of evidence-based medicine, NIOSH should work to promote the development of reference data bases as well as research programs that can begin to answer questions about whether commonly used therapeutic or preventive strategies actually work.

Categorized comment or partial comment:

Finally, there are two additional issues that we feel should be priorities for the coming years. First is the issue of vulnerable populations. There have been tremendous changes in the workforce which continue today. These include the aging of the workforce, an increase in women in the workforce, increasing numbers of migrant and non-English speaking workers, dual working parents, workers with chronic diseases or permanent impairments, and other demographic shifts. NIOSH should promote research to understand what these shifts portend for the health and safety of workers.

The other issue concerns the effects of chronic diseases-asthma, diabetes, HIV/AIDS, obesity, cancer heart disease, rheumatologic disorders, to name a few-on safety, health, and productivity in the workplace. As more and more workers with disabilities are staying in the workforce, the effects of these disorders on safety and health professionals is more complex and deserving special attention.

MCOEM is a professional organization and we firmly believe that professional involvement in the research, application, and policy making at NIOSH is critical. It is commonly recognized that medical care in the United States is in transition. Different approaches are being empirically followed in the quest for quality and fiscal frugality. We applaud NIOSH's continuing commitment to the training of qualified occupational health professionals who can advance the profession of occupational medicine through practice and research. We want to stress that well trained occupational physicians are graduating from some of the nation's finest medical training programs, it is vitally important that there be adequate resources to support research and clinical outreach programs at NIOSH. Partnering with stakeholders should never be substituted for seeking the best medical care possible for American workers. Rather, it should be viewed as an opportunity to educate the decision makers, employers and the work force.

MCOEM appreciates this opportunity to comment on NORA. We remind NIOSH that our patients and our nation's public health benefit from NIOSH research. We steadfastly support quality improvement at NIOSH, and believe that NIOSH must be provided with the resources necessary to carry out this vital public health research agenda.

Respectfully submitted,

Marianne Cloren, MD, MPH
President, Maryland College of Occupational
And Environmental Medicine

Mental Health Issues in the Workplace

Martina Lavrisha, RNC, MSN, MPH

NORA Town Hall Meeting

College Park, Maryland

December 5, 2005

I appreciate this opportunity to describe the need for research regarding mental health issues in the workplace. As mental health professional, I have heard numerous complaints from individuals with mental illness regarding the stress of work on their ability to function. In preparing for today, I spoke with colleagues in the Northern Virginia area regarding job stressors that their patients were experiencing. The following are the responses I received:

- lack of flexibility by management in the service industry regarding childcare and transportation issues

- perceived lack of empathy by management regarding the effects of mental illness on job performance by government services workers
- underutilization of their skills and being "bored" as having chosen a less stressful occupation due to the severity of their illness
- an increase in workload without due compensation and the unvoiced expectation by management that this is acceptable
- difficulty navigating the insurance and short-term disability system and not knowing how much to disclose to the employer and peers upon returning to work
- ineffective interpersonal communication with management especially when receiving a "punitive" attitude to mistakes
- not obtaining treatment due to concern for job loss when working in the corrections field or for fear of jeopardizing one's security clearance.

Mental illness is on the rise worldwide and one of the leading causes of disability in North America and Europe. The Global Burden of Disease study unveiled that mental illness, including suicide, accounts for 15% of the burden of disease in the United States, which is more than the disease burden caused by all cancers.¹

Mental disorders are common in the United States and internationally. An estimated 22 percent of Americans ages 18 and older-about 1 in 5 adults or 44 million people-suffer from a diagnosable mental disorder in a given year with less than a third receiving treatment.² The cost of mental illness in both the private and public sectors in the U.S. is \$205 billion. Direct treatment costs are \$92 billion, with \$105 billion due to lost productivity, and an additional \$8 billion resulting from crime and welfare costs. The cost of untreated and mistreated mental illnesses to American businesses, the government, and families has grown to \$113 billion annually.³

Despite these statistics, US employers have been cutting back mental health services as a means of cutting costs with an 8% reduction of employers offering MH benefits from 1998 to 2002.⁴ This results in increased costs for the organization or society as a whole. For example, when a Connecticut corporation made a 30 percent cost reduction in mental health services, it triggered a 37% increase in medical care use and sick leave by employees using mental health services.⁵ Health plans with the highest financial barriers to mental health services have higher rates of psychiatric long term disability claims compared to companies with easier access and lack of access to care results in increased substance use and incarceration rates. Correctional facility costs are 4-5 time higher than community based treatment of mental illness.⁶

There continues to be stigmas and discrimination regarding mental illness despite scientific research supporting the biologic nature of these illnesses. There are a substantial proportion of Americans who view mental illnesses as a self-induced weakness thus discouraging individuals to seek treatment. At times, the afflicted individual does not have the awareness that they are ill which is due to the neurochemical changes in the brain. If mental health treatment is delayed, there is decreased productivity, greater absences and longer duration of [original was truncated here]

There continues to be stigmas and discrimination regarding mental illness despite scientific research supporting the biologic nature of these illnesses. There are a substantial proportion of Americans who

view mental illnesses as a self-induced weakness thus discouraging individuals to seek treatment. At times, the afflicted individual does not have the awareness that they are ill which is due to the neurochemical changes in the brain. If mental health treatment is delayed, there is decreased productivity, greater absences and longer duration of disability.⁶ Mental illness impacts not only the individual but also co-workers around them who have to compensate for the uncompleted work with an economic burden resulting. When individuals with mental illness return to work, an additional 5-9 hours of time is needed from supervisors and co-workers to help them return to their previous level of functioning.⁷

A current concern in occupational health is the effect of downsizing on the mental and physical health of employees. In the past decade, there have been hundreds of US businesses that have downsized and reorganized to reduce costs and improve efficiency. A number of studies have explored the effects of downsizing on the workers remaining at work. These “survivors”, especially those more directly involved with the downsizing process, have been found to experience worsening mental and physical health, increased stress, increase in job insecurity, or an increase in alcohol use. ^{8, 9} Organizational factors that have been identified as negatively impacting employee’s mental health are an increase in role ambiguity, role conflict, and lack of effective communication from management. Employees who have a negative affect, have an external locus of control, or perceive management as not being supportive or interested in their employees are less likely to accept organizational changes.¹⁰

Focus on ongoing research should include the evaluation of effective ways of disseminating current findings especially to management and policy makers to improve the mental health of US workers in all sectors. On going scientific research regarding the causes and effective treatments of mental illness is needed. Collaboration between occupational health, mental health, public health, advocacy groups, the insurance industry, and the labor industry is encouraged to educate the public about mental illness and encourage a business culture that promotes mental health. Of particular interest is the effect of the organizational restructuring on the mental health of aging American Workers who are more at risk for depression and the onset of chronic medical conditions. Ongoing studies of the economic costs of mental illness at all levels are encouraged for the sake of all Americans and this country’s prosperity.

National Occupational Research Agenda (NORA)

Town Hall Meeting

College Park, MD

December 5th, 2005

Health Care And Social Assistance Sector

Testimony presented by Jane Lipscomb

Center for Occupational and Environmental Health and Justice

University of Maryland

I am here to support NIOSH's approach to the second phase of NORA by focusing on sector specific research. I am strongly in support of the focus on health care and social assistance sector. The University of Maryland's Center for Occupational and Environmental Health and Justice has been conducting research in this sector over the past six years, I have personally been focusing on health care workers health and safety for the past 25 years.

More than 10 percent of workers in the United States are health care workers. Characterized as people committed to promoting health through treatment and care for the sick and injured, health care workers, ironically, confront perhaps a greater range of significant workplace hazards than workers in any other sector. Hazards facing health care workers include biologic hazards, chemical hazards- especially those found in hospitals, including waste anesthetic and sterilant gases, hazardous drugs and industrial-strength disinfectants and cleaning compounds, physical hazards, such as radiation and ergonomic hazards, violence, psychosocial and organizational factors. Of concern great concern are the many health consequences associated with changes in the organization and financing of health care. The Social Services workforce although much more poorly characterized is the source of exposure to many of these same psychosocial and organizational factors that impact health care workers health and safety. Research is needed to begin to understand the risk factors and control strategies for preventing injury among this large and diffuse workforce.

In the limited time allotted here I will provide a brief overview of hazards and research needs associated with the healthcare and social assistance sector, while my colleagues Drs. Johnson and McPhaul will focus on the hazards of occupational stress and workplace violence respectively. We will all speak to the need for support for intervention effectiveness research within these sectors.

In 2004, the BLS injury and illness rate among hospitals workers (8.3 per 100 workers) was nearly double that of the overall private sector rate (4.8) and higher than rates for workers employed in mining, manufacturing, and construction. Although injury and illness rates have been declining among all sector workers, the ratio of hospital worker injuries to the overall private sector workers, the ratio of hospital worker injuries to the overall private sector rate has increased over the past eight years.

The nursing home segment of the health care industry has consistently reported injury and illness rates significantly higher than those for the most hazardous industries-as high as 9.7 per 100 full-time workers in 2004. The home health care industry, the fastest growing segment of health care, has rarely been the subject of occupational health and safety research. Risks for injury and illness found in the home work environment are poorly understood. Hazard controls widely used in other health care work environments are often unavailable or infeasible for the home workplace.

In health care, workers as well as patients are affected when occupational safety and health threats are not inadequately identified and addressed. There is an inextricable link between staff safety and the quality/safety of client care. Physical or psychological injury to direct care staff directly impacts the quality of client care and client safety. Optimal staffing levels and staff performance are essential to providing high quality care. The quality of health care is severely compromised when staff become injured and supervisors and administration are required to replace experienced staff with new hires or staff assigned to other units and therefore unfamiliar with clients' highly individual needs and behaviors. Nonetheless, the health care industry is a decade or more behind other high-risk industries in its attention to ensuring basic safety.

Musculoskeletal disorders (MSDs) rank second among all work-related injuries and the highest proportion of these disorders occur among health care workers. Among all occupations, hospital and nursing home workers experience the highest number of occupational injuries and illnesses involving lost workdays due to back injuries. The nursing home industry experienced a rate of back injuries nearly five times the rate reported among all private sector industries. In a recent survey of nearly 1,200 registered nurses employed across health care practice settings, conducted by Trinkoff, et al at the University of Maryland, nurses reporting highly physically demanding jobs were five to six times more likely than those with low demands to report a neck, shoulder, or back MSD. Ten percent of nurses reported having lifting teams in their workplaces, while half had mechanical lifting devices. Lifting teams and mechanical devices in the workplace were both associated with significantly lower risk of back MSDs. Lipscomb et al have reported that the risk for MSDs increased when nurses work greater than 12 hour shifts and on weekends and non-daytime shifts. The health care industry spends billions of dollars each year in workers' compensation premiums, even though there is strong evidence that reducing low back load by implementing engineering and administrative controls, such as safe staffing levels, lifting teams, and use of newer mechanical patient handling devices, reduces the risk of injury to both patients and workers.

The most prevalent, least reported, and largely preventable serious risk healthcare workers face comes from the continuing use of inherently dangerous conventional needles. Such unsafe needles transmit blood-borne infections to health care workers employed in a wide variety of occupations. Elimination of unnecessary sharps and the use of safer needles can dramatically reduce needlestick injuries. Use of conventional needles in the health care environment today has been compared with the use of unguarded machinery decades ago in the industrial workplace.

Percutaneous injuries continue to occur in unacceptably high numbers in health care despite the promulgation of the original OSHA Bloodborne Pathogen (BBP) Standard in 1991. Yet, the requirement under the BBP Standard that HBV vaccine be made available free of charge to health care workers has greatly reduced the consequences of exposure to this pathogen. Tragically, there is no vaccine or treatment for HCV, and therefore, health care workers, not only those working in the acute care setting or those who traditionally handle needles on a regular basis receive every available protection from occupational exposure to blood and body fluids.

The passage of the federal Needlestick Safety and Prevention Act in 2000, has begun to afford health care workers better protection from this unnecessary and deadly hazard. Not only does the Act amend the 1991 BBP standard to require that safer needles be made available, but it requires employers to solicit the input of frontline health care workers when making safe needle purchasing decisions. Research is needed to evaluate the effectiveness of this and similar provisions of OSHA regulations so that this critical provision can be included in future regulations.

The problem of latex allergy which is attributed, in part, to the increased use of examination and surgical gloves required by OSHA's BBP standard. The prevalence of latex allergy among health care workers is estimated to be between 5 percent and 18 percent, with atopic workers at even greater risk. As a testimony to the NORA process and these Town Hall Meetings specifically, I want to highlight that great progress has been made in preventing latex allergy during the past eight years. NIOSH's 1997, Alert document recommending the use of latex gloves only when protection from infectious agents is needed and the use of powderless, low protein latex gloves for protection from bloodborne pathogens in health care and other settings has had a great impact on glove use. NIOSH supported research has

demonstrated that substituting nonlatex or powder-free nitrile gloves for powdered gloves has been found to decrease the incidence of suspected latex allergy and specifically latex-related occupational asthma.

Health care workers are exposed to a wide range of chemical disinfectants, anesthetic waste gases, and hazardous drugs such as chemotherapeutic drugs that are known to cause human health effects, as well as others for which no or inadequate testing has been conducted. NIOSH estimates that the average hospital contains 300 chemicals, twice the number of the average manufacturing facility. More research is needed to evaluate current exposure levels and feasible hazard control strategies to chemicals used in health care including: Glutaraldehyde (Cidex), Ethylene oxide (EtO), anesthetic agents, and hazardous therapeutic drugs such as antineoplastic agents.

As you will hear from Dr. Mcphaul,

The health care sector also leads all other industry sectors in the incidence of nonfatal workplace assaults. Of all nonfatal assaults against workers resulting in lost workdays in the United States, 32 percent occurred in the health care sector. In over half (51 percent) of non-fatal assault injuries, the perpetrator of the violent act is the health care patient. Most research to date has focused on high risk health care settings such as psychiatric facilities. Our recent work with social service agencies, in particular those that provide care for the developmentally disabled and mentally retarding indicate that there are huge gaps in our knowledge of the magnitude of the risk of workplace violence in these workplaces and successful interventions towards preventing injury.

Organization of Work

Dr Johnson will be providing testimony regarding the importance of occupational stress research within NORA2. In the context of his comments he will discuss the role of OOW in overall worker health and safety. As a segue to his comments and in conclusion, many of the hazards that I have discussed can only be prevented by strategies which address the organization of modern health care work across practice settings. Support for rigorous intervention research targeting the impact of changes in work organization on health care and social service worker injury and illness are desperately needed. Our experience in conducting intervention effectiveness research over the past six years has taught us that it must be done within the framework of community-based participatory research if the intervention is to be accepted and sustained. I also urge NIOSH to recognize the time involved in conducting rigorous intervention effectiveness research and to provide a mechanism for longer periods of research support to allow for this type of research.

Thank you for this opportunity to have a voice in the development of the evolving OHR priorities.

ASTHMA IN HEALTHCARE WORKERS

Important topic, relevant research, unanswered questions

George L. Delclos, M.D., M.P.H.

Division of Environmental and Occupational Health Sciences

The University of Texas School of Public Health

Houston, Texas

NORA II Town Hall Meeting

January 23, 2006

Good Afternoon. There are approximately 16 million people in the United States with asthma. The incidence and prevalence of asthma have been increasing in the general population, both worldwide and in the United States, for the past two decades (Anderson, 1989; NHLBI, 1997; CDC, 2004). Prevalence estimates as high as 19.6% having been reported (CDC, 2004).

The annual economic and social consequences of asthma are staggering, evidenced by more than 100 million days of restricted activity, nearly 500,000 hospitalizations, over 5,000 deaths and more than \$27 billion in costs (NHLBI, 1997; Weiss and Sullivan, 2001; Druss et al 2001). Various factors have been implicated in explaining these worsening epidemiological trends, including, contaminants present in workplaces (NHLBI, 1997).

In the U.S., there are more than 20 million workers potentially exposed to occupational asthmagens; 9 million of these are exposed to established sensitizers and irritants (DHHS, 1996a). Work-related asthma (WRA) is currently the most reported diagnosis of work-related respiratory disease in developed nations. In a study conducted by our group, based on adult population data from the National Health and Nutrition Examination Survey III (1988-1994), we estimated the prevalence of work-related asthma in the U.S. to be 3.7% (95% C.I., 9.9-13.1) (Arif et al, 2003). Estimates of the proportion of asthma attributable to the work environment have varied widely, probably due to several factors, including geographic area, lack of recognition of occupational factors (Milton et al., 1998), differential reporting among occupational groups, an absence of statewide surveillance systems for asthma (DHHS, 1996b), variations in the definitions for 'occupational asthma', and differences among denominator populations. In a review and synthesis of 43 attributable risk estimates, Blanc and Toren (1999) found the median attributable risk to be 15% among the best designed studies.

Certain occupational groups known to be at particular high risk of developing OA, such as Western red cedar workers (Chan-Yeung and Malo, 1994), isocyanate chemical workers (Mapp, et al., 1988), construction workers (Bherer et al., 1994), and farmers (Kogevinas et al, 1999). However, whereas the magnitude of the risk and etiologic agents are well characterized for many of these occupations, this is less well studied in the case of healthcare workers, where data are largely derived from case series and relatively few population surveys.

Healthcare workers (HCWS) comprise approximately 8% of the U.S. workforce, and constitute one of the fastest growing sectors of the workforce, projected to increase to more than 15 million by 2012, a 30% increase from 2002. The greatest growth is occurring in outpatient settings, with average annual increases more than double those of the remainder of the U.S. economy (Hecker and Frank, 2004). Healthcare-related occupations represent 51% of the top 30 fastest growing occupations in the U.S. (Hecker and Frank, 2004). Professions expected to grow by more than 20% include nurses (by>20%), physicians (>20%), respiratory therapists (>35%), occupational therapists/physical therapists (>30%), dental hygienist and dental assistants (>40% growth), and pharmacy professionals (>30%).

Following passage of the 1992 OSHA Bloodborne Pathogens standard, which resulted in a significant increase in the use of latex-containing personal protective equipment, such as gloves, cases of latex-related asthma drew attention to HCWs. Potential asthmagens in healthcare settings go beyond latex, however, and include disinfectants/sterilants (e.g., glutaraldehyde, formaldehyde), pharmaceuticals (e.g., psyllium various antibiotics, platinum-containing antineoplastic agents), sensitizing metals (e.g., dental alloys), methacrylates, aerosolized medications and cleaning agents (Mapp et al, 2005; Pechter et al, 2005). Furthermore, since there are potentially multiple sensitizers in healthcare environments, it is

possible that interactions among these compounds could affect sensitization thresholds (Mapp et al, 2005). Previous studies in several countries have described an increased occurrence of asthma among specific groups of HCWs, including nurses respiratory therapists, and pharmaceutical workers (Lefcoe and Wonnacott, 1970; Bardy et al, 1987; Kern and Frumkin, 1989; Christiani and Kern, 1993; Dimich-Ward, Wymer and Chan-Yeung, 2004; Gannon et al, 1994; Meredith, Taylor and McDonald, 1991; Vandenplas et al, 1995; de la Hoz, Young and Pederson, 1997; Liss et al, 1997; Pechter et al, 2005).

In the U.S., the health services industry is second only to the transportation equipment manufacturing sector in total number of reported asthma cases (16% of the total), and 5 of the top 11 industries and 9 of the 22 leading occupations associated with significantly increased asthma mortality were related to healthcare services (Attfield et al, 2003). Recent surveillance data from California, Massachusetts, Michigan and New Jersey found that work-related asthma among HCWs represented 16% of the total reported cases, exceeding the proportion of the workforce made up by HCWs (8%). Agents most frequently associated with these reported asthma cases included latex, cleaning products and poor indoor air quality (Pechter et al, 2005).

In our own study of asthma prevalence and risk factors conducted in a large representative sample of 5600 Texas healthcare workers (physicians, nurses, respiratory therapists and occupational therapists), analysis of which is still ongoing, the overall prevalence of a physician diagnosis of asthma was 14.7%, ranging from a high of 17% among respiratory therapists to a low of 12% among physicians. These asthma prevalence figures are substantially higher than those reported for the general Texas and U.S. population. Furthermore, the prevalence of asthma with onset after entry into the health profession, a surrogate for occupational asthma, was likewise high (overall-7.1%; physicians-6.5%; nurses-6.7%; respiratory therapists-9.1%; occupational therapists-6.3%). Based on self-reported exposures, the preliminary analyses show elevated ORs for female sex (OR, 2.0), obesity (OR, 1.7), years as a health professional (OR, 1.03), exposure to aerosolized medications (OR, 1.04) and exposure to glutaraldehyde (OR, 1.3).

In summary, there is evidence that workers in healthcare settings are at an increased risk of WRA. However, important gaps exist in the healthcare worker (HCW) literature with respect to risk characterization of HCW subgroups, identification of specific exposure to asthmagenic compounds, estimation of the impact of asthma on work patterns among HCWs, and implementation of proper preventive measures. I urge NIOSH to support continued research into this important topic.

NIOSH Seattle Town Meeting

January 17, 2006

Comments by Ann Backus, M.S.

Instructor Occupational Safety and Health

Director of Outreach
Administrator of the Occupational and Environmental Medicine Residency
Harvard School of Public Health (HSPH)
Boston MA 02115

Greetings from New England. My name is Ann Backus; I am an Instructor in Occupational Safety and Health, Director of Outreach, and Administrator of the Occupational and Environmental Medicine Residency within the HSPH-NIOSH Education and Research Center (Harvard ERC). Thank you Dr. Howard for this opportunity to speak to the NIOSH Town Hall Meeting on Agriculture, Forestry, and Fishing. Over the past five years, I have worked with the fishing community and the U.S. Coast Guard in New England, organized, with NIOSH Alaska Field Station Anchorage, the first International Fishing Industry Safety and Health Conference, (IFISHI), and I have been writing monthly or bimonthly articles under the heading FISH SAFE for Commercial Fisheries News since February 2000. I am currently an active member of the Maine Commercial Fishing Safety Advisory Council, appointed by Governor Baldacci.

I bring comments from a variety of people at HSPH and in the fishing community.

I would like to make five points.

1) The NIOSH-funded Centers are a very important infrastructure and funding source for research in the agriculture and fishing sectors; 2) there is need for a generic research agenda that crosses the industrial sectors such as work-related hearing loss in agricultural and fishing, and probably forestry; 3) there is need for fishery-specific research to reduce traumatic injury and fatalities; 4) there is need for research on exposures of bacterial origin and associated antibiotic resistance; and 5) there is need for toxicological research on pesticides, VOCs, H₂S, and other compounds and chemicals that revisits the PELs, STELS, and TWAs and brings them into line with exposure levels and types in today's work places.

Infrastructure: The NIOSH-funded Education and Research Centers (ERCs) and the Centers of Disease and Injury Research, Education and Prevention are extremely important especially for the success of research in rural and non-urban settings such as farms, forests, a coastal areas. The ability of our researchers to gain the confidence of prospective research subjects and to be seen as having a substantive hypothesis, integrity relative to the research process, and competence for analysis and interpretation is greatly enhanced and supported by the presence of these centers. For example, Melissa Perry, ScD, at HSPH, is investigating the prevalence of hearing loss in farm youth (Vermont), ototoxic effects of solvents and noise with support from NIOSH pilot grants from the New York Center for Agricultural Medicine and Health and the Harvard Education and Research Center. I collaborated with the NIOSH Alaska Field Station in a study on Entanglement of Lobstermen in Trap Rope which was recently published in the NIOSH Workplace Solutions series and have also participated with a local research team in the analysis of indoor exposures of lobstermen to volatile organic compounds, polycyclic aromatic hydrocarbons, PM 2.5, ultrafines, and endotoxin. This research also was funded by pilot project monies from the Harvard ERC.

In each case, coming from a recognized NIOSH-funded Center enhanced access to the study community and extended our reach into rural farms and coastal villages.

NORA Research Areas:

Generic: Some of the research needed is common to agricultural and fishing: 1) Work-related hearing loss from exposures to tractors, conveyors, engines, and winches; 2) Particulate Matter (PM 2.5) and

ultra fines associated with grain dust, and pot buoy sanding and branding; 3) polycyclic aromatic hydrocarbons (PAHs) from diesel exhaust and heat branding styrofoam pot buoys; 4) endotoxin from cotton, fruits, grains, and algae-covered rope; and 5) volatile organic compounds such as paints, degreasers, and solvents.

In both industries there is major concern about child labor and childhood exposures: Kids on farms and in fishing communities are often pressed into service at an early age. Very young children of fisherman-pre-schoolers-are often present in the workshop and exposed to particulates, PAHs, endotoxins, VOCs, etc. High school students apprenticing in fishing are often stuck with the jobs their adult mentors no longer want to do. One adolescent apprentice I interviewed slept above the workshop and often woke up with nose bleeds after painting pot buoys during the day.

Fishery-Specific: Some of the research needed is unique to fishing in that the fishing work environment or work platform is almost always in motion. Either as part of the NORA area Organization of Work, or as a separate category, research on the dynamics of the work platform as a complex system involving heavy gear, human factors, weather-related factors, and fish biting factors is needed. For example, in northern Maine, there are at least six different rigging categories for scallop boats-the fishermen invent them! Each has its own set of advantages and disadvantages-some rig constructions are distinctly more prone to loss of stability than others. Research on the rigs would help determine which rigs are safe to operate and would reduce fatalities, injuries and boat losses. A marine safety officer at the U.S. Coast Guard office in Portland, Maine stressed that fatigue is a major work environment factor that needs serious attention.

Work environment/platform research can be undertaken through a variety of methodologies: injury epidemiology, incident analyses, case studies, and intervention studies, to name a few. Fishery-specific research is needed to augment the marine safety training available from such groups as AMSEA, John McMillan Associates, and others. As the Maine Commercial Fishing Safety Advisory Council gears up to develop and deliver fishery-specific training, fishery-specific research will be needed to inform this comprehensive safety training initiative. For example, the Entanglement in Trap Rope study we did at Harvard in collaboration with the NIOSH Alaska Field Station is an important contribution to fishery-specific safety training. As a result of this research I have written several articles for Commercial Fisheries News, and the Maine Marine Patrol specified that a rope locker be designed-into a new patrol boat prior to construction. This patrol boat now demonstrates an entanglement risk reduction strategy to lobstermen during the process of enforcing marine fisheries rules.

Bacterial Origin: In addition to research on mechanical and chemical exposures, a research agenda is needed for exposures with a bacterial etiology. Some of these exposures are rapidly lethal. Risk communication specific for fisherman regarding the bilge and product storage conditions that foster the generation of hydrogen sulfide (H₂S) gas by anaerobic bacteria is needed in conjunction with confined space management.

With the warming of the oceans, bacterial infections once confined to tropical latitudes may appear seasonally in more temperate zones. In Marion, MA in August 2004, one fisherman died and another required amputation at the hip as a result of exposure to *Aeromonas hydrophila*. – In Chesapeake Bay, August 2005, a fisherman died from exposure to *Vibrio vulnificus* during a crab bite-an exposure more common to the Gulf Coast as we learned during Hurricane Katrina.

In these cases of rapid lethality, hazard communication needs to be both to workers and to the health care professionals. Coupled with research on exposures of bacterial etiology should be studies related to the development of antibiotic resistance. Bacterial studies can be useful to both anti-terrorist and emergency preparedness programs, not just to the fishing community.

Toxicology: The development of new technology and instrumentation has made it possible to detect many chemicals at lower limits, and recent research has shown negative health effects at lower limits, and recent research has shown negative health effects at lower exposure levels. Researchers at the Harvard School of Public Health suggest that this next decade be the time to undertake a systematic review of the PEL, STEL, and TWA values for many exposures and to increase the amount of research on mixtures and synergistic effects of multiple exposures within and across exposure classes.

Beyond all this, it is difficult to undertake research in the fishing industry. The denominator-number of people employed and at what full time equivalent-is very difficult to ascertain, and while the numerator in terms of fatalities is relatively easy, the numerator for injuries is extremely difficult. There is no OSHA 300 log to capture injuries. Fatality and injury data are sorely needed, but require some “creative” digging.

Finally, I would like to suggest a new initiative in materials science or intervention research. Such a study in collaboration with EPA’s Clean Marinas Program could bring research to practice in boatyards and marinas and help ensure that those sites are safe and healthy for workers, boaters, and the environment. There are a number of marinas in the program including Edwards Boatyard in Massachusetts which realized a \$72, 441 cost benefit from the program, Conanicut Marine Services in RI which realized a \$285, 813 cost benefit, and Boat Haven, WA which realized \$10,800. Information is available at www.epa.gov/owow/nps/marinas.

Special populations research will continue to be critical in the next decade and will need to include, minorities, immigrants, and children, as well as non-urban populations living in rural or isolated areas.

Methodologies need to include injury epidemiology, intervention studies, and community-based/participatory studies among others. For agriculture and fishing and probably forestry as well, participatory studies involving the affected population 1) provide vital measure of realism to the study design, 2) facilitate data collection and the interpretation of results toward the eventual goal of effective risk communication and research translation, and 3) increase the likelihood of adoption of recommendations.

Thank you for all of the organizers for providing this excellent forum for exchange of ideas.

Some Facts

Farming 2002:

28,254 farms in New England nearly 4 M acres 115 out of 141 farms were 100-149 acres large market value of goods and products sold-\$2 B. in New England, Maine has the largest number of farms followed by Vermont and Massachusetts largest crop is potatoes followed by corn for silage, corn for grain, oats for grain, barley for grain.

Fishing 2004

\$404M fishing industry in Maine; 70% is lobster; nearly 71 million pounds of lobster landed for a market value of 285.8M.

Fatalities 2004

US total 5703

Agriculture, Forestry, Fishing and Hunting=659 of which 37 were fishing. Massachusetts total fishing fatalities=7.(down from 10 in 2003.)

WORKPLACE HAZARDS OF THE HOSPITALITY INDUSTRY:

THE NEED FOR FURTHER RESEARCH AND INTERVENTIONS

FOR THE REDUCTION AND PREVENTION OF DEBILITATING INJURIES

TESTIMONY OF PAMELA VOSSNAS, MPH

UNITE HERE INTERNATIONAL UNION AND UNITE HERE LOCAL 610,

SAN JUAN, PUERTO RICO

SUBMITTED TO NORA TOWN HALL MEETING

ISLA VERDE, PUERTO RICO

DECEMBER 6, 2006

My name is Pamela Vossen. I am a Senior Health and Safety Educational Representative for the union UNITE HERE's Hotel Division, based at its headquarters in New York City. I am here today to speak about workplace hazards in the hotel industry. I would like to thank OSHA and NIOSH for the opportunity to speak at its NORA town hall meeting held in San Juan, Puerto Rico.

I would also like to express my gratitude to UNITE HERE Local 610, here in San Juan, Puerto Rico, for contributing important information about the hazards UNITE HERE members face currently while working in hotels in San Juan.

Attached in the Addendum for your review are inspection reports from the OSHA Area San Juan Office and the Puerto Rico Fire Department of a particular hotel property, the Diamond Palace Hotel, as a result of complaints filed by UNITE HERE Local 610.

The information I have obtained from UNITE HERE Local 610 and its members helps to build a base of data from which efforts to reduce workplace hazards in the hospitality industry can begin. To achieve this, greater attention must be paid through research; labor-management cooperation; management and worker training; enforcement of local, state and federal regulations; and investment of private and government resources, including NIOSH, to first document these hazards, then propose solutions and finally evaluate their implementation and effectiveness

UNITE HERE had the opportunity to participate in the January 2006 service sector town hall meeting in Los Angeles. Three hotel housekeepers spoke about the demanding workloads and the corresponding injuries to their bodies, and the need to work more than one job due to low wages. Since then we have been able to research further the impact on housekeepers' health of the current demands of the hospitality industry, some of which we presented at the April 2006 NORA Symposium in Washington. In the attached Addendum are highlights of those findings, in addition to an ergonomic evaluation of hotel housekeeping (includes use of lumbar motion monitor technology). UNITE HERE along with several academics is expanding its research to include other job titles so that we have a more comprehensive and accurate assessment of the occupational injuries facing hotel workers. We look forward to submitting those results in the future.

HAZARDS IN THE HOSPITALITY INDUSTRY IN SAN JUAN, PUERTO RICO

During the first week of December 2006, UNITE HERE had the opportunity to discuss with its members the working conditions in various hotels locally. Ergonomic hazards of hotel housekeeping was one of many problems discussed, including pushing heavy carts laden with sheets and pillow cases, extreme bending to reach beds at a low height from the floor, and extreme stretching overhead to clean large mirrors..

Additional hazards identified include:

- Dangerous storage practices of flammable items including chemicals.
- Exposure to chemicals, fumigants; lack of proper training on chemical use; lack of PPE for chemical use
- Heat stress, extreme temperatures

- Ergonomic hazards of hotel housekeeping - pushing heavy carts laden with sheets and pillow cases, extreme bending to reach beds at a low height from the floor, and extreme stretching overhead to clean large mirrors.
- Ergonomic hazards in kitchen, storage areas, and at the front desk
- Poor maintenance of machinery in kitchens, storage area, laundries
- Lack of ventilation in storage areas with exposures to paints, solvents and gases
- Lack of safe drainage of wastewater from hotels
- Lack of attention to water leaks
- Lack of machine guarding
- Slippery surfaces either due to type of surface or due to spills
- Heavy manual lifting
- Pressure, stress due to workload
- Lack of functioning fire safety systems and training affecting workers and guests
- Poor pest management - presence of cockroaches and other insects
- Lack of security systems, lack of security in parking lots, workplace violence hazards
- Lack of provision of personal protective equipment

FURTHER RESEARCH URGENTLY NEEDED

UNITE HERE strongly encourages NIOSH to include in its Research Agenda -- and otherwise encourage support for -- further research on the occupational injuries and illnesses in the hospitality industry.

This must include 1) identifying not only the problems but also the solutions; 2) measuring the effectiveness of interventions; 3) including participatory methods of research so that the expertise of workers and their collective bargaining agents (unions) can contribute to the process; 4) identifying critical moments as opportunities for intervention, i.e. hotel design and renovations; and 5) identifying labor-management initiatives for hazard identification and control.

Occupational hazards facing hospitality workers today are inexcusable, not only because they result in debilitating injuries but also because there exist many interventions to prevent such injuries from occurring in the first place. UNITE HERE looks forward to continued collaboration with NIOSH, with other occupational health professionals, community organizations and with hotel employers in making hotels a source of safe jobs for its community, safe places to work for hotel employees and a safe place to visit for hotel guests.

On behalf of UNITE HERE and its members, especially those in Puerto Rico, I thank you for the opportunity to speak here today.

Sincerely,

Pamela Vossen, MPH
 Senior Health and Safety Educational Representative
 Hotel Division

UNITE HERE

New York, NY 10001

ADDENDUM

1. Highlights of UNITE HERE Research Findings of Hotel Housekeeper Injuries submitted to the April 2006 NORA Symposium.
2. UNITE HERE Report - Risk of Musculoskeletal Injuries to Hotel Housekeepers (includes lumbar motion monitor evaluation findings)
3. OSHA Area San Juan Office – Inspection Report and Penalties for the Diamond Palace Hotel, May 3- July 11, 2006 (in English and Spanish)
4. Puerto Rico Fire Department – Inspection Report for the Diamond Palace Hotel, May 8 and June 7, 2006 (Original report in Spanish along with UNITE HERE English translation)

1. Highlights of UNITE HERE Research Findings of Hotel Housekeeper Injuries submitted to the April 2006 NORA Symposium.

UNITE HERE, in conjunction with academics from the University of Illinois, School of Public Health (Drs. John Halpin, Susan Buchanan and Peter Orris); the University of Massachusetts, Lowell (Dr. Laura Punnett); and the University of California, San Francisco, (Dr. Niklas Krause) presented research findings at the NORA Symposium this past April. These findings evaluated over four thousand injuries occurring to hotel housekeepers gleaned from OSHA 300 logs from over 80 hotels in the United States, in the period 1999-2005. These hotels employed approximately 40,130 workers, of whom 7,149 were hotel housekeepers and the rest were from other job titles. Below are the highlights of these research findings.

Analysis of Hotel Housekeeper Injuries using Hotel Employers'

Injury/Illness Records (OSHA 300 Logs)

Of note:

Average annual injury rate during the period from 1999-2005 in five major US hotel companies.

-- Housekeepers experienced a 10.4% average injury rate compared to a rate of 5.4% for non-housekeepers; this is an increase in risk of 86% for hotel housekeepers

Proportion of hotel employment versus proportion of total injuries

-- Hotel housekeepers represent 17.8% of the hotel workforce but represent anywhere from 26.2 (1999-2001) to 30.4% (2002-2005) of the total injuries in the hotel workforce.

-- The increased risk for housekeepers (compared to all hotel employees) ranges from 47.1% in the 1999-2001 period to 70.8% greater risk in 2002-2005.

-- This indicates an increase in hazards in hotels in the last three years compared to 1999-2001.

Descriptive Injury Data

- Sprains and strains are the most common types of injuries occurring to hotel housekeepers (44%);
- Contact with objects (35%) and overexertion (27%) were the leading causes of these injuries;
- Upper extremities (32%) and the trunk (including back) (22%) are the most common body parts affected;
- Median days away from work due to injury was 14, twice the median for all hotel employees nationally, at 6 days.

ERGONOMIC HAZARDS OF HOTEL HOUSEKEEPING

Clearly, ergonomics is a serious hazard in the hospitality industry and the above data confirms that for hotel housekeepers. In reviewing the job tasks of hotel housekeepers using job description information supplied by hotel employers, the following hazards are present:

Repetitive motion of bed making and bathroom cleaning, including removing and stuffing pillows ranging from four to six per bed;

Forceful motion in pushing loaded carts weighing hundreds of pounds, with heavy linen and supplies;

Awkward postures of bed making and bathroom cleaning;

Heavy lifting of mattresses weighing over 100 pounds, duvets weighing 9-15 pounds;

Repetitive lifting of mattresses to complete bed making using triple sheets;

Our own research identifying ergonomic hazards was also confirmed recently by experts from Ohio State University including Dr. William Marras, using the lumbar motion monitor. This technology dynamically measures spine movement in three dimensions – forward/backward, twisting and sagittal (side to side). This technology predicts the likelihood that a certain job title will fall in the high-risk job category (i.e. annual injury incidence greater than 12%) for low back disorders. Housekeepers wore these machines while performing standard tasks in a hotel room. The findings document not only the existence of ergonomic hazards occurring to hotel housekeepers but also how their risk profile exceeded the risk for certain job titles in industries long-recognized as hazardous – health care, automobile assembly, truck assembly; these findings also document that only warehouse work exceeded the housekeepers' results.

Job Title	Probability of being in "high-risk" group
Warehouse	82%
Hotel housekeeping overall	76%
Hotel Bed Making Task	74%
Auto Door Assembly	71%
Hotel bathroom cleaning task	70%
Nursing/patient handling	64%
Truck hood loading	59%

Additional research by ergonomics expert Gary Orr, CPE, indicated that the task of making a king-size luxury bed resulted in a NIOSH Lifting Index of 1.29, which by NIOSH standards is an unsafe lift for 90% of the population.

RECOMMENDATIONS

- More humane workloads
- Comprehensive re-design
- Ergonomically designed tools
- Increased staffing
- Increased enforcement of occupational health government standards
- Joint labor/management health and safety training for supervisors and employees

2. UNITE HERE Report of Risk of Musculoskeletal Injuries to Hotel Housekeepers (includes lumbar motion monitor evaluation findings)

See [Appendix 13](#) for this document.

3. OSHA Area San Juan Office – Inspection Report and Penalties for the Diamond Palace Hotel, May 3- July 11, 2006.

See [Appendix 14](#) for this document.

4. Puerto Rico Fire Department – Inspection Report and Penalties for the Diamond Palace Hotel, May 8 and June 7, 2006.

See [Appendix 15](#) for the original report in Spanish.

UNITE HERE English translation

Puerto Rico Fire Department – Inspection Report and Penalties for the Diamond Palace Hotel

Page 1

Date: May 3, 2006

Name of Building:	Diamond Palace
Physical Address:	55 Condado Avenue
Town:	Condado
Reference Number:	93869
Classification:	Residential
Owner of the Establishment:	Diamond Palace and Casino
Mailing Address:	P.O. Box 1637

San Juan, PR 00908

Telephone:	721-0810			
Type of Use:	Hotel and Casino			
Emergency Exits	Adequate	Deficient	Fine	N/A
010 Other			P	
Fire Safety Equipment	Adequate	Deficient	Fine	N/A
221 Automatic Spreaders			P	
222 Siamese Connection			P	
Fire Hazards	Adequate	Deficient	Fine	N/A
114 Electrical Systems			P	
Emergency Plans	Adequate	Deficient	Fine	N/A
331 Emergency Plans			P	
332 Evacuation Plans			P	
335 Fire Drills			P	

COMMENTS:

The stove that is located in the 2nd floor is placed inside an appropriate room, because it is protected by automatic sprinklers.

Re-inspection date will be: May 18th, 2006. The following requirements or conditions should be met on the indicated date:

CODE

010:

Obstructions at the Lobby Exit Door should be removed. The exit door should be kept accessible so that it can be opened.

Completion Date: May 18, 2006

PAGE 2

The following requirements or conditions should be met on the indicated dates:

CODE:

114: A certification of electrical work should be provided regarding the tasks that were performed on a temporary basis at the lighting substation.

Completion Date: May 18, 2006

221: The headstocks of the automatic sprinklers should be kept away from the acoustic [ceiling tiles] because on some floors [of the hotel] they are blocked.

Completion Date: May 18, 2006

222: The Siamese connection of the building should be identified by a sign.

Completion Date: May 18, 2006

331: An action plan in case of fire must be created.

Completion Date: May 18, 2006

332: An evacuation floor plan should be provided inside each room indicating access to the exits.

Completion Date: May 18, 2006

335: Drills [fire and evacuation] should be performed at least twice (2) a year. Written records should be kept on each drill, to be reviewed by representatives of the Puerto Rico Fire Department.

Completion Date: May 18, 2006

Submitted on May 8, 2006 to the above property.

UNITE HERE TRANSLATION INTO ENGLISH

Puerto Rico Fire Department, San Juan Division - Inspection Report

Date: June 7, 2006

Name of Building:	Diamond Palace
Physical Address:	55 Condado Avenue
Town:	San Juan
Reference Number:	93869
Classification:	Residential
Owner of the Establishment:	Diamond Palace and Casino
Mailing Address:	P.O. Box 1637 San Juan, PR 00908
Telephone:	721-0810
Type of Use:	Hotel and Casino

Re-inspection date will be: June 17, 2006. The following requirements or conditions should be met on the indicated date:

During the re-inspection it was found that they had complied with the requirement(s) 010-222. The requirements 114, 221, 331, 332, 335 are in process of being completed.

Regarding the 221 requirement - they are working on this.

Completion Date: June 17, 2006

Submitted on June 7, 2006 to the above property.

Editor`s Note: This testimony was prepared for the NORA Town Hall meeting in PR; it was not presented there verbally but was submitted electronically.

The Burden of Occupational Injury - A Challenge for NIOSH and the Rest of the World

Submitted by Tom Leamon, PhD

Reflection on the value of NORA inevitably lead to a consideration and comparison of the actual research and the success, or otherwise, of the implementation of interventions to reduce injury. In a competitive environment, interventions are likely to compete for scarce resources with other priorities - thus the adoption, or otherwise, of NORA research is not solely dependant on the quality, or findings of that research. A key issue is how well the problem is recognized and how an intervener might evaluate potential interventions against other enterprise demands. This occurs at all levels, from global organizations, such as the ILO and WHO, to globe spanning commercial enterprises, from an SME to a national government and the approach suggested involves the determination of the Burden of Occupational Injury. There are significant challenges to achieving such a metric.

In the United States the number of injuries reported exceeds the number of new cases of disease reported by a factor of more than the 13 to one. While this observation does not accommodate the very significant number of long latency disease cases which arise from workplace exposures, it is clear that the resources, both intellectual and financial, devoted to reducing injury are not allocated to reflect the relative significance of each. This is not to say that the resources devoted to avoiding occupational disease should be reduced -- for the evidence is that the current resources have made, and continue to

make, significant improvements to workers health. Instead, it is a cry for the allocation of more resources appropriate to the burden placed upon individual workers, their employers and the broader society.

The unacceptable lack of resources can be readily seen by charting the number of Schools of Public Health in the United States with comprehensive occupational safety programs. An analysis of the web sites, identified by the Association of Schools of Public Health, shows that of the many schools active in occupational safety and health there is not a single one claiming such an occupational safety program. While significant proportions, (but not even a majority) identify safety in their course or activity lists, none appear to address occupational safety in an appropriate manner -- instead topics included under this rubric include violence (spousal, hand gun etc), youth, bicycles, rural & agricultural exposures and automobiles - including collision biomechanics. At the next level of analysis of specific web sites, activities as varied as mental-health economics, various HIV interests, drug abuse, obesity and tobacco products were included under the "safety" banner.

Despite the fact that the direct and indirect cost burdens to society and to enterprises arise from the pain and suffering of individual workers, there appears to be a palpable lack of public concern. This may result from a lack of information on the burden per se and this lack of good data is by no means solely an American problem. The current data produced by the ILO, (and well known by that institution), indicate how serious an issue this is: with Pakistan reporting fewer fatal injuries than Singapore and India reporting fewer fatalities than Hong Kong. Without appropriate data it should be expected that appropriate research and intervention resources will not be available to reduce this burden.

The most significant attempt to determine the burden is perhaps the WHO/Harvard initiative - the Global Burden of Disease, which attempts to measure the burden by the use of DALYs. There is a significant and critical literature, concerning methodological challenges to this metric. Of particular concern to the present commentator is the method of determining disability weights and, more so, the practice of developing monetarized derivatives in order to rank the seriousness of the various sources of disability. Of specific concern is the situation where the estimated "societal cost" is very substantially larger than the actual incurred costs. In this circumstance, despite the well accepted huge variability in these estimated costs, a slight error in this estimated component may totally eclipse the actual costs borne by the appropriate party. If this was not a sufficient challenge to those responsible for the introduction of interventions, the more serious problem is that any savings by reductions in this component are not realizable by those responsible for the introduction of the interventions normally the "workplace owner" i.e. the employer.

A good example the problem with this approach is a paper by Dembe (2001) which had an ever expanding view of social consequences of occupational injuries and illnesses which would have produced a colossal monetarized value. While this appears to be a well-intentioned, and popular, approach to establishing the seriousness of an issue, it appears to depend on attracting the interest of a super-enterprise party and then waiting for a "deus ex machine" intervention to make the improvement. In other circumstances, significant burdens measured by DALYs have attracted governmental interest and have produced legislation which, when coupled with enforcement, have led to safer circumstances. Unfortunately, in the current environment where the expenditures involved in any intervention must be competitive with other financial demands this approach is likely to fail and the "green" dollar savings are inevitably likely to receive more attention than the "white" dollar version.

The unreliability of some estimates of the financial burden is exacerbated by a significant underreporting of injuries which is well documented in the literature. The under-reporting of even fatal workplace injuries has been documented by NIOSH.

In determining the appropriate measure of the burden there are significant technical challenges to be taken up by our National Institute including:

Reporting

Defining injury

Defining work

Defining occupation

The transient nature of workplace

Transient nature of job (improvisation)

Small to medium enterprises, the sampling, aggregation and intervention

The role of transportation

In terms of reporting, there is simply a wide variation in the understanding of what should report. Workers with sharp instruments or glass workers may ignore many minor cuts, and miners with intermittent low back pain may assume this is part of their occupational demand. The wide variability of work environments, from office reception areas, to forestry or fishing in winter also leads to different perspectives on the seriousness, and hence the reportability, of various injuries. The philosophical challenge of developing scales to allow comparisons between risks and, even more appropriately, to allow meaningful legislation to accommodate this immense range of environments is one which should be inherent in NORA.

The definition of work, for pay or not for pay, is significant to the determination of the Burden. In some administrative databases certain categories of exposure to work hazards are excluded including sections of agriculture, self-employment and youth. With the increase in workers working at home this issue needs particular care. In a study in a developing economy, Wellman and Leamon found 42% of injured workers reported injury occurring in the workplace, compared with a 62% response by the same workers to question of where you hurt "while working". The same study found significant differences when injury rates were calculated by using the number of jobs as the denominator compared with using the number of "full-time equivalent". In a society involving an increase in part-time work, post-retirement work and multiple jobs this is a serious issue which requires research in order to develop appropriate corrections.

The question of transient workplaces is acute in construction, forestry and other high risk environments. In these environments, workers as can be exposed for short periods to high risks, risks which may not be replicated for significant periods. In many of these industries, improvisations to overcome unforeseen difficulties are necessary and are likely to continue and generate acute, but short term risks. New approaches, such as case crossover designs may be needed to determine both the burden and the significance of particular hazards.

By the very nature of small to medium enterprises, the risks may not be apparent to the owners, who often lack the aggregated data available to large enterprises or to federal and state authorities. In many cases, even with high hazards, the owners may not have seen adverse outcomes over long periods and are likely to assume that injuries elsewhere were the result of inadequate management or worker carelessness. Known biases in reporting behavior have been identified in SMEs. Parenthetically, there is

a significant need for communication research to address this issue and the associated question of how both informing data and most importantly intervention strategies and methods might be communicated to the owners of small to medium enterprises.

The widespread practice of breaking out transport from occupational exposures obscures the seriousness of occupational exposures. This is certainly the case in the ILO figures - especially for those countries in which much of all transport is associated with occupational uses. Equally, it should be pointed out, that many so-called manufacturing enterprises in this country are in fact huge transportation businesses, with many workers involved in trucking and the use of regular automobiles in the course of their occupation.

The role of surveillance in occupational injury might need to be modified. In traditional health investigations the role of surveillance is to identify subtle or concealed risks. This disease model approach has less value in many traumatic injury exposures which, in themselves, are clearly hazardous. In this case a significant role of surveillance is to activate interventions, by increasing awareness - possibly by appropriately determining the huge burden, estimated to be over \$1 billion a week. Which is paid by American enterprises for the pain-and-suffering borne by their workers as a result of workplace hazards?

Finally, a personal, possibly idiosyncratic view: NORA has paid insufficient concern to the issues of "intervention research". Beyond the evaluation of actual interventions, which appear to be a hallmark of Research to Practice, there is a need to question the value of "intervention research". This is well illustrated by the difficulties recorded in the paper by Sinclair et al. in 2003 which exemplifies the common observation that the research to validate an intervention may be more costly than the intervention itself. The corollary is also true – an intervention such as a machine guard or a well designed fall arresting device may require considerable research expenditures and yet eventually be so "obvious" that the role of research in the R2P paradigm may be undervalued.

Equally there has been sparseness in projects involving methodological development, particularly in surveillance which appears to be a lack of investment in the future reduction of the burden of occupational injury but is surely necessary for an accurate determination of the Burden of Occupational Injuries.

Editor's note: The author later clarified that "DALY" is "disability-adjusted life year."

Note: Submitted as w4622 from an E-mail received by the NORA Coordinator on 10 September 2007.

Technical Writer/Publicist

NASA White Sands Test Facility

P. O. Box 20

Las Cruces, NM 88004

Thank you for inviting me to participate in your NIOSH town hall meeting to develop National Occupational Research Agenda (NORA) in an effort to reduce injuries and promote safety of the American Worker. Our site is made up of departments including construction, engineering, and administration. Our primary mission is to test rocket engines, materials, and components, and also fabricate flight hardware for NASA. Our site is classified as hazardous.

Our site participates in the Voluntary Protection Program (VPP/OSHA) to reduce our injury rate. We have awareness campaigns and have established programs including:

Close Call System

Stop Unsafe Acts!

Safety Professional Consultation

Open Door Policy

Spontaneous Interviews

Safety Working Teams

Rewards and Recognition Programs

The benefits of our VPP program include:

Reduced injuries

Worker's Compensation savings

Lost time savings

Making improvements to processes and equipment

Loyalty

Productive work force

Higher morale

Less employee turnover

Improved site marketability

We believe Safety is a Value, not a priority, and we apply our VPP program across the board to include all employees and all departments.

Our site has 5 OSHA stars: our Agency and all 4 of our contractors. Please contact me if you would like more information. Again, thank you for allowing us to be part of your research.

Note: Submission was received by the NIOSH Docket Office as an E-mail on 12/19/2005.

January 23, 2006

Dr. Sidney C. Soderholm, NORA Coordinator

200 Independence Ave., S.W., Room733 G

Washington, DC 20201

Re: Process Safety Management Compliance

Dear Dr. Soderholm:

Thank you for the opportunity to provide public comments as part of the National Occupational Research Agenda (NORA) Stakeholders Meeting in Houston, Texas on January 23, 2006. My written comments address the need for NORA research projects in specific areas of the petrochemical industry.

I. INTRODUCTION

The Contractors Safety Council of Texas City (CSC/TC) was established as a non-profit safety training organization on June 25, 1987 as a joint venture between the Texas City Petrochemical Owners and the contractors who worked in their facilities. The original mission of the organization was to develop and conduct a basic petrochemical safety orientation program common to all Owner facilities and supplement this training with site-specific training for each individual facility. Since the first training programs were taught in November 1988, CSC/TC has conducted over 200,000 petrochemical safety

orientation sessions, and conducted over 430,000 site-specific training sessions. CSC/TC has offered these training services to over 290,000 contract workers. The success of CSC/TC has resulted in the establishment of additional Safety Councils, especially along the Gulf Coast area, serving our nation's largest concentration of petrochemical facilities. An outgrowth of this effort resulted in the formation of a separate non-profit corporation called the Association of Reciprocal Safety Councils (ARSC). ARSC is involved in establishing a core safety training curriculum, setting testing standards, auditing program effectiveness and ensuring consistency of training. The twenty three Safety Council members of ARSC provided safety training to over 200,000 contract workers in 2005 and conducted over 400,000 site-specific orientations to contract workers.

In 1992, the Occupational Safety and Health Administration (OSHA) promulgated the Process Safety Management (PSM) standard 29CFR1910.119 (the "standard"). This standard contained fourteen essential elements for the elimination of catastrophic events associated with highly hazardous chemicals in the petrochemical industry. One of the principle concerns addressed in the standard involved the use of contractors for maintenance/turnaround activities. As Executive Director of CSC/TC for the past fifteen years, I have witnessed the changing role of the contractor work force in the petrochemical industry. The role of the contractor work force needs to be included in the National Occupational Research Agenda (NORA).

II. CONTRACTORS

Many petrochemical owners have initiated programs to evaluate the safety performance of contractors used in maintenance/turnaround activities. These programs have resulted in numerous best practices that need to be analyzed, reviewed, documented and shared with petrochemical owners so the superior safety performance can be duplicated at other locations. Many contractors have achieved recordable injury rates far superior to permanent plant employees, but experience a significantly higher fatality rate. The causes of these fatalities need to be investigated, researched, documented and analyzed as a NORA project, thus eliminating ultimate failure of the safety system. In addition, efforts like the Contractor Assurance Process (CAP), instituted by CSC/TC for our petrochemical owners, needs to be communicated to other petrochemical owners as an industry best practice. The CAP process is based on four cornerstones for management of an effective safety/security process related to the safe use of contractors for maintenance/turnaround work activities. The four cornerstones ensure that every contract worker is drug free, security background checked, safety trained and skill assessed. The use of technology applications to limited plant facility access to contract workers who do not meet these four requirements is currently under development by CSC/TC. These types of best practices need to be identified and shared with other petrochemical owners as part of a NORA project.

Even though a successful contractor safety management process may be implemented in a petrochemical facility, contract workers still may be at risk due to issues of facility siting. The location of job trailers through out a facility must be given proper review to determine safe distance requirements, anchorage, evacuation procedures and notification of unit start up. The research of the existing recommended industry practice must be analyzed and communicated to the industry to determine the risk level associated with locating job trailers inside a petrochemical facility. The need for this research is evidenced by the events at the BP Texas City refinery on March 23, 2005, in which the location of the job trailers played a major role in the fatalities. It should be noted that the only contractor involvement in the maintenance/turnaround activities and start-up of the ISOM unit was enduring fifteen fatalities and

over 170 injuries due primarily to the location of the job trailers. This is an additional area for a NORA effort.

III. PROCESS HAZARD ANALYSIS

When the standard became law in 1992, petrochemical owners were given a schedule when all the Process Hazard Analysis (PHA) had to be completed. A three year implementation schedule was given with 100% compliance required with this provision by 1995. Ten years have passed since this original mandate and a question concerning the completeness and effectiveness of the PHA must be researched, reviewed and evaluated with the findings communicated back to the petrochemical industry. A NORA research effort outlining the effectiveness of the PHA process is needed. This effort should analyze how and when the petrochemical industry conducts a review of the PHA, how management of change issues are incorporated in the PHA, who ensures the existing PHA is complete and adequate, how are new hazards addressed and incorporated into the PHA, and how is this information documented and communicated back to site supervision, engineers, operators, maintenance supervisors and contractors. The number of petrochemical incidents under investigation by the U.S. Chemical Safety Board should serve as a reminder that issues' involving the effectiveness of the PHA is a principle cornerstone in PSM and must be evaluated for its effectiveness and would serve as a worthy NORA project.

IV. MECHANICAL INTEGRITY

Another area which needs additional research involves issues of determining the effectiveness of mechanical integrity programs. By nature, the petrochemical units are designed to operate without interruption for extended periods of time. Failure of critical components in any unit can have disastrous effects. A systematic approach on ensuring mechanical integrity of these components is required under the PSM standard. The development of industry best practices in mechanical integrity needs to be reviewed, analyzed and evaluated through a NORA research effort. This critical information needs to be distributed to the petrochemical industry through their various trade associations such as American Petroleum Institute, National Petroleum Refiners Association, Texas Chemical Council, and other owner-sponsored organizations.

Respectfully submitted,

R. Ronald Sokol, C.S.P.

Outline for Comments at the NORA Town Hall Meeting - Houston Texas January 23, 2006

Topic - Containment of Hazardous Drugs

Hank Rahe - Director Technology Containment Technologies Group, Inc.

My Background Information:

Work Experience:

-- Containment Technologies Group, Inc. - 1994 to Present - Director Technology

-- Eli Lilly and Company - 1966 to 1993 - Manager Containment Technology (1987-1993)

Professional Organizations and Boards:

-- International Society of Pharmaceutical Engineers

- Past Chairman of the Board

- Board member for five years

-- ISPE Foundation

- Past member Board of Directors

-- CleanRooms Magazine

- Editorial Advisory Board

- Monthly Life Sciences Column (1996-2003)

-- American Pharmaceutical Review

- Editorial Advisory Board (1999-2003)

-- NIOSH Hazardous Drug Committee Member

-- ASHP Sterile Drug Guidelines Committee

-- Hazardous Drug Guidelines Committee

Discussion:

In order to understand containment of hazardous drugs it may help to understand the "journey" a compound takes from discovery to delivery to the patient.

Background:

All pharmaceutical compounds are hazardous. By this I mean all have an effect on people exposed to that compound. The impact of the effect is a function of how much of the compound an individual is exposed too and how frequent the exposure.

The final product forms fall into two categories: solid dosage (capsules and tablets) and parenteral (injectable)

After a compound has been discovered and determined to be of potential value in the very early stages of development testing is conducted to determine therapeutic dose, toxic level and what is call the "no effect level"

Based on this and numerous other data an "exposure level" or limit is established to be used internally for worker protection. (1)

The exposure level is critical in determining the proper contamination control strategies for providing a safe work place for workers.

The elements go into the control strategy: engineering controls; work practices and PPE. Determining the exposure level also helps to determine how the facility and workers will be monitored.

These elements are all in place for the manufacturing environments. In the delivery process including preparation and administration is where a major disconnect occurs.

I am proposing two initiative be considered:

1. Collaboration with Pharma to establish an exchange of information that can be used to establish exposure level bands that can be used to develop the control strategies (engineering controls; work practices and PPE) necessary for the delivery process of preparation and administration.

2. Conduct basic research into the level of contamination generated in the delivery process. An example would be determine the amount of liquid, aerosols and gas produces in the preparation process. The process of removing the drug from a vial using a syringe and injecting the liquid into delivery vessel could be determined. This data would help to prioritize and develop effective control strategies without conducting studies on the hundreds of drugs used in treatments.

The combination of these initiatives would help provide information that can be used to establish a safe workplace for thousands of healthcare workers.

Thank you

Hank Rahe

Genetic Predisposition:

Request for NIOSH Model For Implementation of
Genome-based Occupational Risk Assessment
by Ilise L. Feitshans JD and ScM

120 Warwick Rd Haddonfield NJ USA 08033

856 428 0605 ilise@prodigy.net

Presented to NORA NIOSH Town Hall Washington DC March 13 2006

My name is Ilise Feitshans. I am a lawyer with the public health training from the Johns Hopkins University Bloomberg School of Public Health. I have been writing and lecturing in the field of occupational health for thirty years. I write the treatise for Westlaw.com entitled DESIGNING AN EFFECTIVE OSHA COMPLIANCE PROGRAM. I am sure that you have each memorized that text, or if not, then the version for non-lawyers entitled BRINGING HEALTH TO WORK. Today I am also videotaping a history of OSHA Act for Digital 2000 Productions entitled OSHA 35 Still Alive! (You'll love the movie if you liked the book). I also have been asked to submit written comments on behalf of the Human Ecology Action League, regarding Nurses and Teachers : Worker Health, Worker Concerns.

In my five minute time limit I want to provide an outline, (oversimplified due to time constraints) of something from the past that impacts workplaces today - and in the future: Genetics

The role of genotype, genetic propensities, even the very nature of the interaction between these genetic players and the work environment ultimately plays a role, if not controls, our individual ability to perform work today and tomorrow. My request to NORA NIOSH is narrow and specific: I perceive the role of genetic testing, monitoring and research in the workplace as inevitable, and equally inevitable is a discourse fraught with painful social questions such as : eugenics, social engineering, stigma, genetic discrimination, potential liability, assumption of the risk, right to know and health care costs. Only NIOSH has the statutory permission to openly discuss the hard choices in genetic technologies.

I request that NORA NIOSH take the lead and develop research into practice recommendations that will guide the future role of genetics at work.

Genetics poses hard questions. Genetics is hard to understand but it is important. Perhaps the greatest challenge for NORA NIOSH will be defining not the genetic materials of concern to workers and their employers; and not the criteria for the predictability and reliability of genetic testing, screening and monitoring itself. Genetics is a cross cutting issue, but it has particular importance in specific industries, in agriculture, in the global scientific community, and for small business who will look perhaps a tad more closely at health care and insurance costs compared to larger scale employers. The greatest challenge (and where I hope NORA NIOSH will tap my expertise) is in the area of definition of terms.

No one wants to make employers pay for problems that are inherited. Existing social policies, such as the tradition that state-based funds for workers' compensation fill the void when the injury or occupational illness comes from previous employment is an example of the precedents for this point. At the same time, we, society, and NORA NIOSH especially must reconcile this fundamental notion of preventing the unfairness to pay or serve as a repository for liability that the employer did not create from a third party past with three (3) important realities :

Employers remain responsible for providing employment and places of employment that are free from recognized hazards under Section 5(a)(1) of the Occupational Safety and Health Act of 1970 (OSH Act). This is without regard to the origin of the effect of the hazard, so long as the employer has control of the premises where the recognized hazard is involved. Certainly, genetic technologies will reveal connections between workplace exposures and genetic transformations in workers. Once these connections have been discovered within the scientific community, this will expand the scope and breadth of the term « recognized hazards » NORA NIOSH must explore this new reality very keenly.

ADA—The Americans With Disabilities Act—applies to genetic conditions, so knowledge in the scientific community that meets the employers obligation to provide safe and healthful employment and places of employment does not mean that an employer can simply fire the worker at risk to prevent harms revealed through genetic technologies. Employers cannot easily escape the co-equal obligation to provide reasonable accommodations to people who can perform the essential functions of their work, despite concerns about genetic factors in the workplace that were heretofore unknown or misunderstood.

Lastly, the convergence of new genetic technologies as applied through pathbreaking research may redefine our collective understanding of « safety » « health » or « disability » and may challenge both the fundamental fairness and scientific underpinning of existing standards, which presumes to protect all workers equally without stratifying the requirements of standards to meet the special needs of particular workplace settings, particular genetic risks or specially vulnerable populations. OSHA in particular has refused to allow such stratification even in the case of reproductive health hazards which

impact female workers very differently from male workers, regardless of issues during pregnancy such as fetal protection. Genetic monitoring and related research issues may signal a new era and thus the demise of «one size fits all » regulatory standards. These concerns must be addressed without bankrupting employers, or saddling them with undue liability, but also without creating an underclass of people who lose their employability due to stigma, discrimination, potential future injury based on genetic propensity, insurance costs or potential liability involving genetic factors and harmful workplace exposures that were previous unexplained or misunderstood.

This task is of millennial importance to every workplace and every worker in our society—USA society and globally. That explains why understanding genetics is hard, not easy. NORA NIOSH must rise to meet this challenge; to explore the best future path for applying genetic technologies to work for the 21st century.

Thank you for your attention to this vital matter.

Ilise L. Feitshans JD and ScM

NIOSH/NORA "Town Meeting"

Lowell Massachusetts, March 20, 2006

Testimony of Cathy Boudreau, President of the Massachusetts Teachers Association

The Massachusetts Teachers Association represents 93,000 workers in Massachusetts, including faculty and staff in k-12 schools, as well as higher education. We are the largest union in the Commonwealth and we are affiliated with the National Education Association.

Surveillance

We have joined with a coalition of public employee unions in this state to petition the legislature for a public employees' OSHA in order to ensure that the most basic protections guaranteed to employees in the private sector also apply to our members. Perhaps most important is that in the absence of Federal OSHA surveillance and reporting requirements, there is no systematic collection of data on the occupational injuries and illnesses of teachers. Our members have been exposed to hazardous work environments and building materials - including asbestos - but there are scant data available to inform policy and prevention.

Indoor Air Quality

We are supporting separate state legislation concerning indoor air quality in public buildings because we have innumerable complaints from our members - as well as data collected by the State Department of Public Health - about mold and other air contaminants that threaten the respiratory health of teachers, staff and students. We understand that current OSHA standards do not deal adequately with such indoor air issues. We are deeply concerned about the health of children who spend their days in contaminated schools - as well as the large number of staff who report one form or another of respiratory illness. We would welcome research that examined the relationship between respiratory health of teachers and the variety of indoor air contaminants in schools.

Construction and Renovation Hazards

At a recent meeting, the MTA Environmental Health and Safety Committee heard complaints from members about the difficulties of working in the midst of deteriorating physical plant, renovation projects and new building construction. Noise and unidentified dusts were the principal hazards mentioned. We are concerned that these conditions may pose serious threats to the health of education personnel but are considered mere nuisances by public officials. Investigation of such circumstances is warranted and would be very helpful .

Infectious Disease

We note that the Centers for Disease Control recently recommended flu vaccination for children under 7 years of age. As the New York Times commented in an editorial, it is important to make available vaccination for school age children in order to protect them, their teachers and the community. A recent pilot study of faculty and school personnel by the Massachusetts Department of Public Health suggests that a third of these staff suffer from respiratory diseases. A larger study of school-age children in Massachusetts suggests that about 25% have asthma - not an infectious disease but one which could exacerbate a flu epidemic. We need NIOSH research to examine the school environment as a promoter, if not the sole cause, of illness. And we need studies to establish effective intervention to prevent the spread of disease among staff and children.

School Siting

We are concerned that localities are induced for economic reasons to site new schools on or near wetlands and landfills which may then pose a variety of hazards for children and teachers. We believe that the mold problem in many schools - even new ones - is related to this unfortunate siting. It would be desirable to study the long term health effects of schools sited on contaminated property, particularly those on or near landfills that leak. Some of the schools on landfills have monitoring systems, but we have no information on how frequently they are calibrated or otherwise monitored -- or how often the bells go off. It would be useful to have studies of the health effects of such environmental conditions, since they may have profound effects on children as well as teachers and other school personnel.

Economics of Health and Safety

We believe that many of the occupational health problems experienced by teachers are the result of inadequate (and inequitable) funding of public schools. Maintenance of buildings and staffing levels are serious issues. "Low bid" requirements for maintenance, renovation and school construction are a threat to safety and health of teachers and children. There is virtually no research on the cost effectiveness of interventions to protect school health and safety . NIOSH's previous interest in social

and economic dimensions of health and safety could well be applied to the investigation of problems in the education sector.

Presentation for NORA Morgantown Town Hall Meeting of March 21, 2006

Dan S. Sharp, HELD

NIOSH has historically been influenced by a view point that places a high value on data derived from the study of human beings over "experimental" data. In this context, "experimental" data is meant to imply results derived from animal research using experimental study design techniques. Important distinctions exist between the scientific approaches used in studies of human beings and "experimental" studies involving animals. These distinctions include 1) the contrast between observational and experimental study designs, 2) the contrasts between research focused at the environmental, organism, tissue, and molecular levels of measurement, and 3) the inferential strengths and limitations among these contrasts.

For example, observational research, such as that conducted by epidemiology studies, does not control exposure conditions and thus is subject to a variety of well established biases related to the principles of confounding. This is not to say that experimental studies are not done with people. The disciplines of physiology, pharmacology, and nutrition often and justifiably uses experimental designs in human studies when ethical standards so allow.

In contrast, experimental research involves one of two fundamental approaches. First, if the science has a well constructed and highly validated quantitative set of models, then how the data derived from results of experiments either match or fail to match predictions of the models leads to inferences of causality and validity of the model. This approach works well within the reductionism contexts of the pure physical sciences and engineering.

Secondly, if the science does not as readily lend itself to quantitatively constructed and validated models, then experimental designs and statistical analysis methods allow for randomization of assignment to logical exposure scenarios in order to control the aforementioned confounding that is the bane of observational studies. The use of animals, or tissue from animals or humans, in the disciplines of physiology, toxicology, and molecular biology are illustrative. This strategy, if conducted properly, eliminates the impact of confounding, although it does not eliminate the continued need for creative designs and measurement systems in the greater context of a specific objective of a specific scientific study.

This fundamental contrast between observational and experimental methodologies has two fundamental implications. First, observational studies can never establish causality beyond a reasonable doubt that all and every confounder has been taken into account; and second, experimental studies, while reasonably grounded in a logic system that allows for inferences of causality, can rarely be conducted on human beings for ethical reasons, and thus human relevance must be ascertained independently of the results of the experimental study. In short, observational studies of people are most closely related to human relevance, but not mechanistic causality; while experimental studies in animals or tissue systems are most closely related to establishing mechanistic causality, but not relevance to the human condition.

How NIOSH goes about establishing knowledge of hazard and risk relations as important inputs into formal risk assessment activities depends on integration of information derived from a variety of observational and experimental studies. The validity of this integration depends on these fundamental characteristics and contrasts of scientific method and attendant inference. The utility and validity of NIOSH's research activities would significantly benefit from a better understanding, appreciation, and integration of these principles and these contrasts of strengths and limitations among the dissimilar disciplines that comprise the Institute's scientists, engineers, and leadership.

Written version of presentation to internal NORA Town Hall meeting in Morgantown on March 21, 2006.

The importance of laboratory studies in nanotoxicology

Robert R. Mercer, Ph.D.

Biomedical Engineer,

NIOSH Health Effects Laboratory Division

Morgantown, WV

The development of new nano materials for a myriad of applications for commercial products, drug delivery systems, medical devices, computers, electronics, construction materials, etc., is growing at a rate which has accelerated faster than knowledge about their potential health hazards is being accumulated. The number of workers (estimated to reach 1 million in the U.S. in the next decade) producing or using nanomaterials is expected to grow accordingly. Laboratory studies are critical to provide the information that regulatory agencies and industry must have if adequate control measures and work practices are to be developed to protect the worker.

The key elements in laboratory studies to assess health hazards from new nano materials are:

- Hazard Identification

-- Determine the key chemical component of the nanomaterial that is toxic in order to identify critical target organs and cells.

-- Determine the size class of material that is toxic in order to develop control and protection strategies.

-- Dose Response

-- Determine the response in time and concentration in order to assess the potential hazards due to different workplace exposures.

-- Compare the dose-response to known hazards to provide a comparative basis for standards and practices.

-- Route of Entry

-- Absorption by the skin and uptake by inhalation into the lungs are likely routes for nanomaterial uptake.

-- Size and surface chemistry effects are likely to significantly alter the relative contribution of dermal and respiratory uptake.

-- The physics of airborne transport and deposition of nano materials into the lungs involves unique size and surface properties. The sites of principal deposition in the filtering mechanisms of the lungs may be unique.

-- Translocation

-- The organs and cells most sensitive to the toxic effects of a nano material may not be those at the route of entry.

-- The small size of nano materials suggests that nano materials may easily pass through barriers in the body which normally block hazardous agents. While the unique surface chemistry, such as charge effects, may cause the nano materials to concentrate in specific organs.

-- Unlike most inhaled particles, nano materials may not elicit a phagocytic response from alveolar macrophages and may not be cleared or transported by the lymphatic system. This low clearance from the body poses a long term risk for accumulation and /or translocation.

-- Particle Structure / Function

-- Nano materials have a significantly greater potential for surface chemistry and a significantly lower density than larger particles.

-- Conventional control regulations relying on the mass based toxicity of a compound may not adequately reflect the greater surface toxicity of a compound when it is in a nano form.

-- Relatively minor alterations in nano material manufacturing conditions dramatically alter the shape and hence surface properties of nano materials. How particle shape affects toxicity is largely unknown.

Written version of presentation:

NORA Town Hall Meeting

March 21, 2006

Morgantown, WV

Good morning. My name is Dawn Castillo. I am Chief of the Surveillance and Field Investigations Branch in the Division of Safety Research. I am also a member of the NIOSH Surveillance Coordination Group and actively participate on the Consortium for Occupational State-based Surveillance. I am appreciative of the opportunity to provide input for consideration as NIOSH works with partners to develop an occupational safety and health research agenda for the next decade. My comments are organized around specific recommendations to ensure that as the research agenda unfolds, there is adequate attention to the need to support occupational injury, illness and hazard surveillance.

Recommendation 1: Ensure that adequate resources are provided to maintain and enhance ongoing surveillance that crosses industry sectors.

It is often noted that occupational safety and health surveillance is fundamental to advancing worker health and safety. Surveillance provides empirical data to guide research, foster prevention efforts, and track progress in improving workers' safety and health. With increasing costs and decreasing budgets, several ongoing surveillance systems developed or supported by NIOSH are not realizing their full potential. For example, there are important enhancements that could be made with additional resources, such as:

-- increasing access to data by developing and maintaining easy- to- use internet queryable data systems,

- ensuring the availability of data on industry, especially important as NORA and NIOSH shift to an industry-sector approach to assessing and tackling occupational safety and health problems,
- increasing the timeliness of data, and
- increasing the analysis and interpretation of surveillance data, and associated prevention efforts.

It is encouraging that surveillance will be considered research in the next decade of NORA, allowing surveillance efforts to compete for new funds, but consideration should also be given to bolstering ongoing surveillance efforts. This is especially important given the current establishment of NORA Research Sector Councils which undoubtedly will want to examine existing data to understand the most pressing occupational safety and health problems and identify important gaps in information that are impeding advances in worker safety and health. As well, these groups will also undoubtedly rely on existing data sources to track progress in improving worker safety and health. It is noteworthy that draft goals for the NIOSH construction program include a goal to improve surveillance, including intermediate goals to improve the quality, quantity, and use of industry-wide data from ongoing surveillance systems such as the National Electronic Injury Surveillance System (NEISS) and National Occupational Mortality System (NOMS) [NIOSH 2006]. I anticipate that as NIOSH and NORA Research Sector Councils continue to develop industry sector-based goals, they will similarly identify the need for improvements in existing industry-wide surveillance systems.

Additionally, while the move of NORA II to an industry sector emphasis holds promise for accelerating the application of research findings to worker safety and health, it is critical to recognize the continued responsibility and value of analyzing and tracking populations and outcomes across industry sectors. For example, NIOSH has goals to reduce young worker injuries and pneumoconiosis deaths, among others. We must ensure that data systems that cross industry sectors are maintained and enhanced to facilitate important work and tracking of progress across industry sectors.

The NIOSH Surveillance Strategic Plan established in 2001 with extensive input from partners can be used as a guide for enhancing existing NIOSH supported occupational surveillance [NIOSH 2001].

Categorized comment or partial comment:

Recommendation 2: As NORA Research Sector Councils are formed, they should include at least one representative with expertise in occupational injury and illness surveillance.

Based on my experience in working on teams setting research agendas, one of the first tasks such teams undertake is to examine data to help guide the development of their agendas. Having a surveillance expert on NORA Research Sector Councils can help ensure that the Councils understand available data, the limitations and strengths of the data, and the potential of new surveillance to fill gaps in information. Inclusion of surveillance experts on these Councils would also help facilitate action based on surveillance needs identified by these groups.

State and local labor and health departments

Categorized comment or partial comment:

Recommendation 3: Utilize partnerships with state governments to advance worker safety and health through NORA II.

Partners in state health and labor departments can make unique important contributions to worker safety and health. State government partners have access to unique data that can be used to target and guide interventions, and to fill gaps in national occupational injury and illness surveillance systems. These data sources include workers' compensation systems; data from occupational health clinics, immigrant health centers, emergency departments and hospital records; and systems based on statutory reporting requirements within individual states. Additionally, state health and labor departments can advance worker safety and health through state regulations and establishing and working with state-based coalitions and networks. NIOSH has partnered with states on surveillance and associated prevention efforts based on fatal occupational injuries, lead exposures, pesticide poisonings, and work-related asthma among others. Examples from the Fatality Assessment and Control Evaluation (FACE) program illustrate the impact of such occupational state-based surveillance on worker safety and health. State-based FACE programs have led to new state regulations to improve worker safety and health; national modifications to machinery, equipment and products to increase worker safety; and state-wide safety campaigns and programs. [Division of Safety Research, 2004]. Other state-based occupational surveillance programs similarly have compelling examples of positively impacting worker safety and health.

Two specific ways to integrate state government partners into NORA II include: 1) having a state health or labor department representative on each NORA Research Sector Council, and 2) including an industry focus in future NIOSH funding of state-based occupational surveillance.

Again, I am appreciative of the opportunity to provide input into NORA II, and am hopeful that my comments and suggestions illustrate the importance and potential of ensuring that surveillance is a critical component of NORA II.

Written version of presentation made to the internal NORA Town Hall meeting in Morgantown on March 21, 2006.

My name is David Weissman, MD and I am Director of the Division of Respiratory Disease Studies of NIOSH. Occupational respiratory diseases have been a critical concern of NIOSH since the beginning of the Institute. In fact, the reason that the Appalachian Laboratory for Occupational Safety and Health was built in Morgantown was because of its proximity to the coal fields and miners with black lung disease. Occupational respiratory diseases continue to this day and remain a key concern for many industrial sectors. Today, I will briefly mention a range of occupational respiratory diseases of concern during the second decade of NORA, including those affecting the airways, the pulmonary interstitium, respiratory infectious diseases, respiratory malignancies, and diseases of the upper airways. I will address the importance of emerging diseases and the need for not only health protection, but also health promotion for occupational respiratory diseases.

Occupational airways diseases are those that affect the conducting airways of the lungs. These include work-related asthma, occupationally-related chronic obstructive pulmonary disease (COPD), and others.

Work-related asthma is the most common occupational respiratory disease. It includes the categories of occupational asthma, irritant-induced asthma, and work-exacerbated asthma. Approximately 5% of adults suffer from asthma, and it has been estimated that approximately 15% of this disease burden is attributable to occupation. The annual costs of asthma attributable to occupation were estimated to be \$1.6 billion in 1996. Isocyanates, which are low molecular weight agents used in a wide range of sectors

including manufacturing, services, and construction, are one of the most common causes of occupational asthma. Unfortunately, our understanding of how isocyanates induce asthma is limited. As a result, it remains unclear how best to assess exposure, how to diagnose sensitization, and how best to diagnose isocyanate asthma without resorting to potentially risky and costly inhalation challenges. These problems are also true of most other low molecular weight agents, including the disinfectants and cleaning agents commonly used in health care and the service sectors.

Asthma caused by high molecular weight, mostly protein allergens is a problem in many sectors including agriculture, manufacturing, services, and healthcare. Baker's asthma, lab animal asthma, and latex asthma are all examples. Even for this type of asthma, which is reasonably well-understood, there is a relative paucity of data about exposure-response relationships that might guide primary prevention of disease. Improved tools for early detection of occupational asthma are also needed. Tools for early detection of asthma are often of uncertain reliability, limiting opportunities for secondary prevention.

In some cases, it is unknown exactly what exposures are causing an increased burden of asthma in an occupational population. This is often the case in non-industrial buildings such as office buildings and schools with poor indoor environmental quality. It has been estimated that as many as 15 million indoor workers would benefit from improvements in indoor environmental quality (IEQ). Concerns related to IEQ are by far the most frequent source of health hazard investigation requests. It is well known that building dampness is associated with increase risk of asthma. Microbial agents and their constituents have been incriminated but not confirmed as responsible. It is often impossible to attribute IEQ-related health effects, including asthma, to any particular exposure, complicating efforts to identify and prevent asthma caused by IEQ problems. Although it impacts on many sectors, this controversial area is particularly relevant to the services sector.

In recent years, it has become clear that cigarette smoking is not the sole cause of COPD. Occupational exposure to airborne agents, especially inorganic and organic dusts, is an important cause. Over the past several decades, COPD has been the third leading cause of death in elderly whites and the 4th or 5th leading cause in most other demographic groups. About 15% of COPD has been attributed to occupation, with an estimated cost to the US of \$5 billion per year in 1996. Globally, it has been estimated that 318,000 people per year die from occupational COPD. Clearly identifying the agents causing COPD and exposure-response relationships are important needs for primary prevention. Because COPD takes a period of decades to manifest itself, developing and validating methods for early detection of disease is an important need for secondary prevention.

Occupational interstitial pulmonary diseases (ILD) are those that affect the gas-exchanging areas of the lung distal to the conducting airways. They can be caused by inhalation of a number of agents, including fibers, crystalline silica, coal mine dust, beryllium, and many others. Many of these agents can cause additional respiratory diseases, such as respiratory cancers.

A key concern for all occupational ILDs is to develop approaches for applying current chest imaging technologies in medical screening and surveillance. Most hospitals and clinics in the US have abandoned analog x-ray film technology in favor of more cost-effective digital imaging. A critical need is to develop validated approaches to applying the ILO chest radiograph classification system to digital chest radiographs. This system forms the basis for most x-ray monitoring programs, yet is validated only for analog film-based radiographs. Another key need is to develop validated, cost-effective approaches to use of computed tomography in medical screening and surveillance programs.

Of the many types of fibers that can cause lung disease, asbestos remains one of the greatest concerns and is extremely controversial. Asbestos fibers can cause asbestosis, benign pleural disease, mesothelioma, and lung cancer. The regulatory definition of asbestos is narrow and includes only 6 types of mineral fibers crystallized in an asbestiform habit. It does not include asbestiform fibers of other minerals, or nonasbestiform fibers, even those of the 6 asbestos minerals. Despite this narrow regulatory definition, we lack validated, cost-effective tools to reliably differentiate between asbestos fibers and nonasbestiform fibers, particularly "cleavage fragments" of massive mineral forms. Although it is clear that some nonregulated fibers, such as those of winchite and richterite associated with vermiculite from Libby, MT, have toxicities similar to regulated forms of asbestos, this has not been well-documented for many mineral fiber types. A particularly controversial area of great concern to the mining and construction sectors is the toxicity of non-asbestiform "cleavage fragments" present in mine dusts and in deposits of "naturally-occurring asbestos," such as those in the area of El Dorado Hills, CA. Another controversial area has been risk associated with fiber exposures after collapse of the World Trade Center in 2001. Construction workers continue to encounter these dusts. Understanding the toxicities of the broad range of mineral fibers, developing validated methods for measuring exposure to regulated and unregulated mineral fibers, developing methods for risk assessment for the broad range of mineral fibers, and developing recommendations for prevention based on risk assessment all remain important needs.

Although much progress has been made in preventing silicosis and coal worker's pneumoconiosis in the United States, continued vigilance is important. Silicosis, in particular, can unexpectedly occur in new settings, especially in the construction and manufacturing sectors. These diseases also remain important in less developed countries.

Chronic beryllium disease remains an important priority. The beryllium industry is critical to key US industries such as nuclear power, aircraft manufacturing, and other industries where light, strong metal alloys are needed. Unfortunately, routine mass-based airborne exposure assessment has proved a poor predictor of developing beryllium sensitization or chronic beryllium disease (CBD). Evaluating relationships between novel exposure metrics such as aerosol surface area and sensitization or CBD is an important activity. The beryllium lymphocyte proliferation test has important limitations; developing better tools to assess for beryllium sensitization would be highly desirable. Finally, important genetic susceptibilities have been identified for beryllium sensitization and CBD; developing and validating approaches to genetic counseling would have important implications both for CBD and possibly other diseases with measurable genetic susceptibilities.

In recent years, preventing occupationally-related respiratory infectious diseases has become an area of key importance. Sectors especially affected include the healthcare sector and first responders such as police and firemen in the service sector. In the aftermath of the anthrax attacks of 2001, the US has invested hundreds of millions of dollars in development and implementation of monitoring systems for airborne agents such as BioWatch devices in general public areas and Bio-Detection System (BDS) in the Post Office. Evaluating the effectiveness of these systems, developing other approaches to exposure assessment and determination of exposure-infection relationships, and developing data-based approaches to prevention measures such as disinfection, respiratory protection, and engineering controls are all important priorities. Similar considerations apply to preparation for pandemic influenza, refinement of guidelines for preventing tuberculosis transmission and preparing for outbreaks of emerging diseases such as subacute respiratory syndrome (SARS) and avian influenza.

Given the severe consequences of lung cancer, occupationally-related respiratory malignancies remain an important public concern in many sectors, especially mining, construction, and manufacturing. A number of types of occupational exposures have been documented to be associated with excess risk of lung cancer. It has been estimated that, worldwide, 102,000 deaths could be attributed to occupational lung cancer. There are a number of agents whose carcinogenic potential remains controversial. Of particular note are nonasbestiform mineral fibers; silica; diesel exhaust; and welding fumes. Continued basic and epidemiological research remains important.

Occupationally-related diseases of the upper airways, including the nose, sinuses, and oropharynx are often neglected but important. Although not life threatening, they can have important economic impacts through absenteeism or reduced productivity. In combination with obesity, they can lead to obstructive sleep apnea (OSA). In those exposed to occupational allergens, allergic rhinitis often precedes development of occupational asthma. Upper airways complaints are the most frequent types of symptoms associated with poor indoor air quality. As is the case for IEQ-related asthma, the precise cause of complaints is often unclear. Although epidemiological data are lacking, it is likely that upper airway problems such as rhinitis and sinusitis affect a broad range of sectors with allergic or irritating exposures, including agriculture, mining, construction, manufacturing and services.

It is important to remain vigilant for new occupational respiratory diseases. Examples of new, previously unanticipated diseases recently identified through sentinel field investigations include bronchiolitis obliterans associated with exposure to artificial butter flavorings; and flock worker's lung disease. New exposures create opportunities for new diseases. For example, nanotechnology has been an area of explosive development in the manufacturing sector and is an important priority of the US Government. This new industry is associated with new inhaled nanoparticulate exposures not previously encountered. Developing methods for measuring these novel exposures and monitoring both workplace environments and exposed workers over time will be an important priority. Tenacity of follow up will be particularly important in this area, if disease latencies mirror those of asbestos in which disease can take 20 to 40 years to develop.

A final area I would like to discuss is health promotion. Passive cigarette smoke exposure in workplaces has been documented as an important risk factor for adult onset asthma. For the sake of both the smoker and co-workers, smoking cessation and smoke-free workplaces are an important issue for lung health in all sectors, especially in the services industry where smoking often persists in restaurants, bars, and casinos. Obesity prevention is also important for preventing adverse respiratory effects such as obstructive sleep apnea. Disordered breathing and disrupted sleep associated with OSA have been documented to be risk factors for motor vehicle accidents and are potentially important risk factors for accidents involving anyone operating heavy machinery.

I thank you for having the opportunity to make this statement.

Written comments submitted by E-mail in lieu of a planned presentation at the NORA Town Hall meeting in Lowell, MA.

National Occupational Research Agenda (NORA) Town Hall Meeting

Lowell, MA - March 20, 2006

Comments submitted by:

Thomas St. Louis, MSPH

Occupational Health Program Director, Connecticut Department of Public Health

410 Capitol Avenue, Hartford, CT 06134-0308

thomas.st.louis@po.state.ct.us

First, I would like to thank NIOSH for convening these Town Hall meetings to give interested stakeholders the opportunity to discuss important issues around the next generation of NORA. I would also like to thank my colleagues from around the New England area for coming out to this meeting today to participate in the process.

When NORA was first unveiled ten years ago, it was recognized as an innovative approach to targeting a limited amount of NIOSH resources toward the areas of occupational safety and health that needed them most. With hundreds of agencies and individuals participating in the early stages of NORA's development, including its basic framework, widespread acceptance of the Agenda in its final form by stakeholders was inevitable.

While I applaud NIOSH for keeping the NORA concept going with its next iteration of the Agenda, I am not surprised by the dissenting opinions about the utility of the new framework in being able to appropriately address occupational health and safety issues that we know already exist and to identify emerging issues over the next decade. We all know that change is inevitable and often difficult, but we should not necessarily make the assumption that "new" means "new and improved".

The sector-based approach outlined for NORA2 represents a significant diversion from the basic framework of the original NORA. Although this new approach represents a bold new vision for occupational health and safety research activities in the US, the vision is that of NIOSH and not necessarily that of the stakeholder agencies and other groups whose work will be guided by it during the decade to come.

While there may be health and safety issues that are specific to single industry sectors, the vast majority are multiple, or even all sector issues for which a sector-based approach to research or intervention will likely be inefficient, inconsistent, and duplicative. The concern I share with many of my colleagues is that the momentum that was generated over the past 10 years in addressing the research priority areas identified in development of the original NORA framework will diminish as NIOSH's focus shifts to industry sectors. The potential impact on two of the original NORA priority areas is of particular concern.

Young Workers, Older Workers, and Non-English Speaking Workers

The first is "Special Populations at Risk". Great strides have been made in recent years toward protecting young workers across all industries. Much of this progress is a result of NORA support directed toward research-based initiatives or indirectly through public health initiatives based on information gathered through research.

Similar progress has been made in developing education and intervention activities geared toward non-English speaking workers. NORA directed funds have allowed researchers to shed light not only on the increasing need for Spanish and other non-English language health and safety materials, but also on the need for new strategies in delivering health and safety messages to non-English speaking groups.

In recent years, the population of older workers has significantly increased, as many senior citizens have found it necessary to keep working to make ends meet. Many of these older workers are being pushed out of the office and into new lines of work, where they are encountering new occupational hazards for the first time, such as ergonomic issues related to repetitive movements and static standing.

Each of these special populations has unique cognitive, developmental, and social characteristics that put them at an increased risk for suffering an occupational illness or injury. These risk factors are however characteristics of the population of workers not of specific industry sectors, and therefore it seems a population-based approach to research and intervention activities would be much more efficient and effective than a sector-based approach in protecting these groups of workers.

I understand that NORA2 will include Cross-Sector Research Councils, whose task it will be to identify and address research issues that affect more than one industry. However, the sheer number of issues that impact worker safety and health across most or all industry sectors will undoubtedly be overwhelming and lead to tough decisions on prioritization, which will mean those deemed less important will be left behind.

State-Based Surveillance Activities

My second concern is the potential for dwindling support of state-based surveillance methods research. With technology advancing at an exponential rate, most State health agencies are struggling to find resources to keep up. This has traditionally negatively impacted our ability to perform effective surveillance because, even when compelled to do so by State law, clinicians are less and less inclined to report occupational injury or illness cases over time as the gap widens between antiquated or cumbersome reporting mechanisms operated by State agencies and more automated electronic charting and billing systems offered by private-sector companies.

Funding directed toward surveillance methodology research under the first NORA provided an important boost to many of NIOSH's State partners that helped us to make significant advances in our ability to add electronic data transfer and web-based reporting capability to our occupational illness and injury surveillance systems. While there is no doubt that the technological advances during the next ten years will be even greater than those of the past decade, there is some doubt that the sector-based approach to NORA2 will continue to provide NIOSH's State partners with adequate resources to keep pace.

In the past, NIOSH has recognized State partners as an invaluable resource in pursuing occupational injury and illness surveillance initiatives. This is because State health agencies are uniquely positioned with both the legal authority to collect surveillance data and the obligation to engage in intervention and investigation activities driven by this data. However, this ethical obligation to protect worker health applies to workers in all industry sectors equally and cannot be set aside in favor of the pursuit of research dollars.

While it may be relatively easy for private sector and academic research groups to adapt to NIOSH's new vision for NORA, the public health infrastructure in place at the State level can rarely turn on a dime. As your State partners, we are counting on NIOSH's continued recognition of us as a valuable investment for NORA funds as we attempt to adapt over the next few years to the new framework of NORA, while balancing our statutory and other public health practice responsibilities, many of which were put in place based on findings that resulted from the first decade of NORA.

In closing, I would ask NIOSH to reconsider the utility of a sector-based approach to targeting research dollars. The framework for the first decade of NORA was developed as a shared vision of how to bring support to investigators interested in developing advanced methodologies and tackling the disease types, workplace hazards, and workforce characteristics that affect worker health and safety most.

While we may be beyond the point of abandoning a sector-based approach for NORA2, I would ask NIOSH to consider how other approaches might complement their new NORA vision. In particular, I would ask NIOSH decision makers to remain true to the original vision for NORA, the final design of which included input from a variety of different stakeholders and "end-users". I would ask that NIOSH include Research Councils specific to the disease, environment, and tool categories that we know worked well for prioritization as part of this next NORA iteration, so that the progress that has been accomplished to date is given at least as much focus as an industry sector approach that may or may not work.

Thank you very much for giving me the opportunity to speak with you today.

National Occupational Research Agenda

Monday 20,2006 Lowell, MA

Testimony of

Steven Schrag, SEIU Eastern Region Hazmat Program Coordinator

NORA, NORA, NORA

Purpose

To explore the issues affecting the evaluation of workplace health and safety training programs to determine their effectiveness at informing workers as well and increasing understanding on how to protect themselves on the job

Task

You are the committee responsible for the National Occupational Research Agenda (NORA) and your task is to use your experience, the attached factsheets and other relevant information from the town forums or elsewhere to answer the following questions.

- 1.What is the quality of training that is currently provided to workers to fulfill OSHA mandates?
- 2.Is the length of the training adequate for workers to assimilate the information provided?

3. Is the frequency of the training sufficient to ensure up-to-date info and skill development using necessary safety equipment and protocols?

A. SEIU health and safety training experience

Since 1985 over 20,000 workers have been trained in the Eastern Region of SEIU.

This training has occurred in a wide variety of workplaces:

- Hospitals
- Nursing homes
- Homecare
- Department of Transportation
- Building maintenance

There are holes in many current employers programs:

- 15 minute hazard communication training leaves little time for real discussion
- operations level training with minimal hands-on activity means no opportunity to practice skills
- sign-in sheets requiring participants to state that they understand the material before they have had the training

We need to do better.

B. OSHA sez

OSHA has dozens of training requirements under the General Industries standards:

- Means of egress
- Powered platforms, manlifts and vehicle mounted work platforms
- Occupational health and environmental control (dip tanks, hearing protection)
- Hazardous materials
- Personal protective equipment
- General environmental controls (confined spaces, lockout or tagout et al)
- Medical services and first aid
- Fire protection
- Materials handling and storage
- Machinery and machine guarding
- Welding, cutting and brazing
- Special industries
- Electrical safety related work practices
- Commercial diving operations

- Toxic and hazardous substances
- Explosive and other dangerous atmospheres
- Surface preparation and preservation (painting/flammable liquids)
- Welding cutting and heating
- Scaffold, ladders and other working surfaces
- Gear and equipment for rigging and materials handling
- Tools and related equipment

B. The quality of training is not strained

- 1.OSHA compliance standards mandate a certain training must occur
- 2.OSHA performance standards measure what workers know
- 3.The use of lecture, powerpoint, online training and "experts" dominates many training programs and allows employers the opportunity to fulfill their compliance requirements
- 4.Participatory, small group and use of peer educators offers the opportunity for greater performance success
- 5.Other participatory methods such as using hands-on activities such as donning and doffing personal protective equipment, handling and practicing with specialized safety equipment can increase the retention of info provided and increased understanding
6. When you want to learn how to ride a bike you do not attend a lecture and take a written test, or watch a video or use an online computer program. You find someone who knows how to ride a bike and you watch them, ask questions and get on the bike. And after falling a few times you learn how to do it yourself.

D. How much is enough?

To take care of the health and safety of others there are minimum education requirements for various professionals. If they spend years learning a body of information, why do some employers think that an hour or two is enough for workers?

Job category	Education time required
Emergency medical technician paramedic	2 years
Epidemiologist	4 years
Industrial hygienist	4 years
Masters in public health	6 years
Physician	8 years
Registered Nurse	2 years
Toxicologist	4 years

To understand information on occupational health and safety sufficiently there needs to be enough time allocated so that the students can absorb the material and be able to apply the information to real situations.

E. How much is enough? (part 2)

It is common for many employers to use new employee orientation as their basic health and safety training. Unfortunately a new employee may not have a lot of practical questions on workplace hazards unless they have already worked in that industry previously.

There are some programs that demand more than a single attempt to increase effectiveness:

- Financial audits-businesses conduct an analysis of their financial situation at least annually.
- Performance appraisals are conducted annually for many employees to determine how effective they are at contributing to goals of the employer.
- Continuing education for professionals are required to be taken on a regular basis with many professionals having a minimum number of contact hours required annually

If other training and measuring tools are conducted annually why can't all OSHA mandated training have the same requireme

NORA, NORA, NORA summary points

1. Knowledge is the first step to help protect workers from occupational hazards
2. Without adequate knowledge there is no motivation to change behaviors or working conditions
3. However knowledge alone will not help reduce exposure occupational exposure to hazards
4. Workers should understand the information provided
5. Understanding comes from a combination of absorbing information and practicing using it in combination with their own practical work experience in hands-on activities.
6. There needs to be a greater emphasis on determining the effectiveness of current training practices in order to assess how effective OSHA mandated training is working to help reduce injuries and illnesses on the job.
7. OSHA can issue standards. NIOSH does terrific research. However if workers don't understand what needs to be done, then little will change the worksite. Too many workers are needlessly exposed to hazards. Everyday that another worker gets sick or ill we have failed. We need to stop failing in the future and NORA's research will help in that cause.

Submitted by one person in three E-mails following an invitation to attend the NORA Town Hall meeting in Los Angeles.

Text of the first E-mail:

I am an injured person with carpal tunnel who cannot go to the meeting. But I would like to offer a few suggestions.

I think that injured workers should be used as a way of learning how not to do things. I believe injured people should be asked the following questions. If you had to do things again so you would be healthy what would you do.

In my case, I would speak up. I would ask for breaks. I would suggest that people who have pain do not do what men do all the time tough it out and be macho but seek medical help.

I would suggest that managers let people get leave to seek medical treatment that workers comp such as federal workers comp not cause people to have to get worse before they could get help.

In my own case my hand began to throb. I went to the workers comp section of Kaiser in November 1997. They said you have dequervians not work related. I did the same thing for 6 more months and got worse. The same doctor who said I was not work related said I was and I got approved. But I had to get worse before I could get treatment.

Prevention is needed. President Bush for feds has a strategy called Share to reduce workers comp costs in federal government. But a key is to prevent people from getting so bad that they cannot do things like tie their shoes or have problems getting dressed as I do .

In addition, there are needs to have worker education. Instead we are told to work smarter and harder not to work safer.

I testified at OSHA at least twice including once at the worker forum in 2001 at George Mason University when I gave a Marshall Plan for avoiding injuries and for people looking and acting like me. I would suggest they be looked at.

I cannot go to LA because I am in training for re-learning my job and that too is a hassle. I have a computer with adaptive equipment but when I go do my on the job training I cannot use it and my hands go numb. But I will not give up.

Text in the attachment to the second E-mail:

Personal Experiences as an Injured Worker

Howard Egerman 2005

A popular television commercial for the Hair Club for Men concludes with a follicle/challenged gentleman proclaiming "I'm not just a spokesperson, I am also a client."

So it is with me even though I help ensure hair people perform SGA, I don't just represent injured workers, and I am an injured worker, myself.

How does this "status", this "gift" I have been given help people as a Union Representative?

Simple.

I believe that there is difference.

When I was healthy I represented injured people in one way.

Now that I am "sick" or "injured" I think that I have another path.

When I was a healthy rep I would see a person's case just like my agency work-something to receipt in, develop, clear and finish.

I had a tendency to think that this person's case just reflected what that individual during her or his working day.

I would often just look at things in the way an individual or group of people were impacted just in terms of health and safety.

But when I became injured I saw things differently.

An injured person does not live despite what Dolly Parton might say a 9-5 life.

A person who has suffered an injury is impacted 24 hours a day, 7 days a week, FLSA or no FLSA and truly no overtime or premium night differential pay goes that person.

Everything and anything is a struggle from the time the person goes to bed if she or he is able to do so to the time he or she wakes up.

To paraphrase Brother Henny Youngman, Take my life, please.

My injuries which include carpal tunnel syndrome, deQuervains syndrome, tendonitis with a little arthritis thrown in for good measure has given me

Truly this type of perspective.

Each day, I try to do the best with the accommodations and equipment workers comp has provided me.

But I am in pain.

Often I do not feel the pain while working.

Other times literally I feel nothing. Despite my graduate degree, my hands and arms sometimes feel totally numb.

For a long time when I drove it would kill me to drive. Everything would be fine as long as I could go straight ahead but if I had to turn and use my wrist the pain was almost intolerable.

So I did what my doctor who is a disciple of Brother Henny Youngman said, "If it hurts you to drive, don't drive"

And so I stopped and began to take the bus. But after I return home after a day on the job, I still feel my pain and try to cope by using ice and paraffin wax.

When I get myself calmed down enough to go to sleep I put my Pilo Splints or sleeping splints on to keep my hands in a neutral position and rest them on a pillow.

My pain usually wakes me up early in the morning sometimes around 2 unless an earlier wake up call from my hands and wrist has gotten me so exhausted that I fall asleep longer.

But after I wake up I find that I can take some action to manage the pain by taking a bath and doing my own version of contrast baths, something that I learned in rehab after my first operation.

I would soak my hands and wrist for a while in warm and then cooler water and just try to relax and not think, just to let the soothing water take away the pain.

I then would get dressed the best I could. I have found that in long sleeved shirts I sometimes have trouble with the lower buttons. Not being a cover person for GQ though means that the lack of such activity does not hurt my image.

I cannot tie my shoes and so after some helpful hints from a member of my RSI Support Group I use Velcro and close them.

When it is around 5 a.m. I set forth on my walk. My part of East Oakland at one time was a part of a hacienda and I live not far from a real live East Oakland Park called the Peralta Hacienda which has good lighting and a visual situation that enables you to walk in a rectangle so you can see if anyone is coming behind you.

I walk close to an hour each morning and return home to get things to take to work and then walk another half mile to the bus stop. I find that my walks help improve my circulation and since I listen to music while I walk I don't think about my hands.

During the bus trip which enables me to view 40 blocks of scenic Oakland including perhaps the most beautiful model of an Oakland Raider helmet ever made I relax and read the paper.

I then read some more outside the office inside our mall while I wait for someone from management to open up.

The principles I follow enable me to be able to show up for work relatively pain free.

The author who has influenced me most in my injured worker life is Deborah Quilter who in her wonderful book THE REPETITIVE STRAIN INJURY RECOVERY BOOK speaks of a concept she calls the hand bank.

Each injured person has to do what she or he can do to strengthen his or her hand.

In other words to make deposits.

I do this by my baths, my walking etc.

Then with your hand strengthened you can work at making withdrawals during the day by using your computer.

THAT IS MY DAY.

Then I try to do my job and repeat the whole process.

What have I learned as an injured person enables me to deal better with others.

One thing that we all have to know is that no body is perfect. Injuries and illnesses come to all types of people regardless of ethnic group, sex, etc and bargaining unit or management status. Disability is an equal opportunity employer. Here are some things I learned.

1. I am me, others are she or he. Each of us is different.

When I testified at OSHA I wrote to people. One woman who answered did not tell me that she often feels a failure as a wife and mother because she cannot cook nor do other household work because of her hands.

As a man I can get by if I don't do things. Sometimes other responsibilities enter into an injured person's life—children, spouses (some people can be prolific), parents, other responsibilities. They may not be able to tune their hand or other bank to be able to work.

2. In terms of differences, not everyone may be willing to either invest the time or have an injury that enables them to invest the time to be able to work.

3. Someone who is injured needs time. They cannot simply be dismissed. Their struggle is with them always.

4. Pain is perhaps the most obscene word in English. Pain can truly cause you to use other words as well. Someone in pain may not be able to function in ways other than she or he wants.

5. Sleep is something great if you can get it. Lack of sleep can cause you to make errors or react differently than you want to.

6. It is often great to look at things down the road but many of us who have become injured got that way one day at a time. One way of functioning is to work one day at a time.

7. Not everyone who is injured can succeed or be a star or superstar. But you can cope.

8. Learn what you can about your injury or your illness. Become an expert. Go to the health section of a bookstore or library and read everything you can about your illness. Become an expert on it. That is what Lance Armstrong did when he got cancer. Use the internet.

9. Listen to an injured person. It took them a long time or sometimes an instant to become sick. They have reasons for the way they feel or look. Give them time. Give them respect.

10. Recognize that injured people are not alone. If possible join an injured worker or other type of support group. When you do so you can find one place in which you actually belong. A spouse or friend who takes you might be the one banished to the healthy person's table.

After my first surgery I felt like hell. A friend in my support group invited me to a group chocolate tasting party. We tasted chocolate, trashed doctors and talked. It was wonderful.

The most important thing about being an injured worker is an understanding that an injury while painful and sometimes difficult to live with is not the end all.

At a support group meeting Deborah Quilter told all of us in Berkeley, California an important lesson. We are not just our injury. We have worth. We have value and as Reverend Jackson told some colleagues at a rally across from the office in which I work,

We are all SOMEBODY, even if some of our bodies do not work the way we want them to.

As Sister Aretha puts it, we all need R-E-S-P-E-C-T.

Safety reps need to do what they can to remedy the situation that caused us to become ill if it happened at work.

The hierarchy of controls can be used to abate an accident or injury scene or perhaps work to prevent more of our sisters and brothers from having the same fate that we do.

But what must be remembered is abatement deals with a situation.

WE ARE PEOPLE.

A Claims processing system in which we work deals with policies and principles which ultimately IMPACT PEOPLE.

In the Labor Relations Process actions are taken and we defend situations WHICH IMPACT PEOPLE.

Injured workers are more than anything else
PEOPLE.

The Union's Role in Injured Worker Issues

H. Egerman

AFGE has a responsibility to work with SSA management per article 9, section IB to cooperate in a continued effort to avoid and reduce the possibility of and/or eliminate accidents, injuries and health hazards in all areas under the Employer's control.

Designated health and safety reps under Article 9, Section 3 A 4 receive reports from employees of unsafe or unhealthy conditions. Under A5 they inform management of unsafe or unhealthy conditions as well as making

Possible referrals to OSHA and NIOSH . In accordance with 7 they get copies of any written notice referred to an agency official in response to an employee report of unsafe or unhealthy condition.

Article 9, Section 4 calls for management to take action to abate an unsafe or unhealthy working condition.

But such conditions can result in workers becoming injured. Employees also can be become injured through occupational disease or illness, the whole matter covered in Article 34 of the contract.

President George W. Bush has established an Executive Order calling for each agency to reduce its workers comp costs called Share.

This understood it is important to realize and recognize that we have two issues at work here.

1. Situation which led to the injury or illness.
2. The person—the injured or ill employee.

Here the impact of the injured person will be discussed in this training.

Injured Workers face varied forums:

1. Workers Compensation.

Proper form CA-1 CA-2

Narratives, checklists, witnesses, advice.

What to do if denied—advice

2. EEO issues.

Request reasonable accommodation.

Return to Work.

Limited Duty.

Redesign of job or job tasks.

501/ Reasonable accommodation wizard process.

3. Disability Retirement

Provide information on process.

Issues regarding FERS/CRS retirement.

Interface between disability retirement and workers compensation information.

4. Regular retirement options

Provide information on this process as well as early out

Role of SSA/SSI in the process.

5. Other injured worker issues

Leave sharing if leave is needed.

Leave buy back information and assistance if workers compensation is approved.

Workplace assessment information such as using vocational rehabilitation or other organizations to assist the employee.

Information on other resources for the person's illness—books, articles, doctors, (including reviews of doctors)

Lawyers, physical therapists, web sites, support groups.

6. If problems information on the grievance process and information as to how the process works.

Written version of presentation made to the internal NORA Town Hall meeting in Cincinnati, Hamilton Building.

Remarks from John P. Sestito

NIOSH Hamilton Laboratory, Cincinnati, Ohio

February 23, 2006

I offer the following thoughts for the ongoing support of occupational surveillance generally, and occupational disease surveillance specifically. Occupational surveillance lacks the prominence of a Sector or Cross-sector program within the National Institute for Occupational Safety and Health (NIOSH) Program Portfolio structure. So, as NIOSH moves forward under the Program Portfolio framework, NIOSH leadership should be mindful of the importance of injury, illness, hazard, and exposure surveillance data for establishing research agendas, making judgments about research priorities, and developing program performance metrics. Many of my remarks speak to disease surveillance, but are generally applicable to occupational surveillance.

Surveillance defined. Surveillance is the collection, analysis, interpretation, and dissemination of data describing a health related event, exposure, or hazard. Surveillance is critical to effective occupational safety and health programs. It enables decision-makers to identify the problem and the affected group of workers. Surveillance also describes the magnitude and severity of an issue, and assesses progress made in reducing the burden of occupational injuries and illnesses. As a result, surveillance programs

create added value by establishing baseline and trend data, assisting in priority-setting and providing information to guide research, interventions, control, or prevention.

Congressional oversight in the 1980s. In passing the Occupational Safety and Health Act of 1970 (OSH Act) [29 USC § 651 et seq.], Congress mandated extensive authority to the Secretaries of Labor and Health and Human Services to develop regulations requiring employers to record and report occupational illness, to conduct medical examinations, and to notify employees of clinically significant results [29 USC §§ 655(d)(7), 657(c) and (g), and § 669(a)(5)]. In addition, the OSH Act requires the Secretary of Labor to "compile accurate statistics on work injuries and illnesses which shall include all disabling, serious, or significant injuries, and illnesses, whether or not involving loss of time from work." [20 USC § 673(a).] This authority has been delegated to the Bureau of Labor Statistics (BLS). Unfortunately, much of this broad authority remains unused.

Accurate and reliable data on occupational disease is essential for informed public policy decisions, employer and employee awareness of health problems, and employers' ability to correct harmful working conditions. Congress recognized the importance of good information systems when it passed the Occupational Safety and Health Act of 1970 (OSH Act) [29 USC § 651 et seq.] Today, 35 years after its passage, the state of present national disease surveillance systems is – as described by Dr. J. Donald Millar, the former Director of the National Institute of Occupational Safety and Health (NIOSH) – "90 years behind...[surveillance] of communicable disease." No reliable national estimates exist today, with the exception of a limited number of substance specific studies (such as on asbestos), on the level of occupational disease, cancer, disability, or deaths. It cannot be meaningfully determined if diseases from chronic exposures to hazardous substances represent a greater problem today than when the OSH Act was passed in 1970. The lack of complete, reliable, and accurate injury and illness data greatly hampers any broad-based evaluation of the occupational safety and health programs, and threatens the statistical foundations for the current NIOSH Program Portfolio of Sector and Cross-sector research. Furthermore, the existing data from employer logs, used in BLS's Annual Survey, are generally viewed as unreliable and under-report occupational disease.

Accurate and reliable data on occupational disease is essential. For public policy, these data assist the Occupational Safety and Health Administration (OSHA) and NIOSH in setting and revising health standards under § 6 of the OSH Act, as well as setting enforcement and research priorities. The early reporting of disease causing exposures to vinyl chloride and kepone heightened the public awareness of previously undisclosed dangers of occupational exposures. Occupational disease information is also essential to employees and employers in alerting them to disease patterns as early as they become clinically significant. This is particularly important to the health of the worker, and is also significant to the employer who can take corrective action and understand the full economic cost of doing business.

BLS's ability to implement an occupational disease statistics program is hampered by the nature of occupational disease study, where expertise in epidemiology and occupational medicine is required. If the purposes of the OSH Act are to be achieved – if effective measures of prevention of occupational disease through elimination of hazards in the workplace are to be developed, and the effectiveness of these programs is to be evaluated – NIOSH must find solutions to the problems of obtaining adequate data on occupational diseases.

Future Directions and Challenges for NIOSH

Many of the following comments reflect the ongoing national dialogue on developing and improving the nation's occupational surveillance. The major "bullets" are distilled from the work of the NIOSH NORA Surveillance Research Methods Team.

- NIOSH must maintain a strong national surveillance program to establish priorities. Future surveillance should (1) maintain ongoing surveillance and disseminate of surveillance data as guided by the NIOSH Surveillance Strategic Plan, and (2) respond to emerging occupational health and hazard issues.

Problem: Federal surveillance of occupational disease is fragmented among many agencies; i.e., NIOSH, NCHS, NCI, SSA, and CDC. The current activities of these federal agencies do not assure the nation's workers access to comprehensive occupational surveillance data in the United States.

Comment: Comprehensive information for occupational disease, disability, and mortality is needed to (1) develop effective measures of prevention of occupational disease through elimination of hazards in the workplace, and (2) evaluate the effectiveness of these programs. The one agency which focuses on the surveillance of occupational disease is NIOSH. NIOSH has long-standing expertise both in the study of occupational disease and in focusing research toward better a understanding of the etiological association between disease and workplace hazards and exposures. NIOSH is well-equipped to take on the central role and responsibility for the ongoing collection, analysis, interpretation, dissemination and use occupational disease statistics.

Problem: No reliable national estimates exist today on the magnitude and trend of occupational cancer, disability, and mortality.

Comment: It cannot be meaningfully determined if diseases from chronic exposures to hazardous substances represent a greater problem today than when the OSH Act was passed in 1970. State and local mortality, cancer incidence, and disability data have significant potential as data elements within a comprehensive surveillance system for occupational disease. Such data have yet to realize their potential because of incomplete or inconsistent data collection through local and State-level data sources, insufficient resources to support State and local agencies to collect or compile these data, as well as limited and inconsistent coding and classification of employer\employment (i.e. SIC or NAICS codes) and occupation (Census occupational titles and codes) information.

Problem: Employers are unable to record, and thus report, many chronic and latent occupational diseases.

Comment: Employee and household surveys are excellent alternative sources of data on the prevalence of disease in working populations. The National Health Interview Survey (NHIS) was adapted in 1988 for occupational surveillance purposes, gathering a wide range of occupational health and safety data. Medical examinations provide more accurate methods for determining occupational disease, disease precursors, and biomarkers. The National Health and Nutrition Examination Survey (NHANES) is used by CDC to gather a wide range of population demographic and health data. The NHANES could be adapted to monitor the population for selected occupational conditions and exposure measures.

Problem: BLS surveys of nonfatal occupational illnesses are unable to identify or report diseases with a long latent period. There is no adequate evaluation of the extent of under-recognition, under-reporting, or over-reporting of nonfatal occupational injuries and illnesses.

Comment: NIOSH should establish a dialogue with our federal partners, OSHA and BLS, on the feasibility of undertaking a comprehensive Quality Assurance Program on the OSHA logs. This dialogue should explore options to assess the accuracy and reliability of employer logs and the differences, if any, in levels of occupational disease as found in medical records, the OSHA logs, the Annual Survey forms, and employee surveys. NIOSH should provide epidemiologic, industrial hygiene, medical consultation and other assistance as needed. Such efforts could be expanded to general recordkeeping and reporting for nonfatal injuries. As possible collaborators in such a program, NIOSH's state-based surveillance partners have significant experience in state-level data sources. These data sources should be explored to better understand disease under-reporting.

- NIOSH should support new program initiatives and projects to develop and adapt methods for state and non-governmental partners. New surveillance programs and research methods are advocated in the NIOSH surveillance strategic plan, as well as the reports of NORA research priorities for cancer, emerging technologies, exposure assessment methods, musculoskeletal disorders, traumatic injury, reproductive outcomes, and workplace organization factors.
- NIOSH should link the results from state-level surveillance to intervention and prevention activities. This could produce significant improvements in occupational safety and health. Recent evaluation and planning activities reinforce the importance of expanding and enhancing state-based occupational surveillance.
- NIOSH should advocate an expanded surveillance research program that focuses upon smaller employment establishments in a private sector surveillance research initiative. An estimated 7 million private sector establishments employed 115 million workers in 2001. Establishments with 19 or fewer employees accounted for 85.7% of all workplaces, but only 24.1% of all employees. Establishments with 100 or more employees accounted for only 0.7% of all workplaces, but over 46.8% of all employees.
- NIOSH should establish Collaborating Surveillance Research Centers of Excellence to guide the development of surveillance to prevention practices including new R & D teams that harness the strengths of occupational health researchers, non-government organizations, insurance carriers, and public health agencies. Specific activities within the Centers should include (1) providing technical assistance and consultation with respect to developing and evaluating occupational surveillance methods; (2) establishing outreach programs to identify specific methodological and research needs, evaluate occupational surveillance follow-up methodologies, and develop and evaluate innovative strategies for improving the quality and utility of surveillance data; and (3) expanding surveillance and surveillance research that focuses on smaller scale employment establishments.

NORA Town Hall Meeting

December 6, 2006

Presented by Lida Orta Anés, Ph.D.

Associate Professor

UPR-Medical Sciences Campus

President AIHA Puerto Rico Local Section Intercontinental Hotel

Puerto Rico

American Industrial Hygiene Association

Background

-- Founded in 1939

-- Over 13,000 members

-- Only organization in Puerto Rico representing Industrial Hygienists since 1982 (n=250 members)

Objectives of the organization

-Promote the study, evaluation, and control of environmental stresses in work organizations and its surrounding communities

American Industrial Hygiene Association

(PR Local section)

General Concerns

-- Epidemiologic study about psychosocial nature of Cumulative Trauma Disorders among Latinos employees

-- Epidemiologic study about the impact of the 2001 record keeping standard on the incidence and severity of injuries

Cincinnati, OH 45226

Via: e-mail

RE: *National Occupational Research Agenda (NORA): The Second Decade*

The membership and leadership of the American Association of Occupational Health Nurses, Inc. (AAOHN) actively participated in the first decade of the National Occupational and Research Agenda (NORA) by providing input at NIOSH town hall meetings and written testimony. Occupational and environmental health nurses continue to use the research agenda as a framework to guide occupational safety and health research and professional practice. As the primary association for the largest group of health care professionals serving workplaces and communities, AAOHN is pleased to provide input on the Second Decade of NORA (National Occupational Research Agenda).

The association targeted five out of eight sectors to provide comments including agriculture, health care, retail, transportation and utilities. Comments were developed by soliciting input on the following questions from occupational and environmental health nurses who worked in these sectors.

- What or why should the sector be researchable?
- What are the 2-3 major researchable issues of the sector?
- How would you apply research evidence to practice?

Specific Comments

1. Agriculture

The agriculture industry has ranked among the top three industries for fatal and non-fatal injury rates among U.S. workers. Agriculture is an area that has not been addressed in recent years although there were several initiatives implemented in the 1990s. Today agriculture continues to have some of the same issues it had in the 1990s. These initiatives were only a beginning. Much more needs to be done.

External forces that make this an important sector to research are the changing nature of the workforce (increased diversity) and lifestyle and general health issues such as obesity, aging, etc. The migrant worker has always been a component of the agricultural workforce since agriculture is viewed as entry-level work for inexperienced workers. The agricultural sector also experiences high turn over within the ranks because the jobs are filled with inexperienced and transient workers. The health status of the American workforce in general is becoming older, more obese, etc. One can assume that it is true of the agricultural workforce.

Possible researchable topics could include the following:

- Which group of workers has the most exposure to hazards?
- Have the hazard to farm work been adequately defined?
- What are the precursors to tractor rollovers?
- Has training made a difference in the incidence of tractor rollovers or other farm equipment type injuries?
- How does lifestyle/general health status affect farm workers?
- What prevention strategies are most effective in dealing with aging, weight, etc.?

-- What are the implications of increasing cultural diversity in prevention of farm accidents? In seeking care?

By knowing precursors to tractor rollovers or other farm equipment type injuries, education can be developed and conducted that is relevant and more effective in preventing injuries. Surveillance of farm injuries would also be useful to identify which population group is at risk so effective prevention strategies can be tailored to the task performed. The same approach would apply to culturally diverse work groups and lifestyle issues.

2. Healthcare

Although numerous strides have been made toward ergonomic/musculoskeletal disorders (MSDS) prevention, MSDS continues to be a major problem among healthcare workers as well as exposures to latex, bloodborne pathogens, violence, etc. But, there is also the threat of emerging airborne infections, i.e., SARS, multi-resistant tuberculosis, etc. and many questions such as "fit-test or not fit-test"? And, "what respiratory protection to wear for what exposure?" Now the healthcare worker is faced with the threat of avian flu and flu pandemic.

Because the healthcare environment varies (occupational and community health, jails and correctional facilities, hospices, hospitals) and is always changing (air care, global care, nanotechnology, aging workforce), there will always be researchable topics in healthcare, i.e., the effectiveness of education/training and workplace changes on MSDS injuries, workplace violence, environmental exposures; the health and safety impacts of traditional vs. nontraditional workplaces; the impact of shift work, increasing acuity of workloads, contract and immigrant workers. And, in the current unsettling global environment, the impact of bioterrorism and emerging infections, i.e., pandemic, etc., the health and safety of health care providers should have an increased research priority.

As a research sector category, healthcare is very important and should be given the emphasis warranted due to the nature of the recruitment and retention issues of registered nurses and other health care professionals. An appropriate level of staffing within the health care system is imperative to achieve

quality client care, improvement in the health status of the nation and cost effectiveness in health care delivery.

3. Retail

Employees working in retail often experience repetitive injuries (wrists, shoulders, etc.) even with use of ergonomic engineering and restructuring. These injuries result in lost productivity and lost or modified days, which result in higher economic costs.

A possible research approach would be to look at the effects of body weight, body type, grasping strength, posture, etc. on injuries. Other approaches would be to consider the effects of routine exercise programs and/or stretching programs on repeat injuries, i.e., a cost-benefit and intervention analysis of changes in work conditions.

4. Transportation

Long-distance truck drivers are one of the unhealthiest groups of workers: sitting for hours in the cab of a truck; eating fast foods or truck stop foods that are high in fat and salt; dealing with stress of meeting deadlines, traffic, etc.; and having low to no activity. Therefore, the truck driver meets the criteria of development of cardiovascular disease (CVD), stress related illness, and deep vein thrombosis (DVT).

Although research may be difficult for this segment of workers, there can be economic gains such as the employee and his/her family could live longer with improved health, healthier lifestyles could reduce insurance costs for the employer, and could reduce driving accidents potentially caused by CVD, DW, stress, etc., thereby decreasing work related compensation as well as saving lives.

Categorized comment or partial comment:

5. Utilities

Utilities should in a category of its own because utility workers have exposures not always shared with other workers, i.e., weather, electrical and nuclear hazards. Utility workers also face the possibility of falls while working from very high lifts, musculoskeletal disorders from working overhead and in contorted positions, and sleep deprivation. Because of the specific type of work performed, the utility worker's work can range from sedentary (nuclear plant worker) to high stress (lineman).

The potential for research would focus on lifestyle changes and/or recommendations or regulations on number of hours worked, effective ergonomic strategies, i.e., the cause-effect intervention relationship.

AAOHN appreciates the opportunity to review and comment on the *Second Decade of NORA (National Occupational Health Agenda)*. As always, we will continue to provide our support and assistance to facilitate safe and healthful workplaces and communities.

Sincerely,

Susan A. Randolph, MSN, RN, COHN-S, FAAOHN

Construction Sector

Fatal and Non-Fatal Injury and Illness Surveillance Information

(A version with tables and active links is available in [Appendix 2.](#))

The following summary of fatality, injury, and illness rates in the Construction sector is provided in order to help identify the most important safety and health problems in this sector. The North American Industry Classification System (NAICS), which was used to designate the NORA sectors, was also used by the Bureau of Labor Statistics (BLS) during the collection of their 2003 data. NAICS codes all economic activities using a six-digit hierarchical coding system with industry sectors, subsectors, industry groups, NAICS international industries, and National industries coded with 2, 3, 4, 5, and 6 digits, respectively.

The following sector-based summary is derived from 2003 BLS Census of Fatal Occupational Injuries (CFOI), and the annual Survey of Occupational Injury and Illness (SOII) (BLS, 2005a; BLS, 2005b). BLS non-fatal injury and illness data are based on a survey of 183,700 (of an estimated 7 million) US business establishments and do not include the self-employed, farms with fewer than 11 employees, private households, and governmental agencies. Where possible, references are made to specific BLS tables. In order to encourage internal comparisons, we have converted BLS rates, which are expressed as cases/100 full-time workers/year and cases/10,000 full-time workers/year, to cases/1,000 full-time workers/year.

As with the original BLS tables, the rates reported in our tables cannot be directly calculated from the numbers of cases and numbers of workers provided in our tables. This is because BLS makes post-sampling adjustments of their data and they use the equivalent of full-time workers (not workers) in

their rate denominators (BLS, 1997). Using denominators based on person-time rather than numbers of workers results in rates that provide more accurate estimates of actual risk. Full-time workers are defined as working 40 hours per week for 50 weeks. Denominators for non-fatal injury and illness rates are calculated based on work hours data BLS receives from reporting establishments. Denominators for fatal injury rates come from the Current Population Survey.

According to the BLS-Quarterly Census of Employment and Wages (QCEW) program, there were 6,672,400 workers in the construction sector in 2003 (Table C1). Workers in the specialty trades and building construction comprised 63% and 23% of the sector workforce, respectively.

BLS [2005a]. Census of fatal occupational injuries (CFOI) - current and revised data. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics, Safety and Health Statistics Program. [www.bls.gov/iif/oshcfoi1.htm]

BLS [2005b]. Nonfatal (OSHA recordable) injuries and illnesses. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics, Safety and Health Statistics Program. [www.bls.gov/iif/home.htm]

BLS [1997]. BLS handbook of methods. Chapter 9. Occupational safety and health statistics. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics. [www.bls.gov/opub/hom/pdf/homch9.pdf]

Fatal occupational injuries

Falls accounted for 32% of the fatal occupational injuries in the construction sector. Transportation accidents accounted for 26% of the fatal occupational injuries in the construction sector (half of these involved highway accidents) (Table C3).

Nonfatal occupational injuries involving days away from work

Sector-wide, sprains and strains were the most frequent nonfatal injury type involving days away from work with an incidence rate of 9.30 cases per 1000 full-time workers per year (Table C4). The incidence rate of sprains was highest in the Specialty Trade Contractors (NAICS 238) subsector. Finish Carpentry (NAICS 23835) construction industry had the highest incidence rate of nonfatal amputations involving days away from work that was about 7-fold larger than the construction sector average (Table C7).

Total nonfatal occupational injuries

The Specialty Trade Contractors (NAICS 238) construction subsector had the highest rate and number of nonfatal occupational injuries (Table C5). Construction industries with the highest incidence rates of nonfatal occupational injuries included Framing Contractors (NAICS 23813), Structural Steel and Precast Concrete Contractors (NAICS 23812), and Poured Concrete Foundation and Structure Contractors (NAICS 23811) (Table C6A).

The incidence rate of traumatic injuries and disorders involving days away from work was 24.4 cases/1000 full-time workers/year, compared to an incidence rate of total nonfatal injuries of 67 cases/1000 full-time workers/year (2003 BLS Tables R72 and Table C5). This suggests that the total injury rate is about 3-times larger than the injury rate involving days away from work.

Nonfatal occupational illnesses and injuries involving days away from work

The incidence rates of carpal tunnel syndrome and tendonitis involving days away from work were 0.14 and 0.18 cases/1000 full-time workers/year (Table C8). Incidence rates of carpal tunnel syndrome and tendonitis involving days away from work were highest in the Highway, Street, and Bridge Construction

(NAICS 2373) industry group (Table C9) and the Drywall and Insulation Contractors (NAICS 23831) industry (Table C10), respectively.

Categorized comment or partial comment:

Nonfatal occupational illnesses

The incidence rate of nonfatal occupational skin diseases and disorders was 0.38 cases/1000 full-time workers/year for the construction sector (Table C12). The Heavy and Civil Engineering Construction (NAICS 237) subsector had the highest incidence rate of skin diseases and disorders. However, due to a large workforce, the Specialty Trade Contractors (NAICS 238) subsector had the highest number of cases. The Utility System Construction (NAICS 2371) industry group had an incidence rate of 1.53 cases of skin diseases and disorders/1000 full-time workers/year, which was 4-fold the construction sector average (Table C13).

The incidence rate of nonfatal occupational respiratory conditions was 0.16 cases/1000 full-time workers/year for the construction sector (Table C12). The Specialty Trade Contractors (NAICS 238) subsector had the highest incidence rate and case numbers of nonfatal occupational respiratory conditions. The Other Building Finishing Contractors (NAICS 23839) industry had an incidence rate of 2.45 cases/1000 full-time workers/year, 15-fold the construction sector average (Table C14).

The incidence rate of nonfatal occupational poisonings was 0.09 cases/1000 full-time workers/year for the construction sector (Table C12). The two industries with the highest incidence rates of occupational poisonings were Painting and Wall Covering Contractors (NAICS 23832) and Other Building Finishing Contractors (NAICS 23839), which had incidence rates of 0.87 and 0.75 cases/1000 full-time workers/year, respectively (Table C15).

The incidence rate of all other nonfatal occupational illnesses was 0.91 cases/1000 full-time workers/year for the construction sector (Table C12). The three industries with the highest incidence rates of all other occupational illnesses were Framing Contractors (NAICS 23813), Tile and Terrazzo

Contractors (NAICS 23834), and Other Foundation, Structure, and Building Exterior Contractors (NAICS 23819), which had incidence rates ranging from 1.93 to 2.41 cases/1000 full-time workers/year (Table C16).

Appendix

Notes on Limitations and Interpretation

One of the limitations of occupational safety and health surveillance data is the underreporting of illnesses, which occurs because: 1) some diseases (e.g., cancer and pneumoconiosis) have long latency periods so that reporting mechanisms, such as OSHA logs, as used by BLS, fail to capture many of these events; 2) many diseases have multiple potential causes (e.g., asthma and cardiovascular diseases); and 3) workers and physicians do not recognize an occupational contribution.

BLS data sources do not allow: characterization of occupationally-related illnesses, if these illnesses are not skin diseases and disorders, respiratory conditions, or poisonings; or quantification of fatalities due to occupationally-related illnesses. Other sources have suggested that the occupational illness fatalities in the US workforce outnumber occupational injury fatalities by about 8:1. For example, using 1997 disease fatality numbers, it was estimated that occupationally-related illness and injury deaths numbered, respectively, 25,910-72,121 (Steenland et al., 2003) and 6,238 (BLS). Estimates of 1997 occupationally-related illness deaths by disease category are as follows: 6,805-26,685 for non-malignant respiratory disease; 12,086-26,244 for occupationally-related cancer deaths; 6,037-18,253 for occupationally-related coronary heart disease; and 328-580 for occupationally-related renal disease (Steenland et al., 2003). Sector-based occupationally-related illness fatality data are not provided in this surveillance data summary.

Other limitations of the data include the following. (1) Only BLS data for a single year (2003) are presented. However, data for a single year may not be representative of the long-term experience and health impacts of a sector due to economic, political, technological, or weather characteristics of that year. (2) Many of the rates are based on small denominators, so that a few additional or a few less cases in the numerator might cause a large fluctuation in the magnitude of the rate estimate. Therefore, what may be quantified as large differences in risk may simply be the result of the “random” occurrence of a few cases. (3) Rates are not adjusted for any important potential confounders, the most important of which may be age. Research has shown that younger workers may be at increased risk of injury due to a variety of factors including experience and training. Older workers may be more susceptible to certain occupational illnesses because of pre-existing medical conditions. Therefore what is perceived as a true difference in risk based upon crude rates between two groups may simply be the result of differences in their age distributions. (4) Differences among rates for subsectors and industries of the sector are not tested for statistical significance. Without statistical testing, one cannot conclude that rates are really any different than some of the other rates in the sector.

Discussion of the data focuses on rates, although many of the tables also provide data on the number of workers affected. A subsector or industry which has the highest rate of injuries or illnesses within the sector may have few total workers. Implementing prevention strategies within another subsector or industry within the sector with a high rate of injuries or illnesses and a larger number of workers, may result in a much larger public health impact. If these data are used for planning and priority setting, we suggest that the number of adverse health outcomes and the number of workers potentially impacted be considered concurrently to identify worker groups towards which research should be directed.

Healthcare and Social Assistance Sector

Fatal and Non-Fatal Injury and Illness Surveillance Information

(A version with tables and active links is available in [Appendix 3.](#))

The following summary of fatality, injury, and illness rates in the Healthcare and Social Assistance sector is provided in order to help identify the most important safety and health problems in this sector. The North American Industry Classification System (NAICS), which was used to designate the NORA sectors, was also used by the Bureau of Labor Statistics (BLS) during the collection of their 2003 data. NAICS codes all economic activities using a six-digit hierarchical coding system with industry sectors, subsectors, industry groups, NAICS international industries, and National industries coded with 2, 3, 4, 5, and 6 digits, respectively.

The following sector-based summary is derived from 2003 BLS Census of Fatal Occupational Injuries (CFOI), and the annual Survey of Occupational Injury and Illness (SOII) (BLS, 2005a; BLS, 2005b). BLS non-fatal injury and illness data are based on a survey of 183,700 (of an estimated 7 million) US business establishments and do not include the self-employed, farms with fewer than 11 employees, private households, and governmental agencies. Where possible, references are made to specific BLS tables. In order to encourage internal comparisons, we have converted BLS rates, which are expressed as cases/100 full-time workers/year and cases/10,000 full-time workers/year, to cases/1,000 full-time workers/year.

As with the original BLS tables, the rates reported in our tables cannot be directly calculated from the numbers of cases and numbers of workers provided in our tables. This is because BLS makes post-sampling adjustments of their data and they use the equivalent of full-time workers (not workers) in their rate denominators (BLS, 1997). Using denominators based on person-time rather than numbers of workers results in rates that provide more accurate estimates of actual risk. Full-time workers are defined as working 40 hours per week for 50 weeks. Denominators for non-fatal injury and illness rates are calculated based on work hours data BLS receives from reporting establishments. Denominators for fatal injury rates come from the Current Population Survey.

According to the BLS-Quarterly Census of Employment and Wages (QCEW) program, there were 13,721,900 workers in the healthcare and social assistance sector in 2003 (Table H1). Workers in hospitals, nursing and residential care facilities, and physician offices comprised 31%, 20%, and 15% of sector workforce, respectively.

BLS [2005a]. Census of fatal occupational injuries (CFOI) - current and revised data. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics, Safety and Health Statistics Program. [www.bls.gov/iif/oshcfoi1.htm]

BLS [2005b]. Nonfatal (OSHA recordable) injuries and illnesses. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics, Safety and Health Statistics Program. [www.bls.gov/iif/home.htm]

BLS [1997]. BLS handbook of methods. Chapter 9. Occupational safety and health statistics. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics. [www.bls.gov/opub/hom/pdf/homch9.pdf]

Fatal occupational injuries

Transportation accidents accounted for 48% of fatal occupational injuries in the healthcare and social assistance sector (most involved highway accidents). Assaults and violent acts accounted for 25% of fatal occupational injuries in the healthcare and social assistance sector (about an equal number were due to homicides as were due to suicides) (Table H3).

Nonfatal occupational injuries involving days away from work

Sprains and strains were the most frequent nonfatal injury type involving days away from work with an incidence rate within the healthcare and social assistance sector of 9.5 cases per 1000 full-time workers per year (Table H4). The Nursing and Residential Care Facilities (NAICS 623) subsector had the highest incidence rate of sprains and strains, with an incidence rate of 17.76 cases/1000 full-time workers/year, which was approximately two-fold larger than the healthcare and social service sector average.

Total nonfatal occupational injuries

The Nursing and Residential Care Facilities (NAICS 623) subsector had the highest incidence rate and total number of cases of total nonfatal occupational injuries (Table H5).

Within the healthcare and social assistance sector, the incidence rate of traumatic injuries and disorders involving days away from work was 16.30 cases/1000 full-time workers/year, compared to an incidence rate of total nonfatal injuries of 60 cases/1000 full-time workers/year (Specially requested information and Table H5). This suggests that the total injury rate was about 4-fold larger than the injury rate involving days away from work.

Nonfatal occupational injuries and illnesses involving days away from work

The incidence rate of carpal tunnel and tendonitis for the healthcare and social assistance sector were 0.17 and 0.08 cases/1000 full-time workers/year, respectively (Table H6). Carpal tunnel syndrome and tendonitis incidence rates were highest in the Home Healthcare Services (NAICS 6216) and Hospitals (NAICS 622) industry group and subsector, respectively (Table H6). The musculoskeletal system and connective tissue diseases and disorders incidence rate for the healthcare and social assistance sector was 0.18 cases/1000 full-time workers/year (Special Request); 43% of these cases were diagnosed as tendonitis.

The incidence rate of back pain (without a medical diagnosis) involving days away from work for the healthcare and social assistance sector was 0.65 cases/1000 full-time workers/year (Table H6). The highest rate was in the Nursing and Residential Care Facilities (NAICS 623) subsector, which had an incidence rate of 1.38 cases/1000 full-time workers/year.

Nonfatal occupational illnesses

The incidence rates of nonfatal occupational skin diseases and disorders and nonfatal occupational respiratory conditions for the healthcare and social assistance sector were 0.93 and 0.59 cases/1000 full-time workers/year (Table H7). The Hospitals (NAICS 622) subsector had the highest incidence rates and case numbers for both nonfatal respiratory conditions and skin diseases and disorders. BLS data was not able to further discriminate as to what portions of the hospital workforce were at greatest risk.

The incidence rate of nonfatal occupational poisonings for the healthcare and social assistance sector was 0.05 cases/1000 full-time workers/year (Table H7). The Social Assistance (NAICS 624) subsector had the highest incidence rate of nonfatal occupational poisonings.

The incidence rate of all other nonfatal occupational illnesses for the healthcare and social assistance sector was 2.89 cases/1000 full-time workers/year (Table H7). The Hospitals (NAICS 622) subsector had the highest incidence rate and case numbers of all other nonfatal occupational illnesses.

Appendix

Notes on Limitations and Interpretation

One of the limitations of occupational safety and health surveillance data is the underreporting of illnesses, which occurs because: 1) some diseases (e.g., cancer and pneumoconiosis) have long latency periods so that reporting mechanisms, such as OSHA logs, as used by BLS, fail to capture many of these events; 2) many diseases have multiple potential causes (e.g., asthma and cardiovascular diseases); and 3) workers and physicians do not recognize an occupational contribution.

BLS data sources do not allow: characterization of occupationally-related illnesses, if these illnesses are not skin diseases and disorders, respiratory conditions, or poisonings; or quantification of fatalities due

to occupationally-related illnesses. Other sources have suggested that the occupational illness fatalities in the US workforce outnumber occupational injury fatalities by about 8:1. For example, using 1997 disease fatality numbers, it was estimated that occupationally-related illness and injury deaths numbered, respectively, 25,910-72,121 (Steenland et al., 2003) and 6,238 (BLS). Estimates of 1997 occupationally-related illness deaths by disease category are as follows: 6,805-26,685 for non-malignant respiratory disease; 12,086-26,244 for occupationally-related cancer deaths; 6,037-18,253 for occupationally-related coronary heart disease; and 328-580 for occupationally-related renal disease (Steenland et al., 2003). Sector-based occupationally-related illness fatality data are not provided in this surveillance data summary.

Other limitations of the data include the following. (1) Only BLS data for a single year (2003) are presented. However, data for a single year may not be representative of the long-term experience and health impacts of a sector due to economic, political, technological, or weather characteristics of that year. (2) Many of the rates are based on small denominators, so that a few additional or a few less cases in the numerator might cause a large fluctuation in the magnitude of the rate estimate. Therefore, what may be quantified as large differences in risk may simply be the result of the “random” occurrence of a few cases. (3) Rates are not adjusted for any potential confounders, the most important of which may be age. Research has shown that younger workers may be at increased risk of injury due to a variety of factors including experience and training. Older workers may be more susceptible to certain occupational illnesses because of pre-existing medical conditions. Therefore what is perceived as a true difference in risk based upon crude rates between two groups may simply be the result of differences in their age distributions. (4) Differences among rates for subsectors and industries of the sector are not tested for statistical significance. Without statistical testing, one cannot conclude that rates are really any different than some of the other rates in the sector.

Discussion of the data focuses on rates, although many of the tables also provide data on the number of workers affected. A subsector or industry which has the highest rate of injuries or illnesses within the sector may have few total workers. Implementing prevention strategies within another subsector or industry within the sector with a high rate of injuries or illnesses and a larger number of workers, may result in a much larger public health impact. Manufacturing Sector

Fatal and Non-Fatal Injury and Illness Surveillance Information

(A version with tables and active links is available in [Appendix 4.](#))

The following summary of fatality, injury, and illness rates in the Manufacturing sector is provided in order to help identify the most important safety and health problems in this sector. The North American Industry Classification System (NAICS), which was used to designate the NORA sectors, was also used by the Bureau of Labor Statistics (BLS) during the collection of their 2003 data. NAICS codes all economic activities using a six-digit hierarchical coding system with industry sectors, subsectors, industry groups, NAICS international industries, and National industries coded with 2, 3, 4, 5, and 6 digits, respectively.

The following sector-based summary is derived from 2003 BLS Census of Fatal Occupational Injuries (CFOI), and the annual Survey of Occupational Injury and Illness (SOII) (BLS, 2005a; BLS, 2005b). BLS non-fatal injury and illness data are based on a survey of 183,700 (of an estimated 7 million) US business establishments and do not include the self-employed, farms with fewer than 11 employees, private households, and governmental agencies. Where possible, references are made to specific BLS tables. In order to encourage internal comparisons, we have converted BLS rates, which are expressed as cases/100 full-time workers/year and cases/10,000 full-time workers/year, to cases/1,000 full-time workers/year.

As with the original BLS tables, the rates reported in our tables cannot be directly calculated from the numbers of cases and numbers of workers provided in our tables. This is because BLS makes post-sampling adjustments of their data and they use the equivalent of full-time workers (not workers) in

their rate denominators (BLS, 1997). Using denominators based on person-time rather than numbers of workers results in rates that provide more accurate estimates of actual risk. Full-time workers are defined as working 40 hours per week for 50 weeks. Denominators for non-fatal injury and illness rates are calculated based on work hours data BLS receives from reporting establishments. Denominators for fatal injury rates come from the Current Population Survey.

According to the BLS-Quarterly Census of Employment and Wages (QCEW) program, there were 14,459,700 workers in the manufacturing sector in 2003 (Table M1). Workers in Transportation Equipment, Food, Fabricated Metal Products, Computer and Electronic Products, and Machinery manufacturing comprised 12%, 10%, 10%, 9%, and 8% of the sector workforce, respectively.

BLS [2005a]. Census of fatal occupational injuries (CFOI) - current and revised data. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics, Safety and Health Statistics Program. [www.bls.gov/iif/oshcfoi1.htm]

BLS [2005b]. Nonfatal (OSHA recordable) injuries and illnesses. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics, Safety and Health Statistics Program. [www.bls.gov/iif/home.htm]

BLS [1997]. BLS handbook of methods. Chapter 9. Occupational safety and health statistics. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics. [www.bls.gov/opub/hom/pdf/homch9.pdf]

Fatal occupational injuries

Contact with objects and equipment accounted for 31% of fatal occupational injuries in the manufacturing sector (the largest proportion involved workers being caught in or compressed by equipment or objects). Transportation accidents accounted for 28% of fatal occupational injuries in the manufacturing sector (most involved highway accidents) (Table M3).

Nonfatal occupational injuries involving days away from work

Industry-wide, sprains and strains were the most frequent nonfatal injury type involving days away from work with an incidence rate within the manufacturing sector of 5.92 cases per 1000 full-time workers per year (Table M4). Beverage and Tobacco Products (NAICS 312) manufacturing subsector had an incidence rate of sprains and strains of 17.61 cases/1000 full-time workers/year, which was approximately three-fold larger than the manufacturing sector average.

Furniture and Related Products (NAICS 337), Fabricated Metal Products (NAICS 332), and Wood Products (NAICS 321) manufacturing subsectors had the three highest incidence rates of nonfatal amputation involving days away from work, with the highest manufacturing industry rates in Miscellaneous Fabricated Metal Product (NAICS 332999), Ornamental and Architectural Metal Works (NAICS 332323); and Other Metal Valve and Pipe Fitting (NAICS 332919) manufacturing (Tables M4 and M7).

Total nonfatal occupational injuries

Beverage and Tobacco Products (NAICS 312) and Wood Products (NAICS 321) manufacturing subsectors had the highest incidence rates of total nonfatal occupational injuries (Table M5), with Bottled Water (NAICS 312112) and Truss (NAICS 321214) manufacturing industries having incident rates, respectively, 2.8- and 2.4-fold larger than the manufacturing sector average (Table M6A). The Transportation Equipment (NAICS 336) manufacturing subsector had the highest number of total nonfatal injuries, due to a large workforce and a moderately elevated incidence rate (Table M5).

Within the manufacturing sector, the incidence rate of traumatic injuries and disorders involving days away from work was 13.85 cases/1000 full-time workers/year, compared to an incidence rate of total nonfatal injuries of 60 cases/1000 full-time workers/year (2003 BLS Tables R72 and SNR05). This suggests that the total injury rate was more than 4-fold larger than the injury rate involving days away from work.

Nonfatal occupational injuries and illnesses involving days away from work

Carpal tunnel syndrome and tendonitis incidence rates involving days away from work were highest in the Leather and Allied Products (NAICS 316) manufacturing subsector (Table M8). The incidence rates of carpal tunnel syndrome and tendonitis were, respectively, about 11-fold higher in the Other Leather and Allied Product (NAICS 31699) manufacturing industry and about 50-fold higher in Rubber and Plastic Footwear manufacturing (NAICS 316211) manufacturing industry, compared with the respective manufacturing sector averages (Tables M9A and M10).

The incidence rate of back pain (without a medical diagnosis) involving days away from work for the manufacturing sector was 0.35 cases/1000 full-time workers/year (Table M8). Beverage and Tobacco Products (NAICS 312) had an incidence rate of 0.94 cases/1000 full-time workers/year, which was about three times larger than the sector average.

The incidence rate of hernia (including inguinal and ventral hernias) involving days away from work for the manufacturing sector was 0.44 cases/1000 full-time workers/year (2003 BLS Table R72).

Nonfatal occupational illnesses

Food (NAICS 311), Chemical (NAICS 325), and Transportation Equipment (NAICS 336) manufacturing subsectors had the highest incidence rates and case numbers of nonfatal occupational respiratory conditions. The Flour Milling and Malt (NAICS 31121) manufacturing industry had an incidence rate of nonfatal occupational respiratory conditions 13-fold the manufacturing sector average (Table M12A).

Leather Products (NAICS 316), Transportation Equipment (NAICS 336), and Fabricated Metal Products (NAICS 332) manufacturing subsectors had the highest incidence rates of nonfatal occupational skin diseases and disorders, with the largest number of affected workers being in the Transportation Equipment manufacturing subsector (Table M11). The three manufacturing industries with the highest incidence rates of nonfatal occupational skin disease and disorders involved handling concrete and metalworking and hydraulic fluids (Table M13A).

Appendix

Notes on Limitations and Interpretation

One of the limitations of occupational safety and health surveillance data is the underreporting of illnesses, which occurs because: 1) some diseases (e.g., cancer and pneumoconiosis) have long latency periods so that reporting mechanisms, such as OSHA logs, as used by BLS, fail to capture many of these events; 2) many diseases have multiple potential causes (e.g., asthma and cardiovascular diseases); and 3) workers and physicians do not recognize an occupational contribution.

BLS data sources do not allow: characterization of occupationally-related illnesses if these illnesses are not skin diseases and disorders, respiratory conditions, or poisonings; or quantification of fatalities due to occupationally-related illnesses. Other sources have suggested that the occupational illness fatalities

in the US workforce outnumber occupational injury fatalities by about 8:1. For example, using 1997 disease fatality numbers, it was estimated that occupationally-related illness and injury deaths numbered, respectively, 25,910-72,121 (Steenland et al. 2003) and 6,238 (BLS). Estimates of 1997 occupationally-related illness deaths by disease category are as follows: 6,805-26,685 for non-malignant respiratory disease; 12,086-26,244 for occupationally-related cancer deaths; 6,037-18,253 for occupationally-related coronary heart disease; and 328-580 for occupationally-related renal disease (Steenland et al. 2003). Sector-based occupationally-related illness fatality data are not provided in this surveillance data summary.

Other limitations of the data include the following. (1) Only BLS data for a single year (2003) are presented. However, data for a single year may not be representative of the long-term experience and health impacts of a sector due to economic, political, technological, or weather characteristics of that year. (2) Many of the rates are based on small denominators, so that a few additional or a few less cases in the numerator might cause a large fluctuation in the magnitude of the rate estimate. Therefore, what may be quantified as large differences in risk may simply be the result of the “random” occurrence of a few cases. (3) Rates are not adjusted for any potential confounders, the most important of which may be age. Research has shown that younger workers may be at increased risk of injury due to a variety of factors including experience and training. Therefore what is perceived as a true difference in risk based upon crude rates between two groups may simply be the result of differences in their age distributions. (4) Differences among rates for subsectors and industries of the sector are not tested for statistical significance. Without statistical testing, one cannot conclude that rates are really any different than some of the other rates in the sector.

Discussion of the data focuses on rates, although many of the tables also provide data on the number of workers affected. A subsector or industry which has the highest rate of injuries or illnesses within the sector may have few total workers. Implementing prevention strategies within another subsector or industry within the sector with a high rate of injuries or illnesses and a larger number of workers, may result in a much larger public health impact. Mining Sector

Fatal and Non-Fatal Injury and Illness Surveillance Information

(A version with tables and active links is available in [Appendix 5](#).)

The following summary of fatality, injury, and illness rates in the Mining sector is provided in order to help identify the most important safety and health problems in this sector. The North American Industry Classification System (NAICS), which was used to designate the NORA sectors, was also used by the Bureau of Labor Statistics (BLS) during the collection of their 2003 data. NAICS codes all economic activities using a six-digit hierarchical coding system with industry sectors, subsectors, industry groups, NAICS international industries, and National industries coded with 2, 3, 4, 5, and 6 digits, respectively.

The following sector-based summary is derived from 2003 BLS Census of Fatal Occupational Injuries (CFOI), and the annual Survey of Occupational Injury and Illness (SOII) (BLS, 2005a; BLS, 2005b). BLS non-fatal injury and illness data are based on a survey of 183,700 (of an estimated 7 million) US business establishments that do not include the self-employed, farms with fewer than 11 employees, private households, and governmental agencies; and comprehensive reporting by the Mine Safety and Health Administration (MSHA) for the mining sector (except for oil and gas extraction and related support activities). Where possible, references are made to specific BLS tables. In order to encourage internal comparisons, we have converted BLS rates, which are expressed as cases/100 full-time workers/year and cases/10,000 full-time workers/year, to cases/1,000 full-time workers/year.

The mining sector (NAICS 21), as presented in this summary, includes establishments MSHA rules and reporting, such as those in Oil and Gas Extraction and related support activities. Data for mining

operators in coal, metal, and nonmetal mining are provided to BLS by the MSHA, U.S. Department of Labor. Independent mining contractors are excluded from the coal, metal, and nonmetal mining industries. These data do not reflect the changes OSHA made to its recordkeeping requirements effective January 1, 2002; therefore estimates for these industries are not comparable to estimates for other industries.

As with the original BLS tables, the rates reported in our tables cannot be directly calculated from the numbers of cases and numbers of workers provided in our tables. This is because BLS makes post-sampling adjustments of their data and they use the equivalent of full-time workers (not workers) in their rate denominators (BLS, 1997). Using denominators based on person-time rather than numbers of workers results in rates that provide more accurate estimates of actual risk. Full-time workers are defined as working 40 hours per week for 50 weeks. Denominators for non-fatal injury and illness rates are calculated based on work hours data BLS receives from reporting establishments. Denominators for fatal injury rates come from the Current Population Survey.

According to the BLS-Quarterly Census of Employment and Wages (QCEW) program, there were 500,100 workers in the mining sector in 2003 (Table MG1). Workers in the mining subsector comprised 40% of the sector workforce. Of these, 34% were coal miners.

BLS [2005a]. Census of fatal occupational injuries (CFOI) - current and revised data. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics, Safety and Health Statistics Program. [www.bls.gov/iif/oshcfoi1.htm]

BLS [2005b]. Nonfatal (OSHA recordable) injuries and illnesses. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics, Safety and Health Statistics Program. [www.bls.gov/iif/home.htm]

BLS [1997]. BLS handbook of methods. Chapter 9. Occupational safety and health statistics. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics. [www.bls.gov/opub/hom/pdf/homch9.pdf]

Fatal occupational injuries

Transportation accidents accounted for 34% of fatal occupational injuries in the mining sector (58% of these fatalities were due to highway accidents). Contact with objects and equipment accounted for 32% of fatal occupational injuries in the mining sector (71% of these fatalities were due to the worker being struck by an object) (Table MG3).

Nonfatal occupational injuries involving days away from work

Sprains and strains were the most frequent nonfatal injury type involving days away from work with an incidence rate within the mining sector of 6.04 cases per 1000 full-time workers per year (Table MG4). Coal Mining (NAICS 2121) subsector had an incidence rate of sprains and strains of 19.16 cases/1000 full-time workers/year, which was more than three-fold larger than the mining sector average. Bituminous Coal Underground Mining (NAICS 212112), Dimension Stone Mining and Quarrying (NAICS 212311), and Drilling Oil and Gas Wells (NAICS 213111) had incidence rates of fractures involving days away from work ranging from 3.85 to 8.64 cases/1000 full-time workers/year, which were 2 to 4.5 times larger than the mining sector average (Table MG7). The highest amputation rate involving days away from work was in Bituminous Coal Underground Mining (NAICS 212112), which had an incidence rate of 5.1 cases/1000 full-time workers/year (2003 BLS Table R5).

Total nonfatal occupational injuries

The highest incidence rate of total nonfatal occupational injuries was in the Bituminous Coal Underground Mining (NAICS 212112) industry, which had an incidence rate of 84 cases/1000 full-time workers/year (Table MG6).

Within the mining sector, the incidence rate of traumatic injuries and disorders involving days away from work was 13.11 cases/1000 full-time workers/year, compared to an incidence rate of total nonfatal injuries of 31 cases/1000 full-time workers/year (Special Request and Table MG5). This suggests that the total injury rate was more than two-fold larger than the injury rate involving days away from work.

Nonfatal occupational injuries and illnesses involving days away from work

The incidence rate of occupational back pain (without a medical diagnosis) involving days away from work was highest in the Support Activities for Mining (NAICS 213) subsector (Table MG8) with a rate of 0.28 cases/1000 full-time workers/year. However, the incidence rate for Bituminous Coal Underground Mining (NAICS 212112) was much higher at 5.1 cases/1000 full-time workers/year (2003 BLS Table R5).

Nonfatal occupational illnesses

Bituminous Coal Underground Mining (NAICS 212112) and Bituminous Coal and Lignite Surface Mining (NAICS 212111) industries had incidence rates of nonfatal occupational respiratory conditions of 2.08 and 0.63 cases/1000 full-time workers/year, respectively, compared to the mining sector average of 0.23 cases/1000 full-time workers/year (Tables MG9 and MG10). The incidence rate of nonfatal skin diseases and disorders was highest in the Support Activities for Mining (NAICS 213) industry group, with the Drilling Oil and Gas Wells (NAICS 213112) industry having the highest incidence rate (0.55 cases/1000 full-time workers/year) within this industry group (Tables MG9 and MG11).

The incidence rates of all other nonfatal occupational illnesses were highest in the Bituminous Coal Underground Mining (NAICS 212112) and Iron Ore Mining (NAICS 21221) industries, which had incidence rates of 3.91 and 3.72 cases/1000 full-time workers/year, respectively (Table MG12).

Appendix

Notes on Limitations and Interpretation

One of the limitations of occupational safety and health surveillance data is the underreporting of illnesses, which occurs because: 1) some diseases (e.g., cancer and pneumoconiosis) have long latency periods so that reporting mechanisms, such as OSHA logs, as used by BLS, fail to capture many of these events; 2) many diseases have multiple potential causes (e.g., asthma and cardiovascular diseases); and 3) workers and physicians do not recognize an occupational contribution.

BLS data sources do not allow: characterization of occupationally-related illnesses, if these illnesses are not skin diseases and disorders, respiratory conditions, or poisonings; or quantification of fatalities due to occupationally-related illnesses. Other sources have suggested that the occupational illness fatalities

in the US workforce outnumber occupational injury fatalities by about 8:1. For example, using 1997 disease fatality numbers, it was estimated that occupationally-related illness and injury deaths numbered, respectively, 25,910-72,121 (Steenland et al., 2003) and 6,238 (BLS). Estimates of 1997 occupationally-related illness deaths by disease category are as follows: 6,805-26,685 for non-malignant respiratory disease; 12,086-26,244 for occupationally-related cancer deaths; 6,037-18,253 for occupationally-related coronary heart disease; and 328-580 for occupationally-related renal disease (Steenland et al., 2003). Sector-based occupationally-related illness fatality data are not provided in this surveillance data summary.

Other limitations of the data include the following. (1) Only BLS data for a single year (2003) are presented. However, data for a single year may not be representative of the long-term experience and health impacts of a sector due to economic, political, technological, or weather characteristics of that year. (2) Many of the rates are based on small denominators, so that a few additional or a few less cases in the numerator might cause a large fluctuation in the magnitude of the rate estimate. Therefore, what may be quantified as large differences in risk may simply be the result of the “random” occurrence of a few cases. (3) Rates are not adjusted for any potential confounders, the most important of which may be age. Research has shown that younger workers may be at increased risk of injury due to a variety of factors including experience and training. Older workers may be more susceptible to certain occupational illnesses because of pre-existing medical conditions. Therefore what is perceived as a true difference in risk based upon crude rates between two groups may simply be the result of differences in their age distributions. (4) Differences among rates for subsectors and industries of the sector are not tested for statistical significance. Without statistical testing, one cannot conclude that rates are really any different than some of the other rates in the sector.

Discussion of the data focuses on rates, although many of the tables also provide data on the number of workers affected. A subsector or industry which has the highest rate of injuries or illnesses within the sector may have few total workers. Implementing prevention strategies within another subsector or industry within the sector with a high rate of injuries or illnesses and a larger number of workers, may result in a much larger public health impact. If these data are used for planning and priority setting, we suggest that the number of adverse health outcomes and the number of workers potentially impacted be considered concurrently to identify worker groups towards which research should be directed.

Services Sectors

Fatal and Non-Fatal Injury and Illness Surveillance Information

(A version with tables and active links is available in [Appendix 6](#).)

The following summary of fatality, injury, and illness rates in the Services sectors is provided in order to help identify the most important safety and health problems in this sector. The North American Industry Classification System (NAICS), which was used to designate the NORA sectors, was also used by the Bureau of Labor Statistics (BLS) during the collection of their 2003 data. NAICS codes all economic activities using a six-digit hierarchical coding system with industry sectors, subsectors, industry groups, NAICS international industries, and National industries coded with 2, 3, 4, 5, and 6 digits, respectively.

The following sector-based summary is derived from 2003 BLS Census of Fatal Occupational Injuries (CFOI), and the annual Survey of Occupational Injury and Illness (SOII) (BLS, 2005a; 2005b). BLS non-fatal injury and illness data are based on a survey of 183,700 (of an estimated 7 million) US business establishments and do not include the self-employed, farms with fewer than 11 employees, private households, and governmental agencies. Where possible, references are made to specific BLS tables. In order to encourage internal comparisons, we have converted BLS rates, which are expressed as cases/100 full-time workers/year and cases/10,000 full-time workers/year, to cases/1,000 full-time workers/year.

As with the original BLS tables, the rates reported in our tables cannot be directly calculated from the numbers of cases and numbers of workers provided in our tables. This is because BLS makes post-sampling adjustments of their data and they use the equivalent of full-time workers (not workers) in their rate denominators (BLS, 1997). Using denominators based on person-time rather than numbers of workers results in rates that provide more accurate estimates of actual risk. Full-time workers are defined as working 40 hours per week for 50 weeks. Denominators for non-fatal injury and illness rates are calculated based on work hours data BLS receives from reporting establishments. Denominators for fatal injury rates come from the Current Population Survey.

According to the BLS-Quarterly Census of Employment and Wages (QCEW) program, there were 44,822,300 workers in the services sectors in 2003 (Table S1). Workers in Accommodation and Food Services, Administrative and Support Services, and Professional, Scientific, and Technical Services comprised 23%, 16%, and 15% of services sectors workforce, respectively.

Fatal occupational injuries

Transportation accidents accounted for 49% of fatal occupational injuries in the Services sectors (66% of these were due to highway accidents). Assaults and violent acts accounted for 24% of fatal occupational injuries in the Services sectors (76% of these were due to homicides) (Table S3).

Nonfatal occupational injuries involving days away from work

Sprains and strains were the most frequent nonfatal injury type involving days away from work for all service sectors with sector incidence rates ranging from 0.85 cases/1000 full-time workers/year in the Finance and Insurance (NAICS 52) sector to 15.73 cases/1000 full-time workers/year in the Waste Management and Remediation Services (NAICS 562) subsector (Table S4). The Waste Collection (NAICS 5621) industry group had the highest incidence rate of amputations involving days away from work with a rate of 0.67 cases/1000 full-time workers/year (Table S7).

Total nonfatal occupational injuries

Amusement Parks and Arcades (NAICS 7131), Waste Collection (NAICS 5621), and Consumer Electronics and Appliances Rental (NAICS 53221) were the industry groups and industries that had the highest total nonfatal occupational injury rates, ranging from 82 to 108 cases/1000 full-time workers/year (Table S6).

Nonfatal occupational injuries and illnesses involving days away from work

The highest incidence rate of occupational carpal tunnel syndrome involving days away from work was 1.09 cases/1000 full-time workers/year in the Direct Life, Health, and Medical Insurance Carriers (NAICS 52411) industry (Table S9). The highest incidence rate of tendonitis involving days away from work was 0.21 cases/1000 full-time workers/year in the Spectator Sports (NAICS 7112) industry group (Table S10). The incidence rate of musculoskeletal system and connective tissue diseases and disorders involving days away from work was highest in the Other Services (NAICS 81) sector which had an incidence rate of 0.23 cases/1000 full-time workers/year; 28% of these cases were diagnosed as tendonitis (Special Request). The highest incidence rate of back pain (without a medical diagnosis) involving days away from work was 0.91 cases/1000 full-time workers/year in the Waste Treatment and Disposal (NAICS 5622) industry group (2003 BLS Table R5). Finance and Insurance (NAICS 52) had the highest sector incidence rate of mental illness, with a rate of 0.09 cases/1000 full-time workers/year (Table S8).

Nonfatal occupational illnesses

The incidence rate of nonfatal occupational skin disease was highest in the Recreational Vehicle Parks and Recreational Camps (NAICS 7212) industry group, which had an incidence rate of 11.82 cases/1000 full-time workers/year (Table S12).

The incidence rate of nonfatal occupational respiratory conditions was highest in Hotels and Motels (NAICS 72111), Amusement Parks and Arcades (NAICS 7131), and General Rental Centers (NAICS 5323) industry groups and industries, which had incidence rates ranging from 0.48 to 0.57 cases/1000 full-time workers/year (Table S13).

The incidence rate of nonfatal occupational poisonings was highest in the Lessors of Other Real Estate Property (NAICS 53119) industry, which had an incidence rate of 8.7 cases/1000 full-time workers/year (Table S14).

The incidence rate of all other nonfatal occupational illnesses was highest in the Satellite Communications (NAICS 5174) industry group, which had an incidence rate of 11.22 cases/1000 full-time workers/year (Table S15).

Appendix

Notes on Limitations and Interpretation

One of the limitations of occupational safety and health surveillance data is the underreporting of illnesses, which occurs because: 1) some diseases (e.g., cancer and pneumoconiosis) have long latency periods so that reporting mechanisms, such as OSHA logs, as used by BLS, fail to capture many of these

events; 2) many diseases have multiple potential causes (e.g., asthma and cardiovascular diseases); and 3) workers and physicians do not recognize an occupational contribution.

BLS data sources do not allow: characterization of occupationally-related illnesses, if these illnesses are not skin diseases and disorders, respiratory conditions, or poisonings; or quantification of fatalities due to occupationally-related illnesses. Other sources have suggested that the occupational illness fatalities in the US workforce outnumber occupational injury fatalities by about 8:1. For example, using 1997 disease fatality numbers, it was estimated that occupationally-related illness and injury deaths numbered, respectively, 25,910-72,121 (Steenland et al., 2003) and 6,238 (BLS). Estimates of 1997 occupationally-related illness deaths by disease category are as follows: 6,805-26,685 for non-malignant respiratory disease; 12,086-26,244 for occupationally-related cancer deaths; 6,037-18,253 for occupationally-related coronary heart disease; and 328-580 for occupationally-related renal disease (Steenland et al., 2003). Sector-based occupationally-related illness fatality data are not provided in this surveillance data summary.

Other limitations of the data include the following. (1) Only BLS data for a single year (2003) are presented. However, data for a single year may not be representative of the long-term experience and health impacts of a sector due to economic, political, technological, or weather characteristics of that year. (2) Many of the rates are based on small denominators, so that a few additional or a few less cases in the numerator might cause a large fluctuation in the magnitude of the rate estimate. Therefore, what may be quantified as large differences in risk may simply be the result of the “random” occurrence of a few cases. (3) Rates are not adjusted for any potential confounders, the most important of which may be age. Research has shown that younger workers may be at increased risk of injury due to a variety of factors including experience and training. Older workers may be more susceptible to certain occupational illnesses because of pre-existing medical conditions. Therefore what is perceived as a true difference in risk based upon crude rates between two groups may simply be the result of differences in their age distributions. Transportation, Warehousing, and Utilities Sectors

Fatal and Non-Fatal Injury and Illness Surveillance Information

(A version with tables and active links is available in [Appendix 7.](#))

The following summary of fatality, injury, and illness rates in the Transportation, Warehousing, and Utilities sectors is provided in order to help identify the most important safety and health problems in this sector. The North American Industry Classification System (NAICS), which was used to designate the NORA sectors, was also used by the Bureau of Labor Statistics (BLS) during the collection of their 2003 data. NAICS codes all economic activities using a six-digit hierarchical coding system with industry sectors, subsectors, industry groups, NAICS international industries, and National industries coded with 2, 3, 4, 5, and 6 digits, respectively.

The following sector-based summary is derived from 2003 BLS Census of Fatal Occupational Injuries (CFOI), and the annual Survey of Occupational Injury and Illness (SOII) (BLS, 2005a; BLS, 2005b). BLS non-fatal injury and illness data are based on a survey of 183,700 (of an estimated 7 million) US business establishments and do not include the self-employed, farms with fewer than 11 employees, private households, and governmental agencies. Where possible, references are made to specific BLS tables. In order to encourage internal comparisons, we have converted BLS rates, which are expressed as cases/100 full-time workers/year and cases/10,000 full-time workers/year, to cases/1,000 full-time workers/year.

As with the original BLS tables, the rates reported in our tables cannot be directly calculated from the numbers of cases and numbers of workers provided in our tables. This is because BLS makes post-

sampling adjustments of their data and they use the equivalent of full-time workers (not workers) in their rate denominators (BLS, 1997). Using denominators based on person-time rather than numbers of workers results in rates that provide more accurate estimates of actual risk. Full-time workers are defined as working 40 hours per week for 50 weeks. Denominators for non-fatal injury and illness rates are calculated based on work hours data BLS receives from reporting establishments. Denominators for fatal injury rates come from the Current Population Survey.

According to the BLS-Quarterly Census of Employment and Wages (QCEW) program, there were 3,946,200 workers in the Transportation and Warehousing sectors and 575,900 workers in the Utilities sector in 2003 (Table TR1). Workers in Truck Transportation comprised 33% of the combined Transportation/Warehousing workforce.

BLS [2005a]. Census of fatal occupational injuries (CFOI) - current and revised data. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics, Safety and Health Statistics Program. [www.bls.gov/iif/oshcfoi1.htm]

BLS [2005b]. Nonfatal (OSHA recordable) injuries and illnesses. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics, Safety and Health Statistics Program. [www.bls.gov/iif/home.htm]

BLS [1997]. BLS handbook of methods. Chapter 9. Occupational safety and health statistics. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics. [www.bls.gov/opub/hom/pdf/homch9.pdf]

Fatal occupational injuries

Transportation accidents accounted for 75% of fatal occupational injuries in the Transportation, Warehousing, and Utilities sectors (69% of these were due to highway accidents) (Table TR3).

Nonfatal occupational injuries involving days away from work

Sprains and strains were the most frequent nonfatal injury type involving days away from work. Within the Transportation and Warehousing sectors, the incidence rate of sprains and strains was 17.32 cases/1000 full-time workers/year (Table TR4). However, the Couriers and Messengers (NAICS 492) subsector had an incidence rate of 23.42 cases/1000 full-time workers/year. The incidence rate of amputations involving days away from work was highest in the Local General Freight Trucking (NAICS 48411) industry, which had an incidence rate of 0.44 cases/1000 full-time workers/year.

Total nonfatal occupational injuries

The subsectors with the highest incidence rates of total nonfatal occupational injuries were Couriers and Messengers (NAICS 492) and Air Transportation (NAICS 481) (Table TR5). The incidence rates of total nonfatal occupational injuries were highest in Refrigerated Warehousing and Storage (NAICS 49312), Couriers (NAICS 4921), and Scheduled Air Transportation (NAICS 4811) industry groups and industries, which had incidence rates 47% to 73% higher than the Transportation and Warehousing sectors average (Table TR6A).

Within the Transportation and Warehousing sectors and the Utilities sector the incidence rates of traumatic occupational injuries involving days away from work were 33.49 and 11.11 cases/1000 full-time workers/year (Special Request) compared to 74 and 40 cases of total nonfatal occupational injuries/1000 full-time workers/year (Table TR5), respectively. This suggests that the total injury rates were 2.2 and 3.6 fold larger than the injury rates involving days away from work for these sectors, respectively.

Nonfatal occupational injuries and illnesses involving days away from work

The subsector with the highest incidence rates of occupational carpal tunnel syndrome and tendonitis involving days away from work was Warehousing and Storage (NAICS 493), which had incidence rates of 0.42 and 0.34 cases/1000 full-time workers/year, respectively (Table TR8). The industry with the highest incidence rate of occupational carpal tunnel syndrome involving days away from work was the Long Distance Specialized Freight (except used goods) Trucking (NAICS 48423) industry, which had an incidence rate of 1.13 cases/1000 full-time workers/year, approximately 4 times larger than the Transportation and Warehousing sectors average (Table TR9).

Within the Transportation and Warehousing sectors, the incidence rate of the symptom of back pain (without a medical diagnosis) involving days away from work was 1.27 cases/1000 full-time workers/year (Table TR8). This incidence rate was highest in the Couriers and Messengers (NAICS 492) subsector. The incidence rate of hernia (including inguinal and ventral hernias) involving days away from work for the Transportation and Warehousing sectors was 0.59 cases/1000 full-time workers/year.

Nonfatal occupational illnesses

The incidence rate of nonfatal occupational skin diseases and disorders was highest in the Water Sewage and Other Systems (NAICS 2213) industry group, which had an incidence rate of 2.03 cases/1000 full-time workers/year (Table TR11).

The incidence rate of nonfatal occupational respiratory conditions was highest in the Urban Transit System (NAICS 4851) industry group, which had an incidence rate of 2.83 cases/1000 full-time workers/year (Table TR12).

Appendix

Notes on Limitations and Interpretations

One of the limitations of occupational safety and health surveillance data is the underreporting of illnesses, which occurs because: 1) some diseases (e.g., cancer and pneumoconiosis) have long latency periods so that reporting mechanisms, such as OSHA logs, as used by BLS, fail to capture many of these events; 2) many diseases have multiple potential causes (e.g., asthma and cardiovascular diseases); and 3) workers and physicians do not recognize an occupational contribution.

BLS data sources do not allow: characterization of occupationally-related illnesses, if these illnesses are not skin diseases and disorders, respiratory conditions, or poisonings; or quantification of fatalities due to occupationally-related illnesses. Other sources have suggested that the occupational illness fatalities in the US workforce outnumber occupational injury fatalities by about 8:1. For example, using 1997 disease fatality numbers, it was estimated that occupationally-related illness and injury deaths numbered, respectively, 25,910-72,121 (Steenland et al., 2003) and 6,238 (BLS). Estimates of 1997 occupationally-related illness deaths by disease category are as follows: 6,805-26,685 for non-malignant respiratory disease; 12,086-26,244 for occupationally-related cancer deaths; 6,037-18,253 for

occupationally-related coronary heart disease; and 328-580 for occupationally-related renal disease (Steenland et al., 2003). Sector-based occupationally-related illness fatality data are not provided in this surveillance data summary.

Other limitations of the data include the following. (1) Only BLS data for a single year (2003), are presented. However, data for a single year may not be representative of the long-term experience and health impacts of a sector due to economic, political, technological, or weather characteristics of that year. (2) Many of the rates are based on small denominators, so that a few additional or a few less cases in the numerator might cause a large fluctuation in the magnitude of the rate estimate. Therefore, what may be quantified as large differences in risk may simply be the result of the “random” occurrence of a few cases. (3) Rates are not adjusted for any potential confounders, the most important of which may be age. Research has shown that younger workers may be at increased risk of injury due to a variety of factors including experience and training. Older workers may be more susceptible to certain occupational illnesses because of pre-existing medical conditions. Therefore what is perceived as a true difference in risk based upon crude rates between two groups may simply be the result of differences in their age distributions. (4) Differences among rates for subsectors and industries of the sector are not tested for statistical significance. Without statistical testing, one cannot conclude that rates are really any different than some of the other rates in the sector.

Discussion of the data focuses on rates, although many of the tables also provide data on number of workers affected. A subsector or industry which has the highest rate of injuries or illnesses within the sector may have few total workers. Wholesale and Retail Trade Sectors

Fatal and Non-Fatal Injury and Illness Surveillance Information

(A version with tables and active links is available in [Appendix 8.](#))

The following summary of fatality, injury, and illness rates in the Wholesale and Retail Trade sectors is provided in order to help identify the most important safety and health problems in this sector. The North American Industry Classification System (NAICS), which was used to designate the NORA sectors, was also used by the Bureau of Labor Statistics (BLS) during the collection of their 2003 data. NAICS codes all economic activities using a six-digit hierarchical coding system with industry sectors, subsectors, industry groups, NAICS international industries, and National industries coded with 2, 3, 4, 5, and 6 digits, respectively.

The following sector-based summary is derived from 2003 BLS Census of Fatal Occupational Injuries (CFOI), and the annual Survey of Occupational Injury and Illness (SOII) (BLS, 2005a; BLS, 2005b). BLS non-fatal injury and illness data are based on a survey of 183,700 (of an estimated 7 million) US business establishments and do not include the self-employed, farms with fewer than 11 employees, private households, and governmental agencies. Where possible, references are made to specific BLS tables. In order to encourage internal comparisons, we have converted BLS rates, which are expressed as cases/100 full-time workers/year and cases/10,000 full-time workers/year, to cases/1,000 full-time workers/year.

As with the original BLS tables, the rates reported in our tables cannot be directly calculated from the numbers of cases and numbers of workers provided in our tables. This is because BLS makes post-sampling adjustments of their data and they use the equivalent of full-time workers (not workers) in their rate denominators (BLS, 1997). Using denominators based on person-time rather than numbers of workers results in rates that provide more accurate estimates of actual risk. Full-time workers are defined as working 40 hours per week for 50 weeks. Denominators for non-fatal injury and illness rates are calculated based on work hours data BLS receives from reporting establishments. Denominators for fatal injury rates come from the Current Population Survey.

According to the BLS-Quarterly Census of Employment and Wages (QCEW) program there were 20,519,800 workers in the wholesale and retail trade sectors in 2003 (Table T1). Workers in wholesale trade and retail trade comprised 27% and 73% of the workforce for the combined trade sectors, respectively.

BLS [2005a]. Census of fatal occupational injuries (CFOI) - current and revised data. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics, Safety and Health Statistics Program. [www.bls.gov/iif/oshcfoi1.htm]

BLS [2005b]. Nonfatal (OSHA recordable) injuries and illnesses. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics, Safety and Health Statistics Program. [www.bls.gov/iif/home.htm]

BLS [1997]. BLS handbook of methods. Chapter 9. Occupational safety and health statistics. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics. [www.bls.gov/opub/hom/pdf/homch9.pdf]

Fatal occupational injuries

Assaults and violent acts accounted for 41% of fatal occupational injuries in the Wholesale and Retail Trade sectors (85% of these were due to homicides). Transportation accidents accounted for 32% of fatal occupational injuries in the Wholesale and Retail Trade sectors (79% of these involved highway accidents) (Table T3).

Nonfatal occupational injuries involving days away from work

Within the Wholesale and Retail Trade sectors, sprains and strains were the most frequent nonfatal injury type involving days away from work with incidence rates of 6.78 and 6.97 cases/1000 full-time workers/year, respectively (Table T4). Building Material and Garden Equipment and Supplies Dealers (NAICS 444), Nondurable Goods Merchant Wholesalers (NAICS 424), and Food and Beverage Stores (NAICS 445) subsectors had the highest incidence rates of sprains and strains.

The incidence rate of amputations involving days away from work were 0.12 and 0.03 cases/1000 full-time workers/year for the Wholesale Trade and Retail Trade sectors, respectively (Table T4). Lumber and Other Construction Materials Merchant Wholesalers (NAICS 4233) had an amputation incidence rate of 1.03 cases/1000 full-time workers/year, which was more than 8 times larger than the Wholesale Trade sector average (Table T7).

Total nonfatal occupational injuries

General Merchandise Stores (NAICS 452), Food and Beverage Stores (NAICS 445), and Building Material and Garden Equipment and Supplies Dealers (NAICS 444) had the highest rates of total nonfatal occupational injuries, ranging from 62 to 69 cases/1000 full-time workers/year (Table T5). The Beer, Wine, and Distilled Alcoholic Beverage Merchant Wholesalers (NAICS 4248) industry group had an

incidence rate of total nonfatal occupational injuries of 107 cases/1000 full-time workers/year, which was more than two times higher than the Wholesale Trade sector average. (Table T6A).

Within the Wholesale and Retail Trade sectors the incidence rates of traumatic occupational injuries involving days away from work were 13.97 and 14.43 cases/1000 full-time workers/year (Special Request) compared to 45 and 51 cases of total nonfatal occupational injuries/1000 full-time workers/year, respectively (Table T5). This suggests that the total injury rates were 3.2- and 3.5-fold larger than the injury rate involving days away from work for these sectors, respectively.

Nonfatal occupational illnesses and injuries involving days away from work

Incidence rates of occupational carpal tunnel syndrome and tendonitis involving days away from work incidence rates were, respectively 0.46 and 0.34 cases/1000 full-time workers/year in the Food and Beverage Stores (NAICS 445) subsector (Table T8). The highest incidence rate of carpal tunnel syndrome was in the Machinery, Equipment, and Supplies Merchant Wholesalers (NAICS 4238) and Supermarkets and Other Grocery (except convenience) Stores (NAICS 44511), which had incidence rates of 0.63 and 0.56 cases/1000 full-time workers/year (Table T9). The highest incidence rate of tendonitis was in the Other Specialty Food Stores (NAICS 44529) industry, at 4.61 cases/1000 full-time workers/year, 42 times higher than the Retail Trade average (Table T10).

The incidence rates of the symptom of back pain (without a medical diagnosis) involving days away from work were 0.52 and 0.41 cases/1000 full-time workers/year for Wholesale Trade and Retail Trade, respectively (Table T8). The incidence rate for this symptom was highest in Nondurable Goods Merchant Wholesalers (NAICS 424) subsector and in the Beer, Wine, and Distilled Alcoholic Beverage Merchant Wholesalers (NAICS 4248) industry group (Table T11). For the Wholesale and Retail Trade sectors the incidence rates for hernia involving days away from work were 0.36 and 0.31 cases/1000 full-time workers/year, respectively (Special Request).

Nonfatal occupational illnesses

The incidence rate of nonfatal occupational skin diseases and disorders was 0.31 cases/1000 full-time workers/year in both Wholesale and Retail Trade sectors (Table T12). This rate was highest in the Nursery and Garden Center (NAICS 44422) industry, which had an incidence rate of 3.40 cases/1000 full-time workers/year (Table T13).

The incidence rate of nonfatal occupational respiratory conditions was 0.14 and 0.10 cases/1000 full-time workers/year in the Wholesale and Retail Trade sectors, respectively (Table T12). This rate was highest in the Camera and Photographic Supplies Stores (NAICS 44313) industry, which had an incidence rate of 3.11 cases/1000 full-time workers/year (Table T14).

The incidence rate of nonfatal occupational poisonings was 0.03 and 0.05 cases/1000 full-time workers/year in the Wholesale and Retail Trade sectors, respectively (Table T12). This rate was highest in the Outdoor Power Equipment Stores (NAICS 44421) industry, which had a rate of 4.73 cases/1000 full-time workers/year (BLS Table SNR08).

The incidence rate of all other nonfatal occupational illnesses was 1.01 and 1.21 cases/1000 full-time workers/year in the Wholesale and Retail Trade sectors, respectively (Table T12). This rate was highest in Electronic Shopping and Mail-Order Houses (NAICS 4541) industry group which had an incidence rate of 6.94 cases/1000 full-time workers/year (Table T15).

Appendix

Notes on Limitations and Interpretation

One of the limitations of occupational safety and health surveillance data is the underreporting of illnesses, which occurs because: 1) some diseases (e.g., cancer and pneumoconiosis) have long latency periods so that reporting mechanisms, such as OSHA logs, as used by BLS, fail to capture many of these events; 2) many diseases have multiple potential causes (e.g., asthma and cardiovascular diseases); and 3) workers and physicians do not recognize an occupational contribution.

BLS data sources do not allow: characterization of occupationally-related illnesses, if these illnesses are not skin diseases and disorders, respiratory conditions, or poisonings; or quantification of fatalities due to occupationally-related illnesses. Other sources have suggested that the occupational illness fatalities in the US workforce outnumber occupational injury fatalities by about 8:1. For example, using 1997 disease fatality numbers, it was estimated that occupationally-related illness and injury deaths numbered, respectively, 25,910-72,121 (Steenland et al., 2003) and 6,238 (BLS). Estimates of 1997 occupationally-related illness deaths by disease category are as follows: 6,805-26,685 for non-malignant respiratory disease; 12,086-26,244 for occupationally-related cancer deaths; 6,037-18,253 for occupationally-related coronary heart disease; and 328-580 for occupationally-related renal disease (Steenland et al., 2003). Sector-based occupationally-related illness fatality data are not provided in this surveillance data summary.

Other limitations of the data include the following. (1) Only BLS data for a single year (2003) are presented. However, data for a single year may not be representative of the long-term experience and health impacts of a sector due to economic, political, technological, or climatic characteristics of that year. (2) Many of the rates are based on small denominators, so that a few additional or a few less cases in the numerator might cause a large fluctuation in the magnitude of the rate estimate. Therefore, what may be quantified as large differences in risk may simply be the result of the “random” occurrence of a few cases. (3) Rates are not adjusted for any potential confounders, the most important of which may be age. Research has shown that younger workers may be at increased risk of injury due to a variety of factors including experience and training. Older workers may be more susceptible to certain occupational illnesses because of pre-existing medical conditions. Therefore what is perceived as a true difference in risk based upon crude rates between two groups may simply be the result of differences in their age distributions. (4) Differences among rates for subsectors and industries of the sector are not tested for statistical significance. Without statistical testing, one cannot conclude that rates are really any different than some of the other rates in the sector.

Discussion of the data focuses on rates, although many of the tables also provide data on the number of workers affected. A subsector or industry which has the highest rate of injuries or illnesses within the sector may have few total workers. Implementing prevention strategies within another subsector or industry within the sector with a high rate of injuries or illnesses and a larger number of workers, may result in a much larger public health impact. If these data are used for planning and priority setting, we suggest that the number of adverse health outcomes and the number of workers potentially impacted be considered concurrently to identify worker groups towards which research should be directed.

Steenland K, Burnett C, Lulich N, Ward E, Hurrell J [2003]. Dying for work: the magnitude of US mortality from selected causes of death associated with occupation. *Am J Ind Med* 43:461-482.

Human Vibration Exposures

Human vibration includes hand-transmitted vibration and whole-body vibration. It is estimated that more than nine million workers in the U.S. are occupationally exposed to human vibration.

Human vibration may not be listed in the top three exposures in any of the eight sectors but it is one of the important exposures across the sectors. Human vibration exists in six sectors: construction, transportation, mining, agriculture and forest, services, and manufacture.

Although many studies on human vibration have been reported, several fundamental issues have not been resolved. For example, no one knows the exact relationship between the vibration exposure and the incidence of vibration-induced disorders. A robust theory has not been established to quantify the exposure dose and the health effects. The vibration-induced problems have not gone away.

It is true that several international standards (ISO 5349, 2001; ISO 2631, 1997) have been established for assessing the risk of the vibration exposures. However, one of the major purposes of these standards is to have a set of uniform procedures to collect experimental data so that they can be used to effectively improve the standards.

Therefore, further studies on human vibration exposures are required.

Categorized comment or partial comment:

Musculoskeletal disorders are prevalent in all eight NORA sectors:

- Agriculture, Forestry and Fishing
- Construction
- Healthcare and Social Assistance
- Manufacturing
- Mining
- Services
- Transportation, Warehousing and Utilities
- Wholesale and Retail Trade

Comprehensive strategies for controlling work-related musculoskeletal disorders include:

- Basic research
- Ergonomics
- Biomechanics
- Epidemiological research
- Engineering controls
- Administrative controls
- Applied research and validation studies
- Intervention studies
- And so on

It would be unwise to hang the MSD control hat on just one of these domains. Each of them is important. One often overlooked, but vital aspect of this distributive portfolio is basic research. Basic research provides unbiased facts to answer questions and resolve disputes. Basic research provides the essential objective measurements of forces, movements, and postures used in the workplace. Only basic research can discern underlying fundamental mechanisms of musculoskeletal disorders and injuries and help identify dose-response relationships. The knowledge provided through basic research leads to a better grasp of the etiologies of MSDs and helps us develop the most cost-effective and least-intrusive workplace solutions. Basic research also leads to the development of robust, convenient, objective measurement methodologies and instrumentation for use in laboratory and field studies.

In the past, intervention strategies based on general biomechanical and ergonomics principles have proven to be less than successful. This is because these efforts often lacked the critical information that is provided through basic research. The use of basic research can help safety professionals pinpoint underlying mechanisms and to develop efficient and cost-effective intervention approaches for quantifying important variables and for targeting specific dose-response relationships. The OSHA ergonomics standard was widely criticized because many of its components lacked the support of objective, quantitative data. Basic research is the primary source of such support. In short, basic research must play a significant role in the overall strategy to control workplace musculoskeletal disorders and injuries.

Categorized comment or partial comment:

I am speaking today regarding the Agriculture industry, North American Industry Classification System (NAICS) code 11. In order to assure that the NORA 2 priorities are data driven, I will attempt to provide some data for this industry. What I provide is not comprehensive, but it is compelling.

For 2004, the latest year that data is available from the Bureau of Labor Statistics (BLS), their released - 'National Census of Fatal Occupational Injuries in 2004" (CFOI) reports that the Agriculture, forestry, fishing & hunting industry had the highest fatality rate among all the industrial sectors with 30.1 deaths/100,000 workers. Mining came in second (28.3 deaths) followed by the Transportation and warehousing sector (17.8). This compares to an all industry average rate of 4.1/100,000 workers.(1) The Agriculture industry's rate is over seven times (7.3) the industry average.

The Agriculture, forestry, fishing and hunting industry was ranked 3rd in the total number of deaths (659). Construction was ranked first (1,224) followed by the Transportation and warehousing sector (829). Mining had 152 deaths and was ranked 12/15 industry sectors.(2) Speaking of mining (and since we're in WV), the Sago mine tragedy is still fresh in our minds, even though it is beginning to fade from the headlines. This calamity took the lives of 12 men in a close knit mining community not far from here. There was an outcry by news commentators and editorial writers about the "human cost" of coal as an energy source. However, can you imagine the outcry if farmers were to die in groups of 12? The Agriculture sector could sustain that number every week (12 deaths a week) for a year and still be under the 2004 total number of fatalities (624 vs 659). But these deaths do not generally happen in groups and

thus escape the national media, even though they appear all too often as single incidents in our nations local newspapers. The point I wish to make is that there also is a "human cost" to the most basic of our human necessities, food. We must not forget this point.

Within the industry of Agriculture, crop and livestock production (which most closely parallels the occupation of farming) accounts for 70% (458/659) of the deaths in the agriculture, forestry, fishing and hunting sector. Surveillance studies have shown there are high fatality rates for older agricultural production workers (those older than 64 years of age) along with higher numbers of deaths for these older workers. A 2001 study of 7 years of CFOI data found these older agricultural production workers had a fatality rate of 65.9/100,000 which was 2-3 times the rate of other agricultural production age groups and 13 times higher than the national average (5.0/100,000). Also, these older agricultural production workers incurred 2-4 times the number of deaths of their younger agricultural production age groups.(3)

Additionally, young agricultural workers are at increased risk, too. The youth who work on farms face unique risks which are not present for many other young workers. These include machinery, large animals, electrical hazards, chemical hazards and excessive noise. From 1992-2002, the agriculture production workforce 15-19 years of age comprised 7.1% of the total youth workforce (full time equivalent - FTE adjusted) but incurred 15.8% of all the fatalities. For workers under 16 years of age, the agriculture production sector accounted for 60% of the deaths, and for workers 10 years of age and younger, the agriculture production sector accounted for 79% of all the deaths. The highest fatality rate for this time period among young agriculture production workers was for 15 year olds (18.5/100,000). The rates for young agriculture production workers was 3.6 times higher than their counterparts in all other industries.(4)

The previous statistics have all been fatalities. However, there have been a number of surveys conducted for non-fatal injuries which NIOSH has sponsored that indicates there is a greater percentage of injuries occurring to youth who live on farms from non-work activities.(5) There is no other industrial sector where the workplace is also the home and leisure activity area for the worker and his family. This provides for some unique and complex situations which have to be understood and addressed in order to reduce the unacceptably high numbers and rates of agricultural injuries and deaths.

Let me conclude by noting that the Agriculture industry consistently ranks high in both the rate and number of occupational fatalities. It is an industry sector which warrants priority funding and our attention and efforts in order to alleviate this situation. Within the agriculture production sectors, there are high rates and numbers of death for older farmers. Also, there are high fatality rates for young agricultural production workers as compared to their counterparts in all other industries. Additionally, nonfatal injuries, both work and non-work related, occur to youth who live on farms. The unique situation of working and living on farms creates many opportunities for research and intervention activities that are not found in any other industry. There is a human cost associated with the production of food in the US that I believe is at an unacceptable rate and frequency for those who work in these sectors. I would encourage you to keep this in mind as priorities are selected and put forth for the NORA 2 initiative.

A Town Hall Meeting for the
National Occupational Research Agenda (NORA)
Tuesday, March 21, 2006
Comments by Robert E. Koedam, M.S.
Chief, Fatality Investigations Team
Surveillance and Field Investigations Branch
Division of Safety Research, CDC/NIOSH

Hello, my name is Robert Koedam. I serve as the Chief of the Fatality Investigations Team within the Surveillance and Field Investigations Branch. Division of Safety Research, NIOSH. Within the Fatality Investigations Team lies the Fatality Assessment and Control Evaluation (FACE) program. I would like to speak today to impress upon the NORA Research Program industry sector managers, coordinators. and research sector councils the significant impact that the FACE program can have on NIOSH's research agenda - across those sectors with high numbers and rates of fatalities. As a matter of fact, between

1983 and 2005, the FACE program completed 2,096 fatality investigative reports - including investigations in all **eight** NORA Sector Programs.

The Bureau of Labor Statistics (BLS) Census of Fatal Occupational Injuries collects occupational fatality data that are useful in setting safety research and prevention priorities. We know that the BLS data collected is highly effective in identifying common causes of death and worker groups that have experienced large numbers and/or rates of occupational injury.

What we also know is that unfortunately, there are "gaps" in the data in that it does not completely include the needed detail that would enable researchers to clearly identify a specific hazard, identify the specific factors that allow workers to be exposed to a hazard, and/or identify a specific means to control an emerging or existing hazard. In order to develop effective, sector-specific prevention measures, more in-depth information is needed to understand all of the circumstances and events that lead up to and contribute to fatal injuries.

The NIOSH FACE program fills this niche' nicely through the execution of its primary objectives - which include identifying work situations at high risk for fatal injury, performing in depth on-site investigations, collecting specific, comprehensive information, and performing analysis of collected data. This data analysis includes all information related to the agent, host, and environment in the pre-event, event, and post event phases of the incident. NIOSH FACE has both an intramural and an extramural component (currently active in 15 States.) The State FACE programs, because of their close relationships with other intra-state agencies and safety organizations, as well as with employers and workers, have also been particularly effective at administering FACE programs while reaching out quickly to employers within their respective state when hazards are identified and prevention strategies are developed. This type of collaboration would work well within the NORA sectors as well.

Perhaps the most unique characteristic of the FACE program is that it contains the surveillance component as well as the field investigation component. The field investigation component allows for the gathering of the needed detail pertaining to an incident. This enhances the existing BLS data and fills many of the existing information gaps. Perhaps more importantly, the additional detail collected during field investigations allows for the development of a summary fatality report that includes prevention recommendations that can be immediately used in future or existing training programs, and feeds into the implementation of safety controls and research - including product substitution, developing engineering controls and administrative controls, and addressing the development and/or use of adequate personal protective equipment.

Each of the FACE-generated reports and documents also incorporate a dissemination component. The dissemination component allows the summary reports and their timely, effective, and realistic prevention strategies to reach those who can intervene in the workplace - thereby preventing future similar incidents. The dissemination has included forming partnerships with other government agencies, civilian agencies, trade associations, trade journals, and private and corporate industry. The NIOSH FACE program has been able to direct this information to targeted audiences in a variety of FACE products and interventions - including working with partners such as the OSHA training institute and its satellite training centers to incorporate FACE reports into safety and health training as case studies.

In closing, with very limited resources, FACE has contributed to changes in regulations, equipment, and has identified needs for current research. FACE materials are also used in training for employees, and by employers by creating a safer work environment through the implementation of the aforementioned

safety controls. These direct impacts and R2P examples include, but are not limited to; the State of New Jersey enacting safety laws regarding electrical requirements and inspections of public swimming pools – protecting employees. OSHA implementing CPL 2-1.36 - which covers the Interim inspection procedures during Communication Tower Construction Activities, a North Carolina OSHA telecommunication tower standard, and engineering and administrative controls implemented by the international community following two investigations by Nebraska FACE of accidental injections from Micotil 300®; a deadly cattle antibiotic. Other impacts include the implementation of FACE findings into training programs in the telecommunication tower, roadway construction, and logging industries - just to name a few.

I urge you to consider including surveillance, as well as the FACE program in your NORA recommendations.

Thank you for this opportunity to speak before you today.

Examples Where Laboratory Investigations Have Directly Impacted Occupational Health

Vincent Castranova, Ph.D.

Health Effects Laboratory Division/NIOSH

I. Leather Spray Protectant

A. Issue - Consumers who treated leather products with leather protectant spray were admitted into the hospital with respiratory problems.

B. Lab study -

- Identified that cases were associated with a new formulation of the spray.
- Compared the effects of exposure to the new vs old formulation in an inhalation animal model.
- Found that the new formulation caused severe damage to the alveolar air/blood barrier.
- Identified the potential causative agents in the new formulation.

C. Result - The new product was recalled.

II. Wood/leaf compost

A. Issue - A landscaper was hospitalized with fever and labored breathing.

B. Lab study -

-- Simulated the collection of wood/leaf compost at the worksite and measured high levels of aerosolized fungal spores.

-- Generated an aerosol of wood/leaf compost dust for an animal inhalation study.

-- Documented an acute inflammatory response to this organic dust.

C. Result -

-- Assisted the diagnosis of organic dust toxic syndrome which guided patient treatment.

-- Resulted in control measures at the wood/leaf compost site.

III. Nylon flock

A. Issue - A high incidence of pulmonary disease in a nylon flocking plant.

B. Lab study -

-- Identified airborne fiber-like nylon shreds generated during cutting of the flock.

-- Animal exposures indicated that these shreds were highly inflammatory and durable in the lung.

C. Result -

-- Changes in plant air handling, personal protective equipment, and work practices were instituted.

-- Work practices were changed industry wide.

IV. Artificial butter flavoring

A. Issue - A high incidence of severe lung disease in a popcorn plant.

B. Lab study -

-- Generated a fume by heating the artificial butter flavoring which mimicked plant conditions.

-- Animal inhalation of this fume resulted in severe damage to the airway epithelium.

-- Diacetyl was identified as an etiologic agent.

C. Result -

-- Changes in work practices, use of personal protective equipment, and exposure controls were implemented in the plant.

-- Information changed work practices industry wide.

V. Summary

The above are just a few examples of how laboratory investigations have impacted occupational health. Other examples would be providing information concerning hazard identification, dose-response, and mechanisms of action which support risk assessment and development of prevention strategies. Another example is the discovery of biomarkers for early disease detection.

NORA Town Hall Meeting

March 21, 2006

Morgantown, WV

I would like to highlight the need for research in allergy and immunology. It is one of the identified cross-sectors that doesn't fit nicely into any one of the defined sectors. There is, however, often a very close linkage between work place exposures and the immunological health of the workers. This can range from skin exposures to various chemicals that cause a simple contact dermatitis, to more systemic or inhalational exposures that can cause allergic reactions, sometimes being acute or severe like anaphylaxis, to much more chronic problems such as occupational asthma.

There are work place exposures that are not necessarily related to any particular occupational setting but can occur in relatively clean environments such as office buildings and schools to more hazardous places such as manufacturing plants or farms. In modern society, the increased use of personal protective equipment in the form of latex gloves resulted in a million workers with latex allergy, a difficult and sometime life-threatening condition. Water damaged or damp indoor places, for example, can grow molds that after relatively long but low dose exposures result in allergic reactions such as rhinoconjunctivitis or more serious problems such as asthma or hypersensitivity pneumonitis. Sometime these high dose exposures, but they often low dose, chronic exposures that are difficult to detect and to characterize. There is much work that needs to be done to understand these problems, to develop biomarkers for these kinds of exposures, and to be able to assign workplace risk. Monoclonal antibodies can be developed and used for exposure assessment. We need to establish standards of measurement that relate to the risk. There are relatively new technologies such as proteomics that could be very powerful in identifying and characterizing biomarkers and workplace hazards.

The other side of the coin relate to exposures which do not stimulate the immune system but suppress or injure it. In these situations, such as exposure to welding fumes or certain manufacturing chemicals, an immunosuppression occurs. Here, instead of a hyper-reactivity or allergic response there is a reduced immune activity and this can leave workers more susceptible to infections or the development of cancer and other diseases. Laboratory hazard identification methods can help identify potentially immuno-reactive materials in order to prevent worker exposures. Better methods of assessing the immunological status of a worker should be developed where either hyper-reactivity or immunosuppression can be detected early so intervention can occur before the development of disease.

While allergy and immunology are not readily placed into a sector, they are extremely important for workers health and research in this area should be a priority.

Do CISM techniques mitigate circumstances - "we know return to work rates when there is CISM vs. when not?" Does it save money? Barriers: contractors believe time & money to have CISM - need quantifiable data. Increase in non-English speaking members; what else can we do? DFWP - are they effective? Pre-DFWP stats vs. post DFWP stats. Does DFWP prevent injuries; accidents? Quantify data. The stats out there aren't in relation to construction.

Ergonomics in the demolition industry, what kinds of work practices, tools or work organization would improve this hazard in the industry. NIOSH has sponsored some research showing the value of training. Similar research should be done on whether there is value in construction owner safety requirements in ??????. Does 100% fall protection requirement by owners work to decrease falls and injuries compared to similar sized projects w/out it? Demographics of the workforce - new immigrant populations.

NORA Town Meeting, Hamilton Building

Thursday, February 23, 2006

Janet Ehlers.

Farmworkers on the East Coast rejected use of free eye protection; those farmworkers perceived that the styles selected by the researchers made them look like drug dealers. Eye wear was readily accepted by farmworkers in a community-based research project in IL and TN where the eyewear was selected and distributed by trained, lay health advisors. A safety manager for the largest citrus grower in FL failed to get workers to wear eye protection. However, in 2004, 75% of these same workers wore eye

protection when the same safety manager replicated the community-based program NIOSH funded in IL and IN that utilized lay, peer health advisors.

1. R2P - is much needed concept.

How many hazards do each of us know that have known prevention but - workers or managers don't know about - or - don't feel empowered to implement. All the research in the world won't do much good if those who need to know -both groups and individuals, don't know. The current research on prevention of NIHL among carpenter apprentices focuses on empowering the workers themselves to take preventive action. It is a novel direction for NIOSH - but in the right direction.

2. Prevention of Noise-induced Hearing loss (NIHL) is an area that is very ripe for R2P Research and outreach especially in Agriculture - but in all sectors. NIHL is emerging through increased use of IPODS etc both in and outside of the workplace. Farmers and their families intuitively know that they lose hearing due to noise, but they don't know

-- how young it starts

-- how preventable it is

-- that prevention needs to be started before any loss occurs

NIHL is also a great example of where partnerships are important. The partnerships need to be expanded even beyond the current memorandum of understanding with multiple agencies.

3. Intervention Research (IR), including Community-based research is a broader example of both R2P and partnerships. However, CDC/NIOSH needs to recognize that the successful models for the development and evaluation of intervention research are different than bench research. RFA's and internal programs for IR need to specify IR so proposals are not competing against bench research. IR, especially community-based and with partnerships, take longer - especially those in agriculture take longer because of the seasonality of interventions.

4. Sustainability of interventions needs more focus at NIOSH

-- R2p needs to fund not just program development and evaluation. but demonstration projects then sustainment of programs shown to be effective in partnership with others. Other CDC Centers do this in multiple programs.

-- The Intervention Research program needs funding to look back several years to evaluate the sustainability, impact, and outgrowths of programs NIOSH no longer funds.

You only need to look how much time and \$ the government has put into tobacco use and seat belt use to know that public health change takes time. Essential to maximize impact and measure impact.

5. It is critical to understand the drivers and barriers to the desired change. Those will be different for the particular problems, state of readiness, sub-sectors, and target populations. In the agricultural sector and in interventions like ergonomics, research has been shown that workers and management eagerly incorporate new approaches that are cost effective - those that don't impede - and often improve. NIOSH needs to recognize and support research that identifies and incorporates these concepts.

6. Collaboration between NIOSH researchers and extramural project researchers on NIOSH-funded work is beneficial to NIOSH, the extramural researchers, and the goals of the particular projects. For the types of work NIOSH does, unlike perhaps NIH, there is not the risk for stealing others ideas. The benefits outweigh the risks. Therefore, such collaboration should be encouraged, not inhibited by barriers.

Mary Schubauer-Berigan, PhD

NORA I1 Town Hall Meeting, February 23, 2006

Research Epidemiologist, DSHEFS

Comment on Sector and Cross-Sector approach for exposures and agents that are split among Sectors

Theoretically, the organization of occupational research priorities could be based on population, health outcome or exposure agent. NORA I was organized around a combination of these modes, while NORA II has selected primarily a population approach with its basis in eight NAICS occupational sectors. The proposed approach for addressing exposures and/or diseases that cross sectors is unclear, but presumably research projects that propose a single study in more than one sector would request funding from one of the sectors or from the cross-sector category if it fits into one of this category's designated topics. This could lead to low assigned prioritization by the individual Sector Councils for relatively small populations that are further split into two or more sectors, based solely on the *a priori* decision to use NAICS codes as the basis of evaluating research and research-to-practice proposals.

Example:

Consider a proposed study of *Vibrio vulnificus* infection rates and modes of reducing hazards among workers in the shellfishing and shellfish-processing industries. These workers are among the highest-risk U.S. populations for *V. vulnificus* infection because of their potential for exposure to the agent. However, these workers, despite their common exposure pathways and disease risk, are classified into two different sectors: Shellfishing is in the Agricultural, Forestry & Fishing Sector, and shellfish harvesting is in the Manufacturing Sector. Both are relatively small components of each overall sector, and even a scientifically strong proposal might face a difficult funding path because of the required modes of submission and funding through a single sector.

Comment on need for continued investment in cancer research

It has been estimated that 4 to 10% of U.S. cancers (48,000 incident cases annually) are caused by occupational exposures. NIOSH research, both intramurally and extramurally, has had an enormous impact on recognizing the need to reduce exposures to carcinogenic agents within and outside the workplace. Seminal NIOSH research on the health effects of workplace exposures to carcinogens includes vinyl chloride and hepatic angiosarcoma, TCDD and all-cancers, benzene and leukemia, beryllium and lung cancer, and radon from uranium mining and lung cancer, among many others.

These findings have derived from agency investments in long-term research, and their influence is immediately observed by their incorporation into carcinogenic assessments by the U.S. Environmental Protection Agency, the Reports on Carcinogenicity by the National Institute for Environmental Health Science's National Toxicology Program, the International Agency for Research on Cancer, and NIOSH's own Carcinogen List. These assessments have resulted in the monitoring of and reductions in workplace exposures to carcinogens worldwide, in some cases through the development of protective standards by the Occupational Safety and Health Administration, the Department of Energy, and other standard-setting organizations. The path between the conduct of research and its eventual result in practice changes can be long and indirect for epidemiologic studies of carcinogens, but it is vital to achieving reductions in workplace-attributable cancer.

Speaking personally, these past investments and the promise of continued investment in this area are what attracted me to join NIOSH as a new epidemiology researcher seven years ago. Two years ago, I joined the "Cancer Research Methods" NORA Team, which permitted me to become involved in setting priorities for future cancer research. A top priority of this team was to promote research that would further elucidate the epidemiologic association of suspected (e.g., IARC Group 2A and 2B) carcinogens, many of which are not currently regulated as carcinogens in the US. Placement of Cancer as just one of many research topics in the Cross-Sector group de-emphasizes its importance. There are many emerging issues and exposures (e.g., nanotechnology) whose carcinogenicity should be evaluated. It would be disappointing to see the strong recommendations of the NORA I Cancer Research Methods group (summarized in the "NORA at Nine" document [inserted by Editor: <http://www.cdc.gov/niosh/docs/2006-121/pdfs/2006-121.pdf> in the section on Cancer Research Methods), and the need to study the carcinogenicity of emerging agents, become diluted in the Sector-based approach of NORA II. There should be a mechanism in place to fast-track these strong recommendations resulting from NORA I into the next ten years of NORA.

Categorized comment or partial comment:

Recommended priorities for the NORA2 Research agenda

Geoffrey M. Calvert, MD, MPH, FACP

February 23, 2006

Thank you for this opportunity to share my opinions.

I plea for NIOSH and other federal agencies to provide more support to hazard and disease surveillance activities. Currently there is no comprehensive national surveillance system for occupational illnesses nor for nonfatal occupational injuries. Adopting the following recommendations can help fill this gap. These include:

1. Expand the National Exposure at Work Survey (NEWS). NIOSH supported extensive workplace exposure surveys in the 1970s and 1980s. These provided estimates of the numbers of workers exposed to almost any occupational toxin. Unfortunately, no exposure surveys have been conducted recently. Given the substantial changes in the US economy over the past 20 years, these 1980s exposure estimates provide interesting historical data but are of little relevance for estimating the numbers of

workers exposed to toxins in 2006. Information on the number of exposed workers is one compelling statistic needed for public health prioritization.

2. Support an occupational health supplement to the National Health Interview Survey (NHIS). The NHIS is considered the principal information source on the health of civilians in the US. Unfortunately, the NHIS collects little information on work-related health and safety problems. To rectify this, in 1988, NIOSH supported an occupational health supplement to the NHIS. This supplement was a rich source of data to assess the magnitude and severity of several work-related outcomes including occupational injuries, dermatitis, and lung diseases. The NHIS can provide up-to-date statistics on magnitude and trends that cannot be obtained anywhere else. It has been 18 years since the NHIS supplement was administered. This needs to be repeated.

3. Increase support to state-based surveillance programs. Although a vast majority of states conduct surveillance of adult lead poisoning, relatively few states conduct surveillance of other occupational disease and injuries such as pesticide poisoning, asthma, pneumoconiosis, and fatal injuries. In addition, no states receive targeted funds for surveillance of some of the most important occupational disease and injuries, including dermatitis, musculoskeletal disorders, and noise-induced hearing loss. This information is important to identify the magnitude and trends of occupational disease and injury, to identify emerging occupational health and safety problems, and to target scarce public health interventional resources.

4. Provide support to the National Occupational Mortality Survey (NOMS). NOMS is a mortality statistics database. Since the early 1980s, NIOSH along with NCHS and NCI supported the collection and coding of decedent's usual industry and occupation in 27 states. This program generated a large number of important publications. Unfortunately, this database has not been updated in the past 8 years. As this data becomes more dated, the usefulness of NOMS to detect and access mortality patterns and risks becomes weaker and less relevant.

5. Support development of a computer program that will automatically code industry and occupation information. Industry and occupation information is captured by many public health records systems. These include death certificates, cancer registries, and birth defect registries. However, this information is rarely utilized to its full potential. Coded data is the most electronic-friendly form of industry and occupation information. NIOSH developed an automated coding system to assign 1990 Census codes to industry and occupation. However, the program was prone to coding errors and the codes it assigned are now outdated. A new automated coding program needs to be developed to improve and expand collection of useful industry and occupation information.

6. Re-initiate the writing "criteria for a recommended standard" documents. These are important documents, used to develop and support RELs for consideration by OSHA and MSHA. However, to my knowledge, NIOSH has not released a criteria document in approximately 8 years. More criteria documents need to be created to protect the health and safety of American workers.

This concludes my comments. Thank you.

My name is Rick Davis and I'm co-team leader of the Hearing Loss Prevention Team in the Engineering and Physical Hazards Branch of DART. The Hearing Loss Research program consists of researchers primarily in DART, EID, DSHEFS, and PRL.

I would like to provide input today for the role of Hearing Loss and Hearing Loss Prevention in NORA 2. Noise-induced hearing loss has been a focus of NIOSH activity since the agency's founding. Noise-induced hearing loss was one of the first criteria documents developed by the then new NIOSH. Noise-induced hearing loss is still a major occupational injury. In 2004 Noise induced hearing loss became a separately recordable occupational injury on the OSHA 300 Log. These results recently became available. We believe the 28,400 recordable cases underestimate the true cases of NIHL. However, these data are the best data currently available. Of the separately recordable injuries on the OSHA Form 300, hearing loss is the second largest.

OSHA found that most of these cases (23,800 workers) were in manufacturing with an incidence rate of 3.2 per 10,000 full time workers.

- Some of the highest incidence rates were in the Rolling and Drawing of purchased steel 136.8 worker cases per 10,000;
- Iron and Steel mills 86.2 worker cases per 10,000;
- Motor vehicle metal stamping 97.7 worker cases per 10,000;
- Dried and dehydrated food manufacturing 125.7 worker cases per 10,000;
- Animal slaughtering (except poultry) 94.5 worker cases per 10,000;
- Trades and transportation had 3,200 hearing loss cases; with 1.5 per 10,000.

Over the past year the Hearing Loss Research program has been undergoing a review by the National Academies. This has given us a shining opportunity to identify what we consider emerging issues. We have organized our ideas around four research goals:

Research Goal 1: Contribute to the Development, Implementation and Evaluation of Effective Hearing Loss Prevention Programs.

- Conduct economic cost/benefit analyses of hearing conservation programs versus noise controls.
 - Are hearing conservation programs really more cost effective than placing noise control on machinery?
- Establish a centralized repository of audiometric data that can be accessed by professionals.
 - Allow for mobile workers (carpenters, agricultural workers) to be included in a hearing conservation program.
- Collaborate with partners in education to reach young workers with prevention information and skills.
 - Only by targeting elementary school children can we hope to be able to change attitudes towards loud noise and use of hearing protectors.
- Strengthen efforts to transfer and disseminate information.
 - Develop guidelines to train workers to maximize residual hearing.
 - Develop guidelines for defining hearing-critical jobs.

Research Goal 2: Reduce hearing loss through interventions targeting personal protective equipment.

- Refine hearing protector fit-testing methods.
 - Provide a fast easy tool for workers to ensure they are being protected prior to entering noise.

Research Goal 3: Develop engineering controls to reduce noise exposures.

- Develop basic guidelines on engineering controls and the maintenance of those controls, and provide leadership for noise education in undergraduate and graduate programs in engineering, industrial hygiene and architecture.

- There is currently a shortage of engineers capable of providing noise control solutions. Also, engineers must become aware of the importance of designing out noise when new machines are being developed.

-- Publish available control solutions and update.

- Many noise control solutions are known, getting these solutions into the hands of company owners and engineers is a priority.

-- Develop engineering noise controls for small business.

- It is often the one or two man shop which is benefited least by government research. Developing noise controls which can be implemented by owner-operators to reduce noise in thousands of workplaces is a priority.

- Most businesses in America are small businesses.

-- Encourage manufacturers to provide noise labels.

- Only by making quiet a selling point can we hope to reduce the noise levels of the workplace.

Research Goal 4: Contribute to reductions in hearing loss through surveillance and investigation of risk factors.

-- Establish ongoing surveillance programs for occupational hearing loss and noise exposure; repeat large epidemiologic survey of industry and collect industry/job task specific noise exposure data.

- Only when we know where we are can we develop effective strategies for reducing noise-induced hearing loss.

-- Establish the effectiveness of prophylactic treatments for noise-exposed workers.

- There are workers who will never be able to be brought into safe noise exposures. For them a daily pharmaceutical may be necessary to keep their ears from being damaged. That opens questions to safety over a working lifetime.

-- Establish recommended exposure limits for mixed exposures of ototoxic chemicals and noise.

- Are there safe levels for exposure to ototoxicants? How do we find them?

We are a cross sector program having had partners and projects in manufacturing, construction, mining, agriculture and the military. We are interested in partnering with sectors and companies which will work with us to protect the hearing of the American worker.

We hope that Hearing Loss Prevention will be a priority for NORA II.

Appendix 1. Surveillance Summary for Agriculture, Forestry and Fishing

Agriculture, Forestry, and Fishing Sector Fatal and Non-Fatal Injury and Illness Surveillance Information

The following summary of fatality, injury, and illness rates in the Agriculture, Forestry, and Fishing sector is provided in order to help identify the most important safety and health problems in this sector. The North American Industry Classification System (NAICS), which was used to designate the NORA sectors, was also used by the Bureau of Labor Statistics (BLS) during the collection of their 2003 data. NAICS codes all economic activities using a six-digit hierarchical coding system with industry sectors, subsectors, industry groups, NAICS international industries, and National industries coded with 2, 3, 4, 5, and 6 digits, respectively.

The following sector-based summary is derived from 2003 BLS Census of Fatal Occupational Injuries (CFOI), and the annual Survey of Occupational Injury and Illness (SOII) (BLS, 2005a; BLS, 2005b). BLS non-fatal injury and illness data are based on a survey of 183,700 (of an estimated 7 million) US business establishments and do not include the self-employed, farms with fewer than 11 employees, private households, and governmental agencies. Where possible, references are made to specific BLS tables. In order to encourage internal comparisons, we have converted BLS rates, which are expressed as cases/100 full-time workers/year and cases/10,000 full-time workers/year, to cases/1,000 full-time workers/year.

As with the original BLS tables, the rates reported in our tables cannot be directly calculated from the numbers of cases and numbers of workers provided in our tables. This is because BLS makes post-sampling adjustments of their data and they use the equivalent of full-time workers (not workers) in their rate denominators (BLS, 1997). Using denominators based on person-time rather than numbers of workers results in rates that provide more accurate estimates of actual risk. Full-time workers are defined as working 40 hours per week for 50 weeks. Denominators for non-fatal injury and illness rates are calculated based on work hours data BLS receives from reporting establishments. Denominators for fatal injury rates come from the Current Population Survey.

According to the BLS-Quarterly Census of Employment and Wages (QCEW) program, there were 965,000 workers in the agriculture, forestry, and fishing sector in 2003 ([Table A1](#)). Workers in crop production, support activities for crop production, and animal production comprised 45%, 28%, and 14% of the sector workforce, respectively.

Table A1. Annual employment numbers by agriculture, forestry, and fishing subsectors and industry groups, 2003

Agriculture, forestry, and fishing industry group and subsector	NAICS code	Number of workers
Crop production	111	430,800
Oilseed and grain farming	1111	11,300
Vegetable and melon farming	1112	87,300
Fruit and nut farming	1113	129,300
Greenhouse, nursery, and floriculture production	1114	149,100
Other crop farming	1119	53,800
Animal production	112	139,300
Cattle ranching and farming	1121	71,100
Hog and pig farming	1122	16,300
Poultry and egg production	1123	37,900
Forestry and logging	113	72,800
Fishing, hunting, and trapping	114	10,100
Support activities for agriculture and forestry	115	311,900
Support activities for crop production	1151	270,100
Support activities for animal production	1152	25,400
Support activities for forestry	1153	16,400
Total for agriculture, forestry, and fishing	11	965,000

Numbers were obtained from [2003 BLS Table SNR10](#); numbers of workers were rounded to the nearest 100 workers and are derived primarily from the BLS-Quarterly Census of Employment and Wages (QCEW) program. These worker numbers differ from full-time worker numbers (see discussion in introduction). QCEW captures only those workers covered by unemployment, which may impact the number of workers in many of the subsectors in this sector.

BLS [1997]. BLS handbook of methods. Chapter 9. Occupational safety and health statistics. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics. [www.bls.gov/opus/hom/pdf/homch9.pdf]

Table A2. Comparison of incidence rates (cases/1000 full-time workers/year) of occupational fatalities, injuries, and illnesses for the agriculture, forestry, and fishing sector and the U.S. workforce, 2003

Health outcome	Incidence rate for the agriculture, forestry, and fishing sector	Incidence rate for U.S. workforce	Incidence rate ratio	Comment (pertains to agriculture, forestry, and fishing sector)	Table reference
Fatal occupational injuries	0.31*	0.04*	7.8	Transportation accidents were responsible for 50% of all fatal occupational injuries.	A3
Traumatic nonfatal occupational injuries involving days away from work	19.26	13.79	1.4	The greatest proportion (36%) of the cases was due to trauma to muscles, tendons, ligaments, and joints.	Special Request
Total nonfatal occupational injuries	58	47	1.2	This rate was 3-fold larger than the incidence rate of traumatic injuries involving days away from work.	A5
Occupational musculoskeletal system and connective tissue diseases and disorders involving days away from work	0.29	0.22	1.3	38% of these cases were diagnosed with tendonitis.	Special Request
Occupational back pain (without a medical diagnosis) involving days away from work	0.46	0.43	1.1	The incidence rate in the Fruit and Nut Farming (NAICS 1112) industry was more than three-fold the sector average.	A6
All occupational pain (without a medical diagnosis) involving days away from work	1.77	1.18	1.5	The incidence rate in Forestry and Logging (NAICS 113) subsector was more than two-fold the sector average.	A6

Table A2 (Continued)

Health outcome	Incidence rate for sector	Incidence rate for U.S. workforce	Incidence rate ratio	Comment (pertains to agriculture, forestry, and fishing sector)	Table reference
Nonfatal occupational skin diseases and disorders	1.85	0.49	3.8	The incidence rate in Vegetable and Melon Farming (NAICS 1112) was 2.5 times higher than the sector average.	A7
Nonfatal occupational respiratory conditions	0.21	0.22	1.0	The incidence rate in Support Activities for Forestry (NAICS 1153) was more than 11-fold larger than the sector average.	A7
Nonfatal occupational poisonings	0.22	0.04	5.5	The incidence rate in Fruit and Nut Farming (NAICS 1113) was more than 5-fold larger than the sector average.	A7

* Fatality data are from the BLS Occupational and Safety and Health (OSH)/Census of Fatal Occupational Injuries (CFOI) 2003 Profiles and Charts. Employment data for 2003 are based on estimates derived from BLS Current Population Survey (CPS) monthly microdata files.

Fatal occupational injuries

Transportation accidents accounted for 50% of fatal occupational injuries in the agriculture, forestry, and fishing sector (the largest proportion of these involved non-highway accidents). Contact with objects and equipment accounted for 29% of fatal occupational injuries in this sector (52% involved the worker being struck by an object) ([Table A3](#)).

Nonfatal occupational injuries involving days away from work

Sprains and strains were the most frequent nonfatal injury type involving days away from work with an incidence rate within the sector of 6.93 cases/1000 full-time workers/year ([Table A4](#)). The incidence rate of sprains and strains was highest among the Forestry and Logging subsector, which had an incidence rate of 15.86 cases/1000 full-time workers/year. Amputation rates were highest in Support Activities for Crop Production (NAICS 1151).

Total nonfatal occupational injuries

The incidence rates of total nonfatal occupational injuries were highest in Cattle Ranching and Farming (NAICS 1121) and Hog and Pig Farming (NAICS 1122), which had incidence rates of 87 and 83 cases/1000 full-time workers/year, respectively ([Table A5](#)).

Within the Agriculture, Forestry, and Fishing sector, the incidence rate of traumatic injuries and disorders involving days away from work was 19.26 cases/1000 full-time workers/year, compared to an incidence rate of total nonfatal injuries of 58 cases/1000 full-time workers/year (Special Request and [Table A5](#)). This suggests that the total injury rate was three-fold larger than the injury rate involving days away from work.

Nonfatal occupational injuries and illnesses involving days away from work

This incidence rate of pain (without a medical diagnosis) was highest in subsector Forestry and Logging (NAICS 113) and the industry group Fruit and Nut Farming (NAICS 1113) ([Table A6](#)). Musculoskeletal system and connective tissue disorders had an incidence rate of 0.29 cases/1000 full-time workers/year for the sector; 38% of these cases were diagnosed with tendonitis (Special Request).

Nonfatal occupational illnesses

Vegetable and Melon Farming (NAICS 1112) had an incidence rate of nonfatal occupational skin diseases and disorders of 4.60 cases/1000 full-time workers/year, which was 2.5 times larger than the sector average ([Table A7](#)).

Support Activities for Forestry (NAICS 1153) had an incidence rate of nonfatal occupational respiratory conditions of 2.37 cases/1000 full-time workers/year, which was more than 11-times larger than the sector average ([Table A7](#)).

Fruit and Nut Farming (NAICS 1113) had an incidence rate of nonfatal occupational poisonings of 1.21 cases/1000 full-time workers/year, which was more than 5 times larger than the sector average ([Table A7](#)).

The incidence rate for all other nonfatal occupational illnesses was highest in the Other Crop Farming (NAICS 1119) industry group, which had an incidence rate of 9.52 cases/1000 full-time workers/year ([Table A7](#)).

Table A3. Number and percent of fatal occupational injuries in the agriculture, forestry, and fishing sector by event or exposure, 2003

Event or exposure	Number of fatal injuries	Percent of total fatal occupational injuries in the manufacturing sector
Contact with objects and equipment	208	29
Struck by object	140	
Struck by falling object	94	
Struck by flying object	5	
Struck by swinging or slipping object	7	
Struck by rolling, sliding objects on floor or ground	30	
Caught in or compressed by equipment or objects	49	
Caught in or crushed in collapsing materials	17	
Falls	34	5
Exposure to harmful substances or environments	45	6
Contact with electric current	9	
Contact with temperature extremes	9	
Exposure to caustic, noxious, or allergenic substances	12	
Oxygen deficiency	15	
Transportation accidents	355	50
Highway accident	96	
Non-highway accident (farm, industrial premises)	184	
Worker struck by vehicle, mobile equipment	23	
Aircraft accident	11	
Water vehicle	36	
Railway	4	
Fires and explosions	12	2
Assaults and violent acts	59	8
Homicides	17	
Suicides, self-inflicted injuries	16	
Assaults by animals	26	
Total	713	

Totals for major categories may include subcategories not shown separately; 2003 data were specially requested from BLS.

Table A4. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational injuries involving days away from work by agriculture, forestry, and fishing industry groups and subsectors, 2003

Agriculture, forestry, and fishing industry group and subsector	NAICS code	Sprains, strains	Fractures	Cuts, punctures	Bruises	Amputations
Crop production	111	3,000 (7.41)	580 (1.43)	7 00 (1.73)	740 (1.83)	60 (0.15)

Total for agriculture, forestry, and fishing sector	11	1,600 (1.85)	200 (0.21)	200 (0.22)	-

Numbers of cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR10](#) and [SNR08](#); highest values are in bold font.

Appendix

Notes on Limitations and Interpretation

One of the limitations of occupational safety and health surveillance data is the underreporting of illnesses, which occurs because: 1) some diseases (e.g., cancer and pneumoconiosis) have long latency periods so that reporting mechanisms, such as OSHA logs, as used by BLS, fail to capture many of these events; 2) many diseases have multiple potential causes (e.g., asthma and cardiovascular diseases); and 3) workers and physicians do not recognize an occupational contribution.

BLS data sources do not allow: characterization of occupationally-related illnesses, if these illnesses are not skin diseases and disorders, respiratory conditions, or poisonings; or quantification of fatalities due to occupationally-related illnesses. Other sources have suggested that the occupational illness fatalities in the US workforce outnumber occupational injury fatalities by about 8:1. For example, using 1997 disease fatality numbers, it was estimated that occupationally-related illness and injury deaths numbered, respectively, 25,910-72,121 (Steenland et al., 2003) and 6,238 (BLS). Estimates of 1997 occupationally-related illness deaths by disease category are as follows: 6,805-26,685 for non-malignant respiratory disease; 12,086-26,244 for occupationally-related cancer deaths; 6,037-18,253 for occupationally-related coronary heart disease; and 328-580 for occupationally-related renal disease (Steenland et al., 2003). Sector-based occupationally-related illness fatality data are not provided in this surveillance data summary.

Other limitations of the data include the following. (1) Only BLS data for a single year (2003) are presented. However, data for a single year may not be representative of the long-term experience and health impacts of a sector due to economic, political, technological, or weather characteristics of that year. (2) Many of the rates are based on small denominators, so that a few additional or a few less cases in the numerator might cause a large fluctuation in the magnitude of the rate estimate. Therefore, what may be quantified as large differences in risk may simply be the result of the “random” occurrence of a few cases. (3) Rates are not adjusted for any potential confounders, the most important of which may be age. Research has shown that younger workers may be at increased risk of injury due to a variety of factors including experience and training. Older workers may be more susceptible to certain occupational illnesses because of pre-existing medical conditions. Therefore what is perceived as a true difference in risk based upon crude rates between two groups may simply be the result of differences in their age distributions. (4) Differences among rates for subsectors and industries of the sector are not tested for statistical significance. Without statistical testing, one cannot conclude that rates are really any different than some of the other rates in the sector.

Discussion of the data focuses on rates, although many of the tables also provide data on the number of workers affected. A subsector or industry which has the highest rate of injuries or illnesses within the sector may have few total workers. Implementing prevention strategies within another subsector or industry within the sector with a high rate of injuries or illnesses and a larger number of workers, may result in a much larger

public health impact. If these data are used for planning and priority setting, we suggest that the number of adverse health outcomes and the number of workers potentially impacted be considered concurrently to identify worker groups towards which research should be directed.

Appendix 2. Surveillance Summary for Construction

Construction Sector Fatal and Non-Fatal Injury and Illness Surveillance Information

The following summary of fatality, injury, and illness rates in the Construction sector is provided in order to help identify the most important safety and health problems in this sector. The North American Industry Classification System (NAICS), which was used to designate the NORA sectors, was also used by the Bureau of Labor Statistics (BLS) during the collection of their 2003 data. NAICS codes all economic activities using a six-digit hierarchical coding system with industry sectors, subsectors, industry groups, NAICS international industries, and National industries coded with 2, 3, 4, 5, and 6 digits, respectively.

The following sector-based summary is derived from 2003 BLS Census of Fatal Occupational Injuries (CFOI), and the annual Survey of Occupational Injury and Illness (SOII) ([BLS, 2005a](#); [BLS, 2005b](#)). BLS non-fatal injury and illness data are based on a survey of 183,700 (of an estimated 7 million) US business establishments and do not include the self-employed, farms with fewer than 11 employees, private households, and governmental agencies. Where possible, references are made to specific BLS tables. In order to encourage internal comparisons, we have converted BLS rates, which are expressed as cases/100 full-time workers/year and cases/10,000 full-time workers/year, to cases/1,000 full-time workers/year.

As with the original BLS tables, the rates reported in our tables cannot be directly calculated from the numbers of cases and numbers of workers provided in our tables. This is because BLS makes post-sampling adjustments of their data and they use the equivalent of full-time workers (not workers) in their rate denominators ([BLS, 1997](#)). Using denominators based on person-time rather than numbers of workers results in rates that provide more accurate estimates of actual risk. Full-time workers are defined as working 40 hours per week for 50 weeks. Denominators for non-fatal injury and illness rates are calculated based on work hours data BLS receives from reporting establishments. Denominators for fatal injury rates come from the Current Population Survey.

According to the BLS-Quarterly Census of Employment and Wages (QCEW) program, there were 6,672,400 workers in the construction sector in 2003 ([Table C1](#)). Workers in the specialty trades and building construction comprised 63% and 23% of the sector workforce, respectively.

Table C1. Annual employment numbers by construction subsectors, 2003

Construction subsector	NAICS code	Number of workers
Construction of buildings	236	1,565,400
Heavy and civil engineering construction	237	891,500
Specialty trade contractors	238	4,215,500
Total	23	6,672,400

Numbers were obtained from 2003 BLS Table [SNR10](#); numbers of workers were rounded to the nearest 100 workers and are derived primarily from the BLS-Quarterly Census of Employment and Wages (QCEW) program. These worker numbers differ from full-time worker numbers (see discussion in introduction). QCEW captures only those workers covered by unemployment.

BLS [2005a]. Census of fatal occupational injuries (CFOI) - current and revised data. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics, Safety and Health Statistics Program. [www.bls.gov/iif/oshcfoi1.htm]

Table C2. Comparison of incidence rates (cases/1000 full-time workers/year) of occupational fatalities, injuries, and illnesses work for the construction sector and the U.S. workforce, 2003

Health outcome	Incidence rate for the construction sector	Incidence rate for the U.S. workforce	Incidence rate ratio	Comment (pertains to construction sector)	Table reference
Fatal occupational injuries	0.12*	0.04*	3.0	Most fatal occupational injuries were due to falls and transportation incidents.	C3
Traumatic nonfatal occupational injuries involving days away from work	24.4	13.79	1.8	The greatest proportion (38%) of the cases was due to trauma to muscles, tendons, ligaments, and joints.	2003 BLS R72
Total nonfatal occupational injuries	67	47	1.4	This rate was 3-fold larger than the incidence rate of traumatic injuries involving days away from work.	C5
Occupational back pain (without a medical diagnosis) involving days away from work	0.68	0.43	1.6	The highest incidence rate was in the Other Building Finishing Contractors (NAICS 23839) industry.	C8 and C11A
Occupational musculoskeletal system and connective tissue diseases and disorders involving days away from work	0.18	0.22	0.8	45% and 19% were diagnosed as tendonitis and bursitis, respectively.	2003 BLS R72 and R49
Occupational carpal tunnel syndrome involving days away from work	0.14	0.25	0.6	The highest incidence rate was in the Highway, Street, and Bridge (NAICS 2373) construction industry group.	C8 and C9

Table C2 (Continued)

Health outcome	Incidence rate in the construction sector	Incidence rate in the U.S. workforce	Incidence rate ratio	Comment (pertains to construction sector)	Table reference
Nonfatal occupational skin diseases and disorders	0.38	0.49	0.8	The highest incidence rate was in the Utility System Construction (NAICS 2371) industry group	C12 and C13
Nonfatal occupational respiratory conditions	0.16	0.22	0.7	The highest incidence rates were in the Specialty Trade Contractors (NAICS 238) construction subsector and the Other Building Finishing Contractors (NAICS 23829) construction industry.	C12 and C14
Nonfatal occupational poisonings	0.09	0.04	2.3	The highest incidence rate was in the Painting and Wall Covering Contractors (NAICS 23832) industry	C12 and C15
All other nonfatal occupational illnesses	0.91	2.32	0.4	The highest incidence rate was in the Framing Contractors (NAICS 23813) industry	C12 and C16

* Fatality data are from the BLS Occupational and Safety and Health (OSH)/Census of Fatal Occupational Injuries (CFOI) 2003 Profiles and Charts. Employment data for 2003 are based on estimates derived from BLS Current Population Survey (CPS) monthly microdata files.

Fatal occupational injuries

Falls accounted for 32% of the fatal occupational injuries in the construction sector. Transportation accidents accounted for 26% of the fatal occupational injuries in the construction sector (half of these involved highway accidents) ([Table C3](#)).

Nonfatal occupational injuries involving days away from work

Sector-wide, sprains and strains were the most frequent nonfatal injury type involving days away from work with an incidence rate of 9.30 cases per 1000 full-time workers per year ([Table C4](#)). The incidence rate of sprains was highest in the Specialty Trade Contractors (NAICS 238) subsector. Finish Carpentry (NAICS 23835) construction industry had the highest incidence rate of nonfatal amputations involving days away from work that was about 7-fold larger than the construction sector average ([Table C7](#)).

Total nonfatal occupational injuries

The Specialty Trade Contractors (NAICS 238) construction subsector had the highest rate and number of nonfatal occupational injuries ([Table C5](#)). Construction industries with the highest incidence rates of nonfatal occupational injuries included Framing Contractors (NAICS 23813), Structural Steel and Precast Concrete Contractors (NAICS 23812), and Poured Concrete Foundation and Structure Contractors (NAICS 23811) ([Table C6A](#)).

The incidence rate of traumatic injuries and disorders involving days away from work was 24.4 cases/1000 full-time workers/year, compared to an incidence rate of total nonfatal injuries of 67 cases/1000 full-time workers/year (2003 BLS Tables [R72](#) and [Table C5](#)). This suggests that the total injury rate is about 3-times larger than the injury rate involving days away from work.

Nonfatal occupational illnesses and injuries involving days away from work

The incidence rates of carpal tunnel syndrome and tendonitis involving days away from work were 0.14 and 0.18 cases/1000 full-time workers/year ([Table C8](#)). Incidence rates of carpal tunnel syndrome and tendonitis involving days away from work were highest in the Highway, Street, and Bridge Construction (NAICS 2373) industry group ([Table C9](#)) and the Drywall and Insulation Contractors (NAICS 23831) industry ([Table C10](#)), respectively.

Nonfatal occupational illnesses

The incidence rate of nonfatal occupational skin diseases and disorders was 0.38 cases/1000 full-time workers/year for the construction sector ([Table C12](#)). The Heavy and Civil Engineering Construction (NAICS 237) subsector had the highest incidence rate of skin diseases and disorders. However, due to a large workforce, the Specialty Trade Contractors (NAICS 238) subsector had the highest number of cases. The Utility System Construction (NAICS 2371) industry group had an incidence rate of 1.53 cases of skin diseases and disorders/1000 full-time workers/year, which was 4-fold the construction sector average ([Table C13](#)).

The incidence rate of nonfatal occupational respiratory conditions was 0.16 cases/1000 full-time workers/year for the construction sector ([Table C12](#)). The Specialty Trade Contractors (NAICS 238) subsector had the highest incidence rate and case numbers of nonfatal occupational respiratory conditions. The Other Building Finishing Contractors (NAICS 23839) industry had an incidence rate of 2.45 cases/1000 full-time workers/year, 15-fold the construction sector average ([Table C14](#)).

The incidence rate of nonfatal occupational poisonings was 0.09 cases/1000 full-time workers/year for the construction sector ([Table C12](#)). The two industries with the highest incidence rates of occupational poisonings were Painting and Wall Covering Contractors (NAICS 23832) and Other Building Finishing Contractors (NAICS 23839), which had incidence rates of 0.87 and 0.75 cases/1000 full-time workers/year, respectively ([Table C15](#)).

The incidence rate of all other nonfatal occupational illnesses was 0.91 cases/1000 full-time workers/year for the construction sector ([Table C12](#)). The three industries with the highest incidence rates of all other occupational illnesses were Framing Contractors (NAICS 23813), Tile and Terrazzo Contractors (NAICS 23834), and Other Foundation, Structure, and Building Exterior Contractors (NAICS 23819), which had incidence rates ranging from 1.93 to 2.41 cases/1000 full-time workers/year ([Table C16](#)).

Table C3. Number and percent of total fatal occupational injuries in the construction sector by event or exposure, 2003

Event or exposure	Number of fatal injuries*	Percent of total fatal occupational injuries in the construction sector
Contact with objects and equipment	231	20
Struck by object	111	
Caught in or compressed by equipment or objects	41	
Caught in or crushed in collapsing materials	78	
Falls	364	32
Exposure to harmful substances or environments	179	16
Transportation accidents	290	26
Highway accident	145	
Non-highway accident except rail, air, or water	48	
Pedestrian accident (non-passenger struck by vehicle or mobile equipment)	84	
Railway accident	5	
Water vehicle accident	3	
Aircraft accident	4	
Fires and explosions	29	3
Assaults and violent acts	37	3
Total	1131	

* Totals for major categories may include subcategories not shown separately; numbers were extracted from [2003 BLS Table A-9](#).

Table C4. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational injuries involving days away from work by construction subsectors, 2003

Construction subsector	NAICS code	Sprains, strains	Fractures	Cuts, punctures	Bruises	Amputations
Construction of buildings	236	10,020 (7.26)	3,550 (2.57)	6,030 (4.37)	1,740 (1.26)	230 (0.17)
Heavy and civil engineering construction	237	7,410 (8.70)	2,310 (2.71)	2,220 (2.61)	1,990 (2.34)	180 (0.21)
Specialty trade contractors	238	38,270 (10.18)	12,390 (3.30)	14,250 (3.79)	6,450 (1.72)	680 (0.18)
Total for construction sector	23	55,710 (9.30)	18,250 (3.05)	22,510 (3.76)	10,180 (1.70)	1,080 (0.18)

Number of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [R1](#) and [R5](#); highest values are in bold font.

Table C5. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational injuries by construction subsectors, 2003

Construction subsector	NAICS code	Total nonfatal occupational injuries
Construction of buildings	236	77,400 (56)
Heavy and civil engineering construction	237	53,800 (63)
Specialty trade contractors	238	267,800 (71)
Total for construction sector	23	399,100 (67)

Numbers of cases were rounded to the nearest 100 workers; numbers were extracted from [2003 BLS Table SNR05](#).

Table C6A. Construction industries (5-digit NAICS codes) with the highest nonfatal occupational injury incidence rates, 2003

Construction industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Framing contractors	23813	136,900	117	13,300
Structural steel and precast concrete contractors	23812	83,300	95	7,300
Poured concrete foundation and structure contractors	23811	198,200	94	16,600

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from [2003 BLS Table SNR05](#); the incidence rates of nonfatal occupational injury, regardless whether workdays were lost for the manufacturing sector and the entire U.S. workforce were 67 and 47 injuries/1000 full-time workers/year, respectively.

Table C6B. Construction industry groups (4-digit NAICS codes) with the highest numbers of nonfatal occupational injuries, 2003

Construction industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Building equipment contractors	2382	1,804,700	69	115,800
Foundation, structure, and building exterior contractors	2381	945,600	86	69,900
Building finishing contractors	2383	878,400	68	51,700

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from [2003 BLS Table SNR05](#); the incidence rates of nonfatal occupational injury, regardless whether workdays were lost for the manufacturing sector and the entire U.S. workforce were 67 and 47 injuries/1000 full-time workers/year, respectively.

Table C6C. Sources (2-digit codes) responsible for the highest incidence rates of nonfatal occupational injuries within the construction sector, 2003

Source	Source code	Incidence rate (cases/1000 full-time workers/year)
Floors, walkways, ground surfaces	62	5.42
Solid building materials	41	3.56
Person injured or ill worker	56	3.11

Numbers were extracted from [2003 BLS Table R74](#).

Table C6D. Events (2-digit code) responsible for the highest incidence rates of nonfatal occupational injuries within the construction sector, 2003

Source	Event code	Incidence rate (cases/1000 full-time workers/year)
Overexertion	22	5.07
Fall to lower level	11	3.38
Struck by object	02	4.82

Numbers were extracted from [2003 BLS Table R75](#).

Table C7. Construction industries (5-digit NAICS codes) with the highest nonfatal occupational amputation incidence rates involving days away from work, 2003

Construction industry	NAICS Code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Finish carpentry contractors	23835	143,400	1.21	150
Plumbing, heating, and air-conditioning contractors	23822	848,200	0.32	250
All other special trade contractors	23899	285,000	0.28	70

Numbers of workers were rounded to the nearest 100 workers; numbers of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [SNR10](#), [R1](#) and [R5](#); the incidence rates of nonfatal occupational amputation involving days away from work for the construction sector and the entire U.S. workforce were 0.18 and 0.09 injuries/1000 full-time workers/year, respectively.

Table C8. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational injuries and illnesses involving days away from work by construction subsector, 2003

Construction subsector	NAICS code	Carpal tunnel syndrome	Tendonitis	Back pain (without a medical diagnosis)
Construction of buildings	236	220 (0.16)	90 (0.07)	880 (0.64)
Heavy and civil engineering construction	237	110 (0.13)	60 (0.07)	400 (0.47)
Specialty trade contractors	238	530 (0.14)	350 (0.09)	2,780 (0.74)
Total for construction sector	23	850 (0.14)	490 (0.08)	4,060 (0.68)

Numbers of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [R1](#) and [R5](#); highest values are in bold font.

Table C9. Construction industry groups (4-digit NAICS codes) with the highest incidence rates of occupational carpal tunnel syndrome involving days away from work, 2003

Construction industry group	NAICS Code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Highway, street, and bridge construction	2373	332,300	0.22	70
Foundation, structure, and building exterior contractors	2381	945,600	0.20	160
Nonresidential building construction	2362	731,400	0.18	120

Numbers of workers were rounded to the nearest 100 workers; numbers of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [SNR10](#), [R1](#) and [R5](#); the incidence rates of occupational carpal tunnel syndrome involving days away from work for the construction sector and the entire U.S. workforce were 0.14 and 0.25 cases/1000 full-time workers/year, respectively.

Table C10. Construction industries (5-digit NAICS codes) with the highest incidence rates of occupational tendonitis involving days away from work, 2003

Construction industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Drywall and insulation contractors	23831	320,100	0.25	70
All other special trade contractors	23899	285,000	0.24	60

Numbers of workers were rounded to the nearest 100 workers; numbers of cases were rounded to the nearest 10 workers; numbers were extracted from BLS Tables [SNR10](#), [R1](#), and [R5](#); the incidence rates of occupational tendonitis involving days away from work for the construction sector and the entire U.S. workforce were 0.08 and 0.09 cases/1000 full-time workers/year, respectively.

Table C11A. Construction industries (5-digit NAICS codes) with the highest incidence rates of back pain (without a medical diagnosis) involving days away from work, 2003

Construction industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Other building finishing contractors	23839	64,500	2.63	150
Structural steel and precast concrete contractors	23812	83,300	1.70	130
Plumbing heating and air-conditioning contractors	23822	848,200	1.02	810

Numbers of workers were rounded to the nearest 100 workers; numbers of cases were rounded to the nearest 10 workers; numbers were extracted from BLS Tables [SNR10](#), [R1](#), and [R5](#); the incidence rates of occupational back pain (without a medical diagnosis) involving days away from work for the construction sector and the entire U.S. workforce were 0.68 and 0.43 cases/1000 full-time workers/year, respectively

Table C11B. Construction industry groups (4-digit NAICS codes) with the highest number of cases of back pain (without a medical diagnosis) involving days away from work, 2003

Construction industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Building equipment contractors	2382	1,804,700	0.75	12,500
Foundation, structure, and building exterior contractors	2381	945,600	0.79	6,400
Building finishing contractors	2383	878,400	0.74	5,600

Numbers of workers were rounded to the nearest 100 workers; numbers of cases were rounded to the nearest 10 workers; numbers were extracted from BLS Tables [SNR10](#), [R1](#), and [R5](#); the incidence rates of occupational back pain (without a medical diagnosis) involving days away from work for the construction sector and the entire U.S. workforce were 0.68 and 0.43 cases/1000 full-time workers/year, respectively.

Table C12. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational illnesses by construction subsector, 2003

Construction subsector	NAICS code	Skin diseases and disorders		Respiratory conditions		Poisonings		All other illnesses	
Construction of buildings	236	300	(0.22)	100	(0.09)	100	(0.08)	700	(0.47)
Heavy and civil engineering construction	237	700	(0.80)	100	(0.16)	100	(0.06)	800	(0.98)
Specialty trade contractors	238	1,300	(0.34)	700	(0.18)	400	(0.10)	4,000	(1.05)
Total for construction sector	23	2,300	(0.38)	900	(0.16)	500	(0.09)	5,500	(0.91)

Numbers of cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); highest values are in bold font.

Table C13. Manufacturing industry groups and industries (4- and 5-digit NAICS codes) with the highest incidence rates of nonfatal occupational skin diseases and disorders, 2003

Construction industry group or industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Utility system construction	2371	368,000	1.53	500
Site preparation contractors	23891	301,800	1.04	300
All other special trade contractors	23899	285,000	0.64	200

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); the incidence rates of nonfatal occupational skin diseases and disorders, regardless whether workdays were lost, for the construction sector and the entire U.S. workforce were 0.38 and 0.49 cases/1000 full-time workers/year, respectively

Table C14. Construction industries (5-digit NAICS codes) with the highest incidence rates of nonfatal occupational respiratory conditions, 2003

Construction industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Other building finishing contractors	23839	64,500	2.45	100
Finish carpentry contractors	23835	143,400	0.44	100
Roofing contractors	23816	177,800	0.30	<50

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); the incidence rates of nonfatal occupational respiratory conditions, regardless whether workdays were lost, for the construction sector and the entire U.S. workforce were 0.16 and 0.22 cases/1000 full-time workers/year, respectively.

Table C15. Construction industries (5-digit NAICS codes) with the highest incidence rates of nonfatal occupational poisonings, 2003

Construction industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Painting and wall covering contractors	23832	213,200	0.87	200
Other building finishing contractors	23839	64,500	0.75	<50
Roofing contractors	23816	177,800	0.26	<50

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); the incidence rates of nonfatal occupational poisonings, regardless whether workdays were lost, for the construction sector and the entire U.S. workforce were 0.09 and 0.04 cases/1000 full-time workers/year, respectively.

Table C16. Construction industries (5-digit NAICS codes) with the highest incidence rates of all other nonfatal occupational illnesses, 2003

Construction industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Framing contractors	23813	136,900	2.41	300
Tile and terrazzo contractors	23834	58,100	2.35	100
Other foundation, structure, and building exterior contractors	23819	36,300	1.93	100

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); the incidence rates of all other nonfatal occupational illnesses, regardless whether workdays were lost, for the construction sector and the entire U.S. workforce were 0.91 and 2.32 cases/1000 full-time workers/year, respectively.

Appendix

Notes on Limitations and Interpretation

One of the limitations of occupational safety and health surveillance data is the underreporting of illnesses, which occurs because: 1) some diseases (e.g., cancer and pneumoconiosis) have long latency periods so that reporting mechanisms, such as OSHA logs, as used by BLS, fail to capture many of these events; 2) many diseases have multiple potential causes (e.g., asthma and cardiovascular diseases); and 3) workers and physicians do not recognize an occupational contribution.

BLS data sources do not allow: characterization of occupationally-related illnesses, if these illnesses are not skin diseases and disorders, respiratory conditions, or poisonings; or quantification of fatalities due to occupationally-related illnesses. Other sources have suggested that the occupational illness fatalities in the US workforce outnumber occupational injury fatalities by about 8:1. For example, using 1997 disease fatality numbers, it was estimated that occupationally-related illness and injury deaths numbered, respectively, 25,910-72,121 (Steenland et al., 2003) and 6,238 (BLS). Estimates of 1997 occupationally-related illness deaths by disease category are as follows: 6,805-26,685 for non-malignant respiratory disease; 12,086-26,244 for occupationally-related cancer deaths; 6,037-18,253 for occupationally-related coronary heart disease; and 328-580 for occupationally-related renal disease (Steenland et al., 2003). Sector-based occupationally-related illness fatality data are not provided in this surveillance data summary.

Other limitations of the data include the following. (1) Only BLS data for a single year (2003) are presented. However, data for a single year may not be representative of the long-term experience and health impacts of a sector due to economic, political, technological, or weather characteristics of that year. (2) Many of the rates are based on small denominators, so that a few additional or a few less cases in the numerator might cause a large fluctuation in the magnitude of the rate estimate. Therefore, what may be quantified as large differences in risk may simply be the result of the “random” occurrence of a few cases. (3) Rates are not adjusted for any important potential confounders, the most important of which may be age. Research has shown that younger workers may be at increased risk of injury due to a variety of factors including experience and training. Older workers may be more susceptible to certain occupational illnesses because of pre-existing medical conditions. Therefore what is perceived as a true difference in risk based upon crude rates between two groups may simply be the result of differences in their age distributions. (4) Differences among rates for subsectors and industries of the sector are not tested for statistical significance. Without statistical testing, one cannot conclude that rates are really any different than some of the other rates in the sector.

Discussion of the data focuses on rates, although many of the tables also provide data on the number of workers affected. A subsector or industry which has the highest rate of injuries or illnesses within the sector may have few total workers. Implementing prevention strategies within another subsector or industry within the sector with a high

rate of injuries or illnesses and a larger number of workers, may result in a much larger public health impact. If these data are used for planning and priority setting, we suggest that the number of adverse health outcomes and the number of workers potentially impacted be considered concurrently to identify worker groups towards which research should be directed.

Appendix 3. Surveillance Summary for Healthcare and Social Assistance

Healthcare and Social Assistance Sector Fatal and Non-Fatal Injury and Illness Surveillance Information

The following summary of fatality, injury, and illness rates in the Healthcare and Social Assistance sector is provided in order to help identify the most important safety and health problems in this sector. The North American Industry Classification System (NAICS), which was used to designate the NORA sectors, was also used by the Bureau of Labor Statistics (BLS) during the collection of their 2003 data. NAICS codes all economic activities using a six-digit hierarchical coding system with industry sectors, subsectors, industry groups, NAICS international industries, and National industries coded with 2, 3, 4, 5, and 6 digits, respectively.

The following sector-based summary is derived from 2003 BLS Census of Fatal Occupational Injuries (CFOI), and the annual Survey of Occupational Injury and Illness (SOII) ([BLS, 2005a](#); [BLS, 2005b](#)). BLS non-fatal injury and illness data are based on a survey of 183,700 (of an estimated 7 million) US business establishments and do not include the self-employed, farms with fewer than 11 employees, private households, and governmental agencies. Where possible, references are made to specific BLS tables. In order to encourage internal comparisons, we have converted BLS rates, which are expressed as cases/100 full-time workers/year and cases/10,000 full-time workers/year, to cases/1,000 full-time workers/year.

As with the original BLS tables, the rates reported in our tables cannot be directly calculated from the numbers of cases and numbers of workers provided in our tables. This is because BLS makes post-sampling adjustments of their data and they use the equivalent of full-time workers (not workers) in their rate denominators ([BLS, 1997](#)). Using denominators based on person-time rather than numbers of workers results in rates that provide more accurate estimates of actual risk. Full-time workers are defined as working 40 hours per week for 50 weeks. Denominators for non-fatal injury and illness rates are calculated based on work hours data BLS receives from reporting establishments. Denominators for fatal injury rates come from the Current Population Survey.

According to the BLS-Quarterly Census of Employment and Wages (QCEW) program, there were 13,721,900 workers in the healthcare and social assistance sector in 2003 ([Table H1](#)). Workers in hospitals, nursing and residential care facilities, and physician offices comprised 31%, 20%, and 15% of sector workforce, respectively.

Table H1. Annual employment numbers by healthcare and social assistance subsectors and industry groups, 2003

Healthcare and social assistance subsector and industry group	NAICS code	Number of workers
Ambulatory healthcare services	621	4,783,400
Physician offices	6211	2,006,600
Dental offices	6212	744,200
Offices of other health practitioners	6213	505,700
Outpatient care centers	6214	428,000
Medical and diagnostic laboratories	6215	179,700
Home healthcare services	6216	723,600
Other ambulatory healthcare services	6219	195,500
Hospitals	622	4,201,300
Nursing and residential care facilities	623	2,776,500
Social assistance	624	1,960,700
Total for healthcare and social assistance sector	62	13,721,900

Numbers were obtained from [2003 BLS Table SNR10](#); numbers of workers were rounded to the nearest 100 workers and are derived primarily from the BLS-Quarterly Census of Employment and Wages (QCEW) program. These worker numbers differ from full-time worker numbers (see discussion in introduction). QCEW captures only those workers covered by unemployment.

BLS [1997]. BLS handbook of methods. Chapter 9. Occupational safety and health statistics. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics. [www.bls.gov/opub/hom/pdf/homch9.pdf]

Table H2. Comparison of incidence rates (cases/1000 full-time workers/year) of occupational fatalities, injuries, and illnesses for the healthcare and social assistance sector and the U.S. workforce, 2003

Health outcome	Incidence rate for the healthcare and social assistance sector	Incidence rate for the U.S. workforce	Incidence rate ratio	Comment (pertains to the healthcare and social assistance sector)	Table reference
Fatal occupational injuries	0.01*	0.04†	0.3	Most fatal occupational injuries were due to transportation accidents and assaults and violent acts.	H3
Traumatic nonfatal occupational injuries involving days away from work	16.30	13.79	1.2	Most of these cases (59%) were due to traumatic injuries to muscles, tendons, ligaments, and joints.	Special Request
Total nonfatal occupational injuries	60	47	1.3	This rate was about four-fold larger than the incidence rate of traumatic injuries involving days away from work.	H5
Occupational back pain symptom (without a medical diagnosis) involving days away from work	0.65	0.43	1.5	The incidence rate in the Nursing and Residential Care Facilities (NAICS 623) was more than 2-fold larger than the healthcare and social assistance sector average.	H6
Occupational musculoskeletal system and connective tissue diseases and disorders cases involving days away from work	0.18	0.22	0.8	43% of these cases were diagnosed as tendonitis.	Special Request

Table H2. (Continued)

Health outcome	Incidence rate for the healthcare and social assistance sector	Incidence rate for the U.S. workforce	Incidence rate ratio	Comment (pertains to the healthcare and social assistance sector)	Table reference
Occupational carpal tunnel syndrome cases involving days away from work	0.17	0.25	0.7	Home Healthcare Services (NAICS 6216) industry group had the highest incidence rate of carpal tunnel syndrome cases involving days away from work.	H6
Occupational infectious and parasitic diseases involving days away from work	0.13	0.02	6.5	Bacterial, viral, infectious diseases pertaining to the intestines, and other infectious and parasitic diseases accounted for 12%, 30%, 26%, and 30% of reported cases.	Special Request
Occupational mental disorders or syndromes involving days away from work	0.08	0.05	1.6	11% of these cases were due to post-traumatic anxiety and 23% were due to a neurotic reaction to stress.	Special Request
Nonfatal occupational skin diseases and disorders	0.93	0.49	1.9	The Hospitals (NAICS 622) subsector incidence rate of skin disease and disorders was 43% higher than the sector average.	H7

Health outcome	Incidence rate for the healthcare and social assistance sector	Incidence rate for the U.S. workforce	Incidence rate ratio	Comment (pertains to the healthcare and social assistance sector)	Table reference
Nonfatal occupational respiratory conditions	0.59	0.22	2.7	The Hospital (NAICS 622) subsector incidence rate of respiratory conditions was 66% higher than the sector average.	H7
Nonfatal occupational poisonings	0.05	0.04	1.3	The incidence rate of poisonings in the Social Assistance (NAICS 624) subsector was three-fold larger than in the healthcare and social assistance sector.	H7

* Fatality data are from BLS Census of Fatal Occupational Injuries (CFOI) special research file. Data exclude information for New York City and are preliminary. Employment data are from BLS Current Population Survey monthly microdata files. Fatality totals include all workers regardless of age. Workers under the age of 16 and active duty military were not included in the rate calculations to maintain consistency with the employment data. Rates were calculated by NIOSH and may differ from previously published BLS CFOI rates.

† Fatality data are from the BLS Occupational and Safety and Health (OSH)/Census of Fatal Occupational Injuries (CFOI) 2003 Profiles and Charts. Employment data for 2003 are based on estimates derived from BLS Current Population Survey (CPS) monthly microdata files.

Fatal occupational injuries

Transportation accidents accounted for 48% of fatal occupational injuries in the healthcare and social assistance sector (most involved highway accidents). Assaults and violent acts accounted for 25% of fatal occupational injuries in the healthcare and social assistance sector (about an equal number were due to homicides as were due to suicides) ([Table H3](#)).

Nonfatal occupational injuries involving days away from work

Sprains and strains were the most frequent nonfatal injury type involving days away from work with an incidence rate within the healthcare and social assistance sector of 9.5 cases per 1000 full-time workers per year ([Table H4](#)). The Nursing and Residential Care Facilities (NAICS 623) subsector had the highest incidence rate of sprains and strains, with an incidence rate of 17.76 cases/1000 full-time workers/year, which was approximately two-fold larger than the healthcare and social service sector average.

Total nonfatal occupational injuries

The Nursing and Residential Care Facilities (NAICS 623) subsector had the highest incidence rate and total number of cases of total nonfatal occupational injuries ([Table H5](#)).

Within the healthcare and social assistance sector, the incidence rate of traumatic injuries and disorders involving days away from work was 16.30 cases/1000 full-time workers/year, compared to an incidence rate of total nonfatal injuries of 60 cases/1000 full-time workers/year (Specially requested information and [Table H5](#)). This suggests that the total injury rate was about 4-fold larger than the injury rate involving days away from work.

Nonfatal occupational injuries and illnesses involving days away from work

The incidence rate of carpal tunnel and tendonitis for the healthcare and social assistance sector were 0.17 and 0.08 cases/1000 full-time workers/year, respectively ([Table H6](#)). Carpal tunnel syndrome and tendonitis incidence rates were highest in the Home Healthcare Services (NAICS 6216) and Hospitals (NAICS 622) industry group and subsector, respectively ([Table H6](#)). The musculoskeletal system and connective tissue diseases and disorders incidence rate for the healthcare and social assistance sector was 0.18 cases/1000 full-time workers/year (Special Request); 43% of these cases were diagnosed as tendonitis.

The incidence rate of back pain (without a medical diagnosis) involving days away from work for the healthcare and social assistance sector was 0.65 cases/1000 full-time workers/year ([Table H6](#)). The highest rate was in the Nursing and Residential Care Facilities (NAICS 623) subsector, which had an incidence rate of 1.38 cases/1000 full-time workers/year.

Nonfatal occupational illnesses

The incidence rates of nonfatal occupational skin diseases and disorders and nonfatal occupational respiratory conditions for the healthcare and social assistance sector were 0.93 and 0.59 cases/1000 full-time workers/year ([Table H7](#)). The Hospitals (NAICS 622) subsector had the highest incidence rates and case numbers for both nonfatal respiratory conditions and skin diseases and disorders. BLS data was not able to further discriminate as to what portions of the hospital workforce were at greatest risk.

The incidence rate of nonfatal occupational poisonings for the healthcare and social assistance sector was 0.05 cases/1000 full-time workers/year ([Table H7](#)). The Social Assistance (NAICS 624) subsector had the highest incidence rate of nonfatal occupational poisonings.

The incidence rate of all other nonfatal occupational illnesses for the healthcare and social assistance sector was 2.89 cases/1000 full-time workers/year ([Table H7](#)). The Hospitals (NAICS 622) subsector had the highest incidence rate and case numbers of all other nonfatal occupational illnesses.

Table H3. Number and percent of fatal occupational injuries in the healthcare and social assistance sector by event or exposure, 2003

Event or exposure	Number of fatal injuries	Percent of total fatal occupational injuries in healthcare and social assistance sector
Contact with objects and equipment	4	3
Falls	15	13
Exposure to harmful substances or environments	12	10
Exposure to caustic, noxious, or allergenic substances (3 were due to needlesticks)	8	
Oxygen deficiency	4	
Transportation accidents	55	48
Highway accident	38	
Worker struck by vehicle, mobile equipment	7	
Aircraft accident	8	
Assaults and violent acts	29	25
Homicides	16	
Suicides, self-inflicted injuries	13	
Total	115	

Totals for major categories may include subcategories not shown separately; 2003 data were specially requested from BLS

Table H4. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational injuries involving days away from work by healthcare and social assistance subsectors and industry groups, 2003

Healthcare and social assistance subsector and industry group	NAICS code	Sprains, strains	Fractures	Cuts, punctures	Bruises	Amputations
Ambulatory healthcare services	621	14,020 (3.73)	1,890 (0.50)	1,000 (0.27)	2,710 (0.72)	-

Home healthcare services	6216	400 (0.84)	200 (0.44)	<15	1,100 (2.38)
Other ambulatory healthcare services	6219	200 (1.09)	<50 (0.25)	<15	700 (3.99)
Hospitals	622	4,700 (1.38)	3,300 (0.98)	200 (0.05)	16,600 (4.92)
Nursing and residential care facilities	623	-	900 (0.41)	100 (0.05)	5,700 (2.6)
Social assistance	624	400 (0.3)	500 (0.31)	200 (0.15)	2,400 (1.59)
Total for healthcare and social assistance sector	62	10,100 (0.93)	6,400 (0.59)	600 (0.05)	31,300 (2.89)

Numbers of cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR10](#) and [SNR08](#); highest values are in bold font.

Appendix

Notes on Limitations and Interpretation

One of the limitations of occupational safety and health surveillance data is the underreporting of illnesses, which occurs because: 1) some diseases (e.g., cancer and pneumoconiosis) have long latency periods so that reporting mechanisms, such as OSHA logs, as used by BLS, fail to capture many of these events; 2) many diseases have multiple potential causes (e.g., asthma and cardiovascular diseases); and 3) workers and physicians do not recognize an occupational contribution.

BLS data sources do not allow: characterization of occupationally-related illnesses, if these illnesses are not skin diseases and disorders, respiratory conditions, or poisonings; or quantification of fatalities due to occupationally-related illnesses. Other sources have suggested that the occupational illness fatalities in the US workforce outnumber occupational injury fatalities by about 8:1. For example, using 1997 disease fatality numbers, it was estimated that occupationally-related illness and injury deaths numbered, respectively, 25,910-72,121 (Steenland et al., 2003) and 6,238 (BLS). Estimates of 1997 occupationally-related illness deaths by disease category are as follows: 6,805-26,685 for non-malignant respiratory disease; 12,086-26,244 for occupationally-related cancer deaths; 6,037-18,253 for occupationally-related coronary heart disease; and 328-580 for occupationally-related renal disease (Steenland et al., 2003). Sector-based occupationally-related illness fatality data are not provided in this surveillance data summary.

Other limitations of the data include the following. (1) Only BLS data for a single year (2003) are presented. However, data for a single year may not be representative of the long-term experience and health impacts of a sector due to economic, political, technological, or weather characteristics of that year. (2) Many of the rates are based on small denominators, so that a few additional or a few less cases in the numerator might cause a large fluctuation in the magnitude of the rate estimate. Therefore, what may be quantified as large differences in risk may simply be the result of the “random” occurrence of a few cases. (3) Rates are not adjusted for any potential confounders, the most important of which may be age. Research has shown that younger workers may be at increased risk of injury due to a variety of factors including experience and training. Older workers may be more susceptible to certain occupational illnesses because of pre-existing medical conditions. Therefore what is perceived as a true difference in risk based upon crude rates between two groups may simply be the result of differences in their age distributions. (4) Differences among rates for subsectors and industries of the sector are not tested for statistical significance. Without statistical testing, one cannot conclude that rates are really any different than some of the other rates in the sector.

Discussion of the data focuses on rates, although many of the tables also provide data on the number of workers affected. A subsector or industry which has the highest rate of injuries or illnesses within the sector may have few total workers. Implementing

prevention strategies within another subsector or industry within the sector with a high rate of injuries or illnesses and a larger number of workers, may result in a much larger public health impact. If these data are used for planning and priority setting, we suggest that the number of adverse health outcomes and the number of workers potentially impacted be considered concurrently to identify worker groups towards which research should be directed.

Steenland K, Burnett C, Lalich N, Ward E, Hurrell J [2003]. Dying for work: the magnitude of US mortality from selected causes of death associated with occupation. *Am J Ind Med* 43:461-482.

Appendix 4. Surveillance Summary for Manufacturing

Manufacturing Sector Fatal and Non-Fatal Injury and Illness Surveillance Information

The following summary of fatality, injury, and illness rates in the Manufacturing sector is provided in order to help identify the most important safety and health problems in this sector. The North American Industry Classification System (NAICS), which was used to designate the NORA sectors, was also used by the Bureau of Labor Statistics (BLS) during the collection of their 2003 data. NAICS codes all economic activities using a six-digit hierarchical coding system with industry sectors, subsectors, industry groups, NAICS international industries, and National industries coded with 2, 3, 4, 5, and 6 digits, respectively.

The following sector-based summary is derived from 2003 BLS Census of Fatal Occupational Injuries (CFOI), and the annual Survey of Occupational Injury and Illness (SOII) ([BLS, 2005a](#); [BLS, 2005b](#)). BLS non-fatal injury and illness data are based on a survey of 183,700 (of an estimated 7 million) US business establishments and do not include the self-employed, farms with fewer than 11 employees, private households, and governmental agencies. Where possible, references are made to specific BLS tables. In order to encourage internal comparisons, we have converted BLS rates, which are expressed as cases/100 full-time workers/year and cases/10,000 full-time workers/year, to cases/1,000 full-time workers/year.

As with the original BLS tables, the rates reported in our tables cannot be directly calculated from the numbers of cases and numbers of workers provided in our tables. This is because BLS makes post-sampling adjustments of their data and they use the equivalent of full-time workers (not workers) in their rate denominators ([BLS, 1997](#)). Using denominators based on person-time rather than numbers of workers results in rates that provide more accurate estimates of actual risk. Full-time workers are defined as working 40 hours per week for 50 weeks. Denominators for non-fatal injury and illness rates are calculated based on work hours data BLS receives from reporting establishments. Denominators for fatal injury rates come from the Current Population Survey.

According to the BLS-Quarterly Census of Employment and Wages (QCEW) program, there were 14,459,700 workers in the manufacturing sector in 2003 ([Table M1](#)). Workers in Transportation Equipment, Food, Fabricated Metal Products, Computer and Electronic Products, and Machinery manufacturing comprised 12%, 10%, 10%, 9%, and 8% of the sector workforce, respectively.

Table M1. Annual employment numbers by manufacturing subsectors, 2003

Manufacturing subsector	NAICS code	Number of workers
Food	311	1,513,400
Beverage and Tobacco Products	312	199,400
Textile	313	261,300
Textile Product Mills	314	182,600
Apparel	315	309,000
Leather and Allied Products	316	45,600
Wood Products	321	534,300
Paper	322	514,100
Printing and Related Support Activities	323	672,300
Petroleum and Coal Products	324	115,500
Chemical	325	905,500
Plastics and Rubber Products	326	814,600
Nonmellatic Mineral Products	327	496,000
Primary Metal	331	474,500
Fabricated Metal Products	332	1,476,200
Machinery	333	1,145,800
Computer and Electronic Products	334	1,354,000
Electrical Equipment, Appliance, and Components	335	457,800
Transportation Equipment	336	1,753,700
Furniture and Related Products	337	570,300
Miscellaneous	339	663,600
Total for manufacturing sector	31-33	14,459,700

Numbers were obtained from 2003 BLS [Table SNR10](#); numbers of workers were rounded to the nearest 100 workers and are derived primarily from the BLS-Quarterly Census of Employment and Wages (QCEW) program. These worker numbers differ from full-time worker numbers (see discussion in introduction). QCEW captures only those workers covered by unemployment.

BLS [2005a]. Census of fatal occupational injuries (CFOI) - current and revised data. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics, Safety and Health Statistics Program. [www.bls.gov/iif/oshcfoi1.htm]

BLS [2005b]. Nonfatal (OSHA recordable) injuries and illnesses. Washington, DC: U.S. Department of Labor, Bureau of Labor Statistics, Safety and Health Statistics Program. [www.bls.gov/iif/home.htm]

Table M2. Comparison of incidence rates (cases/1000 full-time workers/year) of occupational fatalities, injuries, and illnesses for the manufacturing sector and the U.S. workforce, 2003

Health outcome	Incidence rate for the manufacturing sector	Incidence rate for the U.S. workforce	Incidence rate ratio	Comment (pertains to the manufacturing sector)	Table reference
Fatal occupational injuries	0.03*	0.04*	0.8	Most fatal occupational injuries were due to contact with objects and equipment and transportation accidents.	M3 , 2003 BLS SNR10
Traumatic nonfatal occupational injuries involving days away from work	13.85	13.79	1.0	The greatest proportion (43%) of the cases was due to trauma to muscles, tendons, ligaments, and joints.	2003 BLS R72 , R49
Total nonfatal occupational injuries	60	47	1.3	This rate was more than four-fold larger than the incidence rate of traumatic injuries involving days away from work.	M5
Occupational back pain (without a medical diagnosis) involving days away from work	0.35	0.43	0.8	Beverage and Tobacco Products (NAICS 312) subsector had the highest incidence rate. The Food (NAICS 311) subsector had the highest number of cases.	M8
Occupational hernia involving days away from work	0.44	0.26	1.7	This includes inguinal and ventral hernias.	2003 BLS R72
Occupational musculoskeletal systems and connective tissue diseases and disorders cases involving days away from work	0.48	0.22	2.2	38% of these cases were diagnosed as tendonitis.	2003 BLS R49 , R72

Table M2. (Continued)

Health outcome	Incidence rate for the manufacturing sector	Incidence rate for the U.S. workforce	Incidence rate	Comment (pertains to the manufacturing sector)	Table reference
Occupational carpal tunnel syndrome cases involving days away from work	0.56	0.25	2.2	The highest incidence rate of carpal tunnel syndrome involving days away from work was in the Leather and Allied Products (NAICS 316) manufacturing subsector and the largest number of cases was in the Transportation Equipment (NAICS 336) manufacturing subsector.	M8
Nonfatal occupational skin diseases and disorders	0.74	0.49	1.5	The highest incidence rate was in the Leather and Allied Products (NAICS 316) manufacturing subsector and the largest number of cases was in the Transportation Equipment (NAICS 336) manufacturing subsector.	M11
Nonfatal occupational respiratory conditions	0.25	0.22	1.1	The highest incidence rate was in the Food (NAICS 311) manufacturing subsector and the largest number of cases was in Food (NAICS 311) and Transportation Equipment (NAICS 336) manufacturing subsectors.	M11
Nonfatal occupational poisonings	0.05	0.04	1.3	The highest incidence rate was in the Furniture and Related Products (NAICS 337) manufacturing subsector.	M11
All other nonfatal occupational illnesses	6.88	2.32	3.0	The highest incidence rates were in Transportation Equipment (NAICS 336) and Food (NAICS 311) manufacturing subsectors.	M11

* Fatality data are from the BLS Occupational and Safety and Health (OSH)/Census of Fatal Occupational Injuries (CFOI) 2003 Profiles and Charts. Employment data for 2003 are based on estimates derived from BLS Current Population Survey (CPS) monthly microdata files.

Fatal occupational injuries

Contact with objects and equipment accounted for 31% of fatal occupational injuries in the manufacturing sector (the largest proportion involved workers being caught in or compressed by equipment or objects). Transportation accidents accounted for 28% of fatal occupational injuries in the manufacturing sector (most involved highway accidents) ([Table M3](#)).

Nonfatal occupational injuries involving days away from work

Industry-wide, sprains and strains were the most frequent nonfatal injury type involving days away from work with an incidence rate within the manufacturing sector of 5.92 cases per 1000 full-time workers per year ([Table M4](#)). Beverage and Tobacco Products (NAICS 312) manufacturing subsector had an incidence rate of sprains and strains of 17.61 cases/1000 full-time workers/year, which was approximately three-fold larger than the manufacturing sector average.

Furniture and Related Products (NAICS 337), Fabricated Metal Products (NAICS 332), and Wood Products (NAICS 321) manufacturing subsectors had the three highest incidence rates of nonfatal amputation involving days away from work, with the highest manufacturing industry rates in Miscellaneous Fabricated Metal Product (NAICS 332999), Ornamental and Architectural Metal Works (NAICS 332323); and Other Metal Valve and Pipe Fitting (NAICS 332919) manufacturing (Tables [M4](#) and [M7](#)).

Total nonfatal occupational injuries

Beverage and Tobacco Products (NAICS 312) and Wood Products (NAICS 321) manufacturing subsectors had the highest incidence rates of total nonfatal occupational injuries ([Table M5](#)), with Bottled Water (NAICS 312112) and Truss (NAICS 321214) manufacturing industries having incident rates, respectively, 2.8- and 2.4-fold larger than the manufacturing sector average ([Table M6A](#)). The Transportation Equipment (NAICS 336) manufacturing subsector had the highest number of total nonfatal injuries, due to a large workforce and a moderately elevated incidence rate ([Table M5](#)).

Within the manufacturing sector, the incidence rate of traumatic injuries and disorders involving days away from work was 13.85 cases/1000 full-time workers/year, compared to an incidence rate of total nonfatal injuries of 60 cases/1000 full-time workers/year (2003 BLS Tables [R72](#) and [SNR05](#)). This suggests that the total injury rate was more than 4-fold larger than the injury rate involving days away from work.

Nonfatal occupational injuries and illnesses involving days away from work

Carpal tunnel syndrome and tendonitis incidence rates involving days away from work were highest in the Leather and Allied Products (NAICS 316) manufacturing subsector ([Table M8](#)). The incidence rates of carpal tunnel syndrome and tendonitis were, respectively, about 11-fold higher in the Other Leather and Allied Product (NAICS 31699) manufacturing industry and about 50-fold higher in Rubber and Plastic Footwear

manufacturing (NAICS 316211) manufacturing industry, compared with the respective manufacturing sector averages (Tables [M9A](#) and [M10](#)).

The incidence rate of back pain (without a medical diagnosis) involving days away from work for the manufacturing sector was 0.35 cases/1000 full-time workers/year ([Table M8](#)). Beverage and Tobacco Products (NAICS 312) had an incidence rate of 0.94 cases/1000 full-time workers/year, which was about three times larger than the sector average.

The incidence rate of hernia (including inguinal and ventral hernias) involving days away from work for the manufacturing sector was 0.44 cases/1000 full-time workers/year ([2003 BLS Table R72](#)).

Nonfatal occupational illnesses

Food (NAICS 311), Chemical (NAICS 325), and Transportation Equipment (NAICS 336) manufacturing subsectors had the highest incidence rates and case numbers of nonfatal occupational respiratory conditions. The Flour Milling and Malt (NAICS 31121) manufacturing industry had an incidence rate of nonfatal occupational respiratory conditions 13-fold the manufacturing sector average ([Table M12A](#)).

Leather Products (NAICS 316), Transportation Equipment (NAICS 336), and Fabricated Metal Products (NAICS 332) manufacturing subsectors had the highest incidence rates of nonfatal occupational skin diseases and disorders, with the largest number of affected workers being in the Transportation Equipment manufacturing subsector (Table M11). The three manufacturing industries with the highest incidence rates of nonfatal occupational skin disease and disorders involved handling concrete and metalworking and hydraulic fluids ([Table M13A](#)).

Table M3. Number and percent of fatal occupational injuries in the manufacturing sector by event or exposure, 2003

Event or exposure	Number of fatal injuries	Percent of total fatal occupational injuries in the manufacturing sector
Contact with objects and equipment	130	31
Struck by object	52	
Caught in or compressed by equipment or objects	70	
Caught in or crushed in collapsing materials	6	
Falls	38	9
Exposure to harmful substances or environments	45	11
Transportation accidents	117	28
Highway accident	61	
Non-highway accident except rail, air, or water	21	
Pedestrian accident (non-passenger struck by vehicle or mobile equipment)	23	
Aircraft accident	12	
Fires and explosions	47	11
Assaults and violent acts	41	10
Total	420	

Totals for major categories may include subcategories not shown separately; numbers were extracted from [2003 BLS Table A-9](#).

Table M4. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational injuries involving days away from work by manufacturing subsectors, 2003

Manufacturing subsector	NAICS code	Sprains, strains	Fractures	Cuts, punctures	Bruises	Amputations
Food	311	9,290 (6.20)	1,990 (1.33)	2,240 (1.49)	3,110 (2.08)	450 (0.30)
Beverage and Tobacco Products	312	3,370 (17.61)	430 (2.25)	250 (1.31)	450 (2.35)	-
Textile	313	650 (2.57)	290 (1.15)	340 (1.35)	220 (0.87)	60 (0.24)
Textile Product Mills	314	810 (4.76)	110 (0.65)	410 (2.41)	190 (1.12)	-
Apparel	315	870 (3.14)	90 (0.33)	200 (0.72)	210 (0.76)	-
Leather and Allied Products	316	240 (5.65)	40 (0.94)	110 (2.59)	40 (0.94)	-
Wood Products	321	5,070 (9.67)	1,310 (2.50)	2,460 (4.69)	1,270 (2.42)	280 (0.53)
Paper	322	3,140 (5.89)	670 (1.26)	830 (1.56)	610 (1.14)	160 (0.30)
Printing and Related Support Activities	323	3,270 (5.15)	470 (0.74)	840 (1.32)	540 (0.85)	120 (0.19)
Petroleum and Coal Products	324	380 (3.17)	120 (1.00)	70 (0.58)	100 (0.83)	-
Chemical	325	3,550 (3.91)	810 (0.89)	440 (0.48)	450 (0.50)	150 (0.17)
Plastics and Rubber Products	326	5,220 (6.45)	1,060 (1.31)	1,360 (1.68)	1,190 (1.47)	160 (0.20)
Nonmetallic Mineral Products	327	4,480 (9.01)	1,010 (2.03)	1,150 (2.31)	780 (1.57)	150 (0.30)
Primary Metal	331	3,380 (7.10)	970 (2.04)	900 (1.89)	640 (1.34)	160 (0.34)
Fabricated Metal Products	332	9,550 (6.59)	2,180 (1.50)	3,490 (2.41)	2,230 (1.54)	850 (0.59)
Machinery	333	6,340 (5.51)	1,160 (1.01)	1,730 (1.50)	1,130 (0.98)	240 (0.21)
Computer and Electronic Products	334	2,810 (2.12)	490 (0.37)	650 (0.49)	510 (0.38)	50 (0.04)
Electrical Equipment, Appliance, and Components	335	2,050 (4.60)	410 (0.92)	430 (0.97)	570 (1.28)	100 (0.22)
Transportation Equipment	336	13,930 (7.97)	1,780 (1.02)	2,230 (1.28)	2,540 (1.45)	180 (0.10)
Furniture and Related Products	337	3300 (6.03)	730 (1.33)	1,450 (2.65)	710 (1.30)	530 (0.97)
Miscellaneous	339	2,530 (4.01)	470 (0.75)	840 (1.33)	600 (0.95)	70 (0.11)
Total for the manufacturing sector	31-33	84,210 (5.92)	16,590 (1.17)	22,410 (1.57)	18,090 (1.27)	3,750 (0.26)

Numbers of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [R1](#) and [R5](#); highest three values are in bold font.

Table M5. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational injuries by manufacturing subsectors, 2003

Manufacturing subsector	NAICS code	Total nonfatal occupational injuries
Food	311	106,600 (71)
Beverage and Tobacco Products	312	19,700 (103)
Textile	313	11,200 (44)
Textile Product Mills	314	8,800 (52)
Apparel	315	8,700 (31)
Leather and Allied Products	316	2,700 (65)
Wood Products	321	49,500 (95)
Paper	322	23,200 (44)
Printing and Related Support Activities	323	27,000 (42)
Petroleum and Coal Products	324	3,000 (25)
Chemical	325	26,700 (29)
Plastics and Rubber Products	326	55,400 (69)
Nonmetallic Mineral Products	327	37,000 (74)
Primary Metal	331	41,800 (88)
Fabricated Metal Products	332	115,800 (80)
Machinery	333	73,500 (64)
Computer and Electronic Products	334	25,500 (19)
Electrical Equipment, Appliance, and Components	335	23,800 (53)
Transportation Equipment	336	129,900 (74)
Furniture and Related Products	337	43,400 (79)
Miscellaneous	339	27,800 (44)
Total for the manufacturing sector	31-33	860,900 (60)

Numbers of cases were rounded to the nearest 100 workers; numbers were extracted from [2003 BLS Table SNR05](#); highest three values are in bold font.

Table M6A. Manufacturing industries (5- and 6-digit NAICS codes) with the highest nonfatal occupational injury incidence rates, 2003

Manufacturing industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Bottled water manufacturing	312112	17,000	167	2,900
Iron foundries	331511	61,800	149	9,600
Truss manufacturing	321214	41,900	146	6,200

Number of workers and cases were rounded to the nearest 100 workers; numbers were extracted from [2003 BLS Table SNR05](#); the incidence rates of nonfatal occupational injuries, regardless whether workdays were lost, for the manufacturing sector and the entire U.S. workforce were 60 and 47 cases/1000 full-time workers/year, respectively.

Table M6B. Manufacturing industries (5-digit NAICS codes) with the highest numbers of nonfatal occupational injuries, 2003

Manufacturing industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Animal slaughtering and processing	31161	512,400	72	37,800
Other plastics product manufacturing	32619	374,200	70	25,900
Printing	32311	615,600	44	25,400
Automobile and light duty motor vehicle manufacturing	33611	227,300	66	23,000

Number of workers and cases were rounded to the nearest 100 workers; numbers were extracted from [2003 BLS Table SNR05](#); the incidence rates of nonfatal occupational injuries, regardless whether workdays were lost, for the manufacturing sector and the entire U.S. workforce were 60 and 47 cases/1000 full-time workers/year, respectively.

Table M6C. Sources (2-digit code) responsible for highest nonfatal occupational injury rates within the manufacturing sector, 2003

Source	Source code	Incidence rate (cases/1000 full-time workers/year)
Person injured or ill worker	56	3.18
Floors, walkways, ground surfaces	62	1.92
Nonpressurized containers	11	1.26

Numbers were extracted from [2003 BLS Table R74](#).

Table M6D. Events (2-digit code) responsible for highest nonfatal occupational injury rates within the manufacturing sector, 2003

Event	Event code	Incidence rate (cases/1000 full-time workers/year)
Bodily reaction	21	1.63
Struck by object	02	2.08
Repetitive motion	23	1.48

Numbers were extracted from [2003 BLS Table R75](#).

Table M7. Manufacturing industries (5- and 6-digit NAICS codes) with the highest nonfatal occupational amputation incidence rates involving days away from work, 2003

Manufacturing industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
All other miscellaneous fabricated metal product manufacturing	332999	60,300	2.83	160
Ornamental and architectural metal work manufacturing	332323	37,900	2.45	90
Other metal valve and pipe fitting manufacturing	332919	22,000	1.84	40

Numbers of workers were rounded to the nearest 100 workers; numbers of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [SNR10](#), [R1](#), and [R5](#); the incidence rates of nonfatal occupational amputations involving days away from work for the manufacturing sector and the entire U.S. workforce were 0.26 and 0.09 cases/1000 full-time workers/year, respectively.

Table M8. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational injuries and illnesses involving days away from work by manufacturing subsector, 2003

Manufacturing subsector	NAICS code	Carpal tunnel syndrome		Tendonitis		Back pain (without a medical diagnosis)	
Food	311	610	(0.41)	340	(0.23)	800	(0.53)
Beverage and Tobacco Products	312	50	(0.26)	30	(0.16)	180	(0.94)
Textile Mills	313	80	(0.32)	-		-	
Textile Product Mills	314	140	(0.82)	70	(0.41)	30	(0.18)
Apparel	315	240	(0.87)	70	(0.25)	50	(0.18)
Leather and Allied Products	316	160	(3.76)	30	(0.71)	20	(0.47)
Wood Products	321	240	(0.46)	90	(0.17)	380	(0.72)
Paper	322	290	(0.54)	80	(0.15)	200	(0.38)
Printing and Related Support Activities	323	310	(0.49)	70	(0.11)	120	(0.19)
Petroleum and Coal Products	324	30	(0.25)	-		30	(0.25)
Chemical	325	170	(0.19)	80	(0.09)	160	(0.18)
Plastics and Rubber Products	326	470	(0.58)	130	(0.16)	270	(0.33)
Nonmetallic Mineral Products	327	110	(0.22)	140	(0.28)	280	(0.56)
Primary Metal	331	310	(0.65)	90	(0.19)	180	(0.38)
Fabricated Metal Products	332	840	(0.58)	180	(0.12)	610	(0.42)
Machinery	333	780	(0.68)	160	(0.14)	340	(0.30)
Computer and Electronic Products	334	460	(0.35)	160	(0.12)	210	(0.16)
Electrical Equipment, Appliance, and Components	335	330	(0.74)	60	(0.13)	140	(0.31)
Transportation Equipment	336	1,320	(0.75)	400	(0.23)	650	(0.37)
Furniture and Related Products	337	400	(0.73)	230	(0.42)	180	(0.33)
Miscellaneous	339	580	(0.92)	170	(0.27)	100	(0.16)
Total for the manufacturing sector	31-33	7,910	(0.56)	2,580	(0.18)	4,940	(0.35)

Numbers of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [R1](#) and [R5](#); highest three values are in bold font.

Table M9A. Manufacturing industries (5- and 6-digit NAICS codes) with the highest incidence rates of occupational carpal tunnel syndrome involving days away from work, 2003

Manufacturing industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Other leather and allied product manufacturing	31699	17,800	6.13	100
Men's footwear (except athletic) manufacturing	316213	9,400	3.32	30
Sign manufacturing	33995	69,300	3.15	200

Numbers of workers were rounded to the nearest 100 workers; numbers of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [SNR10](#), [R1](#), and [R5](#); the incidence rates of occupational carpal tunnel syndrome involving days away from work for the manufacturing sector and the entire U.S. workforce were 0.56 and 0.25 cases/1000 full-time workers/year, respectively.

Table M9B. Manufacturing industries (5-digit NAICS codes) with the highest numbers of occupational carpal tunnel syndrome involving days away from work, 2003

Manufacturing industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Printing	32311	615,600	0.52	300
Aerospace product and parts manufacturing	33641	438,100	0.60	260
Automobile and light duty motor vehicle manufacturing	33611	227,300	0.98	230

Numbers of workers were rounded to the nearest 100 workers; numbers of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [SNR10](#), [R1](#), and [R5](#); the incidence rates of occupational carpal tunnel syndrome involving days away from work for the manufacturing sector and the entire U.S. workforce were 0.56 and 0.25 cases/1000 full-time workers/year, respectively.

Table M10. Manufacturing industries (5- and 6-digit NAICS codes) with the highest incidence rates of occupational tendonitis involving days away from work, 2003

Manufacturing industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Rubber and plastic footwear manufacturing	316211	2,400	8.92	20
Glass product manufacturing made of purchased glass	327215	54,900	1.74	90
Men's and boy's cut and sew work clothing manufacturing	315225	12,100	1.72	20

Numbers of workers were rounded to the nearest 100 workers; numbers of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [SNR10](#), [R1](#), and [R5](#); the incidence rates of occupational tendonitis involving days away from work for the manufacturing sector and the entire U.S. workforce were 0.18 and 0.09 cases/1000 full-time workers/year, respectively.

Table M11. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational illnesses by manufacturing subsector, 2003

Manufacturing subsector	NAICS code	Skin diseases and disorders	Respiratory conditions	Poisonings	All other illnesses
Food	311	1,100 (0.72)	600 (0.42)	<50 (0.02)	20,800 (13.87)
Beverage and Tobacco Products	312	100 (0.76)	100 (0.28)	<15	500 (2.60)
Textile Mills	313	200 (0.62)	<15	<15	1,300 (4.97)
Textile Product Mills	314	100 (0.56)	<15	<15	400 (2.61)
Apparel	315	100 (0.28)	100 (0.23)	<15	1,200 (4.48)
Leather and Allied Products	316	100 (1.55)	<15	<15	500 (11.64)
Wood Products	321	200 (0.38)	100 (0.28)	<15	2,500 (4.75)
Paper	322	200 (0.29)	100 (0.22)	<15	2,100 (3.93)
Printing and Related Support Activities	323	300 (0.40)	100 (0.16)	<15	1,600 (2.47)
Petroleum and Coal Products	324	<50 (0.13)	<15	<15	300 (2.49)
Chemical	325	600 (0.64)	300 (0.37)	100 (0.08)	3,300 (3.59)
Plastics and Rubber Products	326	700 (0.81)	200 (0.29)	<50 (0.03)	3,300 (4.09)
Nonmetallic Mineral Products	327	500 (0.98)	100 (0.17)	<50 (0.04)	1,400 (2.89)
Primary Metal	331	300 (0.59)	100 (0.22)	<50 (0.06)	3,500 (7.32)
Fabricated Metal Products	332	1,600 (1.11)	300 (0.21)	100 (0.06)	5,700 (3.95)
Machinery	333	1,000 (0.86)	300 (0.23)	100 (0.05)	5,000 (4.36)
Computer and Electronic Products	334	500 (0.41)	200 (0.14)	100 (0.11)	5,000 (3.80)
Electrical Equipment, Appliance, and Components	335	300 (0.73)	100 (0.17)	<15	2,800 (6.31)
Transportation Equipment	336	2,000 (1.17)	600 (0.33)	100 (0.06)	29,500 (16.86)
Furniture and Related Products	337	200 (0.39)	100 (0.23)	100 (0.11)	4,000 (7.35)
Miscellaneous	339	500 (0.86)	100 (0.24)	<15	3,100 (4.97)
Total		10,500 (0.74)	3,600 (0.25)	700 (0.05)	97,900 (6.88)

Numbers of cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR10](#) and [SNR08](#); highest three values are in bold font.

Table M12A. Manufacturing industries (5- and 6-digit NAICS codes) with the highest incidence rates of nonfatal occupational respiratory conditions, 2003

Manufacturing industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Flour milling and malt manufacturing	31121	20,200	3.22	100
All other miscellaneous food manufacturing	311999	27,200	2.25	100
Mattress manufacturing	33791	30,200	1.79	100

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); the incidence rates of nonfatal occupational respiratory conditions, regardless whether workdays were lost, for the manufacturing sector and the entire U.S. workforce were 0.25 and 0.22 cases/1000 full-time workers/year, respectively.

Table M12B. Manufacturing industry (5-digit NAICS codes) with the highest numbers of nonfatal occupational respiratory conditions, 2003

Manufacturing industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Animal slaughtering and processing	31161	512,400	0.52	300
Other plastics product manufacturing	32619	374,200	0.41	200

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); the incidence rates of nonfatal occupational respiratory conditions, regardless whether workdays were lost, for the manufacturing sector and the entire U.S. workforce were 0.25 and 0.22 cases/1000 full-time workers/year, respectively.

Table M13A. Manufacturing industries (5- and 6-digit NAICS codes) with the highest incidence rates of nonfatal occupational skin diseases and disorders, 2003

Manufacturing industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Concrete block and brick manufacturing	327331	20,700	5.93	100
Precision turned product manufacturing	332721	42,300	5.46	200
Motor vehicle brake system manufacturing	33634	45,900	4.54	200

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); the incidence rates of nonfatal occupational skin diseases and disorders, regardless whether workdays were lost, for the manufacturing sector and the entire U.S. workforce were 0.74 and 0.49 cases/1000 full-time workers/year, respectively.

Table M13B. Manufacturing industry (5-digit NAICS codes) with the highest number of nonfatal occupational skin diseases and disorders, 2003

Manufacturing industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Animal slaughtering and processing	31161	512,400	0.82	400

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); the incidence rates of nonfatal occupational skin diseases and disorders, regardless whether workdays were lost, for the manufacturing sector and the entire U.S. workforce were 0.74 and 0.49 cases/1000 full-time workers/year, respectively.

Appendix

Notes on Limitations and Interpretation

One of the limitations of occupational safety and health surveillance data is the underreporting of illnesses, which occurs because: 1) some diseases (e.g., cancer and pneumoconiosis) have long latency periods so that reporting mechanisms, such as OSHA logs, as used by BLS, fail to capture many of these events; 2) many diseases have multiple potential causes (e.g., asthma and cardiovascular diseases); and 3) workers and physicians do not recognize an occupational contribution.

BLS data sources do not allow: characterization of occupationally-related illnesses if these illnesses are not skin diseases and disorders, respiratory conditions, or poisonings; or quantification of fatalities due to occupationally-related illnesses. Other sources have suggested that the occupational illness fatalities in the US workforce outnumber occupational injury fatalities by about 8:1. For example, using 1997 disease fatality numbers, it was estimated that occupationally-related illness and injury deaths numbered, respectively, 25,910-72,121 (Steenland et al. 2003) and 6,238 (BLS). Estimates of 1997 occupationally-related illness deaths by disease category are as follows: 6,805-26,685 for non-malignant respiratory disease; 12,086-26,244 for occupationally-related cancer deaths; 6,037-18,253 for occupationally-related coronary heart disease; and 328-580 for occupationally-related renal disease (Steenland et al. 2003). Sector-based occupationally-related illness fatality data are not provided in this surveillance data summary.

Other limitations of the data include the following. (1) Only BLS data for a single year (2003) are presented. However, data for a single year may not be representative of the long-term experience and health impacts of a sector due to economic, political, technological, or weather characteristics of that year. (2) Many of the rates are based on small denominators, so that a few additional or a few less cases in the numerator might cause a large fluctuation in the magnitude of the rate estimate. Therefore, what may be quantified as large differences in risk may simply be the result of the “random” occurrence of a few cases. (3) Rates are not adjusted for any potential confounders, the most important of which may be age. Research has shown that younger workers may be at increased risk of injury due to a variety of factors including experience and training. Therefore what is perceived as a true difference in risk based upon crude rates between two groups may simply be the result of differences in their age distributions. (4) Differences among rates for subsectors and industries of the sector are not tested for statistical significance. Without statistical testing, one cannot conclude that rates are really any different than some of the other rates in the sector.

Discussion of the data focuses on rates, although many of the tables also provide data on the number of workers affected. A subsector or industry which has the highest rate of injuries or illnesses within the sector may have few total workers. Implementing prevention strategies within another subsector or industry within the sector with a high rate of injuries or illnesses and a larger number of workers, may result in a much larger public health impact. If these data are used for planning and priority setting, we suggest

that the number of adverse health outcomes and the number of workers potentially impacted be considered concurrently to identify worker groups towards which research should be directed.

Appendix 5. Surveillance Summary for Mining

Mining Sector Fatal and Non-Fatal Injury and Illness Surveillance Information

The following summary of fatality, injury, and illness rates in the Mining sector is provided in order to help identify the most important safety and health problems in this sector. The North American Industry Classification System (NAICS), which was used to designate the NORA sectors, was also used by the Bureau of Labor Statistics (BLS) during the collection of their 2003 data. NAICS codes all economic activities using a six-digit hierarchical coding system with industry sectors, subsectors, industry groups, NAICS international industries, and National industries coded with 2, 3, 4, 5, and 6 digits, respectively.

The following sector-based summary is derived from 2003 BLS Census of Fatal Occupational Injuries (CFOI), and the annual Survey of Occupational Injury and Illness (SOII) ([BLS, 2005a](#); [BLS, 2005b](#)). BLS non-fatal injury and illness data are based on a survey of 183,700 (of an estimated 7 million) US business establishments that do not include the self-employed, farms with fewer than 11 employees, private households, and governmental agencies; and comprehensive reporting by the Mine Safety and Health Administration (MSHA) for the mining sector (except for oil and gas extraction and related support activities). Where possible, references are made to specific BLS tables. In order to encourage internal comparisons, we have converted BLS rates, which are expressed as cases/100 full-time workers/year and cases/10,000 full-time workers/year, to cases/1,000 full-time workers/year.

The mining sector (NAICS 21), as presented in this summary, includes establishments MSHA rules and reporting, such as those in Oil and Gas Extraction and related support activities. Data for mining operators in coal, metal, and nonmetal mining are provided to BLS by the MSHA, U.S. Department of Labor. Independent mining contractors are excluded from the coal, metal, and nonmetal mining industries. These data do not reflect the changes OSHA made to its recordkeeping requirements effective January 1, 2002; therefore estimates for these industries are not comparable to estimates for other industries.

As with the original BLS tables, the rates reported in our tables cannot be directly calculated from the numbers of cases and numbers of workers provided in our tables. This is because BLS makes post-sampling adjustments of their data and they use the equivalent of full-time workers (not workers) in their rate denominators ([BLS, 1997](#)). Using denominators based on person-time rather than numbers of workers results in rates that provide more accurate estimates of actual risk. Full-time workers are defined as working 40 hours per week for 50 weeks. Denominators for non-fatal injury and illness rates are calculated based on work hours data BLS receives from reporting establishments. Denominators for fatal injury rates come from the Current Population Survey.

According to the BLS-Quarterly Census of Employment and Wages (QCEW) program, there were 500,100 workers in the mining sector in 2003 ([Table MG1](#)). Workers in the mining subsector comprised 40% of the sector workforce. Of these, 34% were coal miners.

Table MG1. Annual employment numbers by mining subsectors and industry groups, 2003

Mining subsectors and industry groups	NAICS code	Number of workers
Oil and gas extraction	211	120,300
Mining (except oil and gas)	212	200,300
Coal mining	2121	68,800
Metal ore mining	2122	26,300
Nonmetallic mineral mining and quarrying	2123	105,100
Support activities for mining	213	179,500
Total for mining sector	21	500,100

Numbers were obtained from 2003 BLS Table [SNR10](#); numbers of workers were rounded to the nearest 100 workers and are derived primarily from the BLS-Quarterly Census of Employment and Wages (QCEW) program. These worker numbers differ from full-time worker numbers (see discussion in introduction). QCEW captures only those workers covered by unemployment. The mining sector (NAICS 21) includes establishments not governed by the Mine Safety and Health Administration (MSHA) rules and reporting, such as those in Oil and Gas Extraction and related support activities. Data for mining operators in coal, metal, and nonmetal mining are provided to BLS by the MSHA, U.S. Department of Labor. Independent mining contractors are excluded from the coal, metal, and nonmetal mining industries.

Table MG2. Comparison of incidence rates (cases/1000 full-time workers/year) of occupational fatalities, injuries, and illnesses for the mining sector and U.S. workforce, 2003

Health outcome	Incidence rate for the mining sector	Incidence rate for the U.S. workforce	Incidence rate ratio	Comment (pertains to the mining sector)	Table reference
Fatal occupational injuries	0.27*	0.04*	6.8	Most fatal occupational injuries were due to transportation accidents and contact with objects and equipment.	MG3
Traumatic nonfatal occupational injuries involving days away from work	13.11	13.79	1.0	The greatest proportion (46%) of the cases was due to trauma to muscles, tendons, ligaments, and joints.	Special Request
Total nonfatal occupational injuries	31	47	0.7	This rate was more than 2-fold larger than incidence rate of traumatic injuries involving days away from work.	MG5
Occupational back pain (without a medical diagnosis) involving days away from work	0.18	0.43	0.4	This rate was highest in the Support Activities for Mining (NAICS 213) subsector.	MG8
All occupational pain (without a medical diagnosis) involving days away from work	0.79	1.18	0.7	This rate was highest in the Coal Mining (NAICS 2121) industry group.	MG8
Occupational musculoskeletal system and connective tissue diseases and disorders involving days away from work	0.32	0.22	1.5		Special Request

Table MG2 (Continued)

Health outcome	Incidence rate for the mining sector	Incidence rate for the U.S. workforce	Incidence rate ratio	Comment (pertains to the mining sector)	Table reference
Nonfatal occupational skin diseases and disorders	0.08	0.49	0.2		MG9
Nonfatal occupational respiratory conditions	0.23	0.22	1.0	The incidence rate of respiratory conditions for the Coal Mining (NAICS 2121) industry group was nearly 6-fold larger than the mining sector average.	MG9
Nonfatal occupational poisonings	0.05	0.04	1.3		MG9

* Fatality data are from the BLS Occupational and Safety and Health (OSH)/Census of Fatal Occupational Injuries (CFOI) 2003 Profiles and Charts. Employment data for 2003 are based on estimates derived from BLS Current Population Survey (CPS) monthly microdata files. The mining sector (NAICS 21) includes establishments not governed by the Mine Safety and Health Administration (MSHA) rules and reporting, such as those in Oil and Gas Extraction and related support activities. Data for mining operators in coal, metal, and nonmetal mining are provided to BLS by the MSHA, U.S. Department of Labor. Independent mining contractors are excluded from the coal, metal, and nonmetal mining industries. These data do not reflect the changes OSHA made to its recordkeeping requirements effective January 1, 2002; therefore estimates for these industries are not comparable to estimates in other industries.

Fatal occupational injuries

Transportation accidents accounted for 34% of fatal occupational injuries in the mining sector (58% of these fatalities were due to highway accidents). Contact with objects and equipment accounted for 32% of fatal occupational injuries in the mining sector (71% of these fatalities were due to the worker being struck by an object) ([Table MG3](#)).

Nonfatal occupational injuries involving days away from work

Sprains and strains were the most frequent nonfatal injury type involving days away from work with an incidence rate within the mining sector of 6.04 cases per 1000 full-time workers per year ([Table MG4](#)). Coal Mining (NAICS 2121) subsector had an incidence rate of sprains and strains of 19.16 cases/1000 full-time workers/year, which was more than three-fold larger than the mining sector average. Bituminous Coal Underground Mining (NAICS 212112), Dimension Stone Mining and Quarrying (NAICS 212311), and Drilling Oil and Gas Wells (NAICS 213111) had incidence rates of fractures involving days away from work ranging from 3.85 to 8.64 cases/1000 full-time workers/year, which were 2 to 4.5 times larger than the mining sector average ([Table MG7](#)). The highest amputation rate involving days away from work was in Bituminous Coal Underground Mining (NAICS 212112), which had an incidence rate of 5.1 cases/1000 full-time workers/year ([2003 BLS Table R5](#)).

Total nonfatal occupational injuries

The highest incidence rate of total nonfatal occupational injuries was in the Bituminous Coal Underground Mining (NAICS 212112) industry, which had an incidence rate of 84 cases/1000 full-time workers/year ([Table MG6](#)).

Within the mining sector, the incidence rate of traumatic injuries and disorders involving days away from work was 13.11 cases/1000 full-time workers/year, compared to an incidence rate of total nonfatal injuries of 31 cases/1000 full-time workers/year (Special Request and [Table MG5](#)). This suggests that the total injury rate was more than two-fold larger than the injury rate involving days away from work.

Nonfatal occupational injuries and illnesses involving days away from work

The incidence rate of occupational back pain (without a medical diagnosis) involving days away from work was highest in the Support Activities for Mining (NAICS 213) subsector ([Table MG8](#)) with a rate of 0.28 cases/1000 full-time workers/year. However, the incidence rate for Bituminous Coal Underground Mining (NAICS 212112) was much higher at 5.1 cases/1000 full-time workers/year ([2003 BLS Table R5](#)).

Nonfatal occupational illnesses

Bituminous Coal Underground Mining (NAICS 212112) and Bituminous Coal and Lignite Surface Mining (NAICS 212111) industries had incidence rates of nonfatal occupational respiratory conditions of 2.08 and 0.63 cases/1000 full-time workers/year,

respectively, compared to the mining sector average of 0.23 cases/1000 full-time workers/year (Tables [MG9](#) and [MG10](#)). The incidence rate of nonfatal skin diseases and disorders was highest in the Support Activities for Mining (NAICS 213) industry group, with the Drilling Oil and Gas Wells (NAICS 213112) industry having the highest incidence rate (0.55 cases/1000 full-time workers/year) within this industry group (Tables [MG9](#) and [MG11](#)).

The incidence rates of all other nonfatal occupational illnesses were highest in the Bituminous Coal Underground Mining (NAICS 212112) and Iron Ore Mining (NAICS 21221) industries, which had incidence rates of 3.91 and 3.72 cases/1000 full-time workers/year, respectively ([Table MG12](#)).

Table MG3. Number and percent of fatal occupational injuries in the mining sector by event or exposure, 2003

Event or exposure	Number of fatal injuries	Percent of total fatal occupational injuries in the mining sector
Contact with objects and equipment	45	32
Struck by object	32	
Caught in or compressed by equipment or objects	10	
Caught in or crushed in collapsing materials	3	
Falls	10	7
Exposure to harmful substances or environments	10	7
Contact with electric current	7	
Contact with wiring, transformers, or other electrical component	3	
Transportation accidents	48	34
Highway accident	28	
Non-highway accident(farm, industrial premises)	10	
Worker struck by vehicle, mobile equipment	3	
Aircraft accident	6	
Fires and explosions	25	18
Fires	9	
Explosions	16	
Total	141	

Totals for major categories may include subcategories not shown separately; 2003 data were specially requested from BLS.

Table MG4. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational injuries involving days away from work by mining subsectors and industry groups, 2003

Mining subsector and industry group	NAICS code	Sprains, strains	Fractures	Cuts, punctures	Bruises	Amputations
Oil and gas extraction	211	390 (3.27)	-	-	-	-
Mining (except oil and gas)	212	2,400 (10.62)	720 (3.19)	400 (1.77)	490 (2.17)	60 (0.27)
Coal mining	2121	1,500 (19.16)	430 (5.49)	220 (2.81)	340 (4.34)	30 (0.38)
Metal ore mining	2122	170 (6.62)	50 (1.95)	20 (0.78)	20 (0.78)	-
Nonmetallic mineral mining and quarrying	2123	730 (5.99)	250 (2.05)	160 (1.31)	130 (1.07)	30 (0.25)
Support activities for mining	213	570 (2.70)	280 (1.33)	80 (0.38)	190 (0.90)	20 (0.09)
Total for mining sector	21	3,360 (6.04)	1,060 (1.91)	550 (0.99)	690 (1.24)	80 (0.14)

Numbers of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [R1](#) and [R5](#); highest values are in bold font. The mining sector (NAICS 21) includes establishments not governed by the Mine Safety and Health Administration (MSHA) rules and reporting, such as those in Oil and Gas Extraction and related support activities. Data for mining operators in coal, metal, and nonmetal mining are provided to BLS by the MSHA, U.S. Department of Labor. Independent mining contractors are excluded from the coal, metal, and nonmetal mining industries. These data do not reflect the changes OSHA made to its recordkeeping requirements effective January 1, 2002; therefore estimates for these industries are not comparable to estimates in other industries.

Table MG5. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational injuries by mining subsectors and industry groups, 2003

Mining subsector and industry group	NAICS code	Total nonfatal occupational injuries	
Oil and gas extraction	211	1,900	(16)
Mining (except oil and gas)	212	9,800	(43)
Coal mining	2121	4,500	(57)
Metal ore mining	2122	900	(35)
Nonmetallic mineral mining and quarrying	2123	4,400	(36)
Support activities for mining	213	5,500	(26)
Total for mining sector	21	17,300	(31)

Numbers of cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Table [SNR05](#); highest value is in bold font. The mining sector (NAICS 21) includes establishments not governed by the Mine Safety and Health Administration (MSHA) rules and reporting, such as those in Oil and Gas Extraction and related support activities. Data for mining operators in coal, metal, and nonmetal mining are provided to BLS by the MSHA, U.S. Department of Labor. Independent mining contractors are excluded from the coal, metal, and nonmetal mining industries. These data do not reflect the changes OSHA made to its recordkeeping requirements effective January 1, 2002; therefore estimates for these industries are not comparable to estimates in other industries.

Table MG6. Mining industries (5- and 6-digit NAICS codes) with the highest nonfatal occupational injury incidence rates, 2003

Mining industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Bituminous coal underground mining	212112	35,800	84	3,300
Anthracite mining	212113	600	58	100
Dimension stone mining and quarrying	212311	6,700	53	400

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Table [SNR05](#); the incidence rate of nonfatal occupational injury rates, regardless whether workdays were lost for the mining sector was 31 cases/1000 full-time workers/year. The mining sector (NAICS 21) includes establishments not governed by the Mine Safety and Health Administration (MSHA) rules and reporting, such as those in Oil and Gas Extraction and related support activities. Data for mining operators in coal, metal, and nonmetal mining are provided to BLS by the MSHA, U.S. Department of Labor. Independent mining contractors are excluded from the coal, metal, and nonmetal mining industries. These data do not reflect the changes OSHA made to its recordkeeping requirements effective January 1, 2002; therefore estimates for these industries are not comparable to estimates in other industries.

Table MG7. Mining industries (5- and 6-digit NAICS codes) with the highest incidence rates of nonfatal occupational fractures involving days away from work, 2003

Mining industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Bituminous coal underground mining	212112	35,800	8.64	340
Dimension stone mining and quarrying	212311	6,700	4.36	30
Drilling oil and gas wells	213111	51,500	3.85	230

Numbers of workers were rounded to the nearest 100 workers; numbers of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [SNR10](#), [R1](#), and [R5](#); the incidence rate of nonfatal occupational fractures, regardless whether workdays were lost, for the mining sector was 6.04 cases/1000 full-time workers/year. The mining sector (NAICS 21) includes establishments not governed by the Mine Safety and Health Administration (MSHA) rules and reporting, such as those in Oil and Gas Extraction and related support activities. Data for mining operators in coal, metal, and nonmetal mining are provided to BLS by the MSHA, U.S. Department of Labor. Independent mining contractors are excluded from the coal, metal, and nonmetal mining industries. These data do not reflect the changes OSHA made to its recordkeeping requirements effective January 1, 2002; therefore estimates for these industries are not comparable to estimates in other industries.

Table MG8. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational injuries and illnesses involving days away from work by mining subsectors and industry groups, 2003

Mining subsector and industry group	NAICS code	Multiple traumatic injuries and disorders	Back pain (without a medical diagnosis)	Back pain and non-back pain (without a medical diagnosis)
Oil and gas extraction	211	-	-	180 (1.51)
Mining (except oil and gas)	212	300 (1.33)	40 (0.18)	170 (0.75)
Coal mining	2121	160 (2.04)	20 (0.26)	100 (1.28)
Metal ore mining	2122	-	-	-
Nonmetallic mineral mining and quarrying	2123	130 (1.07)	-	60 (0.49)
Support activities for mining	213	-	60 (0.28)	90 (0.43)
Total for mining sector	21	340 (0.61)	100 (0.18)	440 (0.79)

Numbers of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [R1](#) and [R5](#); highest values are in bold font. The mining sector (NAICS 21) includes establishments not governed by the Mine Safety and Health Administration (MSHA) rules and reporting, such as those in Oil and Gas Extraction and related support activities. Data for mining operators in coal, metal, and nonmetal mining are provided to BLS by the MSHA, U.S. Department of Labor. Independent mining contractors are excluded from the coal, metal, and nonmetal mining industries. These data do not reflect the changes OSHA made to its recordkeeping requirements effective January 1, 2002; therefore estimates for these industries are not comparable to estimates in other industries.

Table MG9. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational illnesses by mining subsectors and industry groups, 2003

Mining subsector and industry group	NAICS code	Skin diseases and disorders	Respiratory conditions	Poisonings	All other illnesses
Oil and gas extraction	211	<15	<15	<15	200 (1.92)
Mining (except oil and gas)	212	<15	100 (0.53)	<15	400 (1.61)
Coal mining	2121	<15	100 (1.35)	<15	200 (2.75)
Metal ore mining	2122	<15	<15	<15	100 (2.30)
Nonmetallic mineral mining and quarrying	2123	<15	<15	<15	100 (0.73)
Support activities for mining	213	<50 (0.18)	<15	<50 (0.10)	100 (0.49)
Total for mining sector	21	<50 (0.08)	100 (0.23)	<50 (0.05)	700 (1.25)

Numbers of cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR10](#) and [SNR08](#); highest values are in bold font. The mining sector (NAICS 21) includes establishments not governed by the Mine Safety and Health Administration (MSHA) rules and reporting, such as those in Oil and Gas Extraction and related support activities. Data for mining operators in coal, metal, and nonmetal mining are provided to BLS by the MSHA, U.S. Department of Labor. Independent mining contractors are excluded from the coal, metal, and nonmetal mining industries. These data do not reflect the changes OSHA made to its recordkeeping requirements effective January 1, 2002; therefore estimates for these industries are not comparable to estimates in other industries.

Table MG10. Mining industries (5- and 6-digit NAICS codes) with the highest incidence rates of nonfatal occupational respiratory conditions, 2003

Mining industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Bituminous coal underground mining	212112	35,800	2.08	100
Bituminous coal and lignite surface mining	212111	32,400	0.63	<50

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR10](#) and [SNR08](#); the incidence rate of nonfatal occupational respiratory conditions, regardless whether workdays were lost, for the mining sector was 0.23 cases/1000 full-time workers/year. The mining sector (NAICS 21) includes establishments not governed by the Mine Safety and Health Administration (MSHA) rules and reporting, such as those in Oil and Gas Extraction and related support activities. Data for mining operators in coal, metal, and nonmetal mining are provided to BLS by the MSHA, U.S. Department of Labor. Independent mining contractors are excluded from the coal, metal, and nonmetal mining industries. These data do not reflect the changes OSHA made to its recordkeeping requirements effective January 1, 2002; therefore estimates for these industries are not comparable to estimates in other industries.

Table MG11. Mining industry (5- and 6-digit NAICS codes) with the highest incidence rate of nonfatal occupational skin diseases and disorders, 2003

Mining industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Drilling oil and gas wells	213111	51,500	0.55	<50

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); the incidence rate of nonfatal occupational skin diseases and disorders, regardless whether workdays were lost, for the mining sector was 0.08 cases/1000 full-time workers/year. The mining sector (NAICS 21) includes establishments not governed by the Mine Safety and Health Administration (MSHA) rules and reporting, such as those in Oil and Gas Extraction and related support activities. Data for mining operators in coal, metal, and nonmetal mining are provided to BLS by the MSHA, U.S. Department of Labor. Independent mining contractors are excluded from the coal, metal, and nonmetal mining industries. These data do not reflect the changes OSHA made to its recordkeeping requirements effective January 1, 2002; therefore estimates for these industries are not comparable to estimates in other industries.

Table MG12. Mining industries (5- and 6-digit NAICS codes) with the highest incidence rates of all other nonfatal occupational illnesses, 2003

Mining industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Bituminous coal underground mining	212112	35,800	3.91	200
Iron ore mining	21221	5,300	3.72	<50
Other nonmetallic mineral mining and quarrying	21239	14,300	2.08	<50

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); the incidence rate of all other nonfatal occupational illnesses, regardless whether workdays were lost, for the mining sector was 1.25 cases/1000 full-time workers/year. The mining sector (NAICS 21) includes establishments not governed by the Mine Safety and Health Administration (MSHA) rules and reporting, such as those in Oil and Gas Extraction and related support activities. Data for mining operators in coal, metal, and nonmetal mining are provided to BLS by the MSHA, U.S. Department of Labor. Independent mining contractors are excluded from the coal, metal, and nonmetal mining industries. These data do not reflect the changes OSHA made to its recordkeeping requirements effective January 1, 2002; therefore estimates for these industries are not comparable to estimates in other industries.

Appendix

Notes on Limitations and Interpretation

One of the limitations of occupational safety and health surveillance data is the underreporting of illnesses, which occurs because: 1) some diseases (e.g., cancer and pneumoconiosis) have long latency periods so that reporting mechanisms, such as OSHA logs, as used by BLS, fail to capture many of these events; 2) many diseases have multiple potential causes (e.g., asthma and cardiovascular diseases); and 3) workers and physicians do not recognize an occupational contribution.

BLS data sources do not allow: characterization of occupationally-related illnesses, if these illnesses are not skin diseases and disorders, respiratory conditions, or poisonings; or quantification of fatalities due to occupationally-related illnesses. Other sources have suggested that the occupational illness fatalities in the US workforce outnumber occupational injury fatalities by about 8:1. For example, using 1997 disease fatality numbers, it was estimated that occupationally-related illness and injury deaths numbered, respectively, 25,910-72,121 (Steenland et al., 2003) and 6,238 (BLS). Estimates of 1997 occupationally-related illness deaths by disease category are as follows: 6,805-26,685 for non-malignant respiratory disease; 12,086-26,244 for occupationally-related cancer deaths; 6,037-18,253 for occupationally-related coronary heart disease; and 328-580 for occupationally-related renal disease (Steenland et al., 2003). Sector-based occupationally-related illness fatality data are not provided in this surveillance data summary.

Other limitations of the data include the following. (1) Only BLS data for a single year (2003) are presented. However, data for a single year may not be representative of the long-term experience and health impacts of a sector due to economic, political, technological, or weather characteristics of that year. (2) Many of the rates are based on small denominators, so that a few additional or a few less cases in the numerator might cause a large fluctuation in the magnitude of the rate estimate. Therefore, what may be quantified as large differences in risk may simply be the result of the “random” occurrence of a few cases. (3) Rates are not adjusted for any potential confounders, the most important of which may be age. Research has shown that younger workers may be at increased risk of injury due to a variety of factors including experience and training. Older workers may be more susceptible to certain occupational illnesses because of pre-existing medical conditions. Therefore what is perceived as a true difference in risk based upon crude rates between two groups may simply be the result of differences in their age distributions. (4) Differences among rates for subsectors and industries of the sector are not tested for statistical significance. Without statistical testing, one cannot conclude that rates are really any different than some of the other rates in the sector.

Discussion of the data focuses on rates, although many of the tables also provide data on the number of workers affected. A subsector or industry which has the highest rate of injuries or illnesses within the sector may have few total workers. Implementing prevention strategies within another subsector or industry within the sector with a high rate of injuries or illnesses and a larger number of workers, may result in a much larger public health impact. If these data are used for planning and priority setting, we suggest

that the number of adverse health outcomes and the number of workers potentially impacted be considered concurrently to identify worker groups towards which research should be directed.

Appendix 6. Surveillance Summary for Services

Services Sectors Fatal and Non-Fatal Injury and Illness Surveillance Information

The following summary of fatality, injury, and illness rates in the Services sectors is provided in order to help identify the most important safety and health problems in this sector. The North American Industry Classification System (NAICS), which was used to designate the NORA sectors, was also used by the Bureau of Labor Statistics (BLS) during the collection of their 2003 data. NAICS codes all economic activities using a six-digit hierarchical coding system with industry sectors, subsectors, industry groups, NAICS international industries, and National industries coded with 2, 3, 4, 5, and 6 digits, respectively.

The following sector-based summary is derived from 2003 BLS Census of Fatal Occupational Injuries (CFOI), and the annual Survey of Occupational Injury and Illness (SOII) (BLS, 2005a; 2005b). BLS non-fatal injury and illness data are based on a survey of 183,700 (of an estimated 7 million) US business establishments and do not include the self-employed, farms with fewer than 11 employees, private households, and governmental agencies. Where possible, references are made to specific BLS tables. In order to encourage internal comparisons, we have converted BLS rates, which are expressed as cases/100 full-time workers/year and cases/10,000 full-time workers/year, to cases/1,000 full-time workers/year.

As with the original BLS tables, the rates reported in our tables cannot be directly calculated from the numbers of cases and numbers of workers provided in our tables. This is because BLS makes post-sampling adjustments of their data and they use the equivalent of full-time workers (not workers) in their rate denominators (BLS, 1997). Using denominators based on person-time rather than numbers of workers results in rates that provide more accurate estimates of actual risk. Full-time workers are defined as working 40 hours per week for 50 weeks. Denominators for non-fatal injury and illness rates are calculated based on work hours data BLS receives from reporting establishments. Denominators for fatal injury rates come from the Current Population Survey.

According to the BLS-Quarterly Census of Employment and Wages (QCEW) program, there were 44,822,300 workers in the services sectors in 2003 ([Table S1](#)). Workers in Accommodation and Food Services, Administrative and Support Services, and Professional, Scientific, and Technical Services comprised 23%, 16%, and 15% of services sectors workforce, respectively.

Table S1. Annual employment numbers by services sectors and subsectors, 2003

Services sector or subsector	NAICS code	Number of workers
Information	51	3,180,800
Finance and Insurance	52	5,782,100
Real Estate and Rental and Leasing	53	2,044,900
Professional, Scientific, and Technical Services	54	6,638,700
Management of Companies and Enterprises	55	1,660,100
Administrative and Support Services	561	7,241,400
Waste Management and Remediation Services	562	318,200
Educational Services	61	2,016,200
Arts, Entertainment, and Recreation	71	1,816,900
Accommodation and Food Services	72	10,345,300
Other Services	81	3,777,700
Total		44,822,300

Numbers were obtained from 2003 BLS Table [SNR10](#); numbers of workers were rounded to the nearest 100 workers and are derived primarily from the BLS-Quarterly Census of Employment and Wages (QCEW) program. These worker numbers differ from full-time worker numbers (see discussion in introduction). QCEW captures only those workers covered by unemployment.

Table S2. Comparison of incidence rates (cases/1000 full-time workers/year) of occupational fatalities, injuries, and illnesses for the services sectors and the U.S. workforce, 2003

Health outcome	Incidence rate for the services sectors*	Incidence rate for the U.S. workforce	Incidence rate ratio	Comment (pertains to the services sectors)	Table reference
Fatal occupational injuries	0.02 †	0.04 §	0.5	Transportation accidents were responsible for the greatest proportion (49%) of fatalities.	S3
Traumatic nonfatal occupational injuries involving days away from work	2.23 to 15.21	13.79	0.2–1.1	Administrative and Waste Services (NAICS 56) and Arts, Entertainment, and Recreation (NAICS 71) sectors had the highest rates.	S4
Total nonfatal occupational injuries	9 to 80	47	0.2–1.7	Waste Management and Remediation Services (NAICS 562) subsector had the highest rate.	S5
Occupational back pain (without a medical diagnosis) involving days away from work	0.11 to 0.62	0.43	0.3–1.4	Waste Management and Remediation Services (NAICS 562) had the highest rate.	S8
Occupational carpal tunnel syndrome cases involving days away from work	0.07 to 0.36	0.25	0.3–1.4	Finance and Insurance (NAICS 52) sector had the highest rate.	S8
Occupational musculoskeletal system and connective tissue diseases and disorders involving days away from work	0.07 to 0.23	0.22	0.3–1.0	Other Services (NAICS 81) sector had the highest rate.	S8
Occupational mental disorders involving days away from work	0.02 to 0.09	0.05	0.4–1.8	Finance and Insurance (NAICS 52) sector had the highest rate.	S8

Table S2 (Continued)

Health outcome	Incidence rate for the services sectors	Incidence rate for the U.S. workforce	Incidence rate ratio	Comment (pertains to the services sectors)	Table reference
Nonfatal occupational skin diseases and disorders	0.04 to 0.96	0.49	0.1–2.0	Arts, Entertainment, and Recreation (NAICS 71) sector had the highest rate.	S11
Nonfatal occupational respiratory conditions	0.06 to 0.23	0.22	0.3–1.0	Waste Management and Remediation Services (NAICS 562) subsector had the highest rate.	S11
Nonfatal occupational poisonings	<0.005 to 0.07	0.04	<0.1–1.8	Arts, Entertainment, and Recreation (NAICS 71) sector had the highest rate.	S11

* Service sector-grouping rates were not available from BLS; what is provided is the range of rates for the component service sectors and the Administrative and Support Services (NAICS 561) and Waste Management and Remediation Services (NAICS 562) service subsectors.

† Fatality data are from BLS Census of Fatal Occupational Injuries (CFOI) special research file. Data exclude information for New York City and are preliminary. Employment data are from BLS Current Population Survey monthly microdata files. Fatality totals include all workers regardless of age. Workers under the age of 16 and active duty military were not included in the rate calculations to maintain consistency with the employment data. Both Public and Private Services were included. Rates were calculated by NIOSH and may differ from previously published BLS CFOI rates.

§ Fatality data are from the BLS Occupational and Safety and Health (OSH)/Census of Fatal Occupational Injuries (CFOI) 2003 Profiles and Charts. Employment data for 2003 are based on estimates derived from BLS Current Population Survey (CPS) monthly microdata files.

Fatal occupational injuries

Transportation accidents accounted for 49% of fatal occupational injuries in the Services sectors (66% of these were due to highway accidents). Assaults and violent acts accounted for 24% of fatal occupational injuries in the Services sectors (76% of these were due to homicides) ([Table S3](#)).

Nonfatal occupational injuries involving days away from work

Sprains and strains were the most frequent nonfatal injury type involving days away from work for all service sectors with sector incidence rates ranging from 0.85 cases/1000 full-time workers/year in the Finance and Insurance (NAICS 52) sector to 15.73 cases/1000 full-time workers/year in the Waste Management and Remediation Services (NAICS 562) subsector ([Table S4](#)). The Waste Collection (NAICS 5621) industry group had the highest incidence rate of amputations involving days away from work with a rate of 0.67 cases/1000 full-time workers/year ([Table S7](#)).

Total nonfatal occupational injuries

Amusement Parks and Arcades (NAICS 7131), Waste Collection (NAICS 5621), and Consumer Electronics and Appliances Rental (NAICS 53221) were the industry groups and industries that had the highest total nonfatal occupational injury rates, ranging from 82 to 108 cases/1000 full-time workers/year ([Table S6](#)).

Nonfatal occupational injuries and illnesses involving days away from work

The highest incidence rate of occupational carpal tunnel syndrome involving days away from work was 1.09 cases/1000 full-time workers/year in the Direct Life, Health, and Medical Insurance Carriers (NAICS 52411) industry ([Table S9](#)). The highest incidence rate of tendonitis involving days away from work was 0.21 cases/1000 full-time workers/year in the Spectator Sports (NAICS 7112) industry group ([Table S10](#)). The incidence rate of musculoskeletal system and connective tissue diseases and disorders involving days away from work was highest in the Other Services (NAICS 81) sector which had an incidence rate of 0.23 cases/1000 full-time workers/year; 28% of these cases were diagnosed as tendonitis (Special Request). The highest incidence rate of back pain (without a medical diagnosis) involving days away from work was 0.91 cases/1000 full-time workers/year in the Waste Treatment and Disposal (NAICS 5622) industry group ([2003 BLS Table R5](#)). Finance and Insurance (NAICS 52) had the highest sector incidence rate of mental illness, with a rate of 0.09 cases/1000 full-time workers/year ([Table S8](#)).

Nonfatal occupational illnesses

The incidence rate of nonfatal occupational skin disease was highest in the Recreational Vehicle Parks and Recreational Camps (NAICS 7212) industry group, which had an incidence rate of 11.82 cases/1000 full-time workers/year ([Table S12](#)).

The incidence rate of nonfatal occupational respiratory conditions was highest in Hotels and Motels (NAICS 72111), Amusement Parks and Arcades (NAICS 7131), and General Rental Centers (NAICS 5323) industry groups and industries, which had incidence rates ranging from 0.48 to 0.57 cases/1000 full-time workers/year ([Table S13](#)).

The incidence rate of nonfatal occupational poisonings was highest in the Lessors of Other Real Estate Property (NAICS 53119) industry, which had an incidence rate of 8.7 cases/1000 full-time workers/year ([Table S14](#)).

The incidence rate of all other nonfatal occupational illnesses was highest in the Satellite Communications (NAICS 5174) industry group, which had an incidence rate of 11.22 cases/1000 full-time workers/year ([Table S15](#)).

Table S3. Number and percent of fatal occupational injuries in the services sectors by event or exposure, 2003

Event or exposure	Number of fatal injuries	Percent of total fatal occupational injuries in the services sectors
Contact with objects and equipment	289	10
Struck by object	191	
Caught in or compressed by equipment or objects	65	
Caught in or crushed in collapsing materials	21	
Falls	234	8
Exposure to harmful substances or environments	192	6
Contact with electric current	74	
Contact with temperature extremes	16	
Exposure to caustic, noxious, or allergenic substances	60	
Oxygen deficiency	39	
Transportation accidents	1,467	49
Highway accident	973	
Nonhighway (farm, industrial premises)	83	
Worker struck by vehicle, mobile equipment	177	
Aircraft accident	170	
Water vehicle	29	
Railway	33	
Assaults and violent acts	734	24
Homicides	556	
Suicides, self-inflicted injury	152	
Assaults by animals	22	
Fires and explosions	85	28
Total for services sectors	3,013	

Totals for major categories may include subcategories not shown separately; 2003 data were specially requested from BLS.

Table S4. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational injuries involving days away from work by services sectors or subsectors, 2003

Services sector or subsector	NAICS code	Sprains, strains	Fractures	Cuts, punctures	Bruises	Amputations	Traumatic injuries
Information	51	9,380 (3.32)	1,610 (0.57)	920 (0.33)	2,290 (0.81)	40 (0.01)	19,680 (6.97)
Finance and Insurance	52	4,540 (0.85)	1,220 (0.23)	410 (0.08)	1,080 (0.20)	-	11,850 (2.23)
Real Estate and Rental and Leasing	53	11,600 (6.79)	1,410 (0.83)	2,190 (1.28)	2,180 (1.28)	60 (0.04)	22,800 (13.35)
Professional, Scientific, and Technical Services	54	8,410 (1.41)	1,710 (0.29)	1,570 (0.26)	2,050 (0.34)	90 (0.02)	19,760 (3.32)
Management of Companies and Enterprises	55	6,850 (4.45)	1,300 (0.84)	780 (0.51)	1,030 (0.67)	150 (0.10)	12,860 (8.35)
Administrative and Support Services	561	22,620 (6.02)	3,390 (0.90)	5,480 (1.46)	5,940 (1.58)	240 (0.06)	62,130 (15.21)
Waste Management and Remediation Services	562	5,110 (15.73)	750 (2.31)	980 (3.02)	920 (2.83)	90 (0.28)	
Educational Services	61	4,950 (3.45)	1,260 (0.88)	490 (0.34)	960 (0.67)	-	10,600 (7.38)
Arts, Entertainment, and Recreation	71	7,930 (6.83)	1,430 (1.23)	1,520 (1.31)	1,780 (1.53)	60 (0.05)	17,110 (14.74)
Accommodation and Food Services	72	31,000 (4.51)	4,960 (0.72)	11,560 (1.68)	10,390 (1.51)	270 (0.04)	82,660 (12.03)
Other Services	81	12,070 (4.08)	2,160 (0.73)	3,420 (1.16)	2,320 (0.78)	170 (0.06)	29,610 (10.01)

Numbers of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [R1](#) and [R5](#); data for traumatic injuries involving days away from work were specially requested of BLS; highest two values are in bold font.

Table S5. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational injuries by services sectors or subsectors, 2003

Services sector or subsector	NAICS code	Total nonfatal occupational injuries	
Information	51	56,200	(20)
Finance and Insurance	52	49,100	(9)
Real Estate and Rental and Leasing	53	64,500	(38)
Professional, Scientific, and Technical Services	54	73,400	(12)
Management of Companies and Enterprises	55	42,300	(27)
Administrative and Support Services	561	128,900	(34)
Waste Management and Remediation Services	562	26,000	(80)
Educational Services	61	37,000	(26)
Arts, Entertainment, and Recreation	71	65,200	(56)
Accommodation and Food Services	72	332,300	(48)
Other Services	81	96,900	(33)

Numbers of cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Table [SNR05](#); highest two values are in bold font.

Table S6A. Services industry groups and industries (4- and 5- digit NAICS codes) with the highest nonfatal occupational injury incidence rates, 2003

Services industry group or industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Amusement parks and arcades	7131	152,900	108	10,700
Waste collection	5621	113,000	97	11,600
Consumer electronics and appliances rental	53221	29,000	82	2,300

Number of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Table [SNR05](#).

Table S6B. Services industry groups (4- digit NAICS codes) with the highest numbers of nonfatal occupational injuries, 2003

Services industry group or industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Full-service restaurants	7221	4,072,100	44	116,600
Limited-service eating places	7222	3,612,200	48	109,900
Traveler accommodation	7211	1,705,900	64	81,900

Number of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Table [SNR05](#).

Table S7. Services industry groups and industries (4- and 5-digit NAICS codes) with the highest nonfatal occupational amputation incidence rates involving days away from work, 2003

Services industry group or industry	NAICS Code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Waste collection	5621	113,000	0.67	80
Employment services	5613	3,227,300	0.26	140
Other amusement and recreation industries	7139	1,034,500	0.10	60
Drycleaning and laundry services	8123	355,700	0.10	30

Numbers of workers were rounded to the nearest 100 workers; numbers of cases were rounded off to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [SNR10](#), [R1](#), and [R5](#).

Table S8. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational injuries and illnesses involving days away from work by services sector or subsector, 2003

Services sector or subsector	NAICS code	Carpal tunnel syndrome	Tendonitis	Back pain (without a medical diagnosis)	Occupational musculoskeletal system and connective tissue diseases and disorders	Mental disorders
Information	51	580 (0.21)	160 (0.06)	500 (0.18)	330 (0.12)	100 (0.04)
Finance and Insurance	52	1,910 (0.36)	310 (0.06)	560 (0.11)	690 (0.13)	470 (0.09)
Real Estate and Rental and Leasing	53	260 (0.15)	-	580 (0.34)	150 (0.09)	80 (0.05)
Professional, Scientific, and Technical Services	54	1,570 (0.26)	200 (0.03)	760 (0.13)	420 (0.07)	90 (0.02)
Management of Companies and Enterprises	55	290 (0.19)	70 (0.05)	390 (0.25)	260 (0.17)	60 (0.04)
Administrative and Support Services	561	450 (0.12)	200 (0.05)	1,380 (0.37)	670 (0.16)	90 (0.02)
Waste Management and Remediation Services	562	80 (0.25)	-	200 (0.62)		
Educational Services	61	100 (0.07)	60 (0.04)	280 (0.19)	100 (0.07)	60 (0.04)
Arts, Entertainment, and Recreation	71	110 (0.09)	100 (0.09)	570 (0.49)	230 (0.20)	-
Accommodation and Food Services	72	770 (0.11)	320 (0.05)	2,390 (0.35)	730 (0.11)	470 (0.07)
Other Services	81	680 (0.23)	190 (0.06)	750 (0.25)	670 (0.23)	100 (0.03)

Numbers of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [R1](#) and [R5](#); data for musculoskeletal system and connective tissue diseases and disorders and mental disorders were specially requested from BLS; highest two values are in bold font.

Table S9. Services industry groups and industries (4- and 5-digit NAICS codes) with the highest incidence rates of occupational carpal tunnel syndrome involving days away from work, 2003

Services industry group or industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Direct life, health, and medical insurance carriers	52411	661,000	1.09	670
Legal services	5411	1,146,200	0.62	630
Direct insurance (except life, health, and medical carriers)	52412	607,300	0.56	310

Numbers of workers were rounded to the nearest 100 workers; numbers of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [SNR10](#), [R1](#), and [R5](#); the incidence rates of occupational carpal tunnel syndrome involving days away from work for the entire U.S. workforce was 0.25 cases/1000 full-time workers/year.

Table S10. Services industry groups and industries (4- and 5-digit NAICS codes) with the highest incidence rates of occupational tendonitis involving days away from work, 2003

Services industry group or industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Spectator sports	7112	131,000	0.21	20
Direct life, health, and medical insurance carriers	52411	661,000	0.20	120
Newspaper, periodical, book, and directory publishers	5111	692,200	0.15	900

Numbers of workers were rounded to the nearest 100 workers; numbers of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [SNR10](#), [R1](#), and [R5](#); the incidence rates of occupational tendonitis involving days away from work for the entire U.S. workforce was 0.09 cases/1000 full-time workers/year.

Table S11. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational illnesses by services sector or subsector, 2003

Services sector or subsector	NAICS code	Skin diseases and disorders	Respiratory conditions	Poisonings	All other illnesses
Information	51	400 (0.14)	200 (0.06)	100 (0.02)	4,300 (1.54)
Finance and Insurance	52	200 (0.04)	500 (0.09)	<50 (<0.005)	6,100 (1.16)
Real Estate and Rental and Leasing	53	600 (0.33)	300 (0.17)	100 (0.06)	1,100 (0.63)
Professional, Scientific, and Technical Services	54	1,300 (0.22)	600 (0.10)	200 (0.03)	3,900 (0.65)
Management of Companies and Enterprises	55	200 (0.11)	200 (0.10)	<50 (0.02)	2,800 (1.82)
Administrative and Support Services	561	-	-	<50 (0.01)	4,500 (1.19)
Waste Management and Remediation Services	562	100 (0.42)	100 (0.23)	<15	600 (1.85)
Educational Services	61	700 (0.48)	300 (0.18)	<50 (0.02)	1,000 (0.71)
Arts, Entertainment, and Recreation	71	1,100 (0.96)	200 (0.21)	100 (0.07)	2,000 (1.71)
Accommodation and Food Services	72	3,300 (0.48)	1,100 (0.16)	200 (0.02)	5,500 (0.80)
Other Services	81	1,200 (0.39)	300 (0.10)	100 (0.03)	2,200 (0.73)

Numbers of cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR10](#) and [SNR08](#); highest two values are in bold font.

Table S12. Services industry group and industries (4- and 5-digit NAICS codes) with the highest incidence rates of nonfatal occupational skin diseases and disorders, 2003

Services industry group or industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Recreational vehicle parks and recreational camps	7212	50,500	11.82	400
Amusement parks and arcades	7131	152,900	3.30	300
Surveying and mapping	54137	58,300	2.86	200

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); the incidence rate of nonfatal occupational skin diseases and disorders, regardless whether workdays were lost, for the entire U.S. workforce was 0.49 cases/1000 full-time workers/year.

Table S13. Services industry groups and industries (4- and 5-digit NAICS codes) with the highest incidence rates of nonfatal occupational respiratory conditions, 2003

Services industry group or industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Hotels and motels	72111	1,402,400	0.57	600
Amusement parks and arcades	7131	152,900	0.55	100
General rental centers	5323	61,600	0.48	<50

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); the incidence rates of occupational respiratory conditions, regardless whether workdays were lost, for the entire U.S. workforce was 0.22 cases/1000 full-time workers/year.

Table S14. Services industry group and industries (4- and 5-digit NAICS codes) with the highest incidence rates of nonfatal occupational poisonings, 2003

Services industry group or industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Lessors of other real estate property	53119	42,4000	8.7	<50
Other commercial and industrial machinery and equipment rental and leasing	53249	37,300	4.5	<50
Real estate managers	53131	393,800	1.4	<50

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); the incidence rate of nonfatal occupational poisonings, regardless whether workdays were lost, for the entire U.S. workforce was 0.04 cases/1000 full-time workers/year.

Table S15. Services industry group and industries (4- and 5-digit NAICS codes) with the highest incidence rates of all other nonfatal occupational illnesses, 2003

Services industry group or industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Satellite communications	5174	17,200	11.22	200
All other waste management services	56299	28,800	7.44	200
Other publishers	51119	31,800	5.29	100

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); the incidence rate of all other occupational illnesses, regardless whether workdays were lost, for the entire U.S. workforce was 2.32 cases/1000 full-time workers/year.

Appendix

Notes on Limitations and Interpretation

One of the limitations of occupational safety and health surveillance data is the underreporting of illnesses, which occurs because: 1) some diseases (e.g., cancer and pneumoconiosis) have long latency periods so that reporting mechanisms, such as OSHA logs, as used by BLS, fail to capture many of these events; 2) many diseases have multiple potential causes (e.g., asthma and cardiovascular diseases); and 3) workers and physicians do not recognize an occupational contribution.

BLS data sources do not allow: characterization of occupationally-related illnesses, if these illnesses are not skin diseases and disorders, respiratory conditions, or poisonings; or quantification of fatalities due to occupationally-related illnesses. Other sources have suggested that the occupational illness fatalities in the US workforce outnumber occupational injury fatalities by about 8:1. For example, using 1997 disease fatality numbers, it was estimated that occupationally-related illness and injury deaths numbered, respectively, 25,910-72,121 (Steenland et al., 2003) and 6,238 (BLS). Estimates of 1997 occupationally-related illness deaths by disease category are as follows: 6,805-26,685 for non-malignant respiratory disease; 12,086-26,244 for occupationally-related cancer deaths; 6,037-18,253 for occupationally-related coronary heart disease; and 328-580 for occupationally-related renal disease (Steenland et al., 2003). Sector-based occupationally-related illness fatality data are not provided in this surveillance data summary.

Other limitations of the data include the following. (1) Only BLS data for a single year (2003) are presented. However, data for a single year may not be representative of the long-term experience and health impacts of a sector due to economic, political, technological, or weather characteristics of that year. (2) Many of the rates are based on small denominators, so that a few additional or a few less cases in the numerator might cause a large fluctuation in the magnitude of the rate estimate. Therefore, what may be quantified as large differences in risk may simply be the result of the “random” occurrence of a few cases. (3) Rates are not adjusted for any potential confounders, the most important of which may be age. Research has shown that younger workers may be at increased risk of injury due to a variety of factors including experience and training. Older workers may be more susceptible to certain occupational illnesses because of pre-existing medical conditions. Therefore what is perceived as a true difference in risk based upon crude rates between two groups may simply be the result of differences in their age distributions. (4) Differences among rates for subsectors and industries of the sector are not tested for statistical significance. Without statistical testing, one cannot conclude that rates are really any different than some of the other rates in the sector.

Discussion of the data focuses on rates, although many of the tables also provide data on the number of workers affected. A subsector or industry which has the highest rate of injuries or illnesses within the sector may have few total workers. Implementing prevention strategies within another subsector or industry within the sector with a high rate of injuries or illnesses and a larger number of workers, may result in a much larger public health impact. If these data are used for planning and priority setting, we suggest

that the number of adverse health outcomes and the number of workers potentially impacted be considered concurrently to identify worker groups towards which research should be directed.

Appendix 7. Surveillance Summary for Transportation, Warehousing and Utilities

Transportation, Warehousing, and Utilities Sectors Fatal and Non-Fatal Injury and Illness Surveillance Information

The following summary of fatality, injury, and illness rates in the Transportation, Warehousing, and Utilities sectors is provided in order to help identify the most important safety and health problems in this sector. The North American Industry Classification System (NAICS), which was used to designate the NORA sectors, was also used by the Bureau of Labor Statistics (BLS) during the collection of their 2003 data. NAICS codes all economic activities using a six-digit hierarchical coding system with industry sectors, subsectors, industry groups, NAICS international industries, and National industries coded with 2, 3, 4, 5, and 6 digits, respectively.

The following sector-based summary is derived from 2003 BLS Census of Fatal Occupational Injuries (CFOI), and the annual Survey of Occupational Injury and Illness (SOII) ([BLS, 2005a](#); [BLS, 2005b](#)). BLS non-fatal injury and illness data are based on a survey of 183,700 (of an estimated 7 million) US business establishments and do not include the self-employed, farms with fewer than 11 employees, private households, and governmental agencies. Where possible, references are made to specific BLS tables. In order to encourage internal comparisons, we have converted BLS rates, which are expressed as cases/100 full-time workers/year and cases/10,000 full-time workers/year, to cases/1,000 full-time workers/year.

As with the original BLS tables, the rates reported in our tables cannot be directly calculated from the numbers of cases and numbers of workers provided in our tables. This is because BLS makes post-sampling adjustments of their data and they use the equivalent of full-time workers (not workers) in their rate denominators ([BLS, 1997](#)). Using denominators based on person-time rather than numbers of workers results in rates that provide more accurate estimates of actual risk. Full-time workers are defined as working 40 hours per week for 50 weeks. Denominators for non-fatal injury and illness rates are calculated based on work hours data BLS receives from reporting establishments. Denominators for fatal injury rates come from the Current Population Survey.

According to the BLS-Quarterly Census of Employment and Wages (QCEW) program, there were 3,946,200 workers in the Transportation and Warehousing sectors and 575,900 workers in the Utilities sector in 2003 ([Table TR1](#)). Workers in Truck Transportation comprised 33% of the combined Transportation/Warehousing workforce.

Table TR1. Annual employment numbers by transportation, warehousing, and utilities subsectors, 2003

Transportation, warehousing, and utilities subsector	NAICS code	Number of workers
Air transportation	481	527,000
Rail transportation†	482	-
Water transportation	483	53,100
Truck transportation	484	1,322,400
Transit and ground passenger transportation	485	375,400
Pipeline transportation	486	40,300
Scenic and sightseeing transportation	487	26,700
Support activities for transportation	488	513,200
Couriers and messengers	492	565,100
Warehousing and storage	493	519,600
Total for Transportation and Warehousing†	48, 49	3,946,200
Utilities	22	575,900

† Data for employers in railroad transportation are provided to BLS by the Federal Railroad Administration. These data do not reflect the changes the Occupational Safety and Health Administration made to its recordkeeping requirements effective January 1, 2002; therefore estimates for these industries are not comparable to estimates in other industries.

Numbers were obtained from [2003 BLS Table SNR10](#); numbers of workers were rounded to the nearest 100 workers and are derived primarily from the BLS-Quarterly Census of Employment and Wages (QCEW) program. These worker numbers differ from full-time worker numbers (see discussion in introduction). QCEW captures only those workers covered by unemployment, which may impact the number of workers in the Truck transportation sector.

Table TR2. Comparison of incidence rates (cases/1000 full-time workers/year) of occupational fatalities, injuries, and illnesses for the transportation, warehousing, and utilities sectors and the U.S. workforce, 2003

Health outcome	Incidence rate (and incidence rate ratio) for the transportation and warehousing sectors	Incidence rate (and incidence rate ratio) for the utilities sector	Incidence rate for the U.S. workforce	Comment (pertains to the transportation, warehousing, and utilities sectors)	Reference
Fatal occupational injuries	0.12* (3.0)		0.04†	75% of fatal occupational injuries were due to transportation accidents.	TR3
Traumatic nonfatal occupational injuries involving days away from work	33.49 (2.4)	11.11 (0.8)	13.79	52% and 57% of these cases were due to trauma to muscles, tendons, ligaments, and joints for the Transportation and Warehousing sectors and the Utilities sector, respectively.	Special Request
Total nonfatal occupational injuries	74 (1.6)	40 (0.9)	47	These rates were 2.2 and 3.6-fold larger than the incidence rates of traumatic injuries involving days away from work for the Transportation and Warehousing sectors and the Utilities sector, respectively.	TR5
Occupational back pain symptom (without a medical diagnosis) involving days away from work	1.27 (3.0)	0.20 (0.5)	0.43	The subsector with the highest incidence rate was Couriers and Messengers (NAICS 492), which had an incidence rate of 4.88/1000 full-time workers/year.	TR8
Occupational hernia involving days away from work	0.59 (2.3)	0.13 (0.5)	0.26	This includes inguinal and ventral hernias.	Special Request

Table TR2. (Continued)

Health outcome	Incidence rate (and incidence rate ratio) for the transportation and warehousing sectors	Incidence rate (and incidence rate ratio) for the utilities sector	Incidence rate for the U.S. workforce	Comment (pertains to the transportation, warehousing, and utilities sectors)	Reference
Occupational carpal tunnel syndrome involving days away from work	0.27 (1.1)	0.14 (0.6)	0.25	The highest rate was in the Couriers and Messengers (NAICS 492) subsector.	Special Request
Occupational musculoskeletal and connective tissue diseases and disorders syndrome cases involving days away from work	0.31 (1.4)	0.13 (0.6)	0.22	Within the Transportation and Warehousing sectors, most cases were due to rheumatism (non-back).	Special Request
Nonfatal occupational skin diseases and disorders	-	0.74 (1.5)	0.49	The industry group with the highest incidence rate was Water Sewage and Other Systems (NAICS 2213), which had a rate that was about 3-fold larger than the Utilities sector average.	TR10 , TR11
Nonfatal occupational respiratory conditions	0.22 (1.0)	0.22 (1.0)	0.22	The subsector with the highest incidence rate was Transit and Ground Passenger Transportation (NAICS 485), which had an incidence rate about 2.5-fold larger than the Transportation and Warehousing sectors average.	TR10

Table TR2. (Continued)

Health outcome	Incidence rate (and incidence rate ratio) for the transportation and warehousing sectors	Incidence rate (and incidence rate ratio) for the utilities sector	Incidence rate for the U.S. workforce	Comment (pertains to the transportation, warehousing, and utilities sectors)	Reference
Nonfatal occupational poisonings	0.06 (1.5)	0.04 (1.0)	0.04	The subsector with the highest incidence rate was Couriers and Messengers (NAICS 492).	TR10
All other nonfatal occupational illnesses	2.76 (1.2)	3.17 (1.4)	2.32	The subsector with the highest incidence rate was Air Transportation (NAICS 481).	TR10

*Fatality data are from BLS Census of Fatal Occupational Injuries (CFOI) special research file. Data exclude information for New York City and are preliminary. Employment data are from BLS Current Population Survey monthly microdata files. Fatality totals include all workers regardless of age. Workers under the age of 16 and active duty military were not included in the rate calculations to maintain consistency with the employment data. Rates were calculated by NIOSH and may differ from previously published BLS CFOI rates.

† Fatality data are from the BLS Occupational and Safety and Health (OSH)/Census of Fatal Occupational Injuries (CFOI) Profiles and Charts. Employment data for 2003 are based on estimates derived from BLS Current Population Survey (CPS) monthly microdata files.

Fatal occupational injuries

Transportation accidents accounted for 75% of fatal occupational injuries in the Transportation, Warehousing, and Utilities sectors (69% of these were due to highway accidents) ([Table TR3](#)).

Nonfatal occupational injuries involving days away from work

Sprains and strains were the most frequent nonfatal injury type involving days away from work. Within the Transportation and Warehousing sectors, the incidence rate of sprains and strains was 17.32 cases/1000 full-time workers/year ([Table TR4](#)). However, the Couriers and Messengers (NAICS 492) subsector had an incidence rate of 23.42 cases/1000 full-time workers/year. The incidence rate of amputations involving days away from work was highest in the Local General Freight Trucking (NAICS 48411) industry, which had an incidence rate of 0.44 cases/1000 full-time workers/year.

Total nonfatal occupational injuries

The subsectors with the highest incidence rates of total nonfatal occupational injuries were Couriers and Messengers (NAICS 492) and Air Transportation (NAICS 481) ([Table TR5](#)). The incidence rates of total nonfatal occupational injuries were highest in Refrigerated Warehousing and Storage (NAICS 49312), Couriers (NAICS 4921), and Scheduled Air Transportation (NAICS 4811) industry groups and industries, which had incidence rates 47% to 73% higher than the Transportation and Warehousing sectors average ([Table TR6A](#)).

Within the Transportation and Warehousing sectors and the Utilities sector the incidence rates of traumatic occupational injuries involving days away from work were 33.49 and 11.11 cases/1000 full-time workers/year (Special Request) compared to 74 and 40 cases of total nonfatal occupational injuries/1000 full-time workers/year ([Table TR5](#)), respectively. This suggests that the total injury rates were 2.2 and 3.6 fold larger than the injury rates involving days away from work for these sectors, respectively.

Nonfatal occupational injuries and illnesses involving days away from work

The subsector with the highest incidence rates of occupational carpal tunnel syndrome and tendonitis involving days away from work was Warehousing and Storage (NAICS 493), which had incidence rates of 0.42 and 0.34 cases/1000 full-time workers/year, respectively ([Table TR8](#)). The industry with the highest incidence rate of occupational carpal tunnel syndrome involving days away from work was the Long Distance Specialized Freight (except used goods) Trucking (NAICS 48423) industry, which had an incidence rate of 1.13 cases/1000 full-time workers/year, approximately 4 times larger than the Transportation and Warehousing sectors average ([Table TR9](#)).

Within the Transportation and Warehousing sectors, the incidence rate of the symptom of back pain (without a medical diagnosis) involving days away from work was 1.27 cases/1000 full-time workers/year ([Table TR8](#)). This incidence rate was highest in the

Couriers and Messengers (NAICS 492) subsector. The incidence rate of hernia (including inguinal and ventral hernias) involving days away from work for the Transportation and Warehousing sectors was 0.59 cases/1000 full-time workers/year.

Nonfatal occupational illnesses

The incidence rate of nonfatal occupational skin diseases and disorders was highest in the Water Sewage and Other Systems (NAICS 2213) industry group, which had an incidence rate of 2.03 cases/1000 full-time workers/year ([Table TR11](#)).

The incidence rate of nonfatal occupational respiratory conditions was highest in the Urban Transit System (NAICS 4851) industry group, which had an incidence rate of 2.83 cases/1000 full-time workers/year ([Table TR12](#)).

Table TR3. Number and percent of fatal occupational injuries in the transportation, warehousing, and utilities sectors by event or exposure, 2003

Event or exposure	Number of fatal injuries	Percent of total fatal occupational injuries in the transportation, warehousing, and utilities sectors
Contact with objects and equipment	64	7
Struck by object	44	
Caught in or compressed by equipment or objects	14	
Caught in or crushed in collapsing materials	4	
Falls	28	3
Exposure to harmful substances or environments	31	3
Transportation accidents	658	75
Highway accident	452	
Non-highway accident (farm, industrial premises)	19	
Worker struck by vehicle, mobile equipment	82	
Aircraft accident	63	
Water vehicle	20	
Railway	22	
Fires and explosions	12	1
Assaults and violent acts	82	9
Homicides	62	
Suicides, self-inflicted injuries	17	
Total	877	

Totals for major categories may include subcategories not shown separately; 2003 data were specially requested from BLS.

Table TR4. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational injuries involving days away from work by transportation, warehousing, and utilities subsectors, for 2003

Transportation, warehousing, and utilities subsector	NAICS code	Sprains, strains	Fractures	Cuts, punctures	Bruises	Amputations
Air transportation	481	16,060 (37.12)	670 (1.55)	750 (1.73)	2,710 (6.26)	80 (0.18)
Rail transportation†	482	2,440 (10.86)	420 (1.87)	290 (1.29)	660 (2.94)	30 (0.13)
Water transportation	483	-	-	-	-	-
Truck transportation	484	21,460 (15.70)	4,750 (3.47)	1,950 (1.43)	4,400 (3.22)	380 (0.28)
Transit and ground passenger transportation	485	3,870 (13.80)	360 (1.28)	180 (0.64)	570 (2.03)	-
Pipeline transportation	486	100 (2.53)	-	-	-	-
Scenic and sightseeing transportation	487	120 (6.79)	-	100 (5.66)	-	-
Support activities for transportation	488	4,650 (9.74)	800 (1.67)	760 (1.59)	1,670 (3.50)	40 (0.08)
Couriers and messengers	492	10,080 (23.42)	1,010 (2.35)	720 (1.67)	2,010 (4.67)	20 (0.05)
Warehousing and storage	493	6,630 (13.93)	1,010 (2.12)	970 (2.04)	1,400 (2.94)	40 (0.08)
Total for Transportation and Warehousing†	48, 49	65,920 (17.32)	9,120 (2.40)	5,770 (1.52)	13,520 (3.55)	600 (0.16)
Utilities	22	3,520 (6.32)	480 (0.86)	240 (0.43)	480 (0.86)	-

† data for railroad transportation was provided to BLS by the Federal Railroad Administration of the US Department of Transportation, therefore estimates for this industry are not comparable to estimates in other industries; number of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [R1](#) and [R5](#); highest two values are in bold font.

Table TR5. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational injuries by transportation, warehousing, and utilities subsectors, 2003

Transportation, warehousing, and utilities subsector	NAICS code	Total nonfatal occupational injuries	
Air transportation	481	44,600	(103)
Rail transportation†	482	6,400	(28)
Water transportation	483	-	
Truck transportation	484	91,400	(67)
Transit and ground passenger transportation	485	17,500	(62)
Pipeline transportation	486	700	(17)

Couriers and messengers	492	100 (0.15)	100 (0.21)	<50 (0.09)	2,500 (5.85)
Warehousing and storage	493	300 (0.57)	100 (0.31)	<15	-
Total for Transportation and Warehousing*	48, 49	-	800 (0.22)	200 (0.06)	10,500 (2.76)
Utilities	22	400 (0.74)	100 (0.22)	<50 (0.04)	1,800 (3.17)

* Data for railroad transportation were provided to BLS by the Federal Railroad Administration of the US Department of Transportation, therefore estimates for this industry are not comparable to estimates in other industries; numbers of cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); highest two values are in bold font.

Table TR11. Transportation, warehousing, and utilities industries (5- and 6-digit NAICS codes) with the highest incidence rates of nonfatal occupational skin diseases and disorders, 2003

Transportation, warehousing, and utilities industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Water sewage and other systems	2213	47,000	2.03	100
Support activities for water transportation	4883	92,700	1.24	100
Specialized freight (except used goods) trucking, long-distance	48423	101,900	1.10	100

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); the incidence rate of nonfatal occupational skin diseases and disorders, regardless whether workdays were lost, for the entire U.S. workforce was 0.49 cases/1000 full-time workers/year.

Table TR12. Transportation, warehousing, and utilities industry groups and industries (4-, 5-, and 6-digit NAICS codes) with the highest incidence rates of nonfatal occupational respiratory conditions, 2003

Transportation, warehousing, and utilities industry group or industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Urban transit system	4851	36,800	2.83	100
Water supply and irrigation systems	22131	36,500	1.33	<50
Motor vehicle towing	48841	44,100	0.55	<50

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); the incidence rates of nonfatal occupational respiratory conditions, regardless whether workdays were lost, for the transportation and warehousing sectors and the entire U.S. workforce were 0.22 and 0.22 cases/1000 full-time workers/year, respectively.

Appendix

Notes on Limitations and Interpretations

One of the limitations of occupational safety and health surveillance data is the underreporting of illnesses, which occurs because: 1) some diseases (e.g., cancer and pneumoconiosis) have long latency periods so that reporting mechanisms, such as OSHA logs, as used by BLS, fail to capture many of these events; 2) many diseases have multiple potential causes (e.g., asthma and cardiovascular diseases); and 3) workers and physicians do not recognize an occupational contribution.

BLS data sources do not allow: characterization of occupationally-related illnesses, if these illnesses are not skin diseases and disorders, respiratory conditions, or poisonings; or quantification of fatalities due to occupationally-related illnesses. Other sources have suggested that the occupational illness fatalities in the US workforce outnumber occupational injury fatalities by about 8:1. For example, using 1997 disease fatality numbers, it was estimated that occupationally-related illness and injury deaths numbered, respectively, 25,910-72,121 (Steenland et al., 2003) and 6,238 (BLS). Estimates of 1997 occupationally-related illness deaths by disease category are as follows: 6,805-26,685 for non-malignant respiratory disease; 12,086-26,244 for occupationally-related cancer deaths; 6,037-18,253 for occupationally-related coronary heart disease; and 328-580 for occupationally-related renal disease (Steenland et al., 2003). Sector-based occupationally-related illness fatality data are not provided in this surveillance data summary.

Other limitations of the data include the following. (1) Only BLS data for a single year (2003), are presented. However, data for a single year may not be representative of the long-term experience and health impacts of a sector due to economic, political, technological, or weather characteristics of that year. (2) Many of the rates are based on small denominators, so that a few additional or a few less cases in the numerator might cause a large fluctuation in the magnitude of the rate estimate. Therefore, what may be quantified as large differences in risk may simply be the result of the “random” occurrence of a few cases. (3) Rates are not adjusted for any potential confounders, the most important of which may be age. Research has shown that younger workers may be at increased risk of injury due to a variety of factors including experience and training. Older workers may be more susceptible to certain occupational illnesses because of pre-existing medical conditions. Therefore what is perceived as a true difference in risk based upon crude rates between two groups may simply be the result of differences in their age distributions. (4) Differences among rates for subsectors and industries of the sector are not tested for statistical significance. Without statistical testing, one cannot conclude that rates are really any different than some of the other rates in the sector.

Discussion of the data focuses on rates, although many of the tables also provide data on number of workers affected. A subsector or industry which has the highest rate of injuries or illnesses within the sector may have few total workers. Implementing prevention strategies within another subsector or industry within the sector with a high rate of injuries or illnesses and a larger number of workers, may result in a much larger public health impact. If these data are used for planning and priority setting, we suggest

that the number of adverse health outcomes and the number of workers potentially impacted be considered concurrently to identify worker groups towards which research should be directed.

Appendix 8. Surveillance Summary for Wholesale and Retail Trade

Wholesale and Retail Trade Sectors Fatal and Non-Fatal Injury and Illness Surveillance Information

The following summary of fatality, injury, and illness rates in the Wholesale and Retail Trade sectors is provided in order to help identify the most important safety and health problems in this sector. The North American Industry Classification System (NAICS), which was used to designate the NORA sectors, was also used by the Bureau of Labor Statistics (BLS) during the collection of their 2003 data. NAICS codes all economic activities using a six-digit hierarchical coding system with industry sectors, subsectors, industry groups, NAICS international industries, and National industries coded with 2, 3, 4, 5, and 6 digits, respectively.

The following sector-based summary is derived from 2003 BLS Census of Fatal Occupational Injuries (CFOI), and the annual Survey of Occupational Injury and Illness (SOII) (BLS, 2005a; BLS, 2005b). BLS non-fatal injury and illness data are based on a survey of 183,700 (of an estimated 7 million) US business establishments and do not include the self-employed, farms with fewer than 11 employees, private households, and governmental agencies. Where possible, references are made to specific BLS tables. In order to encourage internal comparisons, we have converted BLS rates, which are expressed as cases/100 full-time workers/year and cases/10,000 full-time workers/year, to cases/1,000 full-time workers/year.

As with the original BLS tables, the rates reported in our tables cannot be directly calculated from the numbers of cases and numbers of workers provided in our tables. This is because BLS makes post-sampling adjustments of their data and they use the equivalent of full-time workers (not workers) in their rate denominators (BLS, 1997). Using denominators based on person-time rather than numbers of workers results in rates that provide more accurate estimates of actual risk. Full-time workers are defined as working 40 hours per week for 50 weeks. Denominators for non-fatal injury and illness rates are calculated based on work hours data BLS receives from reporting establishments. Denominators for fatal injury rates come from the Current Population Survey.

According to the BLS-Quarterly Census of Employment and Wages (QCEW) program there were 20,519,800 workers in the wholesale and retail trade sectors in 2003 ([Table T1](#)). Workers in wholesale trade and retail trade comprised 27% and 73% of the workforce for the combined trade sectors, respectively.

Table T1. Annual employment numbers by wholesale and retail grade subsectors, for 2003

Wholesale and retail trade subsector	NAICS code	Number of workers
Merchant wholesalers, durable goods	423	2,929,200
Merchant wholesalers, nondurable goods	424	1,998,400
Wholesale electronic markets and agents and brokers	425	661,400
Total for wholesale trade sector	42	5,589,000
Motor vehicle and parts dealers	441	1,878,800
Furniture and home furnishings	442	547,700
Electronics and appliance stores	443	517,600
Building material and garden equipment and supplies dealers	444	1,190,600
Food and beverage stores	445	2,842,400
Health and personal care stores	446	935,800
Gasoline stations	447	879,200
Clothing and clothing accessories stores	448	1,309,200
Sporting goods, hobby, book, and music stores	451	655,300
General merchandise stores	452	2,813,400
Miscellaneous store retailers	453	937,500
Nonstore retailers	454	423,400
Total for retail trade sectors	44, 45	14,930,800

Numbers were obtained from [2003 BLS Table SNR10](#); numbers of workers were rounded off to the nearest 100 workers and are derived primarily from the BLS-Quarterly Census of Employment and Wages (QCEW) program. These worker numbers differ from full-time worker numbers (see discussion in introduction). QCEW captures only those workers covered by unemployment.

Table T2. Comparison of incidence rates (cases/1000 full-time workers/year) of occupational fatalities, injuries, and illnesses for the wholesale and retail trade sectors and the U.S. workforce, 2003

Health outcome	Incidence rate (and incidence rate ratio) for the wholesale trade sector	Incidence rate (and incidence rate ratio) for the retail trade sectors	Incidence rate for the U.S. workforce	Comment (pertains to the wholesale and retail trade sectors)	Table reference
Fatal occupational injuries	0.03* (0.8)		0.04†	Most fatal occupational injuries were due to assaults and violent acts and transportation accidents.	T3
Traumatic nonfatal occupational injuries involving days away from work	13.97 (1.0)	14.43 (1.0)	13.79	49% of these cases were due to trauma to muscles, tendons, ligaments, and joints for both the Wholesale Trade and Retail Trade sectors.	Special Request
Occupational back pain (without a medical diagnosis) involving days away from work	0.52 (1.2)	0.41 (1.0)	0.43	This incidence rate was highest in Nondurable Goods Merchant Wholesalers (NAICS 424) within Wholesale Trade; and in General Merchandise Stores (NAICS 452) within Retail Trade.	T8
Occupational hernia involving days away from work	0.36 (1.4)	0.31 (1.2)	0.26	This includes inguinal and ventral hernias.	Special Request
Total nonfatal occupational injuries	45 (1.0)	51 (1.1)	47	These rates were 3.2- and 3.5-fold larger than the incidence rates of traumatic injuries involving days away from work for the Wholesale Trade and Retail Trade sectors, respectively.	T5 and Special Request

Table T2. (Continued)

Health outcome	Incidence rate (and incidence rate ratio) for the wholesale trade sector	Incidence rate (and incidence rate ratio) for the retail trade sector	Incidence rate for the U.S. workforce	Comment (pertains to the wholesale and retail trade sectors)	Table reference
Occupational musculoskeletal system and connective tissues diseases and disorders cases involving days away from work	0.16 (0.7)	0.19 (0.9)	0.22	35% and 73% of these cases were diagnosed with tendonitis in the Wholesale and Retail trade sectors, respectively.	Special Request
Occupational carpal tunnel syndrome cases involving days away from work	0.19 (0.8)	0.22 (0.9)	0.25		Special Request
Nonfatal occupational skin diseases and disorders	0.31 (0.6)	0.31 (0.6)	0.49	This incidence rate was highest in Nondurable Goods Merchant Wholesalers (NAICS 424) within Wholesale Trade; and in Building Material and Garden Equipment and Supplies Dealers (NAICS 444) within Retail Trade.	T12
Nonfatal occupational respiratory conditions	0.14 (0.6)	0.10 (0.5)	0.22	This incidence rate was highest in Durable Goods Merchant Wholesalers (NAICS 423) within Wholesale Trade; and in General Merchandise Stores (NAICS 452) within Retail Trade.	T12

Table T2. (Continued)

Health outcome	Incidence rate (and incidence rate ratio) for the wholesale trade sector	Incidence rate (and incidence rate ratio) for the retail trade sector	Incidence rate for the U.S. workforce	Comment (pertains to the wholesale and retail trade sectors)	Table reference
Nonfatal occupational poisonings	0.03 (0.8)	0.05 (1.3)	0.04	This rate was highest in Building Material and Garden Equipment and Supplies Dealers (NAICS 444).	T12
All other nonfatal occupational illnesses	1.01 (0.4)	1.21 (0.5)	2.32	This rate was highest in Nonstore Retailers (NAICS 454).	T12

* Fatality data are from BLS Census of Fatal Occupational Injuries (CFOI) special research file. Data exclude information for New York City and are preliminary. Employment data are from BLS Current Population Survey monthly microdata files. Fatality totals include all workers regardless of age. Workers under the age of 16 and active duty military were not included in the rate calculations to maintain consistency with the employment data. Rates were calculated by NIOSH and may differ from previously published BLS CFOI rates.

† Fatality data are from the BLS Occupational and Safety and Health (OSH)/Census of Fatal Occupational Injuries (CFOI) 2003 Profiles and Charts. Employment data for 2003 are based on estimates derived from BLS Current Population Survey (CPS) monthly microdata files.

Fatal occupational injuries

Assaults and violent acts accounted for 41% of fatal occupational injuries in the Wholesale and Retail Trade sectors (85% of these were due to homicides). Transportation accidents accounted for 32% of fatal occupational injuries in the Wholesale and Retail Trade sectors (79% of these involved highway accidents) ([Table T3](#)).

Nonfatal occupational injuries involving days away from work

Within the Wholesale and Retail Trade sectors, sprains and strains were the most frequent nonfatal injury type involving days away from work with incidence rates of 6.78 and 6.97 cases/1000 full-time workers/year, respectively ([Table T4](#)). Building Material and Garden Equipment and Supplies Dealers (NAICS 444), Nondurable Goods Merchant Wholesalers (NAICS 424), and Food and Beverage Stores (NAICS 445) subsectors had the highest incidence rates of sprains and strains.

The incidence rate of amputations involving days away from work were 0.12 and 0.03 cases/1000 full-time workers/year for the Wholesale Trade and Retail Trade sectors, respectively ([Table T4](#)). Lumber and Other Construction Materials Merchant Wholesalers (NAICS 4233) had an amputation incidence rate of 1.03 cases/1000 full-time workers/year, which was more than 8 times larger than the Wholesale Trade sector average ([Table T7](#)).

Total nonfatal occupational injuries

General Merchandise Stores (NAICS 452), Food and Beverage Stores (NAICS 445), and Building Material and Garden Equipment and Supplies Dealers (NAICS 444) had the highest rates of total nonfatal occupational injuries, ranging from 62 to 69 cases/1000 full-time workers/year ([Table T5](#)). The Beer, Wine, and Distilled Alcoholic Beverage Merchant Wholesalers (NAICS 4248) industry group had an incidence rate of total nonfatal occupational injuries of 107 cases/1000 full-time workers/year, which was more than two times higher than the Wholesale Trade sector average. ([Table T6A](#)).

Within the Wholesale and Retail Trade sectors the incidence rates of traumatic occupational injuries involving days away from work were 13.97 and 14.43 cases/1000 full-time workers/year (Special Request) compared to 45 and 51 cases of total nonfatal occupational injuries/1000 full-time workers/year, respectively ([Table T5](#)). This suggests that the total injury rates were 3.2- and 3.5-fold larger than the injury rate involving days away from work for these sectors, respectively.

Nonfatal occupational illnesses and injuries involving days away from work

Incidence rates of occupational carpal tunnel syndrome and tendonitis involving days away from work incidence rates were, respectively 0.46 and 0.34 cases/1000 full-time workers/year in the Food and Beverage Stores (NAICS 445) subsector ([Table T8](#)). The highest incidence rate of carpal tunnel syndrome was in the Machinery, Equipment, and

Supplies Merchant Wholesalers (NAICS 4238) and Supermarkets and Other Grocery (except convenience) Stores (NAICS 44511), which had incidence rates of 0.63 and 0.56 cases/1000 full-time workers/year ([Table T9](#)). The highest incidence rate of tendonitis was in the Other Specialty Food Stores (NAICS 44529) industry, at 4.61 cases/1000 full-time workers/year, 42 times higher than the Retail Trade average ([Table T10](#)).

The incidence rates of the symptom of back pain (without a medical diagnosis) involving days away from work were 0.52 and 0.41 cases/1000 full-time workers/year for Wholesale Trade and Retail Trade, respectively ([Table T8](#)). The incidence rate for this symptom was highest in Nondurable Goods Merchant Wholesalers (NAICS 424) subsector and in the Beer, Wine, and Distilled Alcoholic Beverage Merchant Wholesalers (NAICS 4248) industry group ([Table T11](#)). For the Wholesale and Retail Trade sectors the incidence rates for hernia involving days away from work were 0.36 and 0.31 cases/1000 full-time workers/year, respectively (Special Request).

Nonfatal occupational illnesses

The incidence rate of nonfatal occupational skin diseases and disorders was 0.31 cases/1000 full-time workers/year in both Wholesale and Retail Trade sectors ([Table T12](#)). This rate was highest in the Nursery and Garden Center (NAICS 44422) industry, which had an incidence rate of 3.40 cases/1000 full-time workers/year ([Table T13](#)).

The incidence rate of nonfatal occupational respiratory conditions was 0.14 and 0.10 cases/1000 full-time workers/year in the Wholesale and Retail Trade sectors, respectively ([Table T12](#)). This rate was highest in the Camera and Photographic Supplies Stores (NAICS 44313) industry, which had an incidence rate of 3.11 cases/1000 full-time workers/year ([Table T14](#)).

The incidence rate of nonfatal occupational poisonings was 0.03 and 0.05 cases/1000 full-time workers/year in the Wholesale and Retail Trade sectors, respectively ([Table T12](#)). This rate was highest in the Outdoor Power Equipment Stores (NAICS 44421) industry, which had a rate of 4.73 cases/1000 full-time workers/year ([BLS Table SNR08](#)).

The incidence rate of all other nonfatal occupational illnesses was 1.01 and 1.21 cases/1000 full-time workers/year in the Wholesale and Retail Trade sectors, respectively ([Table T12](#)). This rate was highest in Electronic Shopping and Mail-Order Houses (NAICS 4541) industry group which had an incidence rate of 6.94 cases/1000 full-time workers/year ([Table T15](#)).

Table T3. Number and percent of fatal occupational injuries in the wholesale and retail trade sectors by event or exposure, 2003

Event or exposure	Number of fatal injuries	Percent of total fatal occupational injuries in the manufacturing sector
Contact with objects and equipment	65	12
Struck by object	37	
Caught in or compressed by equipment or objects	18	
Caught in or crushed in collapsing materials	8	
Falls	39	7
Exposure to harmful substances or environments	23	4
Transportation accidents	174	32
Highway accident	138	
Non-highway accident (farm, industrial premises)	10	
Worker struck by vehicle, mobile equipment	14	
Aircraft accident	6	
Railway	5	
Fires and explosions	12	2
Assaults and violent acts	220	41
Homicides	187	
Suicides, self-inflicted injury	31	
Total	535	

Totals for major categories may include subcategories not shown separately; 2003 data were specially requested from BLS.

Table T4. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational injuries involving days away from work by wholesale and retail trade subsectors, 2003

Wholesale and retail trade subsector	NAICS code	Sprains, strains	Fractures	Cuts, punctures	Bruises	Amputations
Merchant wholesalers, durable goods	423	14,570 (5.19)	2,240 (0.80)	3,710 (1.32)	3,360 (1.20)	540 (0.19)
Merchant wholesalers, nondurable goods	424	18,110 (9.47)	3,160 (1.65)	1,640 (0.86)	3,440 (1.80)	90 (0.05)
Wholesale electronic markets and agents and brokers	425	†	†	†	†	†
Total for wholesale trade sector	42	36,030 (6.78)	5,800 (1.09)	5,660 (1.07)	7,030 (1.32)	660 (0.12)
Motor vehicle and parts dealers	441	10,550 (5.96)	1,980 (1.12)	2,810 (1.59)	1,850 (1.05)	-
Furniture and home furnishings	442	3,980 (8.77)	560 (1.23)	440 (0.97)	740 (1.63)	-
Electronics and appliance stores	443	1,650 (3.74)	200 (0.45)	240 (0.54)	310 (0.70)	-
Building material and garden equipment and supplies dealers	444	10,750 (9.83)	1,830 (1.67)	1,740 (1.59)	2,210 (2.02)	80 (0.07)
Food and beverage stores	445	19,310 (9.33)	2,240 (1.08)	6,840 (3.30)	4,900 (2.37)	130 (0.06)
Health and personal care stores	446	3,030 (4.29)	350 (0.50)	310 (0.44)	680 (0.96)	-
Gasoline stations	447	4,190 (5.92)	350 (0.49)	930 (1.31)	840 (1.19)	-
Clothing and clothing accessories stores	448	2,650 (2.97)	400 (0.45)	290 (0.32)	980 (1.10)	-
Sporting goods, hobby, book, and music stores	451	1,460 (3.30)	170 (0.38)	260 (0.59)	310 (0.70)	-
General merchandise stores	452	17,260 (8.24)	2,250 (1.07)	2,780 (1.33)	4,760 (2.27)	-
Miscellaneous store retailers	453	4,040 (5.78)	750 (1.07)	530 (0.76)	840 (1.20)	-
Nonstore retailers	454	2,960 (7.92)	390 (1.04)	440 (1.18)	460 (1.23)	40 (0.11)
Total for retail trade sectors	44, 45	81,810 (6.97)	11,470 (0.98)	17,590 (1.50)	18,880 (1.61)	350 (0.03)

† no data was available for this NAICS code; number of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [R1](#) and [R5](#); highest three values for subsectors are in bold font.

Table T5. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational injuries by wholesale and retail trade subsectors, 2003

Wholesale and retail trade subsector	NAICS code	Total nonfatal occupational injuries	
Merchant wholesalers, durable goods	423	117,900	(42)
Merchant wholesalers, nondurable goods	424	105,400	(55)
Wholesale electronic markets and agents and brokers	425	16,400	(28)
Total for wholesale trade sector	42	239,700	(45)
Motor vehicle and parts dealers	441	88,000	(50)
Furniture and home furnishings	442	23,600	(52)
Electronics and appliance stores	443	14,200	(32)
Building material and garden equipment and supplies dealers	444	68,000	(62)
Food and beverage stores	445	136,300	(66)
Health and personal care stores	446	17,700	(25)
Gasoline stations	447	25,600	(36)
Clothing and clothing accessories stores	448	24,100	(27)
Sporting goods, hobby, book, and music stores	451	15,400	(35)
General merchandise stores	452	144,400	(69)
Miscellaneous store retailers	453	24,600	(35)
Nonstore retailers	454	19,300	(52)
Total for retail trade sectors	44, 45	601,200	(51)

Numbers of cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Table [SNR05](#); highest three values for subsectors are in bold font.

Table T6A. Wholesale and retail trade industry groups and industries (4-, 5-, and 6-digit NAICS codes) with the highest nonfatal occupational injury incidence rates, 2003

Wholesale and retail trade industry group or industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Beer, wine, and distilled alcoholic beverage merchant wholesalers	4248	135,100	107	14,400
Warehouse clubs and superstores	45291	891,400	75	55,600
Grocery and related product merchant wholesalers	4244	677,300	74	50,200

Number of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Table [SNR05](#); the incidence rate of nonfatal occupational injuries, regardless whether workdays were lost, for the entire U.S. workforce was 47 cases/1000 full-time workers/year.

Table T6B. Wholesale and retail trade industry groups (4-digit NAICS codes) with the highest number of nonfatal occupational injuries, 2003

Wholesale and retail trade industry group or industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Grocery stores	4451	2,454,900	69	122,200
Department stores	4521	1,610,500	69	78,000
Building material and supplies dealers	4441	1,041,600	63	60,900

Number of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Table [SNR05](#); the incidence rate of nonfatal occupational injuries, regardless whether workdays were lost, for the entire U.S. workforce was 47 cases/1000 full-time workers/year.

Table T7. Wholesale and retail trade industry groups and industries (4-, 5-, and 6-digit NAICS codes) with the highest nonfatal occupational amputation incidence rates involving days away from work, 2003

Wholesale and retail trade industry group or industry	NAICS Code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Lumber and other construction materials merchant wholesalers	4233	228,400	1.03	230
Other direct selling establishments	45439	54,000	0.41	20
Machinery, equipment, and supplies merchant wholesalers	4238	645,300	0.29	180

Numbers of workers were rounded to the nearest 100 workers; numbers of cases were rounded to the nearest 10 workers; numbers were extracted from 2003 BLS Tables [SNR10](#), [R1](#), and [R5](#); the incidence rate of nonfatal occupational amputations involving days away from work for the entire U.S. workforce was 0.09 cases/1000 full-time workers/year.

Table T8. Number (and incidence rates in cases/1000 full-time workers/year) of nonfatal occupational injuries and illnesses involving days away from work by wholesale and retail trade subsector, 2003

Wholesale and retail trade subsector	NAICS code	Carpal tunnel syndrome	Tendonitis	Back pain (without a medical diagnosis)

Total for retail trade sectors	44, 45	3,700 (0.31)	1,200 (0.10)	600 (0.05)	14,200 (1.21)

Numbers of cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR10](#) and [SNR08](#); highest three values for subsectors are in bold font.

Table T13. Wholesale and retail trade industry groups and industries (4-, 5-, and 6-digit NAICS codes) with the highest incidence rates of nonfatal occupational skin diseases and disorders, 2003

Wholesale and retail trade industry group or industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Nursery and garden centers	44422	118,000	3.40	300
Chemical and allied product merchant wholesalers	4246	130,100	3.02	400
Used car dealers	44112	114,900	1.29	100

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); the incidence rate of nonfatal occupational skin diseases and disorders, regardless whether workdays were lost, for the entire U.S. workforce was 0.49 cases/1000 full-time workers/year.

Table T14. Wholesale and retail trade industry groups and industries (4-, 5-, and 6-digit NAICS codes) with the highest incidence rates of nonfatal occupational respiratory conditions, 2003

Wholesale and retail trade industry group or industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Camera and photographic supplies stores	44313	20,000	3.11	<50
Men's clothing stores	44811	74,600	1.09	100
Chemical and allied products merchant wholesalers	4246	130,100	0.74	100

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); the incidence rate of nonfatal occupational respiratory conditions,

regardless whether workdays were lost, for the entire U.S. workforce was 0.22 cases/1000 full-time workers/year.

Table T15. Wholesale and retail trade industry groups and industries (4-, 5-, and 6-digit NAICS codes) with the highest incidence rates of all other nonfatal occupational illnesses, 2003

Wholesale and retail trade industry group or industry	NAICS code	Number of workers	Incidence rate (cases/1000 full-time workers/year)	Number of cases
Electronic shopping and mail-order houses	4541	214,700	6.94	1,300
Warehouse clubs and superstores	45291	891,400	2.85	2,100
Tire dealers	44132	156,900	2.80	400

Numbers of workers and cases were rounded to the nearest 100 workers; numbers were extracted from 2003 BLS Tables [SNR08](#) and [SNR10](#); the incidence rate of all other nonfatal occupational illnesses, regardless whether workdays were lost, for the entire U.S. workforce was 2.32 cases/1000 full-time workers/year.

Appendix

Notes on Limitations and Interpretation

One of the limitations of occupational safety and health surveillance data is the underreporting of illnesses, which occurs because: 1) some diseases (e.g., cancer and pneumoconiosis) have long latency periods so that reporting mechanisms, such as OSHA logs, as used by BLS, fail to capture many of these events; 2) many diseases have multiple potential causes (e.g., asthma and cardiovascular diseases); and 3) workers and physicians do not recognize an occupational contribution.

BLS data sources do not allow: characterization of occupationally-related illnesses, if these illnesses are not skin diseases and disorders, respiratory conditions, or poisonings; or quantification of fatalities due to occupationally-related illnesses. Other sources have suggested that the occupational illness fatalities in the US workforce outnumber occupational injury fatalities by about 8:1. For example, using 1997 disease fatality numbers, it was estimated that occupationally-related illness and injury deaths numbered, respectively, 25,910-72,121 (Steenland et al., 2003) and 6,238 (BLS). Estimates of 1997 occupationally-related illness deaths by disease category are as follows: 6,805-26,685 for non-malignant respiratory disease; 12,086-26,244 for occupationally-related cancer deaths; 6,037-18,253 for occupationally-related coronary heart disease; and 328-580 for occupationally-related renal disease (Steenland et al., 2003). Sector-based occupationally-related illness fatality data are not provided in this surveillance data summary.

Other limitations of the data include the following. (1) Only BLS data for a single year (2003) are presented. However, data for a single year may not be representative of the long-term experience and health impacts of a sector due to economic, political, technological, or climatic characteristics of that year. (2) Many of the rates are based on small denominators, so that a few additional or a few less cases in the numerator might cause a large fluctuation in the magnitude of the rate estimate. Therefore, what may be quantified as large differences in risk may simply be the result of the “random” occurrence of a few cases. (3) Rates are not adjusted for any potential confounders, the most important of which may be age. Research has shown that younger workers may be at increased risk of injury due to a variety of factors including experience and training. Older workers may be more susceptible to certain occupational illnesses because of pre-existing medical conditions. Therefore what is perceived as a true difference in risk based upon crude rates between two groups may simply be the result of differences in their age distributions. (4) Differences among rates for subsectors and industries of the sector are not tested for statistical significance. Without statistical testing, one cannot conclude that rates are really any different than some of the other rates in the sector.

Discussion of the data focuses on rates, although many of the tables also provide data on the number of workers affected. A subsector or industry which has the highest rate of injuries or illnesses within the sector may have few total workers. Implementing prevention strategies within another subsector or industry within the sector with a high rate of injuries or illnesses and a larger number of workers, may result in a much larger public health impact. If these data are

used for planning and priority setting, we suggest that the number of adverse health outcomes and the number of workers potentially impacted be considered concurrently to identify worker groups towards which research should be directed.

FROM: Muriel Dando, President
Human Ecology Action League, Inc. (HEAL)

RE: National Occupational Research Agenda (NORA)

Thank you for the opportunity to contribute to the National Occupational Research Agenda.

We urgently recommend that NORA undertake research to investigate work-related asthma in nurses and teachers, to identify workplace exposures related to asthma in nurses and teachers, and to recommend ways to reduce or eliminate these exposures.

Nurses and teachers are of critical importance to the nation, as they are entrusted with the well being of our most vulnerable citizens — the sick, and children. The Department of Labor anticipates a dramatic increase in demand for workers in both professions in the near future, yet current data indicate that worker turnover is high in both professions. We believe that work-related asthma may be playing a role in worker turnover in nurses and teachers, and that preventing workplace asthma exacerbations could help increase worker retention and productivity in both fields.

Our concern about the workplace health of nurses and teachers arises from the purpose and goals of the Human Ecology Action League, Inc. (HEAL). HEAL is a national nonprofit education and information organization concerned about the health effects of environmental exposures, particularly low-level exposures common in daily life and in many workplaces. One of the oldest environment and health organizations in the country, HEAL is an independent organization, funded solely by membership fees and donations. While HEAL has a primary responsibility to serve its own members, it also has an important responsibility to educate and inform the general public.

We have received reports from nurses and teachers about workplace conditions that they believe are harmful to their respiratory health. As the attached report illustrates, this perception is widespread in both professions. We believe that there is enough evidence to warrant a vigorous and extensive research effort to uncover the extent and nature of the problem of work-related asthma in nurses and teachers, to identify contributing factors that undermine respiratory health in these workers, and to recommend effective means of mitigating or eliminating these factors.

We hope that you will consider including this issue in the NORA agenda.

Introduction

Nurses and teachers suffer from very high rates of asthma. This much is clear. That some of their asthma is work-related is also clear, though it is not known to what extent workplace exposures cause asthma in these workers. It is widely recognized that, regardless of what initially caused their asthma, workers with established asthma require good asthma management, including workplace exposure management, to remain healthy and productive. When workers are unable to work in their professions, society does not benefit from their training and skills, and the economy does not benefit from their full participation. Nurse and teacher workplace health should be of great concern to NORA, because of the high demand for these professionals in the current labor market, and the surge in demand for these workers that is anticipated by labor experts.

Identification of troublesome exposures — those that incite asthmatic responses — and mitigation or elimination of such exposures, play an important role in good asthma management, and are prudent practices in ensuring workplace health. Identification of exposures troublesome to nurses and teachers has been slow, but there is evidence these two groups of workers share similar concerns about similar workplace exposures. These exposures need to be investigated, and mitigation and elimination methods developed and implemented. Some of these same exposures are troublesome to people who report adverse health effects from low-level chemical exposures; these individuals report many exposure-related activity limitations and related adverse impacts on work. All of these workers need to be heard, understood, and helped. NORA has a vital role to play in this effort.

Respiratory health in nurses and teachers, scope of the problem.

The Bureau of Labor Statistics *Occupational Outlook Handbook 2005-2006* reports that in 2004, there were 2.4 million registered nurses in the U.S., and growth in demand for R.N.s was expected to grow rapidly, a projected 27 percent or more by 2014.¹ Teachers K-12 (not including special education teachers) numbered 3.8 million in 2004, and job opportunities were expected to grow in this sector by 9 percent to 17 percent by 2014.²

¹ Bureau of Labor Statistics, U.S. Department of Labor, *Occupational Outlook Handbook, 2006-07 Edition*, Registered Nurses, <http://www.bls.gov/oco/ocos083.htm>

² Bureau of Labor Statistics, U.S. Department of Labor, *Occupational Outlook Handbook, 2006-07 Edition*, Teachers — Preschool, Kindergarten, Elementary, Middle, and Secondary, on the Internet at <http://www.bls.gov/oco/ocos069.htm>

However, both occupations are also currently plagued with work-related health problems. The Bureau of Labor Statistics reported that in 2004, healthcare and social assistance workers experienced 18.4 percent of all the non-fatal occupational illnesses reported, and education service workers accounted for 0.7 percent.³

Workers in both healthcare and in education settings have well-documented elevated rates of one exposure-related illness — asthma. Some data sources used in this report suggest or indicate that the asthma cases under discussion are caused by work conditions; other sources differentiate between asthma caused by work, and asthma exacerbated by work. *Regardless of the cause*, once asthma is present, it must be managed appropriately in the workplace, for the health and productivity of the worker. There is mounting evidence that nursing and teaching workplaces are failing in this regard.

A survey of asthma prevalence in U.S. industry found that while the overall prevalence of asthma in the U.S. is 6.5 percent, the prevalence of asthma among male workers in healthcare settings is 8.5 percent — and among female workers it is 10.1 percent.

Asthma prevalence among male workers in education settings (K-12 and college) is 6.0 percent — and among females it is 9.5 percent (compared with 6.5 percent in industry overall).⁴ In a recent analysis of SENSOR data, education services workers accounted for 9 percent of all SENSOR-recorded occupational asthma cases between 1993 and 2000. Nearly 70 percent of these asthma cases were new-onset, 31 percent were work-aggravated, and 8 percent were RADS. The study's authors note: "The number of WRA cases among teachers and reported from elementary and secondary schools indicate that asthma in educational settings is an occupational health problem. Workers in this industry are primarily public sector employees, and in half of the states Occupational Safety and Health Administration (OSHA) provisions do not apply."⁵

Work-related asthma and exposures

The NIOSH *Worker Health Chartbook 2004* (all workers) indicates significant associations between work-related asthma (WRA) and exposures: "During 1993 –1999, the largest proportion of WRA cases was associated with miscellaneous chemicals (19.7%). This category of agents includes many exposures that are not easily classified (for example, perfumes, odors, and glues)." Other exposures associated with work-related asthma reported in the NIOSH *Chartbook* were indoor air pollutants (9.9 percent), cleaning materials (11.6 percent), solvents not otherwise specified (8.2 percent) and polymers (5.3 percent).⁶

As noted above, regardless of the cause, once asthma is present, it must be managed appropriately in the workplace, for the health and productivity of the worker. Identification of troublesome exposures — those that incite asthmatic responses — and mitigation or elimination

of such sources, are part of good practice in asthma management, and prudent practice in workplace health.⁷ The exposures listed in the *Chartbook* as associated with work-related asthma are strikingly similar to those about which nurses and teachers have expressed concern.

Occupational health and nursing

“Hospitals have led the list of industries reporting 100,000 or more cases [of occupational illnesses] for the past two years. The rate of illnesses experienced by workers in the hospital industry was 72.9 cases per 10,000 full-time workers, compared to 27.9 cases for private industry as a whole,” according to the Bureau of Labor Statistics.⁸

Research on nurses’ occupational health has focused on *task*-related exposures (latex, glutaraldehyde, needle sticks, lifting) but has been scant in focus on other *workplace*-related exposures. In 2001, the American Nurses Association conducted an online health and safety survey, which gathered nearly 5000 responses in about a month. Over 70 percent of respondents had been nurses for 10 years or more, and more than half worked in acute care hospitals. Nearly 80 percent reported that they do not feel entirely safe in their workplaces. Nearly half reported a work-related illness, or illness exacerbation, in the year previous to taking the survey. Over 30 percent reported little information from employer about workplace health hazards, and an additional eight percent reported receiving no hazard information at all from employers. Three-quarters of the respondents indicated that unsafe work conditions interfered with delivery of patient care. Nearly 88 percent said that health and safety considerations influence their decision to remain in the profession.⁹

In March 2005, the Massachusetts Department of Health reported that among Massachusetts workers in healthcare settings, “Cleaning products were the agents most frequently reported by [asthma] cases (74/305, 24%), but the exposures that triggered asthma varied by occupation. Nurses most commonly reported latex, followed by cleaning products then aldehydes (glutaraldehyde and formaldehyde). Office workers in health care settings most often identified miscellaneous chemicals, paints, solvents and glues, followed by cleaning products and new carpet, dust (including renovation), molds, smoke and perfume. Laboratory workers and technicians reported aldehydes (glutaraldehyde and formaldehyde) most often and dental workers reported latex.”¹⁰ The substances identified as problematic are allergens, sensitizers and irritants, all of which have potential to cause or contribute to exacerbations of worker asthma.

The increasing need for additional nurses in the U.S. workforce, plus the high rate of occupational illnesses in nursing professionals, point to the need to make workplace health in healthcare facilities a national health priority. Work-related asthma alone may be having a significant negative current impact on worker productivity, retention and recruitment in both healthcare and education occupations. Unless addressed in a timely fashion, conditions contributing to these high rates of work-related illness could have serious negative impacts in the

future. Prevention of workplace illness exacerbations is indicated by both the nature of the substances reported as present in the work environment, and the association between these substances and work-related asthma exacerbations.¹¹

Occupational health and teaching

Education initiatives have been a Bush administration priority: After passage of the No Child Left Behind Act in 2002, the White House announced its program, “A Quality Teacher in Every Classroom,” saying, “This program represents the largest and most comprehensive Federal investment in preparing, training and recruiting teachers and principals. Nearly \$3 billion will be made available to States through formula grants to prepare, train, and recruit high-quality teachers.” The program is authorized under the Elementary and Secondary Education Act as amended by No Child Left Behind: Title II, Part A (P.L.107-110) 2002. About \$44.5 million was appropriated for the Transition to Teaching portion of the program in the FY 2006 budget, along with \$14.7 million for the Troops to Teachers portion.¹²

However, the program contains no funds for ensuring that schools are healthy workplaces. Teacher health is clearly important to teacher retention, and this in turn is clearly necessary to achieve administration education quality goals. However, nationwide, about one in four beginning teachers leaves the profession within four years.¹³ At the end of the 1999-2000 school year, the teacher workforce lost about eight percent of its personnel, including two percent to retirement, and four percent to other occupations. The rate of teacher loss to other occupations was double the rate found at the end of the 1987-88 and 1990-91 school years; losses to retirement were double the rate at the end of the 1987-88 school year.¹⁴ Though an estimated 700,000 teachers will retire by 2010, those losses will account for less than 30 percent of the projected teacher losses during the period 2002-2010; non-retirement reasons are anticipated to outnumber retirement reasons by three to one.¹⁵

Although there is widespread recognition that environmental conditions in schools can affect student health and performance, particularly for those with asthma, data is sparse on teacher work-related health and related concerns. However, a 1999 survey conducted by the U.S. National Center for Education Statistics found that the majority of complaints about unsatisfactory environmental conditions in U.S. public schools were related to ventilation (26 percent nationwide) and indoor air quality (18 percent nationwide). Nationwide, 29 percent of schools reported inadequate ventilation systems.¹⁶

In a recent analysis of SENSOR data for work-related asthma 1993-2000, researchers found that the agents most frequently reported as associated with work-related asthma in teachers and teachers' aides were indoor air pollutants (28%), cleaning products (19%), mold (18%), and mineral and inorganic dusts (18%).¹⁷

A 2003 study that surveyed teachers in Chicago and Washington D.C. found that many respondents reported health problems related to the work environment (Chicago over 25 percent; D.C. over 30 percent), with respiratory symptoms predominating. The author of this report notes that the teacher-reported rates of health problems in this study far exceed OSHA reports of such problems (4 percent), but adds that the OSHA figures are derived from *employer* reports. About half the teachers surveyed in this report rated their schools' condition at "C" or lower, and of these, 40 percent were considering changing workplaces, with 30 percent of those contemplating change considering leaving the profession altogether.¹⁸ In a subsequent study of teacher retention in Washington D.C., a study found that good school quality was nearly as important as pay scale in teacher retention.¹⁹

Teacher dissatisfaction with facility quality is also reflected in recent a Canadian survey. Sixty percent of all respondents to this (very small) Canadian online survey about school indoor air quality were teachers, and teachers reported 41 percent of the indoor air concerns expressed in the survey. In all respondents, health problems related to school indoor air quality were reported by 16 percent, and dissatisfaction with ventilation was reported by 24 percent. Health problems reported were "headaches, nausea, asthma, allergies, chronic throat problems, severe sinus infections, respiratory illness, skin rashes, eye infections, watery eyes, cold-like symptoms, drowsiness, and mental confusion."

Problem exposures identified in this survey were poor ventilation; biological contaminants (mold, dust, bacteria); thermal discomfort; "fumes from vehicles; perfume; air fresheners; Volatile Organic Compounds (VOCs) from wallboard, furniture, and building materials; smelly markers; chlorine smell in water; sewer smells; musty stale air; photocopier ink; furnace fumes; cafeteria odours; smoke and gas smells; laundry soap smells on clothing; cleaning product fumes; floor wax;" CO₂; CO; carpet (emissions from new; mold/dust/bacteria from old); asbestos building materials; pesticides; rodent excrement; leaking roofs and foundations.²⁰ Many of these are allergens and irritants having the potential to exacerbate existing respiratory conditions.²¹

Two recent Scandinavian studies shed light on some of the exposures present in the school workplace. In one, dust samples obtained from known ‘problem’ schools provoked inflammation in cell cultures to a greater extent than dust from ‘no problem’ schools.²² In the other, long-lasting physiological effects were found in teachers working in a water-damaged school, effects that persisted for years after the schools were renovated.²³

HEAL member survey responses explicate exposure-related problems in the workplace.

²²Allermann, L. et al. Inflammatory potential of dust from schools associated with building related symptoms. *Occupational and Environmental Medicine* 60 (9): E5. September 2003.

<http://oem.bmjournals.com/cgi/content/full/60/9/e5> See also *Proceedings*, Ninth International Conference on Indoor Air Quality and Climate, Monterey, California. 2002. www.chps.net/info/iaq_papers/PaperV.1.pdf The authors note: “[I]nflammation could . . . be considered an integrated effect of the total biological and chemical exposure load from an indoor environment.” They collected dust samples from 20 schools (10 previously identified as having a high number of occupant health complaints (19.6% - 31.9%) and 10 with low numbers of such complaints (4.4% - 11.0%)) and added dust in different concentrations to lung cell cultures. They found a positive correlation between the inflammatory responses of the lung cells to dust obtained from schools with high occupant health complaints, and were able to distinguish high and low occupant complaint buildings by the inflammatory responses provoked by their respective dust samples. Itching eyes, nose congestion, and fatigue were positively correlated with cell inflammation, and prickly sensation of the skin, and headache were borderline correlated with it. A positive index of at least two of five symptoms of the mucous membrane and the skin, and a positive index of at least one symptom from the central nervous system, were positively correlated to inflammation in the lung cell cultures. The authors noted that, while inhalation of the dust itself may not be the culprit in the occupants’ reported health problems, the dust may serve as a characterization of problem materials in the building. The dust may have absorbed these materials, promoting inflammation. Those source materials may constitute the exposures of interest in school occupant health complaints.

²³Rudblad, S., *Nasal mucosal reactivity after long-time exposure to building dampness*. Doctoral dissertation, Karolinska University, October 2004. <http://diss.kib.ki.se/2004/91-974455-5-X/thesis.pdf> Abstract at <http://diss.kib.ki.se/2004/91-974455-5-X/> This investigation involved nasal mucosa reactivity in 28 teachers who had worked for at least five years in a school heavily damaged by moisture. Symptoms persisted in the teachers even after the school had been renovated. Compared with teachers working in a school with no known moisture problems, the teachers in the problem school had a clearly different pattern of reactivity to histamine challenge. The teachers also had a markedly different pattern of reactivity from incoming students without long exposure to the school. Two years after this phase of the study, the teachers were tested again, and again the originally hyper-reactive teachers were more reactive than teachers not exposed to the former problem conditions at the school, though the difference was less than it had been two years previously. Six years after initial testing, the reactive and non-reactive teachers were again tested, and this time the difference between the two groups was negligible. However, the reactive teachers displayed a continued difference in swelling and plasma leakage in nasal mucosa. The researcher concluded, “Consequently, longtime exposure to building dampness may increase the risk for hyper reactivity of the upper air-ways. This acquired hyper reactivity may last for years and decrease only slowly, even after the indoor climate has been properly improved.” An important finding in this study is that the students, who were also tested and followed during the study, did not show any increased reactivity — thus school environmental conditions that may be sufficient to protect student health may fail to fully protect teachers or to restore them to health after building remediation. For many years, HEAL has been aware that many HEAL members have multiple chemical sensitivities (MCS). In drafting a member survey in 1999, many of the questions included were directed at assessing the impact of MCS on daily activities, including work. The purpose of the survey was to assess the health and well being of the members, their life experiences with healthcare and work, their information needs and interests, and other matters.²⁴

In December 1999, a survey form was published in *The Human Ecologist*, HEAL’s flagship publication. That issue was distributed to all active HEAL members, and the survey form was also distributed to all incoming new members during 2000 (total number about 1700; response rate about 18 percent).²⁵ A noticeable number described themselves as current or former teachers and nurses, and reported difficulties with exposures related to (though not necessarily exclusive to) their work environments. (It was this pattern of response that initiated the research that resulted in this document.)

As the survey forms were returned, articles were published in *The Human Ecologist* on various topics covered by the survey. In December 2001, such an article appeared in the magazine regarding MCS and work, and could be considered a pilot study of MCS and worker health.²⁶ As far as we know, it is the first survey-based description of the impact of MCS on working life. It covered all of the member responses gathered from December 1999 to December 2000, and discussed the survey returns from all of those who answered ‘yes’ to the question, “Do you have MCS?” There were 269 surveys in this sample, age range from 26-86 years. There were 196 respondents of working age (64 and younger). Responses of the working-age group to selected survey items were compared to responses about those same items from the entire sample (269) in the article. Some information from previous articles about the survey results was used in the analysis of responses about work.

Rated on a scale of 1-10, with one being ‘nuisance’ and 10 being ‘life-threatening,’ average reported MCS severity in the entire sample was 6.55. In the working-age group, average reported MCS severity was 6.66, while in the employed sub-group it was 5.68.

In a previous article on the survey results²⁷, MCS had significant impacts on ordinary daily activities (see Table 1.) Many of these activities are also common to many workplaces.

Table 1. Activity levels reported by 8 women with self-reported MCS severity 5. (Workers with MCS self-reported MCS severity 5.68.)

MCS severity 5 “I can...	Read print material	Use a computer	*Attend meetings	Eat at restaurants	Take day trip	Over night trip	Stay hotel/motel
% usually	50.00	75.00	37.50	62.50	75.00	50.00	50.00
% sometimes	50.00	12.50	37.50	37.50	25.00	50.00	25.00
% never	0.00	12.50	12.50	0.00	0.00	0.00	12.50

From Kosta, L. MCS and work. Adapted from HEAL Member survey: MCS and activities. *The Human Ecologist* No. 90, Summer 2001.

*In the original table, this category was called “Attend worship services.” This activity has been interpreted here as the ability to remain for an hour in an enclosed space with a moderate to large group of people.

²⁴ HEAL member survey, *The Human Ecologist* No. 84, Winter 1999.

²⁵ Personal communication, Human Ecology Action League, Inc. (HEAL) 2000.

²⁶ Kosta, L. MCS and work: Data from the HEAL member survey. *The Human Ecologist* No. 92, Winter 2001.

²⁷ HEAL Member survey: MCS and activities. *The Human Ecologist* No. 90, Summer 2001.

The December 2001 article on work and MCS says, “It is plain that, even for those moderately affected by MCS, the ability to engage in activities common to many workplaces and essential for some jobs, can be severely restricted. Some workers must read and handle large quantities of print materials and use a computer for significant portions of the day. These include teachers, administrators, managers, and some technical workers.”²⁸

The survey also asked if respondents limited their activities to avoid exposures that exacerbated their symptoms. See Table 2 for the responses to this question. “These reported limitations on time spent using equipment, having unlimited contact with people, restrictions on destinations, and the use of devices to reduce contact with problematic substances have serious potential to disrupt or limit the working life of people with MCS.”²⁹

Table 2. Activity limitations reported by 8 women with self-reported MCS severity 5

Limitation	% reported MCS severity 5
Limit contact with people	50.0
No smoking	37.5
Limit time	25.0
Limit destination	12.5
Use device (filter, mask)	12.5
No fragrance	12.5
Air out items	12.5
Ill from activity	12.5

Kosta, L. HEAL member survey: MCS and activities. *The Human Ecologist* No.90 Summer 2001.

These limitations are also consistent with survey respondents’ reports of their “most troublesome” exposures reported in a previous sample from the same survey. (This question was open-ended in the survey, so respondents did not receive prompting or make a selection from a list.) In that sample, the top-ranking troublesome exposures were fragrance (40%), formaldehyde (8%), and mold (6%), with other troublesome exposures reported as well: pesticides, paint, carpet, cleaning products, building materials, volatile organic compounds, sprays, plastics, air fresheners, inks, printed materials and new textiles.³⁰

All of these are very common in many working environments, and many have been independently identified by nurses and teachers as being troublesome in their workplaces. The limitations reported by HEAL respondents can be seen as efforts to avoid exposures to these substances. In the HEAL survey, avoidance of troublesome exposures was, by far, the intervention reported as most helpful (72%). Other surveys have found similar responses from people with MCS: 95% in the Johnson survey; 74% in the Gibson survey.³¹ However in some workplaces, avoidance is very difficult — if not impossible — to achieve. (It is important to note that many people with MCS also report drug allergies and intolerances, and thus are unable

²⁸ Kosta, L. MCS and work: Data from the HEAL member survey. *The Human Ecologist* No. 92, Winter 2001.

to rely on pharmacological tools to manage their responses to exposures in the workplace and elsewhere.³²⁾

In the working age sample, 37 percent of the respondents were employed at the time of the survey. (Of the others in the working age sample, 33.2 percent received Social Security Disability benefits, most of them for MCS; their average reported MCS severity was 7.9 (nearly “severe.”). Nearly half of all respondents reported having lost a job because of MCS, 35 percent said they had taken early retirement because of MCS (often with a smaller-than-anticipated pension), and over 24 percent said they had had to make a career change because of MCS.

In the working-age sample, there were 63 survey responses that contained enough information to allow an estimate of the respondents’ lost earnings from MCS-related inability to work at their former jobs. In this subgroup, 27 percent were former teachers, and 10 percent were former nurses. Thus nearly 40 percent of these former workers were qualified to work in occupations in which there are currently worker shortages. For teachers K-12, personal earned income was reduced by 82%; for the nurses, it was reduced by 78%.

The picture that emerged from the HEAL member survey was of people who, though they themselves described their MCS as moderate, were unable to tolerate conditions common in many workplaces, had suffered financial and professional losses because of MCS, and were, in some cases, formerly employed in nursing and teaching — occupations that are highly respected in society, and greatly needed at this time and in the future.

The cost of MCS to individuals and society appears to be high, based on this sample. When the worker is unable to work in his or her profession, society does not benefit from the worker’s training and skills, and the economy does not benefit from the full participation of these workers.

The prevalence of MCS in the general population is unknown, but (other) surveys (all of them small) indicate that “unusual sensitivity to chemicals” may affect from 6% to 37% of the population.³³ Even at the low end of this range, chemical sensitivity in some form may be hindering many workers from full participation in the workforce, and it is possible that it is having a disproportionate impact on nurses and teachers. “Unusual sensitivity to chemicals” may be responsible for some of the work-related asthma that afflicts nurses and teachers in the U.S. For these workers, as for people with MCS, exposure control and avoidance is critical to maintaining health and preventing work-related exacerbations.

A model intervention to improve worker health: The Fragrance Controlled Workplace Policy at Brigham and Women’s Hospital, Boston, Massachusetts

³² Ashford, N. and Miller, C. *Chemical Exposure: Low levels and high stakes*. 2nd edition. New York et al.: Van Nostrand Reinhold. 1997. “[T]here seems to be an important overlap between individuals who react badly to medications and chemically sensitive patients.” This may be a particularly important observation, given the number of adverse drug reactions reported annually in the U.S. (245,750 reported to FDA in 2000 alone; see <http://www.fda.gov/cder/reports/RTN2000/RTN2000-3.HTM>).

The Human Ecologist published a series of articles beginning in 1992 regarding fragrance and health, and in 1998 published a book on the subject. One section of the book is called “Fragrance in the workplace: Who shouldn’t use it?” It notes that “some occupations are particularly unsuited to on-the-job fragrance use, because of the nature of the work, the people involved, or both.” The article identifies health care and educational facilities as two workplaces that should institute fragrance-free policies, noting that both employers and employees have an interest in protecting the health of susceptible individuals, and thus promoting the mission of the organization’s enterprise.³⁴ In 2000, one such workplace, Brigham and Women’s Hospital in Boston, independently came to the same conclusion and instituted a fragrance controlled workplace policy.

In December 2002, *The Human Ecologist* published an interview about this policy with Marlene Freeley R.N., M.S., Director of Occupational Health Services at Brigham and Women’s Hospital, Boston, Massachusetts.³⁵ Brigham and Women’s, a major teaching hospital of Harvard Medical School, employs 9000 workers, and has a daily occupant load of 20,000 people.

At Brigham and Women’s, policies for managing indoor contaminants were set in place in the 1990s, together with a beeper system for workers to report unfavorable working conditions. Worker awareness of indoor air quality issues is high, and workers are very likely to report health problems related to indoor air to the hospital’s Occupational Health Service. Such workers fill out a questionnaire about their views of what caused the problem, and their answers enabled the Occupational Health Service to notice a pattern of workers complaining about fragrance exposures on the job. “The pattern was so pronounced that we felt we had to look into fragrance and health. When I did, I found reasons for trying to reduce the exposures that both our patients and our workers were having to fragrance,” Freeley said.

The hospital’s senior management assigned Freeley to chair a task force to draft a fragrance policy for the hospital. The task force determined that, while they could not control all of the fragrance use of every one who came to the hospital, they “agreed that we could and should have a policy to control fragrance use within the hospital by people who work in the hospital.... We also agreed that we should take steps to limit fragrance use by inpatients.”

“We had clear evidence that our workers were having problems with fragrance exposures and that this was affecting their productivity [...] ... a bottom-line issue for managers. We also had scientific evidence that fragrance was causing these problems. It wasn’t hard to see that if workers were being affected, patients were also.... and this was very important to us as a premier health care organization. Finally, the policy was so clear-cut that...management was comfortable being responsible for it. We weren’t promising anything that we weren’t able to deliver, and we were committed to delivering what we knew we could: control of fragrance exposures in our workplace.”³⁶

³⁴ Kosta, L. *Fragrance and Health*. Atlanta, Georgia: HEAL Presents. 1998.

³⁵ Kosta, L. Fragrance control and health care facilities: an interview with Marlene Freeley R.N., M.S., Director of Occupational Health Services, Brigham and Women’s Hospital, Boston, Massachusetts. *The Human Ecologist* No.96, Winter 2002.

³⁶ As noted above, workers, in general, nurses, teachers, and HEAL members have all identified cleaning products as problematic. Freeley discussed the challenges involved in obtaining unscented cleaning products for use in the hospital. Noting that worker misuse of cleaning products (using too much, the wrong dilution, or no dilution at all) had already been identified by the hospital and addressed by the hospital’s Product Safety Committee, Freeley said that it was easy to add the requirement that cleaning products used in the hospital be unscented as well as not a threat to health or the environment. Finding the products was more difficult but was addressed though banding

The policy was accepted in September 2000, and the hospital launched an employee education campaign about it that was still ongoing in 2002. Informational brochures were distributed to all departments in the hospital, and to all incoming patients prior to their stay at the hospital. Nursing Grand Rounds were given on fragrance and health, and presentations were given to department personnel on request.³⁷

Compliance has been good. “The physicians have been very supportive, especially in the respiratory, OB/GYN and oncology services,” Freeley said, “Once the policy was in place, many of our workers ‘came out of the woodwork’ on this issue and said they’d been troubled for years by fragrance exposure on the job.” Patients report that they want to come to Brigham and Women’s in part *because* of the fragrance policy.

When asked what advice she would give to others interested in seeing similar policies adopted, she said the following:

- “It was an enormous help that our entire workplace was so aware of IAQ and health. Before we introduced the fragrance issue, workers and managers were already attuned to being aware of IAQ conditions, and used to reporting IAQ conditions that affect health, comfort and well being. Including fragrance in this context was very natural for us. So it helps to have good workplace awareness of IAQ.
- “Gathering information about worker complaints is important. It was very helpful that we were able to gather clear evidence of worker complaints about fragrance exposure. Since we already had the reporting mechanisms in place because of our IAQ awareness, it was relatively easy to see the pattern of these complaints.
- “Providing information about the impact of fragrance on health was also important. We’re a research and teaching institution, and our senior people were very interested in the science that underlies this issue. So getting and presenting reliable information is important.

together with another major hospital in Boston and using their combined purchasing power to convince product manufacturers to supply their products unscented.

³⁷ Excerpts from “Brigham and Women’s Hospital is a Fragrance-Controlled Environment,” brochure produced and distributed by Brigham and Women’s Hospital, Boston, Massachusetts: “There has been a significant increase in concerns that contact with strong scents and fragrances can cause discomfort in sensitive individuals and even cause troublesome health effects in people with certain medical conditions.”

“Moderate to strongly scented fragrance produces can adversely effect [sic] the health of individuals who have certain medical conditions such as asthma, allergies and migraine headaches. Also, individuals who are undergoing different medical therapies. . . are especially sensitive to odors and scents in the environment.”

“Some fragrances have also been shown to trigger symptoms in otherwise healthy individuals. Some of the concerns may include watery or itchy eyes, sneezing, nasal congestion, sinusitis, fatigue, dizziness, coughing, shortness of breath, difficulty with concentration, and headaches. Fortunately, these symptoms are self-limiting and will easily disappear after the individual is able to get some fresh air and *when fragrances are removed from the environment.*” (emphasis added)

“For the comfort and health of all patients cared for at the hospital, as well as all the employees who work here, BWH must provide the safest and healthiest environment. For this reason, the use of scents and fragrant products, other than minimally scented personal care products, is discouraged on all hospital property, particularly in the clinical areas.”

- “Last, but definitely not least, is that we were able to clearly state what the policy was and who was affected by it. As I said, we’re an institution that sees a lot of people coming in every day, and there was no way we could control or be responsible for what they did. But we’re a health care institution, and it was clear that we were responsible for taking action *as an institution* to protect the health of both our workers and our patients. Our policy does that.”

As noted earlier, respondents to HEAL’s member survey reported that fragrance was their “most troublesome exposure” far more often than any other exposure. We asked about the “most troublesome” exposure to capture several elements of exposure avoidance: the link with symptoms, the severity of the symptoms, and the difficulty in avoiding the exposure. It is striking that employees of Brigham and Women’s also experienced fragrance as a troublesome exposure — and that their workplace was prepared to take their concerns seriously. The symptoms shared in common between Brigham and Women’s workers, HEAL members who responded to the HEAL survey, and nurses and teachers, are also strikingly similar. It is likely that workplace interventions like the fragrance-controlled workplace policy at Brigham and Women’s Hospital could promote worker health and productivity in many workplaces, including those employing nurses and teachers.

Asthma and exposures — the same chemicals in different media can boost total exposure loads

The link between asthma exacerbations and allergen exposure is well-established, as is the association between asthma exacerbations and exposure to inhaled irritants, both chemical and particulate.³⁸ There has been a tendency to investigate the emissions of single products types (carpeting, fragrance products and the like), in order to better understand their constituents and potential for causing adverse respiratory and other responses. Many of the products investigated emit a variety of substances at comparatively low levels, after an initial ‘airing out’ period. Nevertheless, some individuals continue to experience adverse effects in environments containing comparatively low levels of irritant vapors, gases and particles emitted from products such as carpet, scented cleaning products, and other materials identified by various workers as troublesome workplace exposure sources.

Allergic responses to low-level allergen exposures are a hallmark of allergy and allergic asthma. But the reason for the exquisite sensitivity of some individuals to low-level chemical exposures remains elusive. There is one exposure factor that is easily overlooked if only single source emissions are considered as incitants of adverse responses. This is simultaneous total exposure to single chemicals from multiple sources.

The table below illustrates this factor. It shows chemicals occurring in three groups of very different substances: fragrances, building materials, and tobacco smoke. All three have been identified as sources of indoor air pollution, and two are clearly associated with asthma.³⁹ All have been identified as problematic exposures by HEAL members, workers in general, and

*Note that aldehydes are present in some foods and are also produced by both fixed and mobile (vehicle) combustion sources; thus they truly ubiquitous in the environment, and therefore extremely difficult to avoid.

Fragrance materials are ubiquitous in personal care, cleaning, and air freshening products. Although fragrance formulas are protected by trade secrecy and their ingredients are not listed on product labels, enough is known about fragrance materials to indicate that not only do some of them have irritant, sensitizing and allergenic potential, but also that some of their constituent chemicals may be present in other, less “pleasant” substances that are also commonly encountered in the environment. Some of these have identified as problematic by HEAL members, and nurses and teachers also indicate that they are troublesome workplace exposures.

Much has been made of the “many” chemicals to which people report sensitivity. Some skeptics argue that this is an indication that claims of chemical sensitivity lack plausibility.⁴⁰ However, it may be that some people who report “unusual sensitivity” to common chemicals, or who experience IAQ-related workplace health effects, have the most difficulty with a comparatively small group of chemicals that are very difficult to avoid. It is noteworthy that the fragrance-controlled policy adopted at Brigham and Women’s not only reduced worker and building occupant exposures to fragrances as such, but also reduced their total exposures to aldehydes, terpenes, and phenols. No-smoking policies have a similar effect on total exposure reductions.

It is certainly likely that, in some environments, worker exposures to single chemicals emitted from multiple sources could approach, or even exceed, health-based limits. It is at least intriguing that products as widely divergent as building materials, tobacco smoke, and fragrance materials, share some chemical constituents in common, and that symptoms associated with these common chemicals resemble symptoms reported by HEAL members, teachers, nurses, and employees of Women’s and Brigham Hospital (see note 27).

⁴⁰ For example, see Staudenmayer, H. *Environmental Illness: Myth and Reality*. Boca Raton, Florida: Lewis Publishers. 1999.

Recommendations

NORA can engage in multiple activities to investigate nurse and teacher respiratory health, with the goal of producing real-world, fact-based recommendations for nurse and teacher workplace health and worker retention.

1. Survey nurses and teachers about their respiratory health, and about the workplace exposures that they think cause adverse effects. Recruit participants from nurse and teacher professional associations, to provide cross-sections of workers from a variety of workplaces.
2. Compile data on suspect exposures and exposure sources identified in 1.
3. Do a literature search on materials known to be present in school and health care facilities, and their potential health effects. Look for commonalities between the two workplaces.
4. Do a literature search on the exposure sources identified as troublesome by nurses and teachers in 2., looking for links (or lack thereof) between what is known about the sources and their possible connection to nurse and teacher health complaints. Pay particular attention to those sources present in both work environments.
5. If the results of 1-4 justify it, conduct health and work satisfaction surveys of nurses and teachers who work in buildings of several different kinds:
 - Conventional buildings in good repair
 - Conventional buildings that have implemented comprehensive indoor environment policies (e.g. Brigham and Women's indoor air policy, including its fragrance controlled workplace policy; schools that have EPA Tools for Schools, health care facilities that have implemented EPA/NIOSH Building Air Quality — A guide for building owners and facility managers.)
 - Conventional buildings in poor repair.
 - New buildings built to “green” standards such as those promulgated by LEED.

Compare the survey results among all types of these buildings, matching survey responses for age, length of time in the workplace, plans to continue at that workplace, plans to continue in the profession.

6. Identify factors (from the surveys conducted in 5.) that contribute to worker health, satisfaction, and retention.
7. Formulate and publicize recommendations for health-promoting strategies that favor teacher and nurse workplace health based on 1-6.

This is an ambitious plan, but can be spread over several years, thus limiting its budget impact. It also provides many opportunities to publish results obtained from steps along the way to final completion in 7. These results should be disseminated widely to nurse and teacher professional organizations, to ensure continued public support for the effort.

Preventing Needless Work Disability by Helping People Stay Employed

A Report from the

Stay-at-Work & Return-to-Work Committee

of the

American College of Occupational & Environmental Medicine

TABLE OF CONTENTS

Executive Summary

Overview of the Report

Introduction

Background

What is the SAW/RTW Process?

Table 1 – The SAW/RTW Process Begins Simply But Can Become Very Complex

Table 2 – Examples of the Variability of Medical Conditions and Their Impact on Work

Table 3 – Five Parallel Processes Triggered by a Health event That Affects Ability to Function

Observations and Recommendations

I. *Adopt a Disability Prevention Model*

1. Need to Increase Awareness of How Rarely Work Disability is Medically REQUIRED
Table 4 – When is Disability Medically Required, Medically Discretionary, and Medically Unnecessary?
2. Urgency is Required Because Prolonged Time Away From Work is Harmful

II. *Address Behavioral and Circumstantial Realities that Create and Prolong Work Disability*

3. People's Normal Human Reactions Need to Be Acknowledged & Dealt With
4. Investigate and Address Social and Workplace Realities
5. Find a Way to Address Psychiatric Conditions Effectively

III. *Acknowledge the Powerful Contribution that Motivation Makes to Outcomes and Make changes that Improve Incentive Alignment*

6. Pay Doctors for Disability Prevention Work to Increase Their Professional Commitment to It
7. Support Appropriate Patient Advocacy by Getting Doctors out of a Loyalties Bind
8. Increase availability of On-The-Job Recovery or Transitional Work Programs
9. Reduce Distortion of the Medical Treatment Process by Hidden Financial Agendas
10. Be Rigorous, Fair and Kind to Reduce Minor Abuses and Cynicism
11. Devise Better Strategies to Deal with Bad Faith Behavior

IV. *Invest in System and Infrastructure Improvements*

12. Educate Physicians on How to Play Their Role in Preventing Disability
13. Disseminate Evidence on the Benefits for Recovery of Staying Active and At Work
14. Improve/Standardize Methods of Information Exchange Between Employers/Payers & Medical Offices
15. Improve and Standardize the Methods and Tools that Provide Data for SAW/RTW Decision-Making
Table 5 – Examples of Methods Currently Used By Physicians
16. Increase the Study of and Knowledge About SAW/RTW

Preventing Needless Work Disability by Helping People Stay Employed

A Report from the Stay-at-Work and Return-to-Work Committee of the American College of Occupational & Environmental Medicine

EXECUTIVE SUMMARY

As physicians our fundamental precept is “first, do no harm.” However, we see daily the contrast between well- and poorly managed health-related employment situations and the harm that results. Identical medical problems end up having very different impacts on people’s lives. The differences in impact cannot be explained by the biology alone. We know that much work disability is not required from a strictly medical point of view. We see devastating psychological, medical, social, and economic effects caused by unnecessarily prolonged work disability and loss of employability. We also see wasted human and financial resources and lost productivity.

Finding better ways of handling key non-medical aspects of the process that determines if an injured or ill person will stay at work or return to work will improve outcomes. Until now, the distinct nature and importance of the stay at work and return to work process (SAW/RTW) has been overlooked. Improvements to that process will support optimal health and function for more individuals, encourage their continuing contribution to society, help control the growth of disability program costs, and protect the competitive vitality of the North American economy.

The first half of our Committee’s report provides the groundwork for readers to understand the second half. Most importantly, the first half describes the SAW/RTW process, how it works and how it parallels other related processes. The second half discusses factors that lead to needless work disability and what can be done about them. Sixteen sections with our observations and specific recommendations are grouped under these four general recommendations:

1. Adopt a disability prevention model.
2. Address behavioral and circumstantial realities that create and prolong work disability.
3. Acknowledge the powerful contribution that motivation makes to outcomes and make changes that improve incentive alignment.
4. Invest in system and infrastructure improvements.

A committee of 21 physicians prepared this report because we feel compelled to speak.¹ The insights we have gleaned about the preventable nature of much work disability must be shared. Our primary goals at this time are to draw attention to the SAW/RTW process and shift the way many people think. Our intent is to open a dialogue between the American College of Occupational and Environmental Medicine (ACOEM) and other stakeholders in the workers’ compensation and non-work-related disability benefits systems: employers, unions, working people, the insurance industry, policymakers, the healthcare industry, lawyers, and healthcare professionals, especially all physicians. We invite you to work with us towards solutions.

¹ We are all members of the American College of Occupational and Environmental Medicine, and are specialists in emergency medicine, family practice, internal medicine, occupational medicine, orthopedics, physiatry, and psychiatry. We are in private medical practice, government, academia, heavy industry, as well as workers’ compensation and disability insurance companies. We work in Canada and 15 of the United States.

Preventing Needless Work Disability by Helping People Stay Employed

OVERVIEW OF THE REPORT

The fundamental questions this paper is designed to answer are these:

1. Why do some people who develop common everyday problems like backache, wrist pain, depression, fatigue, and aging have trouble staying at work or returning to work?
2. How can employers and insurers work more effectively with healthcare providers to reduce the disruptive impact of injury, illness and age on people's daily lives and work, and help them remain fully engaged in society as long as possible?

This report is the end product of extensive and vigorous deliberation by the 21 physician members of the ACOEM Stay at Work and Return to Work Committee. The Committee used a collaborative and consensus-seeking process to develop the observations and recommendations.. The report has been approved by ACOEM.

In order to build a more profound awareness among all stakeholders that collaboration is required to make the SAW/RTW process work better, we request that you read our report in its entirety. Every stakeholder will be more familiar with some parts than others, so we suggest that you focus on the portions with which you are less familiar.

The report begins with an introduction that describes the growing pressures in North America caused by an aging workforce, rising medical costs and lengthening periods of disability. It also describes the Committee that produced the report and the American College of Occupational and Environmental Medicine's growing commitment to help meet the needs of workers, employers and insurers in the twenty-first century by working collaboratively with all parties to keep the workforce healthy and productive.

Next comes the background section that defines key terms like "disability" and "disability benefits systems" and the SAW/RTW process, and describes in very broad terms how malfunction of the SAW/RTW process is causing harm to the health and well-being of the same people that these systems were designed to protect – and harm to their families, employers, communities, and society as a whole. Lastly, the background materials explain why the Committee chose to develop this report.

The third section describes in detail how the SAW/RTW process works by using a simple case example. There are two tables: one that shows how the process can escalate and increase in complexity through a series of iterations due to circumstances; and a second one with examples of different kinds of medical conditions that have very different impacts on function and work over time. Next the relationship of the SAW/RTW process to four other parallel processes is described. Three are much more well-known and studied; the other has been studied in academia but largely ignored by disability benefits programs. The failure to distinguish among these separate processes underlies much current system dysfunction. These four other processes are:

- The ill or injured individual's personal adjustment (coping) process.
- The medical care process.
- The benefits administration process.
- The reasonable accommodation process under the ADA.

The second half of the paper consists of observations and recommendations about the current status of and potential improvements to the SAW/RTW process in North America today. Sixteen specific recommendations are described in groups under the four general recommendations. Each of the 16 specific recommendation sections:

- Identifies specific challenges and non-medical factors that now combine to create needless disability and its negative consequences.
- Recommends ways that many of the issues can be addressed.
- Points out initiatives underway and best practices in preventing needless disability among working people who are faced with injury or illness.

The major points and recommendations made in this report are:

- I. Adopt a disability prevention model.
 - o Legislators, regulators, policymakers, and benefits program designers should address the reality that much work disability is preventable, and that successful SAW/RTW requires collaboration among several parties.

- Shift the focus of the SAW/RTW process away from certifying or evaluating work disability towards preventing it. Unless complete work avoidance is medically-required for healing or for protection of the worker, co-workers or the public, we should be looking for ways to prevent or reduce absence from work. Expecting and allowing people to contribute what they can at work and keeping them active as productive members of society is good for them -- and for us all.
- Instill a sense of urgency to normalize daily routine because prolonged time away from work is often harmful. In only a few weeks, most people make adjustments and adopt a new view of themselves and their situation. Some people begin to think they are permanently disabled regardless of the medical facts. Once that idea is implanted, it is hard to shake.
- Employers, unions, and insurance carriers should devote more attention and resources to preventing disability by focusing on the “front end” of disability episodes while the window of opportunity to make the most difference is still open. In practice, this means ensuring that the right things happen during the first few days and weeks of work absence. Injured/ill workers should routinely receive the support and services they need to get their daily lives back to normal as soon as possible.

II. Address behavioral and circumstantial realities that create and prolong work disability.

- Acknowledge and address people’s normal human reactions to illness and injury. Life disruption may be significant and hard for some to cope with. Failure to acknowledge this distress or offer help breeds trouble. Common courtesy may be all that is needed.
- Rather than ignore them, investigate and address social and workplace realities. Scientific research shows that workplace factors like job dissatisfaction or poor job fit have a powerful effect on disability outcomes. Despite reluctance to intervene, some issues can be readily resolved once brought to the surface.
- Reduce distortion of the medical treatment process by hidden financial and legal agendas. A physician who is kept in the dark is not necessarily more independent, and is vulnerable to manipulation.
- Find a way to effectively reduce disability due to psychiatric conditions, whether occurring in isolation or in combination with physical ailments. Do so in a manner that avoids creating more harm and pouring resources into ineffective physical or mental health treatment.

III. Acknowledge the powerful contribution that motivation makes to outcomes and make changes that improve incentive alignment.

- Pay doctors for disability prevention work in order to increase their commitment to it.
- Support appropriate patient advocacy by getting treating doctors out of a loyalties bind Stop asking treating doctors to “certify” disability or to set a return to work date. Instead ask them about functional ability (unless there is a clear reason why it would be medically-inappropriate for the worker to do all work of any kind.)
- Increase availability of on-the-job recovery and transitional work programs. Make it faster and easier to arrange permanent job modifications since workers who stay active during recovery have better outcomes. Requirements or incentives for employer participation will be required.
- Good faith efforts should be required of the patient / employee, the doctor, and the employer to prevent or mitigate disability.
- Reduce cynicism and improve customer service to injured and ill employees by being more rigorous, more authentic and helpful, fairer, and kinder.
- Restore integrity to programs rife with minor abuse. Make people aware how minor benefits abuse breeds still more abuse and cynicism that in turn leads to negative and prejudicial treatment of innocent people.
- Devise better strategies to deal with bad faith behavior/exploitation/fraud. In particular, provide workers who believe they need help with alternatives to lawyers.

IV. Invest in system and infrastructure improvements.

- Programs are needed that will provide basic training to practicing clinicians on why and how to prevent disability, as well as why and when to disqualify patients from work. This education should encourage physicians and other healthcare professionals to broaden the focus of their care to include disability prevention and to develop clinical skills in this arena.

- Disseminate the scientific evidence regarding the benefit of staying at work and being active on recovery and preserving function. Doctors, patients and employers all need to know this.
- Improve information exchange between employers/payers and medical offices.
- Improve and standardize the methods and tools that provide data for SAW/RTW decision-making.
- Increase the study of and knowledge about the SAW / RTW process. Policymakers, government agencies, labor organizations, employers, insurance carriers, and interested citizens should underwrite efforts to learn more about how the SAW/RTW process works and to understand its outcomes, and should support research to develop methods that prevent disability more often or more effectively.

The basis for each recommendation, along with suggestions for how to implement it, is described in the full report that follows. The bibliography of literature references is arranged in groups that correspond to the sixteen specific recommendation sections. Full implementation of many recommendations will require collaboration among all system participants, but forward progress can and is already being made by committed individuals and companies on their own.

This report is the latest in a series of initiatives launched by ACOEM (www.acoem.org) to better meet the needs of patients, employers and insurers in the twenty-first century. We are doing what we can to help keep the workforce as healthy and productive as possible.

INTRODUCTION

The North American workforce has been aging. The burden of chronic disease in the population and its resulting impact on function has been rising. Episodes of prolonged disability due to common conditions such as depression and low back pain are becoming more common. As the population is aging, the fraction of the US population now receiving social security disability payments is also rising. Although the incidence of work-related injuries and illnesses has been falling steadily for the last several decades, the length of disability following work-related injury has been climbing, as have the number of medical services and their costs. Paradoxically, employers are paying for more -- and more expensive -- medical services but people are nevertheless losing more time from work for medical reasons.

Until now, mitigating the impact of illness and injury on everyday life and work – with the goal of preventing needless disability, preserving function, and protecting quality of life – has not been within the traditional purview of medicine. We think it is time to broaden the scope.

We believe that this report is the first ever description of the workings (and failings) of the SAW/RTW process. Our Committee is well-qualified to address these matters from an informed and fact-based perspective because of the unusual breadth and depth of our cumulative experience:

- All of us have practiced medicine and have seen the SAW/RTW process in action first hand, since all of the disability benefit programs require a doctor's participation and signature at one point or another.
- As physicians involved in occupational medicine, the members of our Committee deal every day with work concerns that people have because of their health, as well as health concerns caused by their work.
- As physicians, we have all been trained to distinguish what is medical from what is not.
- We come at the SAW/RTW process from multiple vantage points. We are specialists in emergency medicine, family practice, internal medicine, occupational medicine, orthopedics, physiatry, and psychiatry. We are in private medical practice, government, academia, heavy industry, as well as workers' compensation and disability insurance companies. We are hands-on clinicians, executives, thought leaders, and consultants. We work in Canada and 15 of the United States.

The development of this report is one concrete example of ACOEM's commitment to meet the needs of workers, employers and insurers in the twenty-first century. Our members have begun moving beyond our specialty's traditional role in preventing and treating work-related health problems. Increasingly, we will be working collaboratively with all parties to keep the workforce healthy and productive. That means taking on a broader role in preventing, treating, and mitigating the impact of all types of health conditions on function, particularly on occupations.

This particular document is intended to begin an on-going dialogue between ACOEM and employers, payers (insurers, third party claims administrators and self-insured employers), and regulators of the work-related and non-work-related disability benefits systems. Given that there are so few of us available (occupational medicine is among the smallest of medical specialties), we are interested in exploring how ACOEM can best demonstrate leadership and its members can best assist the nation's workers, employers, and insurers in preventing needless disability.

For more discussion of the implications of the SAW/RTW process for the hands-on practice of medicine, please see:

- The 2nd edition of the ACOEM Practice Guidelines, Chapter 5 entitled "Cornerstones of Disability Prevention and Management" (www.acoem.org/education/tools/pracguide.asp).
- The American Medical Association's new book "A Physician's Guide to Return to Work" edited by Drs. James Talmage and Mark Melhorn who are ACOEM members as well as members of our Committee.

BACKGROUND

Each year, millions of American workers develop health problems that have the potential to temporarily or permanently prevent them from working. In the large majority of cases, these employees are either able to stay at work in spite of the condition, or return to productive work after a brief recovery period. For the balance, roughly a tenth, significant work absence and life disruption occurs, sometimes leading to prolonged or permanent withdrawal from work. During the period while they are not working, these individuals are described as "disabled" and many of them become involved with one or more disability benefits systems.

The disability benefits systems we refer to include all the programs that protect workers when they become unable to work for medical reasons – especially those that provide financial support – such as sick leave, workers' compensation, short-term disability (STD), long-term disability (LTD), and Social Security Disability Income (SSDI). Other closely related programs include the Family Medical Leave Act (FMLA) and ADA (in the US) and their Canadian counterparts, though they do not pay benefits per se. The estimated total annual cost of disability benefits paid under all these systems in the US exceeds \$100 billion.

Every disability benefit program usually requires a physician's signature on a letter, note, or form of some kind before benefits can be awarded or denied. Other than that one similarity, disability benefit programs and the processes for administering them are better characterized by their many differences. Each has its own complex rules and processes for eligibility determination and for administration of benefits. Experts in one system often do not know much about the others. Each of the programs has generally received significant study and attention on process improvements and benefit program design, but each one has been considered in isolation. The programs are not knit together into a coherent, coordinated whole, and the whole has not received similar attention to potential improvements.

In this paper, we use the word "disability" the same way that employers use it in their benefits programs and employment policies, and the same way that insurance laws, regulations, and policies do. We use "disabled" to mean someone who is absent from work or not working at full productive capacity for reasons related to a medical condition. Please note that confusion is common regarding the word "disability" since it is sometimes used to describe physical or functional impairments. For example, a person who has an impairment that affects one or more life functions is considered to have a disability under the Americans with Disabilities Act (ADA). However, people with ADA-qualifying impairments who are working at full productive capacity would NOT be considered disabled according to our definition, because they are at work.

The focus of this paper is on the surprisingly large number of people who end up with prolonged or permanent withdrawal from work due to medical conditions that normally would cause only a few days of work absence. Many of those who end up receiving long-term disability benefits of one sort or another have conditions that began as common everyday problems like sprains and strains of the low back, neck, shoulder, knee and wrist, or depression and anxiety. As we will discuss below, prolonged work withdrawal (disability absence) by itself can produce unfortunate consequences, and this is one of our major concerns.

On the other hand, many of the people who receive disability benefits have severe illnesses like a major cancer or schizophrenia or have suffered catastrophic injuries such as amputations, blinding, major burns, or spinal cord injuries, or have had major surgery. These people, too, are susceptible to the influences described in this paper, although the effects may be overshadowed by the obvious difficulties of coping with medical problems of this magnitude, and the need to learn skills and methods to deal with any resulting impairments. In these cases, a prolonged period of work absence is often unavoidable. The traditional rehabilitation approach delivered by an array of professionals was designed to meet the needs of these people. The question still sometimes arises: what amount of this work disability could be prevented?

We contend that a considerable amount of the work disability due to common everyday conditions (and an unknown fraction of the disability that follows more serious conditions) is avoidable, as are its social and economic consequences. We believe that a lot of work disability can be prevented or reduced by finding new ways of handling important non-medical factors that are fueling its growth.

In particular, we want to draw attention to a little-known but fundamental process shared by all the disability benefits systems in the US and Canada today – what we call the Stay at Work and Return to Work (SAW/RTW) process. It is a fundamental underlying set of actions and decisions that determines whether a worker will stay at work in spite of a medical condition, and if not, determines whether, when, and how the worker will return to work during or after recovery. This SAW/RTW process is the topic of this paper. We abbreviate this process as SAW/RTW and will define and describe it fully later in this paper.

Some non-medical aspects of the SAW/RTW process are causing harm to the health and well-being of the same people that these systems were designed to protect – and harm to their families, employers, communities, and society as a whole. We see how often participation in the disability benefits system is counterproductive in our patients' lives, some of whom are particularly susceptible. The disability system typically turns an impersonal face towards a person whose life has been disrupted and who may need guidance in managing a new life situation. We also see how often the SAW/RTW process is both openly and surreptitiously distorted by other interests. As a result, the disability benefits system too often:

- fails to provide non-financial support to people who need help because their life has been disrupted by illness or injury
- fails to help people adapt or understand the course of their illness and their future life options, and defeats what would otherwise be a successful medical result
- wastes resources on people who do not need them
- causes people to refocus their lives and adopt a new identity as a disabled person, resulting in society's loss of potentially productive members.

As physicians our fundamental precept is “first, do no harm.” Because we see harm occurring in this arena, with physicians as unwilling or unwitting participants, we feel compelled to speak. We also see how disability programs affect costs, productivity, and the competitive viability of companies and states as well as national economies. An ineffective SAW/RTW process causes damage at many levels.

We are in agreement that the word needs to be spread: work disability is potentially preventable, there are good ways to prevent it, and collaboration across professional boundaries is part of the solution. In this paper we are speaking to policymakers, legislators, and regulators, to business and industry, to insurers and other payers, to lawyers, organized labor and working people directly, in addition to all our colleagues in medicine and the other healthcare professions. As more and more people come to see things from this perspective, creative efforts to address the major issues will become possible.

Some employers, insurers, healthcare providers and employees achieve better-than-expected outcomes under difficult circumstances, and some deliver better-than-usual program or system results. Their success stories are the proof that much disability is preventable. They can serve as models for others to follow. In most instances, a simple formula of kindness, straightforward communication, common sense practicality, and good management is all that is required to make the system work better and achieve better outcomes for all.

In summary, the results produced by the SAW/RTW process have a profound impact on the overall health and well-being of our patients, and also their families, employers, communities, and ultimately society as a whole. It determines whether people stay engaged in or withdraw from work and all the consequences that derive from that decision. However, the SAW/RTW process has been hidden amidst all the complex technical, financial, and legal details of multiple disability benefit programs. This little-studied and under-resourced process has enormous personal and economic consequences for the lives of millions and for American society, and deserves attention in its own right.

WHAT IS THE SAW/RTW PROCESS?

At its heart, the stay-at-work/return-to-work process is a very common, everyday process. Every working person who wakes up with a cold or a backache has to decide whether to go to work, and if the answer is yes, how to get through the day. Let's walk through the usual steps in this process by considering the simple case of a worker named Tom.

1. The SAW/RTW process is triggered whenever a medical condition arises or another precipitating event occurs, and the question arises whether the worker can or should do his usual job today. *In Tom's case, he woke up with a badly infected cut on his foot.*
2. The worker's current ability to work is assessed on three important dimensions, either formally or informally:

- Functional capacity – what can he do today? *Has Tom's infection made him so sick he simply can't function at all and has to be in bed? If not, what can he do in his current condition?*
 - Functional impairments or limitations – what can't the worker do now that he normally can? *In Tom's case, the acute pain he is experiencing means he is too uncomfortable to wear his normal shoes and do any activities that require him to be on his feet – prolonged standing, walking, jumping, etc.*
 - Medically-based restrictions – what he should not do lest specific medical harm occur? *In Tom's case, would walking, standing, and being on his feet all day actually worsen the infection or delay healing?*
3. The next question is whether the worker's temporarily-altered capacities, limitations, and restrictions are sufficient to perform the tasks required by his job.
- In order to answer this question, the functional demands of the job must be known. Functional demands include the knowledge, skills, and abilities – physical, cognitive and social – required to perform a job. *In our case example, Tom already knows what it takes to do his usual job.*
4. The last question is what must occur in order for the situation to be resolved and the worker actually go to work?
- If it is clear that the worker can be safe and comfortable doing his usual job, or if he can make any necessary modifications himself, he simply goes to work. *In Tom's case, that is what he decided to do, since he works at a desk all day and can keep his foot elevated on a chair.*
 - However, there may be legal requirements, company policies, or concerns about the safety of co-workers, the public, or the business that will affect what happens. Examples of medical qualification standards include those for airline pilots, truck drivers, school bus drivers, crane operators, scuba divers, and the like. Examples of company policies include performance standards especially for those with customer or public contact, fiduciary responsibilities, or executive authority.
 - If a temporary alternative task or job is possible but would require the cooperation of others, it has to be arranged and implemented.
 - If a satisfactory temporary arrangement is made available, the worker goes to work.
 - If not, the worker remains out of work until something changes: his condition (and thus his functional capacities, restrictions, and limitations), the available options for working under those conditions, or the motivation to find a solution to achieve return-to-work.

Usually all these steps are completed in an instant because most medical conditions are minor, the job doesn't put too much demands on the impaired body part or function, and the worker is willing to go to work. But sometimes the situation cannot be acceptably resolved on the first pass, and additional steps are required. At this stage, the SAW/RTW process evolves into a de facto negotiation between the employee (and his advisors) and the employer (and its advisors) about whether the employee will be able to come back to work.

The SAW/RTW process is often *iterative* – meaning that finding a solution may take more than one try, and may even require going over the same ground several times as the situation escalates. Steps 2 through 4 above may need to be repeated at each level. During each repetition, more participants tend to become involved, and progressively more opinions, data, resources and time are required in order to figure out what to do.

Escalation Level #0: Tom goes through the process in his mind in an informal way. It will simply seem like he is deciding whether he should go to work or not. He will take cues from those around him – his doctor, supervisors, and friends – and will be influenced by his own realistic and unrealistic fears, motives, and life history. His thinking will also be constrained by his current personal life situation.

Escalation Level #1: If Tom decides he can't work or is unsure what to do, his supervisor, the claims adjuster and/or his doctor get involved. The employer may be asked to send the doctor a job description or list of tasks. The doctor may be asked to provide information about Tom's medical restrictions or his work capacity. The employer then decides whether or not it is able to (or will) provide transitional work that matches what Tom can do.

Escalation Levels #2 and 3: In more difficult situations, successive passes add progressively more participants and more specialized assistance: a nurse case manager, a physical therapist, the employer or insurer’s medical consultant, an occupational medicine physician, an independent medical examiner, a vocational rehabilitation consultant, union representatives, lawyers, and/or other experts. Functional capacity evaluations may be done to document work capacity. Job analyses including ergonomic measurements and even video photography may be done to document the nature of the job demands. With each pass, the time and money consumed increases along with the amount of information assembled. Because there is usually no one in charge and the participants have not agreed on the goal of finding an optimal resolution to the situation, the additional effort and resources often have a paradoxical effect: clouding the situation rather than clarifying it, obscuring basic issues, causing confusion, hardening positions and polarizing the participants.

Table 1 displays the escalation levels of the SAW/RTW process, moving from simplest to most complex. In reality, the process often occurs as a ragged continuum rather than a structured series of rounds. As soon as there is a definitive answer – the worker returns to work or it becomes clear that will never happen – the process stops. Every time the process reaches the end without a definitive answer, we go back to the beginning – but the complexity goes up: the number of participants increases, more detailed data is used as the basis for decision-making, and the formality of the resolution process increases dramatically. However, the three basic issues that need factual answers always remain the same:

- What are the worker’s current work capacity, medical restrictions, and functional limitations?
- What are the functional demands of the intended job?
- If the workers’ functional capacity is adequate to meet the functional demands, what is required to make an actual return to work happen?

Table 1				
The Stay at Work / Return to Work Process Begins Simply But Can Become Very Complex				
<i>The SAW/RTW process is triggered whenever a precipitating event, usually health-related, raises the question whether a worker can or should remain at work.</i>				
Escalation Level #	Who is involved?	How is current work capacity determined?	How are job demands determined (both usual job and alternatives)?	What triggers the actual return to work?

There is a lot of variability in medical conditions, and also a lot of variability in their impact on work. Table 2 below shows examples of the wide range of circumstances under which the SAW / RTW process is taking place.

Table 2
Examples of the Variability of Medical Conditions and Their Impact on Work

Medical Condition	“A Cold” or Acute Food Poisoning	Sprained Ankle or Influenza or Asthma Attack	Femur Fracture or Abdominal Surgery or Treatable Cancer or Major Depression	Bipolar Disorder or Multiple Sclerosis or Congestive Heart Failure
Length of time away from work	None/Days	Days	Weeks	Weeks/Months
Biological Impairment	Trivial Isolated episodes	Minor Isolated episode	Moderate Isolated episode May recur	Moderate /Severe Chronic/Recurring May be progressive
Medical care required	None	Single provider 1-2 visits	Several providers Several curative visits/service Relapse prevention may be necessary s	Multiple providers On-going services Relapse prevention is required
Likelihood of full resolution	Always	Always	Usually Some residual impairment is possible	Unlikely Fluctuation in functional ability is common
Time course of the illness/condition	Days	Days	Weeks	Months/Years
Career Impact	None	Irrelevant	Significant temporary impact (Residual but stable permanent impairment may affect ability to perform essential job functions)	Progressive impairment often affects ability to perform essential job functions long term
Number of other professionals involved	0-1	0 - 2	0 - 3	Multiple
SAW/RTW information exchanges required	0-1	0 - 1	0 - 3	Multiple

The SAW/RTW process does not occur in isolation. It is closely tied to, but distinct from, four other important, related processes:

- Perhaps most importantly, the injured or ill worker is engaged in a **personal adjustment process**, dealing with the disrupted life situation around the illness or injury. Getting sick or hurt suddenly disturbs the equilibrium that life was in before the change occurred. Often workers are dealing simultaneously with a mixture of things in different dimensions: physical, logistical, financial, emotional, social, and psychological. Virtually everyone has to cope with at least some transient disruption even though some medical conditions are so minor there is little objective impact to cope with. However, not everyone has the same resilience and level of coping skill, so some people find it hard to adjust to things that others barely notice.
- If the medical situation calls for treatment, the SAW/RTW process occurs in parallel with the **medical care process** that consists of diagnosis and treatment.
- If the initial SAW/RTW process results in the worker staying at home and if there is a possibility of coverage under one or more disability benefit programs (sometimes there is not), the **benefits administration process** will begin, and will operate in parallel with SAW/RTW. Benefits administration may include initial and ongoing eligibility and compensability investigation and determination, benefit calculations and payments, and benefit termination, among other activities.
- If a permanent or long-lasting alteration of work capacity occurs, the **ADA “reasonable accommodation” process** will probably be triggered. It will operate in parallel with SAW/RTW, and if ADA is determined to apply, will heavily influence what occurs in SAW/RTW.

These four other processes (summarized in Table 3 below) involve many of the same participants as SAW/RTW, but exist to address different questions, employ different activities, and have different end-points.

The first process – personal adjustment, which is the natural human response to injury and illness – is neither explicitly acknowledged nor addressed in any of the other processes. Ironically, unresolved issues in the poorly-known personal adjustment process often foul up all four of the other processes. The failure to attend to the human needs of people who are normal but lack the resilience and coping skills required by their circumstances probably accounts for much of the system dysfunction we are discussing.

The other three processes – medical treatment, benefit administration, and ADA reasonable accommodation – have each received much more attention than SAW/RTW. Each has a coherent body of strong advocates with an interest in improving their process and advancing their agendas. The SAW/RTW process has been overlooked because so much attention is focused on the other well-known processes, and because of a longstanding but incorrect assumption that if the medical condition is promptly and properly treated, the worker will naturally return to work.

The SAW/RTW process deserves more attention in its own right. Those whose interest centers in another process need to become more attuned to and supportive of the SAW/RTW process because of its potential impact on their area.

Below is an example that illustrates the circumstances that lead to optimal versus sub-optimal outcomes, using the cases of two fictitious but typical men with identical medical conditions and treatment. Mr. A. and Mr. B. both had back problems severe

enough to require surgery, but Mr. B. returns to work in 6 weeks while Mr. A. ends up on permanent disability. Mr. A. was not supported through his personal adjustment process and the workplace environment did not support functional recovery.

MR. A	MR. B
• Mediocre work history	• Mediocre work history
• Bad back, herniated disc	• Bad back, herniated disc
• Treatment: surgery	• Treatment: surgery
• Supervisor never called: “Let George do it”	• Supervisor kept in touch: “We need you”
• Weak supervisor	• Good supervisor
• Teasing by co-workers	• Support from co-workers
• Naïve doctor: “Stay home until you’re able to do your job.”	• Function-oriented MD: “Stay as active as possible.”
• PERMANENT DISABILITY	• On-the-job recovery; adaptive equipment
	• BACK TO WORK IN 6 WEEKS

OBSERVATIONS AND RECOMMENDATIONS

The first half of this report described the SAW/RTW process, how it works, and how it is related to the other processes that often are running in parallel with it. The second half of the report describes our Committee’s observations and recommendations, which are divided into 16 sections. Each section begins with a specific recommendation concerning a single feature or aspect of the process. The 16 sections are grouped under four general recommendations:

- I. Adopt a disability prevention model.
- II. Address behavioral and circumstantial realities that create and prolong work disability.
- III. Acknowledge the powerful contribution that motivation makes to outcomes and make changes that improve incentive alignment.
- IV. Invest in system and infrastructure improvements.

For each of the 16 specific recommendations, we describe how the status quo currently interferes with achieving optimal outcomes, discuss the reasoning for our recommendation, and make suggestions for ways to implement the recommendations. Where available and as space permits, we give concrete examples of improvement initiatives underway or programs getting better-than-average results by using best practices. Note that many of the issues and suggested solutions are interrelated, so there is some duplication and overlap in the text.

In the extensive deliberations of our committee, a number of the issues raised were agreed to be important but applicable only to specific sub-segments of the overall disability benefits system – e.g. particular industries, benefit programs, labor arrangements, medical conditions, patient types, job types. We decided to exclude those narrower issues from this report, and only include those aspects of the SAW/RTW process that are pervasive, applying across most or all of the various disability systems. The deferred issues are still important and should be discussed and addressed at some future time.

I. ADOPT A DISABILITY PREVENTION MODEL

1. Increase Awareness of How Rarely Disability is Medically-REQUIRED

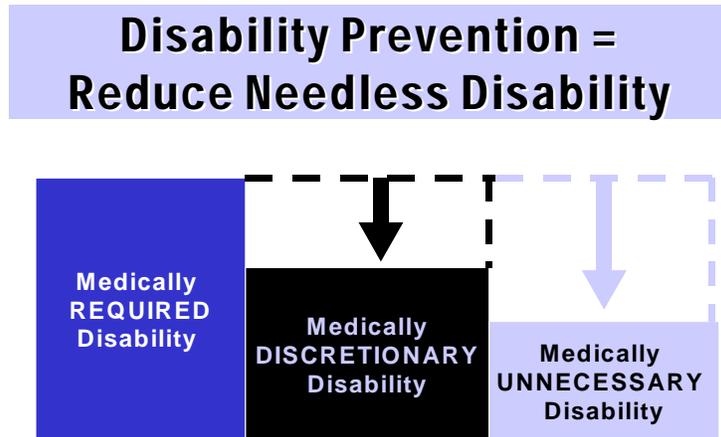

At least one formal survey and numerous informal polls of treating physicians consistently estimate that only a small fraction of medically excused days off work are medically *required* – meaning that all work of any kind is medically contraindicated. The rest of the days off work are caused by a variety of non-medical factors such as administrative delays of treatment and specialty referral, lack of transitional work, ineffective communications, lax management, logistical problems, and so on. These days off work are discretionary – the result of decisions that are fundamentally non-medical – or just plain unnecessary.

Participants in the disability benefits system seem largely unaware that so much disability is not medically required. Absence from work is “excused” and benefits are generally awarded based on a doctor’s signature on a letter or form confirming that a medical condition exists, implying that a diagnosis creates disability. However, from a strictly medical point of view, people can generally work at something productive as soon as there is no specific medical contraindication to them being out of bed and back out in the “real” world (see Table 4).

The key question is: work doing what? Many obstacles that look like they are medical are really situation-specific. For example, an employee with a cast on the right foot cannot drive a forklift, but that worker could do a lot of other potentially

useful tasks until the cast comes off. Someone who has had recent surgery may not be able to work a full day in the office yet, but could come back half days or do some work at home.

In fact, people often end up sitting at home collecting benefits because their employers have made the discretionary business decision not to take advantage of their available work capacity. Today, these decisions are generally misclassified as “medical” and so are not examined. Sometimes those discretionary decisions make good business sense, but often they do not for reasons that will be discussed in more detail later in this report.

As shown in the figure above, there is much more opportunity to reduce medically-discretionary and medically-unnecessary disability than there is to prevent medically-required disability. Although it is unlikely that all of the discretionary and unnecessary disability can be prevented, substantial reductions are possible.

Recommendation: Stop assuming that absence from work is medically-required, and that correct medical diagnosis and treatment are the only ways to reduce disability. Pay attention to the non-medical causes that underlie discretionary and unnecessary disability. Reduce discretionary disability by increasing the likelihood that employers will provide on-the-job recovery. Reduce unnecessary disability by removing administrative delays and bureaucratic obstacles, strengthening flabby management, and by following other recommendations in this report. Participants should be educated about the nature and extent of preventable disability. Employers in particular should be educated about their powerful role in determining SAW/RTW results.

Current Initiatives and Best Practices: Clinicians, employers, and insurers can all now use the criteria in Table 4 below to determine whether disability is medically-required, discretionary or unnecessary. The definitions in Table 4 come from Chapter 5, the disability prevention and management chapter, in the 2nd edition of the ACOEM Practice Guidelines. If all parties begin using these definitions, clearer communication and better decision-making will result. In particular, physicians will no longer be asked to make employment decisions, and employers will stop misclassifying business decisions as medical ones.

<p align="center">Table 4</p> <p align="center">When is Disability Medically-Required, Medically-Discretionary and Medically-Unnecessary?</p> <p align="center">(Source: ACOEM Practice Guidelines, 2nd edition, Chapter 5, Cornerstones of Disability Prevention and Management, pp 80-82)</p>

---	---	--

2. Urgency Required Because Prolonged Time Away From Work is Harmful

Unnecessary prolonged absence from work can cause needless but significant harm to well-being. While on extended disability, many patients lose their footing in three major dimensions: they lose social relationships with co-workers, lose the self-respect that comes from earning a living, and lose a major identity component for most people – what they do for a living.

As treating physicians, we have often seen patients voluntarily and unnecessarily take on a new identity as a disabled person. This is sad for us to watch, since our patients' quality of life deteriorates significantly as a result.

Taking a few days off work may seem harmless enough, and most of us occasionally take advantage of a cold or a sore back to get a needed break from stressful or boring work. The problem is that for some people, a few days off stretches out and becomes needlessly extended disability and leads to significant harm. The quandary is how to tell in advance whose life will go that way and whose will not. Experienced disability claims handlers report that more than three-quarters of their most problematic cases started out as seemingly-minor problems.

Some may argue that it is not worth trying to prevent unnecessary disability in all cases because it will only lead to harm in some. However, there are good examples where as a society we endorse universal prevention activities under similar circumstances. Not every smoker will get lung cancer, not every driver who fails to wear a seatbelt will be injured as a result, and not every worker who flaunts safety rules will get hurt. But, we still tell everyone to stop smoking, wear seatbelts, and follow safety rules. Needless disability should be treated in the same way.

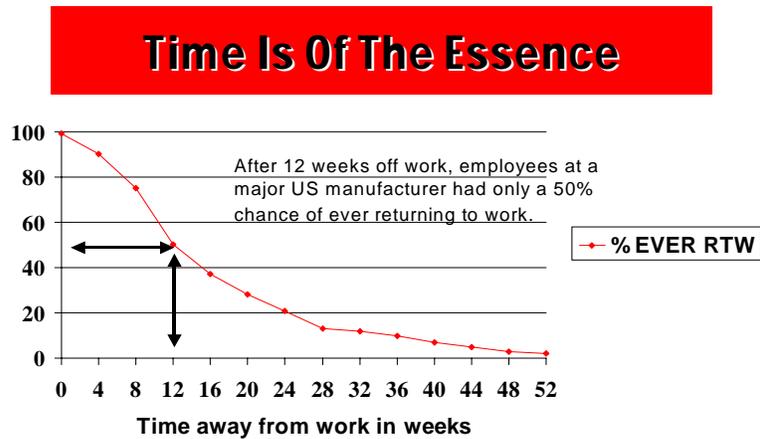

Many of the key players in the SAW/RTW process (patients/workers, their employers, physicians and claims administrators) are not sufficiently aware of the potential harmful effects of prolonged medically excused time away from work. Many think that being away from work reduces stress or allows healing. Many think getting disability benefits is just an administrative or financial issue, and they simply don't consider the fact that the worker's daily life has been disrupted. With these attitudes, iatrogenic or system-induced disability becomes a significant risk.

A recent article by Harris et al in the Journal of the American Medical Association has confirmed again what we doctors have known for years: people who are receiving disability benefits of some kind recover less quickly and have poorer clinical outcomes than those with the same medical conditions but who are not receiving disability benefits. The Harris study was a meta-analysis of all studies with data on surgical outcomes by compensation status. The researchers reported that 175 out of the 211 studies that met their inclusion criteria reported worse surgical outcomes for the patients on workers' compensation or in litigation. (Only one study reported better outcomes in compensated patients, and 35 studies reported no difference.) In the 86 studies where patients in litigation were excluded, the odds of an unsatisfactory outcome were more than three and a half times higher for the patients on workers' compensation than for those not receiving compensation. These are similar to findings of multiple other studies, including two previous meta-analyses of studies of outcomes, one for workers with chronic pain and the other for closed-head injuries.

The current practice of focusing disability management effort on those who have already been out of work a long time is rarely successful. After months of providing "proof of disability" and regular doctor's notes to justify their on-going compensation, these individuals have usually revised their view of themselves and taken on a new identity as disabled. This new identity justifies their life style and protects their financial security. In the meantime, the employer has moved on and filled that person's job slot, and no longer sees the individual as one of their workers.

The key to preventing disability is intervening while the situation is still fresh and fluid. Research has confirmed that people who never lose time from work have better outcomes than people who lose some time from work. Several studies confirm that the odds of returning to work drop with every passing day not at work. Some studies have shown that the odds for return to work to full employment drop to 50-50 by the time 6 months of absence has occurred. Even less encouraging is the study

behind Figure 1, showing the decay curve for workers' compensation cases at a major US manufacturer. In this population, the odds of a worker ever returning to work had dropped to 50% by just the 12th week. The author of a recent meta-analysis of research on the factors that predict prolonged disability reported that the window of opportunity for successful intervention may be as short as 6 weeks.

Recommendations: Shift the focus and shorten the response time. The way that all of us think about disability needs to shift from “managing” it to “preventing” it. Disability benefits systems need to be revamped to reflect the reality that resolving disability episodes is an urgent matter because the window of opportunity to re-normalize life is short. Emphasis needs to be placed on preventing or immediately ending unnecessary time away from work for everyone, because that will prevent the development of the disabled mindset. An educational campaign supporting this position needs to be formulated and widely disseminated. The SAW/RTW process needs to incorporate mechanisms to ensure withdrawal from work is prevented whenever possible, and its effects minimized when not.

On the individual level, all treating physicians, along with the other healthcare professionals on the healthcare team, should keep all of their patients’ lives as normal as possible during illness and recovery, and establish as a universal goal of treatment the fastest possible return to function and resumption of the fullest possible participation in life.

Current Initiatives and Best Practices: Many employers and some insurers now begin return to work efforts within 72 hours and some now begin on the day of injury -- rather than the more traditional approach of waiting to intervene until after 90 days of work disability. One large workers’ compensation insurer has a group of “pre-injury consultants” who work with employers to set up plans and systems beforehand so that they are prepared to respond promptly to avert needless lost work days from the moment of injury.

Attempts are also underway in several quarters to detect workers with pre-existing risk factors for prolonged disability and then manage those cases more intensively right from the onset. Dr. Alan Colledge (a member of this Committee) and some colleagues developed and published a Disability Apgar test, in which a few features of a situation are evaluated and then a risk score can be assigned. The State Fund of California has recently completed a pilot of a program that assesses risk factors at claim intake and makes suggestions for claim management. A workers’ compensation insurer in the Australian Northern Territory uses a situation assessment tool at claim intake and revisits it at intervals, in order to speed detection (and intervention) on claims that have signs of delayed recovery.

II. ADDRESS BEHAVIORAL & CIRCUMSTANTIAL REALITIES THAT CREATE & PROLONG WORK DISABILITY

3. People’s Normal Human Reactions Need to Be Acknowledged and Dealt With

In order to return to work, an injured or ill worker must navigate the Personal Adjustment Process described earlier in this paper. Most people accomplish this without problems. But for those who have difficulty handling that process on their own – coming up with a strategy for coping and adapting and reaching the decision to try to return to work – the other processes in the disability management system do a very poor job of providing assistance. (Some of the issues to be addressed in the Personal Adjustment Process are practical or logistical – how to get to work, who will mow the lawn. The need for better assistance in resolving such problems is discussed in the next section.)

In this section, we focus on a different critical issue – the normal human response to upset and change, and the variability in our ability to cope and adapt. We are not talking about mental illnesses here, such as depression – though psychiatric conditions will be addressed in a later section. We are talking about normal human emotional reactions that are experienced to a greater or lesser degree by every person in these circumstances.

People who have been injured or become ill have had their life disrupted. Even a minor injury may seem like a big event to the person who is injured because it is out of the ordinary. People may suddenly find themselves in pain, upset, worried, dependent on strangers. They may suddenly feel uncertain or uneasy because they don't know where to turn for help, or what doctor to go to. They may be angry at the person who caused their injury, or embarrassed and mad at themselves for being careless or breaking a safety rule. They may be afraid that they will get in trouble, may need surgery, or may never be able to walk again, or that this will mean the end of their career. They may be worried about who is going to pick the kids up from the sitter. Most of the time, they also have to figure out how to deal with an unfamiliar bureaucracy and set of rules – the workers' comp or disability benefits system.

Other parties often contribute to the uncertainty involved. Employers and insurers often neglect to tell or intentionally choose not to tell injured or ill employees very much about how their disability benefit programs work, what to expect, and what they can do to make the process work smoothly. Doctors often do not tell their patients much about their condition – how it will affect their daily life and work, what the eventual outcome and options are likely to be, the expected timeline for treatment and recovery, and what they can do to achieve the best possible result.

These issues and uncertainties can be a lot to cope with, and many workers with a significant illness or injury experience it as a stressful predicament. According to the Holmes Stress Scale, most human beings would find it quite stressful to get sick or be injured, and also stressful to change jobs or work responsibilities. People who are absent from work due to illness or injury are contending with both kinds of stress simultaneously. Of course, the amount of stress felt by a specific individual in a specific situation will vary widely based on factors like the magnitude of the medical problem, the personal and family situation at the time, and the job situation.

According to the view of medical anthropologists, the patient takes on the Sick Role and the Dependent Patient Role after becoming ill or injured. In order to recover, these roles must be relinquished. Since the Sick Role carries with it exemption from normal responsibilities, the right to receive care from others, and freedom from fault, it is a seductive role. Those who have trouble coping with their circumstances are very likely to resist relinquishing those roles, using them instead to feel good about themselves and ensure their future security.

A person's native ability to function and deal with life's problems varies from individual to individual, even without injury or illness involved. People under stress are less able to function well and have been shown to be more prone to illness or injury than those not under stress. If the demands of a situation exceed the individual's ability to cope under those circumstances and no assistance is provided, the Personal Adjustment Process will get stalled. Recovery and return to work will be delayed, needless loss of function occur, or permanent disability created.

In our experience, the current processes do not acknowledge these emotional realities. The medical care, benefit administration, and SAW/RTW processes do not powerfully and openly acknowledge the existence of these issues. Workers are typically left alone to cope regardless of their situation and their coping skills. Little empathy is provided to help bolster their strength and resilience. Little effort has been devoted to reducing uncertainty and other sources of stress. Individuals who are caught up in stress and complexity that they cannot handle by themselves are not identified. This is unfortunate because emotional adjustment has a profound effect on the largely discretionary effort at recovery made by the worker in the Personal Adjustment Process.

Even when emotional factors are recognized by today's participants in SAW/RTW, effective assistance is not usually available. In non-occupational disability, since medical treatment costs are not covered by the benefit program, there is generally no thought given to paying for supportive services that will aid recovery and return-to-work. In workers' compensation, claims adjusters are reluctant to acknowledge these issues and authorize care in the form of mental health services out of concern that it will lead to a claim for a psychological illness and drastically increased claim cost. In fact, though, most of these sick or injured people do not really need psychiatric care. They need the kind of simple education, minor supportive counseling, and reassurance that would normally be provided by a wise friend, a caring family member, a pro-active customer service department, a social worker, an employee assistance program, an ombudsman, or so on. Also, much uncertainty and stress would be removed if treating physicians were pragmatic and clear in pointing out the functional aspects of medical conditions, options, and time frames over the course of treatment, and actively empowered people to cope on their own.

Recommendations: All participants need to expand their model of SAW/RTW to include appropriate handling of the normal human emotional reactions that accompany temporary disability in order to prevent it becoming permanent. Payers need to devise methods to provide these services themselves or pay for reasonable aids to recovery along these lines.

Current Initiatives and Best Practices: Some US employers are creating linkages between their disability benefit programs (workers' compensation, short- and long-term disability) and their employee assistance programs (EAPs) and/or their disease management programs in order to assure that employees are made aware of the option to tap into existing support services. An insurance agency in New Jersey makes immediate solicitous inquiries after a work-related injury occurs to ensure that injured workers feel cared for and all their questions are answered.

4. Investigate and Address Social and Workplace Realities

Research is steadily accumulating showing that the social realities of an individual's connection to the workplace provide powerful predictors for the occurrence of injury and illness as well as for the outcome of the SAW/RTW process. Does the worker like his job? How much pressure and how much decision latitude does the employee have at work? Does the worker get along with her supervisor? Is he perceived as a good employee? Does the employer want her back? Do co-workers respect him, or instead cause him distress? Has she had performance or discipline problems? Is the workplace a hostile or unsafe environment? These factors can have a major impact on the parties' willingness to work towards SAW/RTW, especially when coupled with the emotional adjustment issues raised in the section above. The fact that job dissatisfaction has been shown to be one of the strongest statistical predictors of disability underlines this point.

Home and family life may also pose problems for the worker entering the SAW/RTW process – such as the need to care for aging parents or children, or logistical problems getting to and from work. The worker may be tempted to resolve such problems by prolonging disability benefits. A similar but 180° opposite situation occurs when the family or personal situation leads workers to insist on remaining at work when they medically should not. They may be desperate for money, workaholic, or so identified with their work role that they want to hide illness or incapacity and keep working even though it may harm them, pose a danger to co-workers or the public, or put their employer in violation of the law.

Still another dimension of unacknowledged workplace realities is that employers are often unwilling to admit they are unsure or ignorant of what to do. For example, it is much easier for a supervisor to flatly refuse to provide temporary transitional work than to ask for help because he doesn't know how to interpret the doctor's note, figure out appropriate tasks, and manage the worker who will be performing that assignment.

Though many players in the SAW/RTW process acknowledge the importance of these factors, little has been done to effectively address them in the SAW/RTW process. In fact, a significant problem for SAW/RTW is that employers and workers alike often use the disability benefit system as a way to sidestep difficult workplace issues. Typically these issues are obvious to the employer and/or employee but not disclosed to the outside parties – the doctor, the insurance adjuster – unless they exert significant effort to discover the underlying truths. As a result, these facts are seldom acknowledged or discussed so interventions to address the real issues are seldom attempted.

When key parties to the SAW/RTW process do not know what is really going on because they are not privy to this “inside information,” their effort expended on SAW/RTW will often be misguided or futile. Resources and time are wasted.

Recommendations: The SAW/RTW process should routinely involve inquiry into and articulation of workplace and social realities, since hidden issues rarely resolve themselves. The bio-psycho-social model of disease currently on the ascendant in medicine takes into account these issues. Better communication pathways between SAW/RTW parties should be established. Screening instruments that flag situations where workplace and social issues should be investigated or addressed should be developed and disseminated. Pilot programs that explore the effectiveness of various interventions should be conducted.

Current Initiatives and Best Practices: An innovative program developed by David Brown, a member of our Committee, is now being used successfully by several employers and insurers, particularly in Canada. It has as its centerpiece face-to-face conversations between the employee and the first line supervisor in structured sessions conducted by a trained facilitator. The focus of each session is “what part of your job can you do today?” All other parties (human resources and benefits staff, doctors, unions, etc.) become resources and advisors for the two key participants as they work towards a resolution of the situation. Among the many other positive outcomes of this process have been substantial increases in both employee and supervisor satisfaction with how potentially-disabling situations are being handled – and a near-total demedicalization of the SAW/RTW process.

Pilot studies are underway or complete in British Columbia and Alberta, Scotland, and Victoria (Australia) to intervene early in cases that are showing signs of delayed recovery. Both the evaluation and the intervention consider dimensions other than the medical. Initial results are very promising.

5. Find a Way to Address Psychiatric Conditions Effectively

A substantial minority of the population has undiagnosed / untreated psychiatric illness. When a potentially disabling physical illness or injury occurs to a person with underlying psychiatric illness, the risk of permanent disability increases unless the psychiatric problem is treated. A clinically significant psychiatric disorder becomes symptomatic during a period of serious medical illness in over 50% of cases, especially in those with a prior history of a major psychiatric disorder. In addition, many more previously-undiagnosed workers are vulnerable to developing their first frank episode of anxiety or depression when sick or injured. In these cases, the physical illness or injury precipitates the psychiatric episode.

Mental health treatment is required for these cases because the mental condition significantly affects the patient's reaction to the illness, adherence to medical treatment, the course of illness, its impact on function, and functional recovery from the physical condition. For example, symptoms of depression often include pain, fatigue, poor sleep and apathy. Poor sleep in turn increases sensitivity to pain. In short, psychiatric factors make a significant contribution to the risk of permanent disability unless there is active and effective treatment.

Psychiatric issues are usually undetected, ignored, or ineffectively addressed in the current SAW/RTW process. As a result, many people "stuck" in the disability benefit system have undiagnosed / untreated psychiatric conditions, experiencing the poor outcomes predicted in the paragraphs above.

The reluctance of treating physicians to make a psychiatric diagnosis comes primarily from lack of awareness and stigma. Patients often do not want these diagnoses.

Even when a psychiatric diagnosis is made, whether for a primary mental condition or one that is accompanied by a physical ailment, treatment is often inadequate or inappropriate. Limited benefits coverage and shortages of skilled mental health professionals often mean that expert treatment is unavailable. And, although all healthcare professionals understand the need to protect and foster role functioning in personal relationships, the similar importance of role functioning at work is often overlooked. Faced with a patient who talks about marital stress, few therapists would suggest a separation as the first step, but when a patient describes stress due to difficulties at work, leaving work is often seen as the solution rather than good faith attempts at conflict resolution and preservation of relationships.

There have been dramatic improvements in psychiatric diagnosis and the effectiveness of treatment over the past 15 years. Some employers are well aware of the potential cost-effectiveness of psychiatric treatments, but they also have spent considerable sums on ineffective and expensive therapy. They correctly feel that many mental health providers do not focus on functional recovery and continue overlong with treatments that have no apparent objective benefit. Payers for their part have not conditioned access and payment on providers' adherence to current treatment principles. Like other chronic conditions, psychiatric disorders may intermittently require intensive early treatment of new episodes as well as long-term low-level treatment for prevention of recurrence.

Recommendations: Effective means of acknowledging and treating psychiatric co-morbidities need to be found and widely adopted. Participants in SAW/RTW need to be educated about the interaction of psychiatric and physical problems, and be better prepared to deal with it. Psychiatric assessments of people with slower-than-expected recoveries should become routine. Whether for primary or secondary mental health conditions, payment for psychiatric treatment should be made conditional on the use of evidence-based and cost-effective treatments as well as demonstrated effectiveness.

Current Initiatives and Best Practices: An innovative program to make needed psychiatric services available to injured workers has been pioneered by the Washington State Department of Labor & Industries. This agency handles all the workers' compensation claims and pays all the benefits on behalf of insured employers in the state. The Department has made an agreement with the State Medical Association to pay for up to 90 days of psychiatric treatment "as an aid to cure" of a physical work-related injury as long as the initial evaluation, the treatment plan, and the ongoing progress notes meet certain specifications. It is essential to show a clear connection between the diagnosis and specific barriers to return to work, as well as a connection between the treatment plan and the removal of those barriers. As long as progress is clearly documented in the ongoing treatment notes, payment continues up to 90 days.

6. Reduce Distortion of the Medical Treatment Process by Hidden Financial Agendas

We often observe the medical treatment process being distorted by non-medical factors in cases where the disability benefit system is involved. This most often takes the form of patients seeking particular diagnoses or treatment pathways in order to obtain or maximize benefits. (The specific approach taken will vary based on the details of the benefit plans involved.) Another example of distortion occurs when employers or benefits claims administrators ask precise questions and elicit particular language from naive physicians that is subsequently used as the basis for benefit, claim, or employment determinations.

One cause is the complex and differing sets of rules for eligibility and benefit determination in the various disability benefit programs. Since there are thousands of different disability benefit plan designs, few doctors are ever able to accurately or clearly see the impact their actions may have on a given patient's benefit payments, and where hidden agendas may lie.

Doctors are often aware, either explicitly or subliminally, when patients, employers or payers make requests based on hidden agendas, and it makes them uncomfortable. But they seldom have a clear understanding of what is at stake, do not want to take the time and energy to become more informed, and do not want to risk offending their patient. Treating clinicians often find it simplest to practice a version of “don’t ask, don’t tell” in these situations, particularly because they will not be compensated for time spent learning more about the situation.

Recommendations: Develop effective ways and best practices for dealing with these situations. Treating clinicians should be trained what to do when they sense hidden agendas. Employers and payers should educate the provider about financial aspects that could distort the process. Procedures meant to ensure independence of medical caregivers should not keep the doctor “above it all” and in the dark about the actual factors at work. Limited and non-adversarial participation by impartial doctors may be helpful (for example, ask an occupational medicine physician to brief the treating clinician).

Where possible, the differences between benefit programs that create incentives to distort treatment should be reduced. Employers are in a better position to do this than other payers. However, we understand that some differences exist for important reasons, and that little change is likely to occur here.

Current Initiatives and Best Practices: Many employers are now examining their various benefit programs to see how they dovetail with one another, and whether they create unwanted incentives for employees to behave in a certain way. For example, some employers have set up paid time off banks in lieu of sick leave in order to decrease abuse and increase the predictability of employee absence. Others have redesigned their short-term disability program benefits to more closely match the workers’ compensation benefit and vice versa. An increasing number of employers who provide salary continuation or short-term disability coverage are expanding their workers’ compensation return-to-work programs to cover non-occupational conditions as well.

III. ACKNOWLEDGE THE POWERFUL CONTRIBUTION THAT MOTIVATION MAKES TO OUTCOMES AND MAKE CHANGES THAT IMPROVE INCENTIVE ALIGNMENT

7. Pay Doctors For Disability Prevention Work to Increase Their Professional Commitment to It

Disability prevention and management takes both physician time and cognitive work; it requires a lot more than just filling out a form. Yet doctors are seldom paid extra for collaborating in the SAW/RTW process. This in part reflects reluctance of payers to pay for these services, and in part is due to doctors not knowing how, or whether, to ask for payment. In either case, the doctor is prone to presume this work is unimportant because it has no market value, and give it low priority. For routine cases this has only minor impact. In more complex situations that could benefit from the doctor's initiative or active participation, the monetary disincentive reflected by lack of payment often deters the doctor from responding quickly or making the extra effort, often delaying SAW/RTW.

Since most doctors don’t consider disability prevention their responsibility, their passivity does not represent a failure to carry out their perceived duty. Although employers and insurers may assert that disability management should be included in the price of the medical visit, those words have little impact on physician behavior.

Recommendation: Develop ways to compensate physicians for the cognitive work and time spent on evaluating patients and providing needed information to employer and insurers, and on resolving SAW/RTW issues. ACOEM has developed a proposal for new multi-level CPT codes for disability management that reveals the variety and extent of the intellectual work that physicians must do in performing this task. Simple adoption of a new CPT code (and payment schema) for functional assessment and triage of patients could achieve similar goals. Payers may be understandably reluctant to pay all doctors new fees for disability management because of reasonable concerns about billing abuses -- extra costs without improvement in outcomes. We recommend that the ability to bill for these services be a privilege, not a right, for providers, and that the privilege be contingent on completion of training and an on-going pattern of evidence-based care and good faith effort at achieving optimal functional outcomes.

Current Initiatives and Best Practices:

- An innovative operation in Victoria and New South Wales, Australia, builds working relationships between selected local providers and employers. Instead of contracting for discounted fees, the employer customers agree to pay full fees in exchange for the selected providers’ agreement to learn about the employer’s programs, and collaborate and communicate promptly. The selected providers are also paid additional fees for the extra effort spent on communications. Under

Australian state law, the employers cannot direct the employee where to go for injury care, but are nevertheless generally able to voluntarily channel more than 85% of injured workers to the selected providers.

- A workers' compensation insurer in Massachusetts selected and trained a network of primary occupational medicine providers (POPs) and asked them to help manage the situation caused by the injury or illness as well as manage the medical condition. The insurer paid these doctors their full fee-schedule rates for medical care PLUS a modest fixed fee for "situation management" for every case they handled. Half of the new fee was held back and paid as a bonus if the doctor's overall pattern of care revealed good overall results – appropriate medical costs, good patient and employer satisfaction, and low disability rates. Another aspect of the program was a very aggressive effort at teaching employers to channel to the POPs. Many employers were able to channel more than 85%. The net results were good: the fraction of workers' compensation injuries that became lost time injuries was 6-8% lower when the treating physician was a POP.

8. Support Appropriate Patient Advocacy by Getting Treating Doctors Out of a Loyalties Bind

Governmental agencies, insurers and employers expect doctors to provide unbiased information that verifies what their claimants / employees have said about their medical conditions and ability to work. Some of this information will be used as a means to validate claims and manage attendance, and may be used to award or deny monetary or other benefits, or as the basis for personnel actions. Doctors are often made aware of this by their patients. The medical profession does not acknowledge any duty to play this role as corroborator of fact for third parties, especially considering that negative financial consequences for patients may result. In fact, the doctor has a sworn and solemn duty to advocate for the patient, and to consider the patient's interest before his or her own.

That said, many doctors have not thought carefully about what patient advocacy means in the context of SAW/RTW. Most of the time, being an effective advocate for a patient's health and safety would mean promoting employment and full social participation. But the scope of "patient advocacy" varies from doctor to doctor, with some using their role as physician to advocate for whatever their patient wants, or their economic well-being, or even for social justice. Historically, the main way that employers and insurers have dealt with this is through the independent medical examination process.

Recommendations: The SAW / RTW process needs to recognize the treating doctor's allegiance, reinforce the primacy of the commitment to the patient / employee's health and safety and avoid putting the treating doctor in a bind of conflicting loyalties. Focusing on function will reduce split loyalties and avoid breaches of confidentiality. Simpler, quicker, and less adversarial means of obtaining corroborative information need to be employed. Creative ways to allow treating physicians to participate in SAW/RTW without betraying their sense of loyalty to patients need to be developed.

Current initiatives and best practices:

Employers and insurers who get the best return-to-work results and have the lowest disability rates:

- Take charge of the process from the start, not letting it ever appear the doctor is in charge of making employment decisions.
- Inform treating doctors that the employer has a temporary transitional work program and that most workers are expected to recover on the job.
- Make it clear that they can provide work within a wide range of functional abilities, and will be careful to abide by any guidelines set by the doctor.
- Stop asking doctors to set return to work dates, and instead ask the doctors to provide functional capacities, restrictions, and limitations.
- Use metrics such as work days lost per 100 injury/illness episodes to track the effectiveness of their programs.

9. Increase "Real-Time" Availability of On-The-Job Recovery, Transitional Work Programs, and Permanent Job Modifications

A cornerstone of disability prevention is allowing workers to recover on the job. Most commonly this takes the form of transitional work programs (sometimes referred to by other terms such as temporary modified work, alternative duties, or light duty) that let workers return to work at partial capacity during their recuperation period. On-the-job recovery usually involves a temporary change in job tasks, work schedule, or work environment, and often requires a reduction in performance expectations for the limited duration of the assignment, generally not more than 90 days. Workers in on-the-job recovery programs are expected to return to their usual jobs, with or without permanent accommodations, once the temporary assignment is complete.

Permanent job modifications such as task re-design or a switch to ergonomically-designed tools may also allow for recovery on the job. However, permanent modifications are usually made to enable employees to continue working their usual jobs without interruption, and to meet the regular performance expectations of that job.

Currently, the main problems that get in the way of workers recovering on the job are:

- Employers whose formal or informal practice is not to take workers back until they can do their regular jobs, and employers who have return to work programs on paper only. There are many employers who still refuse to provide temporarily modified work, and there are many labor agreements that prohibit it. Insurers that give discounts to employers who say they have transitional work programs typically fail to confirm that the programs are actually used. Few employers provide financial incentives to supervisors to make arrangements for on-the-job recovery by subsidizing the labor cost of transitional work programs. Few also appropriately allocate the cost of disability benefits to the operating units whose failure to keep workers safe or provide transitional work has created the lost workdays.
- The bad reputation of “light duty.” Based on their past experience, both employers and workers may see light duty as a dead-end, a permanent sinecure, a parking lot for favorites and aging workers who can no longer keep up. Others have seen light duty used as a punishment. They resist it out of fear they will be given nothing or only meaningless work to do, or will be ordered or pressured to violate their work restrictions, or will be left isolated, or teased and harassed.
- Long lag times. Many companies that do have return to work programs do not use them promptly. They are reactive rather than pro-active. When one of their workers becomes ill or injured, they do not anticipate the need for transitional work assignments but instead wait to hear what is needed. After the doctor writes restrictions or the physical or occupational therapist recommends job modifications, the employer has the responsibility to make concrete arrangements for return to work – but the employer often has no internal resource with expertise, operational processes and budget authority to make it happen quickly. This is true for both temporary and permanent job modifications.

Recommendations: Employers should be encouraged, incentivized, or required to have **and actually use** transitional work programs. Employers need to have clearly-written policies and procedures that provide instruction and direction to people in carrying out their responsibilities. Supervisors should be held accountable for the cost of benefits if temporary transitional work is not made available to their injured/ill employees when possible. Where applicable, unions should be consulted in the design of on-the-job recovery programs. Program participation by workers should either be required or strongly incentivized, with ombudsman services made available to protect against abuse. Expert resources should be made available to employers to assist them in implementing and managing these programs on an on-going basis.

Current initiatives and best practices: Successful transitional work programs are now in place in many well-managed organizations, large and small. Over the last several years, these organizations can point to concrete and significant reductions in costs and absenteeism rates caused by implementing transitional work programs. They generously share their success stories at industry conferences.

The Ohio Bureau of Workers’ Compensation has made a remarkable investment in statewide Transitional Work Program (TWP) Grants. Under this program, employers are eligible for a state-funded grant of up to \$5200 to develop a TWP. Employer participation has been enthusiastic, and program results have improved. Many of the employers have used vocational rehabilitation professionals or physical/occupational therapists to develop the transitional work program for them, and they maintain ongoing service relationships.

California’s recent workers’ compensation reform legislation includes a program to reimburse small employers who purchase adaptive equipment or otherwise modify jobs for injured workers for up to \$2500.

An employer consortium sponsored and led by the occupational medicine program at a clinic in Illinois provides guidance and support to small- and medium-sized local employers in setting up and running their transitional work programs. Employers are grateful and provide enthusiastic support.

The Australian state of New South Wales requires all employers with more than 200 employees to appoint an in-house injury manager who is responsible for creating return to work plans.

10. Be Rigorous Yet Fair and Kind to Reduce Minor Abuses and Cynicism

As described earlier, the disability benefit system is often used inappropriately as a means to solve other problems – taking sick leave in order to stay home and care for a child, using sick leave for “mental health days”, developing a headache and staying home the day after a disappointing or upsetting event at work – and the rules are stretched in order to receive benefits when there is no real medical justification.

The more this is allowed to happen, the more people start to assume that everyone is engaging in such behavior. Eventually, anyone who files a claim is treated with cynicism or suspicion. Those with legitimate needs may be treated unkindly and the SAW/RTW process may become unpleasant for them. In many industries, such an attitude is widespread and seriously hampers the SAW/RTW process. Additionally, if transitional work programs are allowed to become permanent havens for non-productive workers, both employees and supervisors lose enthusiasm for them. Likewise, if light duty is used to demean, harass, or ostracize workers, the programs may become counterproductive.

Recommendations: Programs that allow employees to take occasional time off without the need of a medical excuse (such as paid time off programs) should be encouraged. The negative effect of turning a blind eye to inappropriate use of disability benefit programs should be more widely understood. Petty corruption should be discouraged by means of consistent and rigorous program administration. Methods of reducing widespread cynicism among management and workers about disability benefit programs should be devised and deployed. All parties should be trained how to face situations squarely without becoming adversarial. Workers involved in the SAW/RTW process should be treated with courtesy, kindness, and fairness.

11. Devise Better Strategies To Deal With Bad Faith Behavior

There are many parties to individual cases in the disability benefits system: employees, their families, their supervisors, employer management, treating clinician(s), insurance carriers, benefits administrators, case managers, union representatives, and lawyers.

A few individuals in each group step beyond the line of appropriate behavior, manipulating the SAW/RTW process to the point of serious abuse or clearly fraudulent activity. For example, some employers pressure workers not to report work-related injuries, fire those who do, force recovering workers to work beyond their limits, or continue to put injured workers in unsafe work environments. Some insurers take advantage of unsophisticated workers or employ unethical claims practices. Some employees manufacture injuries, intentionally exaggerate symptoms, or fraudulently claim benefits for prolonged periods. Some treating clinicians attempt to maximize their fees by continuing treatment and authorizing disability past the point of medical necessity, sometimes to the detriment of the patient and sometimes in collusion with the patient. Other clinicians have lost their independence and simply do the bidding of employers, insurers, or lawyers.

Employers and insurers exert a lot of effort identifying and dealing with employees who take advantage of the system, and to a lesser extent with doctors that do the same. In comparison, little attention has been paid to the harm done to injured or ill employees when their claims adjuster or employer gives them poor service or engages in inappropriate or illegal behavior.

Often, the only recourse available to the injured worker or employee with a complaint is a lawyer. Most people who seek counsel do so only after a problem has arisen. The legal system is a poor substitute for good customer service and fair treatment. Judicial remedies are not usually therapeutic in nature or in timing. People who feel they have been ill-served and retain lawyers get involved in a system that by its adversarial nature hardens and polarizes positions, delays resolution until after the window of opportunity to prevent needless disability has closed, and increases the likelihood of poor functional outcomes.

One multi-state insurer's analysis shows that the median cost of a workers' compensation claims in which the claimant has legal representation is about \$30,000 more than those without lawyers involved. The median cost of represented claims is between 10 and 20 times higher than the median cost of unrepresented ones.

Recommendations: In addition to continuing efforts to rein in bad behavior by claimants and doctors, more effort needs to be devoted to identifying and dealing with employers or insurers who do not play fair in SAW/RTW efforts and do not respect the legitimate needs of employees who are dealing with a medical condition. We recommend that some form of complaint investigation and resolution service, such as ombudsman services, be made available to employees who feel they have received poor service or are being treated unkindly, inappropriately, or unfairly.

IV. INVEST IN SYSTEM AND INFRASTRUCTURE IMPROVEMENTS

12. Educate Physicians on Why and How to Play Their Role in Preventing Disability

Few doctors have ever received training in disability prevention and management. Virtually no medical school courses address this area, and neither do residencies and internships. Two specialties are the exception: occupational medicine and psychiatry, both of which consider the issue of functional ability a major focus of their work.

Doctors in most other specialties don't clearly understand how the process works; don't see SAW/RTW as part of the practice of medicine; don't see it as their duty; and so are uninterested in it. Yet the average doctor who treats working-age adults usually signs five or more work-related letters or notes to employers and payers per week, and is by definition a regular participant in SAW/RTW. Because of this, they may allow workers to return to work who should not, and then disable those who could be working.

Medical educators are already overwhelmed by the volume of knowledge that must be transmitted to students and practitioners. Although function is now acknowledged as having a greater impact on quality of life than serious illness, most requests to medical schools from employers and insurers to integrate evaluation of function in their teaching and testing of skills have been politely ignored.

Recommendations: All treating physicians should be educated in the basics of disability prevention, disability management, and their role in the SAW/RTW process. Advanced training should also be provided using methods and modes that will be attractive to and effective with physicians. Most likely, such training will have to take place at the behest of employers and insurers – not the medical profession itself. Appropriate privileges and reimbursements should be available to physicians who have been trained (e.g. membership in special networks). Treatment guidelines should routinely include attention to function where adequate supporting medical evidence exists. Note that the knowledge and skills to be imparted are consistent with current recommendations that medicine in general shift from a reactive disease-oriented paradigm to a proactive health-oriented one.

Current Initiatives and Best Practices: ACOEM and the American Academy of Orthopedic Surgeons have active educational efforts underway within their professional societies, with courses on disability-related topics at all annual conferences.

As part of a larger initiative to focus disease management and benefit cost reduction programs at the community level, several employers in West Virginia and Idaho have embarked on an initiative to award quality points towards bonuses to those local physicians who attend a live training session or take a short web-based course in disability prevention and return to work communications.

Two workers' compensation healthcare provider networks in California and Florida have already strongly encouraged their physicians to take a course in disability prevention. Other networks have similar programs now in development. The State Compensation Insurance Fund of California has recently decided to make disability management training a requirement for key clinicians in its medical provider network (MPN).

13. Disseminate Medical Evidence Regarding the Benefits on Recovery of Staying at Work and Being Active

There is strong evidence that activity is necessary for optimal recovery from injury / illness / surgery, while inactivity delays it. Moreover, for an array of conditions including depression, chronic pain, fibromyalgia, and chronic fatigue syndrome, simple aerobic physical activity has been shown to be an effective treatment. There also is evidence that remaining at or promptly returning to some form of productive work improves clinical outcomes as compared to passive medical rehabilitation programs. Therefore, the ACOEM Practice Guidelines consistently recommend exercise, active self-care, and the earliest possible safe return to work. In spite of this evidence, inactivity, work avoidance, and passive medical rehabilitation programs are often prescribed as treatment, leading to adverse patient outcomes.

Recommendations: Large scale educational efforts need to be undertaken so that treating clinicians and other system participants prescribe inactivity only when medically required, and activity recommendations become a routine part of all medical treatment plans. Wherever possible, regulations or policies should specify that medical care must be consistent with current medical best practices, or even better, an evidence-based guideline should be adopted as the standard of care.

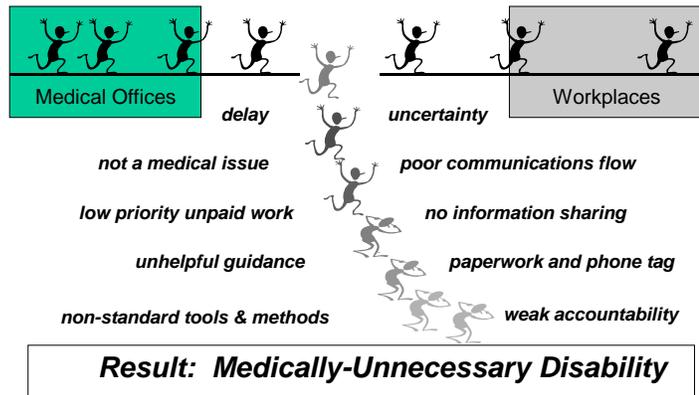

Current Initiatives and Best Practices: The State of California has recently adopted ACOEM's Practice Guidelines as the best available evidence-based standard of care for new workers' compensation injuries. California law says that the Guidelines shall be "presumptively correct on the issue of extent and scope of medical treatment." (www.dir.ca.gov/dwc/DWCPropRegs/UR_ISOR.doc) The State of Colorado also has developed evidence-based treatment guidelines, and requires those who perform independent medical evaluations to take a rigorous state-sponsored training course. Their opinions must conform to state standards.

14. Simplify and Standardize Methods of Information Exchange between Employers/Payers and Medical Offices

Though doctors play an important role in the SAW/RTW process, they are typically given too little information to play their role effectively. Often the employee is the doctor's only source of information, because the employer is not visible. Employers usually do not send any information to the doctor about an employee's functional job requirements, their SAW/RTW programs, their commitment (or lack of it) to employee well-being, or how to get questions quickly answered or problems addressed.

Claim administrators often request information from the doctor to help in managing their claim. They tend to use a generic approach that does not match up the information requested with the actual simplicity or complexity of the situation. Questions often seem designed to determine eligibility for benefits rather than to find a way to help the worker return to work. Not enough focus is placed on discussion of patient functionality, which is not subject to confidentiality restrictions. Employers and claims administrators often find it easier and more efficient to send volumes of material to the doctor instead of paring it down to the essential questions for the doctor's convenience.

This Gap Creates Disability

For their part, many doctors seem unaware of employers' and benefit administrators' legitimate needs for information. Then, when doctors receive poorly-conceived requests for guidance or opinions, they have little tolerance or time for poring through irrelevant or redundant information to find the few useful pieces of data. Many doctors are simply unaware of the impact of their delays or inadequate responses on achieving optimal functional outcomes for their patients. Both sides of the communication divide are exasperated by the enormous variability in the other's paper forms.

Recommendations: Employers, insurers and benefits administrators should stop using communication methods that are convenient for them but waste the doctor's (largely unpaid) time. They should spend the time to digest, excerpt, or highlight key information so the doctor can quickly and easily spot the key issues and meet the need for prompt and pertinent information in return. In particular, prior medical records should always be sent to the doctor prior to the appointment, since the lack of any documented historical information is a very common problem. Focusing communications more on function will provide a better justification for disability benefit payments and foster return to employment. All parties need to learn to discuss the issues, verbally or in writing, in terms of function, and engage in a mutual search for ways to resolve obstacles.

Current Initiatives and Best Practices: Training can make employer and insurer staff more aware of the practical realities of the doctor's office, and teach how to make information requests that will succeed by fitting in with this rhythm. Successful case managers often fax a single page sheet to the doctor's office the day before a patient's appointment. The sheet contains one or a handful of questions or options, accompanied by checkboxes the doctor can use to answer them. Several new companies are seeking to link medical provider offices with employers and insurers, using various business models to help make the process valuable for all participants

15. Improve and Standardize the Methods and Tools that Provide Data for SAW-RTW Decision-Making

As soon as other people get involved in a worker's SAW/RTW process, they need data about work capacity and job demands on which to base their decisions or take action. Existing methods and tools for obtaining and analyzing data are non-standard and rather crude considering the impact they have on hundreds of thousands of work disability episodes per year.

In the time-pressured setting of everyday patient care, treating doctors typically just improvise and use some form of informed guesswork to come up with work capacity, medical restrictions, and functional limitations on the spur of the moment. Similarly, employees and employers typically use informed guesswork to describe the functional demands of workplace tasks. Most of the time, this method seems to work well enough.

However, whenever ability to work is uncertain or disputed, everyone, especially the courts, develops an appetite for "hard facts" and data. Most of the wide variety of proprietary methods and technologies for determining work capacity now in current use were developed by the private sector.

Although almost all commercial methods and machines claim to have been "scientifically tested," very little high quality research has been published in rigorously peer-reviewed scientific journals. Most of the studies relating tests to work are not published in the leading testing journals because the studies are typically produced for a single employer or entrepreneur under contract. As a result, there is little incentive to publish the results.

Paradoxically, one major study showed that functional capacity evaluations (FCEs) were worse than no testing at all at facilitating appropriate job placement. In that study, a group of patients all underwent functional capacity evaluations. Those whose doctors used data from the FCEs as the basis for their return to work advice did worse than those whose doctors ignored the FCE results and simply reassured and returned the workers to their usual jobs.

Testing of almost any kind is more accurate when people want to pass rather than fail it (for example, when they want to be hired for a job, rather than when the insurance company wants to cut off their benefits). It is ironic, therefore, that work capacity testing is most often done because someone suspects and wants to document weak motivation or malingering – the circumstances under which the technology is weakest. The lack of rigorous scientific support for the accuracy and practical usefulness of existing work capacity measurement methods has not deterred the measurement industry, because its customers continue to think that “objective hard data” is better than no data.

Table 5 provides examples of the methods commonly used by physicians to obtain the data needed for SAW/RTW decision-making. For each question or issue to be resolved, the table shows the fast and low cost or simple method typically used in an everyday medical office visit compared to a high cost or complex method that is typically used in a complex or litigated situation. As can be inferred from the table, the range in technical sophistication, time required, and cost is considerable.

Preparing this table made us realize that one important reference has not yet been developed. Physicians who are looking for authoritative information have no resource for the occupational implications of various specific medical conditions or descriptions of patient-specific or task-specific considerations that would generate the need for specific medical restrictions.

Table 5		
Examples of Methods Currently Available to Physicians		
Question/Issue To Be Resolved	Low-Cost and/or Simple Method	High-Cost and/or Complex Method
What are the functional demands of the worker’s usual job?	Doctor asks the worker what he/she usually does at work.	Doctor relies on data from a job analysis. Doctor reads a multi-page comprehensive functional job description possibly with digital photos/video. The report has been prepared by a trained expert hired by the employer or insurer. The expert did a formal job analysis including making actual measurements at the worksite.
What is the worker’s current work capacity and functional limitations?	Doctor asks what the worker can’t do; observes the worker’s behavior in the exam room; performs a physical exam – and then mentally projects those answers and observations into likely workplace activities	Use data from tests such as treadmill testing (aerobic exercise capacity), functional capacity evaluation (musculoskeletal work capacity) or neuropsychological testing (cognitive ability). Tests of other capacities are available but much more rarely used. Doctor reads a report of the worker’s visit to a special testing facility, in which he/she performed a set of maneuvers to ascertain the worker’s maximum work capacity.
Is there a medical reason why the worker should be removed from work? Is there any specific activity/exposure the worker should avoid for medical reasons?	Doctor uses his/her own knowledge of workplaces and jobs, then thinks about potential situations that might pose a risk to the health / safety of the worker or others -- and writes medical restrictions to avoid them.	Other than disability duration guidelines that specify the length of time people are typically absent from work for various conditions, no clinical resource is available. We are unaware of any reference that systematically reviews the occupational implications (medical concerns and functional issues) of various medical conditions. Neither a consensus-based encyclopedic reference nor a systematic and comprehensive review of evidence-based medical literature exists yet.
Can this worker with this functional capacity and these medical restrictions do this particular job?	Make an informed guess. The doctor uses whatever information is available to decide whether the worker’s current capabilities match with the job demands. <i>OR</i> The employer or insurer looks for a match. They compare the employee’s abilities as portrayed in a doctor’s note with the demands of available jobs	Doctor relies on data from functional testing. Using information about a particular job, a testing facility devises a set of maneuvers that duplicate the maximum functional demands required by the tasks of that particular job. Then the worker attempts to perform those critical tasks. The areas of mismatch are the tasks that the worker cannot perform.
Ways of modifying jobs/ making accommodations	The doctor makes a suggestion based on his/her previous life and practice experience. The employer may seek advice from a consulting physician with occupational medicine expertise.	Doctor relies on data in a report written by a vocational counselor or similarly trained and qualified professional who has evaluated the situation in detail and made recommendations.

Recommendations: Standardization of key information and processes could help doctors participate more efficiently in SAW/RTW. Sending functional job descriptions to doctors at onset of disability should become routine. In order to be available at time of need, these descriptions must be prepared ahead of time by employers and stockpiled at the benefit administrator. They should focus on critical (meaning maximum) functional demands of individual job tasks, and be both accurate and up-to-date. Practical “bedside” methods of determining and documenting functional capacity should be routinely taught to doctors. Purveyors of functional capacity evaluation methods and machines should be required to provide published evidence of high quality peer-reviewed trials comparing their adequacy to other methods. Government, employers, insurers, or foundations may be appropriate sources for funding that research.

Current best practices and initiatives: Many occupational medicine physicians ask workers carefully-designed questions about everyday activities or observe them while they perform a simple set of office-based maneuvers in order to quickly obtain objective information on which to base their opinions. Occupational medicine specialists commonly tour the plants of their industrial clients in order to familiarize themselves with the physical work environment and the tasks of specific jobs. Many employers have already developed detailed functional job descriptions as part of their ADA compliance program. Some have modified their claim intake process to include mailing the worker’s job description to the treating physician. Some large companies are developing a computerized database of all tasks including each task’s critical (most difficult) functional demands. A few companies are using job-specific functional testing at time of hire as well as at routine intervals after injury or illness in order to assure that workers are assigned tasks within their capabilities. Both vendors and purchasers of evaluation methodologies are beginning to see the necessity of demonstrating validity and reliability in well-designed and controlled peer-reviewed trials.

16. Increase the Study of and Knowledge About SAW/RTW

The SAW / RTW process has not been systematically and formally studied in much detail, and certainly not in proportion to its significance for the well-being of millions of workers. Little data exists describing process metrics or patient outcomes. There is a dearth of solid methodological foundation or medical evidence to support methods and tools commonly in use, or to form the basis for improving them.

Many millions of public health dollars have been spent studying the adequacy of healthcare services and experimenting with ways to improve outcomes for the poor in Medicaid programs, and the elderly in Medicare programs. Virtually no public health funding or research has asked or answered similar questions regarding the adequacy of healthcare services and resulting outcomes for the employed population served by the workers’ compensation system. The failure of the states and the private sector to address these issues is good fodder for those who think that workers’ compensation should be federalized, or who argue for a larger federal role in regulating it.

With regard to disability benefits, some publicly-funded published research has been done only on the long-term disabled population served by Social Security disability insurance in the United States. This is in contrast to Europe, which distinguishes between the long-term disabled and the newly or temporarily disabled, and does research on both. Virtually no U.S. research money or effort has been devoted to studying the adequacy of medical services and outcomes of care for the people served by the state-based and private disability benefits systems. As with workers’ compensation, the failure to address these issues may point to a need for a federal agenda.

Recommendations: A description of the SAW/RTW process should be compiled and widely disseminated, along with recommendations on how to best implement change to achieve desired results in disability outcomes. Industry-specific as well as broad-based research programs should be established and funded, perhaps in the form of independent institutes or as enhancements to university-based programs. Existing research findings should be collected, tabulated, and the findings should be analyzed and published. Research agendas should be formulated in order to gain a richer understanding of current practices and outcomes, to determine best practices, and to test alternative solutions to addressing problems. A dissemination framework should be developed that effectively communicates the findings of completed research to all stakeholders, especially decision-makers. This framework should also solicit needs for future research.

A sampling of research topics of interest might include:

- Screening tools that accurately predict relative risk of long-term functional disability, and provide a basis for therapeutic interventions.
- The long term natural history of prolonged absence or withdrawal from work. What does happen to these people?
- Controlled trials of various claims and clinical interventions designed to improve medical and functional outcomes.
- A systematic assessment and catalogue of the functional implications and occupational considerations related to the 300 or so medical conditions that most commonly cause disability.
- Comparison of means to assess work ability/capacity.

- Ways to standardize and increase the availability and usability of functional job descriptions.
- Study of physician behavior in dealing with role conflict.
- Controlled trials that compare different methods for training physicians in disability prevention, and assess the impact of that training on clinical, functional, and financial outcomes.
- Ways to increase the recognition and effective treatment of psychiatric co-morbidities.
- Effective ways to streamline communications between participants in SAW/RTW.
- Comparison of different methods to reward physicians for active participation in the SAW/RTW process.

SUMMARY AND CONCLUDING REMARKS

It is our opinion that the current SAW/RTW process too often fails to meet the needs of patients, their employers, benefits payers, and society as a whole.

Although most people with injury or illness are able to cope with their problem and receive the support needed to adjust their life and work either temporarily or permanently, a very important minority of them are not. These people do not recover successfully, do adopt a disabled self-concept, and end up either with needlessly prolonged absence or permanent withdrawal from work – and are lost to the productive side of the economy. In problematic situations, the SAW/RTW process is usually inadequate and ill-suited to detect and effectively address the issues that are most important to the outcome. The small fraction of troublesome situations accounts for the vast bulk of needless expenditures for disability benefits. Because this small number of claims accounts for such a large portion of all disability program costs, a one percent reduction in cases with prolonged disability should generate a substantially larger reduction in overall system cost.

In keeping with our roots as a preventive specialty, we recommend that the focus of the SAW/RTW process shift away from “managing” or “evaluating” disability towards preventing it. We contend that the fundamental reason for a considerable fraction of lost workdays and lost jobs is not medical necessity but rather non-medical decision-making and poor functioning of the SAW/RTW process.

Employers, insurance carriers and governmental agencies that are currently burdened by the costs of preventable disability, and that are worried about the implications of an aging workforce for future trends, should consider underwriting efforts to prevent disability more effectively.

As is reflected in the recommendations we have made throughout this paper, improving the SAW/RTW process will require:

- A sense of urgency
- Attention and priority
- Research
- Experimentation with new methods and interventions
- Infrastructure development
- Policy revision
- Methodological improvement and dissemination
- Education and training
- Incentive alignment
- Funding

Common sense evidence abounds that keeping people at work and productively contributing to society is good for them and for society. To avoid the unfortunate outcome of iatrogenic or system-induced disability is worthwhile. To improve the appropriateness and usefulness of services available to people who are coping with illness and injury in their lives is also of value. And it is sensible, if not urgent, for us as a society to curtail the needless use of resources and loss of personal and industrial productivity.

Making improvements in the SAW/RTW process will require sustained attention and effort, and a willingness to explore new ways of doing things. We hope that our report will stimulate thinking and begin a regular dialogue with other stakeholders to explore this topic in progressively more depth. We also hope that the national and international conversation about the societal issue of disability will be more informed and fruitful as a result, and that this will catalyze productive changes in the system.

ATTACHMENT B: TOPICAL BIBLIOGRAPHY

Below is a list of references that we have used in educating ourselves and preparing this document. This topical bibliography is divided into sections that correspond roughly with the sections of the report. Some references are applicable to more than one area. In general, these materials corroborate the major points made in this paper. The SAW/RTW process has itself not been the subject of as much scientific research as other medical and public policy areas of comparable import to society. Some of our major concerns lie in areas that have not been rigorously investigated yet, probably due to lack of interest or availability of funding. (This in itself is one of our major concerns.) As a result, some topics have fewer or weaker supporting references than would be available if more research had already been done.

Nurses and Stressors

Author(s) Year Title	Purpose of Study	Study Design Sample, Setting	Instruments	Findings & Conclusions
Anderson (2002). <i>Workplace violence: Are some nurses more vulnerable?</i>	Describe <i>workplace violence events</i> (WPVE) by type, frequency, perpetrator, and contributing factors and explore relationship between WPVE and <i>history of childhood or adult abuse</i>	Randomly selected RNs from BNE; mailed out 800, N=70 responded, final n=67 88% Caucasian, 95.4% female, 46-years-old, mostly BS degree	<u>Workplace violence</u> = Workplace Violence Questionnaire & Demographics (WVQD); modified version (n=26) <u>History of abuse</u> = Child Abuse & Trauma (CAT); modified (n=41)	58.2% childhood abuse; primarily sexual abuse (89%) 41.8% witness adult abuse 37.3% victim of adult abuse 1.5% perp of abuse 71% emotional/verbal WPVE 41.8% sexual WPVE 38.8% physical WPVE 41.3% from physician 20.6% from nurses 20.6% from pts. Nurses with a history of abuse reported more WPVE
Anderson & Parish (2003). <i>Report of workplace violence by Hispanic nurses</i>	Explore association between <i>workplace violence</i> (WPV) and <i>victim characteristics</i> (prior childhood or adult violence)	Random selection of 900 Hispanic nurses representing 3 counties in Texas; names obtained from BNE and STTI. N=90 (10%) responded 91% female, 43% BS degree, 49-years-old, experienced their first significant WPV event at less than 4 years in the profession	<u>Workplace violence</u> = Workplace Violence Questionnaire & Demographics (WVQD) developed by the researcher	94% emotional-verbal WPV 66% sexual WPV 43% physical WPV 63.9% child or adult abuse All male nurses (n=8) reported child or adult abuse Nurses with a history of abuse, more emotional-verbal WPV

<p>Hayhurst, Saylor, Stuenkel (2005). <i>Work environmental factors and retention of nurses</i></p>	<p>Describe factors in work environment (peer cohesion, supervisory support, autonomy, and work pressure) and relate these factors to retention on RNs</p>	<p>Descriptive, correlational RNs, who provide inpatient bedside care, from large county hospital in Northern California. 692 questionnaires sent out, N=272 (39%) returned. 96% female, in 40s, 43% Caucasian, 60% BS degrees</p>	<p>Perceptions of work environment = Moos' Work Environment Scales (WESs), 90-items true/false examines: peer cohesion, supervisory support, autonomy, work pressure</p>	<p>Did not find statistical differences between nurses who stay or nurses who leave.</p>
<p>Lynn & Redman (2005) <i>Faces of the nursing shortage: Influences on staff nurses' intentions to leave their position or nursing</i></p>	<p>Examine the relationship between nurses' organizational commitment, job satisfaction, professional satisfaction, and intent to leave Examine if nurses' organizational commitment, professional and job satisfaction predict intent to leave position or nursing as a career</p>	<p>Mailed survey to staff nurses (N=3000) in acute care settings in 8 states. Received 787 usable surveys (26% return rate) 44-year-old, European American, BS degree, in current position for 8 years</p> <p>Stepwise multiple regression</p>	<p>Surveys from a larger study, Canaries in the Coalmine. Measurements: Professional satisfaction = 6 items focusing on career choice and meaningfulness of work Job satisfaction = Satisfaction in Nursing Scales (SINS), 54-item Likert scale measures workload, intrinsic satisfiers, collegiality, and administrative support Organizational commitment = Organizational Commitment Questionnaire (OCQ), 15-item Likert scale. used in hundreds of studies Intent to leave = 2 questions for intent to leave position and 3 question for intent to leave nursing</p>	<p>Intent to leave position = Negative predictors: professional satisfaction, satisfaction with workload, extent to which nurse liked the work, satisfaction with colleagues. Positive predictor: satisfaction with administration Intent to leave nursing = Negative predictors: professional satisfaction, satisfaction with intrinsic rewards, financial situation. Positive predictor: reason for working</p>

<p>McVicar (2003) <i>Workplace stress in nursing: A literature review</i></p>	<p>To identify nurses' perceptions of workplace stress, effectiveness to reduce distress, and identify directions for future research</p>	<p>Literature search from January 1985 to April 2003: nursing, stress, distress, stress management, job satisfaction, staff turnover, coping. Search restricted to adult and pediatric nursing.</p>	<p>6 Main Sources of Stress: <u>Workload, leadership/management style, professional conflict, emotional cost of caring, lack of reward, shift work</u></p>	<p>Organizational intervention and their effectiveness likely to be limited Lack of understanding how stress varies between practice areas Lack of understanding how personal and workplace factors interact Essential that personal/workplace interactions be researched</p>
<p>Reinech & Furino (2005) <i>Nursing career fulfillment: Statistics and statements from registered nurses</i></p>	<p>To describe the complexity and intensity of the nursing experience</p>	<p>Qualitative analysis from a larger study, the Texas RN Career Fulfillment Survey. Content analysis on 495 RNs out of 1,111 employed and unemployed RNs who responded to the survey with written comments 44.5-year-old, 91% female, mostly ADN nurses from Texas. 51% primary wage earners in households 80% full-time 63% work in acute care</p>	<p>Majority of handwritten comments related to <u>economic needs</u>. Health = 66% rated general health as very good to excellent 44% have <u>chronic health conditions</u> 12% wrote about stress <u>Work environment</u> = increasing aged, severely ill, and obese patients, paperwork, turnover, overtime, need for 2nd language skills, gov't regulations, workplace violence and harassment</p>	<p>Several themes emerged: Nurses love the intrinsic rewards of nursing. Negative aspects = compensation, recruitment valued over retention, stressors such as paperwork, patient complexity, turnover, and overtime.</p>

<p>Ruggiero (2005) <i>Health, work variables, and job satisfaction among nurses</i></p>	<p>Explore relationships of work, health, and demographic variables to job satisfaction</p>	<p>Descriptive, correlational Random, national sample of critical care RNs; female RN members of the AACN. 500 nurses invited and N=247 (49%) consented. Data from a study of chronic fatigue among critical care nurses 43-year-old, European-American, BS degrees</p>	<p>Job satisfaction = General Job Satisfaction Scale (GJSS), 5-item Likert scale Sleep quality = Pittsburgh Sleep Quality Index (PSQI), 19-items Depression = Beck Depression Inventory-II (BDI-II), 21-items Demographic data = Standard Shiftwork Index General Biographic Information Section. Age, domestic situation, shift, schedule, emotional stress, work load details, care of people after work, # of weekends off/month.</p>	<p>No significant differences between shift workers (day, night, rotating) and study variables. Nurses' emotional stress, depression, and number of weekends off per month influence job satisfaction. 65% nurses met criteria for "poor sleeper." 41% met criteria for clinical depression Possible overlap between sleep quality and depression.</p>
<p>Sofield & Salmond (2003). <i>A focus on verbal abuse and intent to leave the organization</i></p>	<p>Describe the experience of verbal abuse and examine the relationship of verbal abuse with intent to leave</p>	<p>Descriptive correlational survey Randomized list of 1000 RNs (33% of total population) from a 3-hospital health system. List provided by Human Resources. Consisted of equal number of RNs from each campus. N=461 usable surveys (46.1% responded), 95% female, 90% staff RNs</p>	<p>Verbal abuse and intent to leave = Cox's Verbal Abuse Survey, modified to 40-items</p>	<p>67% reported experiencing 1-5 verbally abusive incidents in last month 50% verbal abuse unrelated to high stress incidents Physicians most common source of verbal abuse, then pts., families, peers, supervisors, and subordinates Nurses' feeling response: Anger, powerlessness, harassment, embarrassment, desire to problem-solve 56% RNs not able to handle verbal abuse 13.6% left due to verbal</p>

				abuse
Ulrich, Buerhaus, Donelan (2005). <i>How RNs view the work environment</i>	To determine RNs views of the <i>work environment</i>	Sample of 3500 RNs randomly drawn from national database of licensed RNs in US. N=1783 (53%) returned survey 96% female, 84% Euro-American, 44-years-old, 45% work in an urban setting, 65% direct patient care	<u>Workplace health and safety</u> = back or musculoskeletal injuries, unprotected contact with blood-borne pathogens, workplace violence, sexual harassment, hostile work environment, stress <u>Professional practice</u> = only 19% rated excellent/very good opportunities to influence workplace organization <u>Work relationships</u> = relationships among nurses 71% excellent/very good, nurse-physician relationships 11% excellent, 34% very good, nurse-mgmt relationships 27% excellent/very good <u>Respect, support, recognition</u> =	Health, safety, violence remain major problems. Sexual harassment, hostile work environments, discrimination experienced by substantial number of RNs. Nurses need more influence and control over their practice. Working relationships between nurses have improved; need to improve with physicians and management.

Risk of Musculoskeletal Disorders Among Hotel Housekeeping Workers

UNITEHERE!

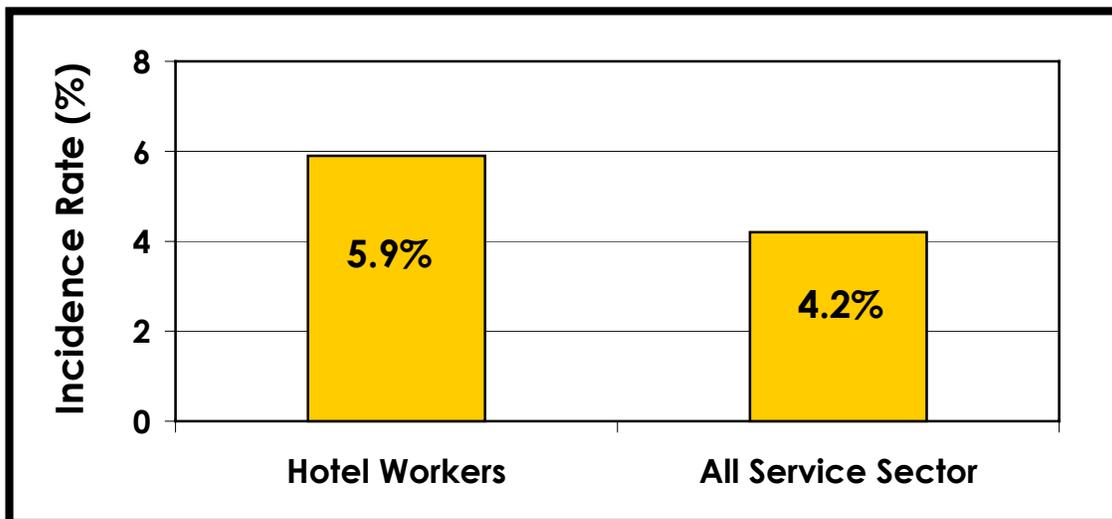

October 19, 2006

Eric Frumin, MA, and Pamela Vossen, MPH, UNITE HERE, New York City

Introduction: Hotel Housekeeper Characteristics

- 1.3M hotel employees in U.S., 23% hotel housekeepers (Source: BLS)
- Hotel Housekeepers are overwhelmingly female
- Hotel Housekeepers are predominantly women of color and largely immigrant
- Hotel housekeeping work is low-wage work
2004 annual earnings = \$17,340 (below the poverty line)
(Source: BLS)

**Injury/Illness Incidence Rates,
Hotel Workers vs. Service Sector, 2004**

Source: BLS

- Worker injury/illness incidence rate is 40% higher than the rate for all service workers

Trends in Work Organization

New and upgraded room amenities

Hotels have upgraded existing and added new amenities like coffeepots, robes, slippers and other items. Most prominent among these changes are the **introduction of luxury beds**, with heavy mattresses, thick duvets, triple sheeting and extra pillows.

Luxury beds exceed NIOSH's safe lifting index:

NIOSH JOB ANALYSIS WORKSHEET											
Department	Housekeeping					Job Description					
Job Title	Housekeeper					Making a king bed					
Analyst	G. Orr										
Date	11/11/2004										
STEP 1. Measure and record task variables

Lumbar Motion Monitor: Analysis of Hotel Housekeeping Tasks

- This Lumbar Motion Monitor (LMM) analysis identifies jobs with high and low incidence of low back injuries and assesses the probability that a job will be in the “high” risk group. “High” risk is defined as 12 or more new low back injuries per 200,000 hours of exposure.
- The LMM results are expressed as a percentage, e.g. a score of 50% means that the job has a 50% chance of being in the high risk category of low back disorders.
- The overall hotel housekeeping job has a very high likelihood (79%) of high risk of low back injuries. This exceeds the risks associated with all 20 manufacturing jobs previously studied as well as nursing/patient handling. Only some warehousing jobs had a higher risk.

<p>Probability of High Risk of Lower Back Disorders: Hotel Housekeeping vs. Selected Other Occupations</p>

Sources: Ohio State Univ., 2006; Ferguson et al, 2006 (Housekeeper data only)

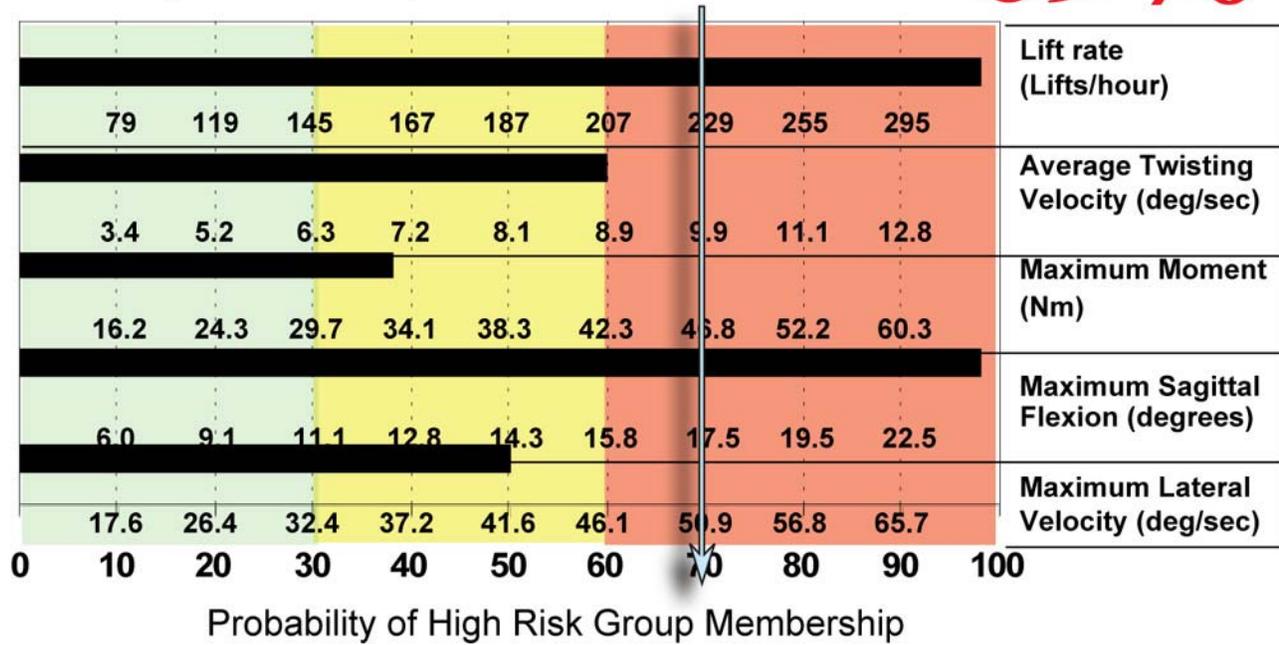

- Certain tasks of the housekeeper's job are associated with particularly high risk:
 - Bed making (69%)
 - Bathroom Cleaning (66%)

Overall Job Risk -No Push/Pull Cart **79%**

Average Probability of Low Back Disorder Risk

Source: Ferguson et al; note: including cart push/pull task raises the probability to 86%

Summary of Task Risks

Source: Ferguson et al.

Discussion

LMM evaluation predicts that hotel housekeepers face high risks of Low Back Disorders (LBD).

Housekeeping LBD risks are as high or higher than those found in LMM analyses of other well-documented high-risk populations (manufacturing jobs; Nursing/Patient Handling)

Individual housekeeping tasks pose especially high risks: vacuuming, lifting mattresses, cleaning floors and pushing carts.

Simple interventions are readily available to reduce these risks, such as use of mops or other handled cleaning tools, motorized carts, and fitted sheets. But implementation has been limited to initiatives by isolated hotels.

Such interventions are only part of the solution; further workload reductions such as reducing the number of rooms cleaned and beds made need to be considered as part of a comprehensive solution to a serious occupational health problem.

Hotel management is obliged to consider the effects of increased workloads when designing new beds, furnishings and tasks for housekeepers -- and to use available technology to reduce existing risks.

Recommendations

Hotel employers must improve the organization of hotel housekeeping work:

- Humane workloads & reasonable quotas
- Comprehensive re-design (i.e. beds, carts)
- Ergonomically designed tools (i.e. long handles)
- Increased staffing
- Enforced break time
- Joint labor/management health & safety training for supervisors and employees

Increased support for studies on hotel housekeeper hazards and interventions, by NIOSH, industry and academia is needed.

Atm: Sr. Wilfredo Rodríguez
 Presidente

La(s) violación(es) que se describe(n) en esta Citación y Notificación de Penalidad alegadamente ocurrieron en o alrededor de la fecha en que se realizó la inspección a menos que se indique lo contrario en la descripción de la violación.

Esta Citación y Notificación de Penalidad describe violaciones a la Ley de Seguridad y Salud en el Trabajo de Puerto Rico (Ley Número 16 del 5 de agosto de 1975, según enmendada). La(s) penalidad(es) indicada(s) en esta Citación está(n) basada(s) en dicha(s) violación(es). Usted tiene que corregir las violaciones mencionadas en esta Citación para las fechas límite indicadas y pagar las penalidades propuestas, a menos que dentro de 15 días laborables (excluyendo sábados, domingos y días feriados) después de recibir esta Citación y Notificación de Penalidad usted envíe un aviso de impugnación a la Administración de Seguridad y Salud Ocupacional del Departamento del Trabajo y Recursos Humanos, a la dirección arriba indicada. Favor de referirse al folleto adjunto (OSHO 3000) que esboza sus derechos y responsabilidades y el cual usted debe leer, además de este formulario. La emisión de esta Citación no constituye una decisión de que se ha encontrado una violación a la Ley, a menos que se deje de impugnar según

This Citation and Notification of Penalty describes violations to the Puerto Rico Occupational Safety and Health Act (Act No. 16 of August 5, 1975 as amended). The penalty(ies) listed herein is (are) based on these violations. You must abate the violations referred to in this Citation by the dates listed and pay the penalties proposed, unless within 15 working days (excluding weekends and holidays) from your receipt of this Citation and Notification of Penalty you mail a notice of contest to the Occupational Safety and Health Office, Department of Labor and Human Resources, at the address shown above. Please refer to the enclosed booklet (OSHO 3000) which outlines your rights and responsibilities and which should be read in conjunction with this form. Issuance of this Citation does not constitute a finding that a violation of the Act has occurred unless there is a failure to contest as provided for in the Act or, if contested, unless this Citation is affirmed by the Secretary of Labor.

REFIERASE A LAS PAGINAS 1 A LA 5 DE ESTA CITACION Y NOTIFICACION DE PENALIDAD PARA MAS INFORMACION SOBRE LOS DERECHOS Y RESPONSABILIDADES DEL PATRONO Y LOS EMPLEADOS.

se provee en la Ley o, de ser impugnada, a menos que la Citación sea confirmada por el Secretario del Trabajo

Fijación - La Ley exige que inmediatamente se exhiba una copia de esta Citación y Notificación de Penalidad en un sitio conspicuo en o cerca de la localización de la(s) violación(es) citada(s) o, si no es posible debido a la naturaleza de las operaciones del patrono, donde pueda ser fácilmente visible por todos los empleados afectados. Esta Citación deberá permanecer expuesta hasta que las violaciones citadas aquí hayan sido corregidas, o por 3 días laborables (excluyendo sábados, domingos y días feriados), lo que ocurra más tarde. Las penalidades no tienen que ser exhibidas y pueden ser tachadas o cubiertas antes de exhibir la Citación.

Conferencia Informal - La conferencia informal no es un requisito. Sin embargo, si usted desea tener tal conferencia, puede solicitarla al Director de Area dentro del periodo de los 15 días laborables para impugnar. Durante la conferencia informal usted puede presentar evidencia o puntos de vista que entienda puedan apoyar una modificación a la citación(es) y/o penalidad(es).

Si está considerando solicitar una conferencia informal para discutir cualquier asunto relacionado con esta Citación y Notificación de Penalidad, debe programarla lo antes posible para que disponga de tiempo suficiente luego de la conferencia informal para impugnar, si así lo decide. Recuerde que la Notificación de Impugnación deberá ser sometida al Director de Area dentro de los 15 días laborables luego de recibir esta Citación. **El periodo de impugnación no se interrumpirá por una conferencia informal.**

Si decide solicitar una conferencia informal, por favor complete, remueva y fije la página 5, 5, (Notificación de Conferencia Informal a los Empleados) al lado de la Citación y Notificación de Penalidad, tan pronto se haya determinado la fecha y hora de la conferencia informal. Asegúrese de traer a la conferencia toda la documentación que apoye las condiciones existentes, así como las medidas de corrección tomadas hasta ese momento. Si las condiciones lo permiten, podemos entrar en un acuerdo de transacción informal, el cual puede resolver este asunto sin necesidad de impugnar o litigar.

Derecho a Impugnar - Usted tiene el derecho de impugnar esta Citación y Notificación de Penalidad. Puede impugnar todos los renglones de la citación o solamente renglones individuales. También puede

Posting - The law requires that a copy of this Citation and Notification of Penalty be posted immediately in a prominent place at or near the location of the violation(s) cited herein, or, if it is not practicable because of the nature of the employer's operations, where it will be readily observable by all affected employees. This Citation must remain posted until the violation(s) cited herein has (have) been abated, or for 3 working days (excluding weekends and holidays), whichever is longer. The penalty dollar amounts need not be posted and may be marked out or covered up prior to posting.

Informal Conference - An informal conference is not required. However, if you wish to have such a conference you may request one with the Area Director during the 15 working day contest period. During such an informal conference you may present any evidence or views which you believe would support an adjustment to the citation(s) and/or penalty(ies).

If you are considering a request for an informal conference to discuss any issues related to this Citation and Notification of Penalty, you must take care to schedule it early enough to allow time to contest after the informal conference, should you decide to do so. Please keep in mind that a written letter of intent to contest must be submitted to the Area Director within 15 working days of your receipt of this Citation. The contest period is not interrupted by an informal conference.

If you decide to request an informal conference, please complete, remove and post page 5 (Notice to Employees of Informal Conference) next to this Citation and Notification of Penalty as soon as the time, date, and place of the informal conference have been determined. Be sure to bring to the conference any and all supporting documentation of existing conditions as well as any abatement steps taken thus far. If conditions warrant, we can enter into an informal settlement agreement which amicably resolves this matter without litigation or contest.

Right to Contest - You have the right to contest this Citation and Notification of Penalty. You may contest all citation items or only individual items. You may also contest proposed penalties and/or abatement dates without

REFIÉRASE A LAS PAGINAS 1 A LA 5 DE ESTA CITACION Y NOTIFICACION DE PENALIDAD PARA MAS INFORMACION SOBRE LOS DERECHOS Y RESPONSABILIDADES DEL PATRONO Y LOS EMPLEADOS.

impugnar las penalidades propuestas y/o fechas de corrección sin impugnar las violaciones señaladas. Además, se le notifica que a menos que usted informe por escrito al Director de Area que desea impugnar la(s) citación(es) y/o penalidad(es) propuesta(s) dentro de 15 días laborables desde la fecha en que la recibe, esta citación y la(s) penalidad(es) propuesta(s) se convertirán en la orden final del Secretario y no estarán sujetas a revisión por ningún tribunal o agencia.

Pago de Penalidades - Las penalidades vencen dentro de 15 días calendarios, después de la fecha de expiración de los 15 días laborables del período de impugnación (Véase folleto adjunto). Envíe cheque certificado o giro pagadero a nombre del "Secretario de Hacienda". Por favor, indique el Número de Inspección en su remesa.

OSHO no está de acuerdo con restricciones o condiciones o endosos puestos en cualquier cheque o giro por menos de la cantidad total adeudada, y se cobrará el cheque o giro como si estas restricciones, condiciones o endosos no existieran.

Notificación de Acción Correctiva - Para las violaciones que usted no impugne, deberá notificar prontamente por escrito a la Administración de Seguridad y Salud Ocupacional del Departamento del Trabajo y Recursos Humanos, que usted ha tomado la acción correctiva pertinente dentro del tiempo señalado en esta Citación. Favor de informar por escrito al Director de Area las medidas correctivas tomadas y las fechas en que se corrigieron las condiciones junto con la documentación adecuada para sustentarlas; por ejemplo: fotografías o dibujos de las condiciones corregidas, órdenes de compra/trabajo relacionadas con estas medidas, resultados de muestreos de aire, etc..

Discriminación por parte del Patrono es Práctica Prohibida - La Ley prohíbe la discriminación por un patrono contra cualquier empleado que radique una querrela o ejercite sus derechos bajo la Ley. El empleado que crea que ha sido víctima de discriminación puede radicar una querrela ante el Secretario del Trabajo, dentro de los 30 días siguientes a la fecha en que ocurrió la discriminación, a través de la Administración de Seguridad y Salud Ocupacional antes indicada.

Derechos y Responsabilidades del Patrono - El folleto adjunto (OSHO 3000) esboza los derechos y responsabilidades del patrono y debe leerse como parte de esta notificación.

contesting the underlying violations. Furthermore, you are notified that unless you inform the Area Director in writing that you intend to contest the citation(s) and/or proposed penalty(ies) within 15 working days after receipt, the citation(s) and the proposed penalty(ies) will become a final order of the Secretary of Labor and may not be reviewed by any court or agency.

Penalty Payment - Penalties are due within 15 calendar days after the date of the expiration of the 15-working-day contest period (See the enclosed booklet). Make your check or money order payable to "Secretary of Treasury". Please indicate the Inspection Number on the remittance.

OSHO does not agree to any restrictions or conditions or endorsements put on any check or money order for less than the full amount due, and will cash the check or money order as if these restrictions, conditions, or endorsements do not exist.

Notification of Corrective Action - For violations which you do not contest, you should notify the Occupational Safety and Health Office of the Department of Labor and Human Resources, promptly by letter that you have taken appropriate corrective action within the time frame set forth on this Citation. Please inform the Area Director in writing of the abatement steps you have taken and of their dates, together with adequate supporting documentation, e.g., drawings or photographs of corrected conditions, purchase/work orders related to abatement actions, air sampling results, etc.

Employer Discrimination Unlawful - The law prohibits discrimination by an employer against an employee for filing a complaint or for exercising any rights under this Act. An employee who believes that he/she has been discriminated against may file a complaint no later than 30 days after the discrimination occurred with the Secretary of Labor, through the Area Office afore mentioned.

Employer Rights and Responsibilities - The enclosed booklet (OSHO 3000) outlines additional employer rights and responsibilities and should be read in conjunction with this notification.

REFIERASE A LAS PAGINAS 1 A LA 5 DE ESTA CITACION Y NOTIFICACION DE PENALIDAD PARA MAS INFORMACION SOBRE LOS DERECHOS Y RESPONSABILIDADES DEL PATRONO Y LOS EMPLEADOS.

Aviso a los Empleados - La Ley ofrece al empleado o a su representante la oportunidad de objetar cualquier fecha límite fijada para corregir una violación si la cree irrazonable. La impugnación se deberá enviar a la Administración de Seguridad y Salud Ocupacional del Departamento del Trabajo y Recursos Humanos, a la dirección antes indicada, dentro de 15 días laborables (excluyendo sábados, domingos y días feriados) a partir del recibo de esta Citación y Notificación de Penalidad por el patrono.

Notice to Employees - The law gives an employee or his/her representative the opportunity to object to any abatement date set for a violation if he/she believes the date to be unreasonable. The contest must be mailed to the Occupational Safety and Health Office of the Department of Labor and Human Resources, at the address afore mentioned and postmarked within 15 working days (excluding weekends and holidays) of the receipt by the employer of this Citation and Notification of Penalty.

Notificación de Conferencia Informal a los Empleados
Notice to Employees of Informal Conference

Se ha programado una conferencia informal con la Administración de Seguridad y Salud Ocupacional (OSHA), para discutir la(s) citación(es) emitida(s) el 08/03/2006. Esta conferencia tendrá lugar en la Administración de OSHA localizada en 577 AVE. PONCE DE LEON, ANTIGUO EDIF. REAL HERMANOS, HATO REY, PR 00918, en la fecha y hora abajo indicada. Los empleados y/o sus representantes tienen el derecho a asistir a la conferencia informal.

An informal conference has been scheduled with the Occupational Safety and Health Administration (OSHA) to discuss the citation(s) issued on 08/03/2006. This conference will be held at the OSHA office located at 577 AVE. PONCE DE LEON, ANTIGUO EDIF. REAL HERMANOS, HATO REY, PR 00918, on the date and time indicated below. Employees and/or representatives of employees have a right to attend an informal conference.

FECHA (Date) _____

HORA (Time) _____

CITACION Y NOTIFICACION DE PENALIDAD

COMPANIA: Pulsar PR/DBA Diamond Palace Hotel & Casino
SITIO DE LA INSPECCION: Ave. Condado #55, San Juan, PR 00908

CITACION 1 RENGLON 1 TIPO DE VIOLACION: Seria

Section 6(a) of the Puerto Rico Occupational Safety and Health Act: The employer did not furnish employment and a place of employment which were free from recognized hazards that were causing or likely to cause death or physical harm to employees in that employees were exposed to:

Sección 6(a) de la Ley de Seguridad y Salud en el Trabajo de Puerto Rico: El patrono no proveyó empleo y un sitio de empleo libre de riesgos reconocidos que estén causando o que puedan causar muerte o daño físico a los empleados, por cuanto empleados estaban expuestos a:

At Pulsar PR/DBA Diamond Palace Hotel & Casino, bar area, it was evidence of water spots on the acoustic panels and walls due to water ceiling filtrations. The employees served beverages to customers, they cleaned and performed services in that area.

Hazard: Slips and falls.

Among other correction methods, one feasible and acceptable to correct this hazard is repair the ceiling.

En Pulsar PR/ DBA Diamond Palace Hotel & Casino, área de la barra, existía evidencia de manchas de agua en los plafones acústicos y paredes debido a filtraciones de agua por el techo. Los empleados servían bebidas a clientes, limpiaban y realizaban servicios en dicha área.

Riesgo: Resbalones y caídas.

Entre otros métodos de corrección, uno factible y aceptable para corregir este riesgo es reparar el techo.

FECHA LIMITE PARA CORREGIR VIOLACION: 09/20/2006
PENALIDAD: \$ 975.00

CITACION 1 RENGLON 3 TIPO DE VIOLACION: Seria

4 OSH 1910.1200(h)(1): Employees were not provided with effective information and training on hazardous chemicals in their work area at the time of their initial assignment, and whenever a new physical or health hazard was introduced into their work area:

4 OSH 1910.1200(h)(1): Empleados no fueron provistos con información y adiestramiento en químicos peligrosos en su área de trabajo al tiempo de su asignación inicial o siempre que se introdujera un nuevo riesgo físico o de salud a su área de trabajo:

At Pulsar PR/DBA Diamond Palace, the employer didn't provide employees training in the Hazard Communication Program that contained the material safety data sheets to evaluate and recognize the hazard condition caused by chemical substances, personal protection equipment and emergencies situation. The employees cleaned and used the following products: Snapour, Kleen All, NDC Morning Fresh, Kontrol SE (liquid), Carpet Estraction, Kontrol SE (spray), Tri Star L-2000, Eco-Star Destainer and F222, that contained chemicals substances such as: Ethoxylated Alcohols, Sodium Metasilicate, Dypropylene Glycol Monomethyl Ether, Amphoteric Surfactant, Trisodium Phosphate Dodecahydrate, Didecyl Dimethyl Ammonium Chloride, Sodium hydroxide, Sodium hypochlorite, among others, in the laundry and maintenance areas.

Hazard: Contact with hazardous chemical substances.

En Pulsar PR/DBA Diamond Palace el patrono no proveyó adiestramiento a empleados en el Programa de Comunicación de Riesgos que contenía la hojas seguridad de materiales para evaluar y reconocer las condiciones de riesgos causadas por las sustancias químicas, equipo de protección personal y situaciones de emergencia. Los empleados limpiaban y utilizaban productos tales como: "Snapour", "Kleen All", "NDC Morning Fresh", "Kontrol SE (liquid)", "Carpet Estraction", "Kontrol SE (spray)", "Tri Star L-2000", "Eco-Star Destainer" y F222, que contenían sustancias químicas tales como: "Ethoxylated Alcohols", "Sodium Metasilicate", "Dypropylene Glycol Monomethyl Ether", "Amphoteric Surfactant", "Trisodium Phosphate Dodecahydrate", "Didecyl Dimethyl Ammonium Chloride", "Sodium hydroxide", "Sodium hypochlorite", entre otros, en las áreas de lavandería y mantenimiento.

Riesgo: Contacto con sustancias químicas peligrosas.

Emerging Issues

Introduction

The NIOSH HLR program has a history of identifying and advancing an agenda of research on the most important issues related to occupational hearing loss. The 1998 NIOSH criteria document on occupational noise exposure identified nine research needs: noise control, impulsive noise, non-auditory effects of noise exposure, auditory effects of ototoxic chemical exposures, exposure monitoring, hearing protectors, training and motivation, program evaluation, and rehabilitation. With the exception of non-auditory effects, the HLR program has implemented specific research efforts to address each one of the topic areas since the criteria document's publication. The HLR research goals outlined in this evidence package originated from these topic areas, with some goals overlapping multiple topics in the earlier set of nine research needs. However, the field of hearing loss prevention is broad and continues to evolve and the work done so far has been insufficient to resolve the issues identified previously. Several new areas of importance to occupational hearing loss have emerged over the last several years, and the research focus in long-standing issues needs to be reexamined. The NORA Hearing Loss Team has been active in evaluating research priorities (see Appendix H). With the work of the NORA team, and earlier NIOSH research needs as a backdrop, the HLR program hosted the "Hearing Loss Prevention – Futures Workshop" in April 2005 to seek input from a variety of outside experts as another step toward identifying emerging issues and redefining the HLR program research priorities.

New developments in engineering noise control hold the promise of reducing hazardous noise exposures through identification of noise hazards at the source and targeting solutions to create a quieter workplace. Promulgation of new regulations for noise exposure¹, recordability of hearing loss² and the potential for updated rules related to hearing protection devices³ change the dynamics for hearing loss prevention programs and require new approaches to protecting the hearing health of workers. In the area of causative mechanisms, pharmacologic treatment of acute noise exposure and genetic testing for susceptibility represent new fields of research with challenges for occupational safety and health. Progress in the area of training research, motivation and evaluation of hearing loss prevention program effectiveness brings the challenge and opportunities to address affected workers by transforming research into practical implementations that protect workers' hearing.

The following emerging research issues are presented in relation to the four general HLR program research goals.

Research Goal 1: Contribute to the Development, Implementation, and Evaluation of Effective Hearing Loss Prevention Programs

Training tools based on social psychology have proven to be effective for communicating hearing loss prevention messages to worker populations such as carpenters and other construction workers. The future challenges will be to translate the lessons learned from reaching one audience to reaching more diverse audiences. Because of a unique opportunity to partner with the U.S. Navy and the University of Washington, our near-term efforts will focus on reaching shipyard construction workers. Research questions which need to be addressed include: Will the same training and motivational elements be effective with workers in other sectors? How can a hearing loss prevention program be designed to communicate to the broad spectrum of ages and to those who have already suffered a hearing loss? The work to create and evaluate effective training materials is one of the components of the HLR program that is further down the path in the effort to translate research findings into a comprehensible message that can be practiced in the workplace.

Conduct economic cost/benefit analyses of hearing conservation programs/noise controls.

Occupational safety and health managers often lack the evidence for the cost-effectiveness of engineering noise control solutions and hearing conservation programs in order to aggressively pursue full implementation. Cost-benefit analysis tools could be used to demonstrate the advantages of comprehensive hearing loss prevention programs for specific industrial case studies. The results of the case study analyses could be transferred to safety and health professionals through downloadable electronic documents made available on the NIOSH internet website and through other venues for information transfer.

Establish a centralized repository of audiometric data that can be accessed by professionals.

For over ten years the HLR program has recognized that one of the problems facing itinerant workforces is the inability to track the status of their hearing ability. Past efforts to develop a practical system where workers could carry their health data with them were limited by technology. However, with newer smart card/chip technology and the internet, the concept of workers carrying a key fob or a smart card which includes biometric identification technology is now more feasible. Establishing such a program could develop the repository of audiometric data, job description information, and provide workers with an access method. This information would enable providers to have access to more comprehensive hearing test results. Hearing conservation data may be able to be integrated with new national initiatives to centralize all medical records. NIOSH needs to be proactive and be sure that hearing information (as well as all occupational health information) is incorporated into the new national databases.

Collaborate with partners in education to reach young workers with prevention information and skills.

NIOSH is a member of the Wise Ears![®] program that was developed at the National Institute on Deafness and Other Communication Disorders (NIDCD). Wise Ears![®] was intended to reach school-aged children with health communication messages to promote healthy hearing. NIOSH is also working to develop materials and curricula that will target young workers to make them aware of the consequences harmful noise exposures.

Strengthen efforts to transfer and disseminate information.

The new NIOSH Research to Practice (r2p) initiative focuses on the transfer and translation of research findings, technologies, and information into prevention practices and products for the workplace. The HLR program will use r2p to strengthen its communication efforts with workers about hearing health risks. Some specific examples of this include:

- Develop guidelines to train workers to maximize residual hearing (e.g., listening strategies, lip-reading, optimal utilization of hearing aids, use of alternative communication methods). This research need was identified in the 1998 criteria document. The recommendation resulted from focus group study participants who indicated the extent of their reliance on non-verbal communication techniques. Because these techniques must be learned, new workers in particular may be at a disadvantage and possibly at increased risk for accidents. Training in nonverbal communication techniques could be useful for hearing-impaired workers.
- Develop guidelines defining hearing-critical jobs. Consistent and reliable methods of determining minimum auditory requirements for a particular job must be established in order to (a) ensure that the safety of the employee and other workers is not compromised, and (b) prevent undue discrimination against persons with hearing loss when such loss would not compromise safety or productivity.

Research Goal 2: Reduce Hearing Loss through Interventions Targeting Personal Protective Equipment

The greatest challenges in the area of personal hearing protection will no longer be in the traditional technology of passive earplugs and earmuffs. The integration of communication systems with hearing protection have resulted in highly sophisticated equipment that necessitate the development of yet another generation of new measurement and rating standards. The development of recommendations for the accommodation of hearing impaired workers will continue. The use of personal music players with the ability to produce potentially damaging sound pressure levels presents additional challenges in hearing loss prevention particularly if such devices are used as both hearing protection and entertainment. Practical workplace recommendations will require targeted research involving cooperation between our industrial partners and hearing protector manufacturers.

Refine hearing protector fit-testing methods.

A more effective fit-testing protocol is needed for hearing loss prevention programs. Several aspects of fit-testing must be improved: error checking during threshold assessment, coupling occluded testing with audiometric testing to reduce testing times and using workers' noise exposures to estimate adequacy of protection. Laboratory and field research have demonstrated that fit-testing can improve the attenuations workers achieve. Fit-testing coupled with the targeted training materials will improve the effectiveness of HLP programs.

Research Goal 3: Develop Engineering Controls to Reduce Noise Exposures

NIOSH's efforts in developing engineering noise controls are relatively recent, and were initially focused on the mining and construction sectors. While we will continue our efforts on those sectors, there is a need for engineering control technology efforts to be directed toward other sectors as well. Implementation of noise controls must not diminish production or interfere with operation when integrated with the equipment design. Infrastructure development has provided laboratory measurement capabilities that were not in place in 2001 when the HLR program commenced the NORA research in noise control. External partnerships between government, academia and industry are being pursued to institute a consortium for noise control solutions. Results in construction and mining will have application to similar problems in other sectors. Technology advances in both microprocessors and control theory hold the promise of low-cost implementation of active noise control at the source. While noise controls are considered to be of primary importance in protecting the worker, safety and health professionals cannot implement noise control solutions if they lack information. Toward that purpose, we will publish practical noise control solutions and noise emission levels from noisy products on the internet and in a compendium of noise control materials.

Develop basic guidelines on engineering controls and the maintenance of those controls, and provide leadership for noise education in undergraduate and graduate programs in engineering, industrial hygiene, and architecture.

Currently, engineers, industrial hygienists, and architects receive little or no training in the area of noise control. This results in a lack of understanding of its importance to the health of noise-exposed workers. Establishing curriculum guidelines and requiring more noise control related coursework will help create a better qualified professional workforce.

Publish available noise control solutions and updates.

In 1978, NIOSH published an Industrial Noise Control Manual which has 61 case studies of noise control solutions. This manual is being updated in a format that is web-accessible and searchable. Additionally, a feedback mechanism will be created so that users can contribute additional solutions.

Develop engineering noise controls for small businesses.

NIOSH has a wealth of information on noise control solutions that were developed in the 1970s. They are available but not in an easily accessible format. Developing a new web-based noise control solution site could provide simple solutions that manufacturers and engineering personnel could easily access and implement. The web provides a means of distributing noise-control tools to small business owners and managers allowing them to proactively choose quieter machines and environments for their workers.

Encourage manufacturers to provide noise labels.

The lack of regulatory requirements to provide product labels that carry information about the product's noise emissions leaves workers and consumers unaware of potential hazards to their hearing. The label should be based on sound power, and it should include the exposure level that the product user receives at the ear. The HLR program can work with the Institute of Noise Control Engineering and standards setting bodies to effect consensus standards for such labels.

Research Goal 4: Contribute to Reductions In Hearing Loss through the Understanding of Causative Mechanisms

In the past decade, basic research in hearing science has witnessed the advent of many significant findings. While genetic linkage of specific syndromes has been recognized for several decades, the identification of genetic markers for hearing loss susceptibility is relatively new. Although noise-induced hearing loss has been believed to be an equal-opportunity disease, genetic testing for susceptibility presents practical and ethical issues for the protection of workers in noisy environments. In the area of mixed exposures, the HLR program has been successful in bringing attention to the effects of ototoxic chemical exposure in combination with noise exposures. The European Union, Department of Defense and ACGIH have recognized the potential hazards, but research in mixed exposures to define the risk must continue before it will be possible to establish safe exposure limits. NIOSH can develop recommended exposure limits and provide technical support to regulatory agencies to establish national policy for mixed exposures which cause hearing loss. There continues to be a need to examine the normative data collected by surveillance activities. Due to its representative sampling, NHANES will prove to be valuable in revisiting the risk assessment that is the basis of the standards for occupational hearing loss and the effects of aging. Finally, basic research in functional hearing assessment such as measuring otoacoustic emissions and wide band reflectance of the middle ear may lead to practical techniques to better identify workers that have suffered noise exposure and are at risk of developing hearing loss. Early identification of risk through impaired auditory function can provide the opportunity for a health professional to intervene before hearing loss becomes a permanent reality.

With the cost of digital computing on an ever downward spiral and the capabilities doubling every 18 months, the prospect of developing an "impulse meter" and "impulse dosimeter" is achievable. These hardware tools will allow researchers to better analyze the workers acoustic environment and lead to development of a damage risk criterion for impulsive noise. For the near future these instruments must be experimental and will include a number of proposed metrics including, for example, kurtosis, AHAH modeling, and analytic wavelet transform.

Establish ongoing surveillance programs for occupational hearing loss and noise exposure; repeat large epidemiologic survey of industry (e.g., the NIOSH National Occupational Exposure Survey of the 1980's); and collect industry/job task specific noise exposure data.

One of the deficiencies of hearing loss research is the paucity of accurate noise exposure data for workers in a variety of industries. The last attempts at comprehensive noise surveys for large target industries were conducted in the 1970s. New tools must be developed to obtain surveillance data to determine the appropriate target audience (i.e. identify which jobs are at risk) for HLR program activity.

Establish the effectiveness of prophylactic treatments for noise-exposed workers.

Cheap, safe and effective prophylactic compounds should be developed for workers who cannot avoid high level noise exposure. These compounds do not substitute for an effective hearing loss prevention program. These compounds interfere with apoptotic events in the inner ear and maintain hearing function. The U.S. Department of Defense is currently looking at such compounds for high noise operations (e.g. combat infantry, pilots). Whether these compounds would remain safe and effective for the entire 30-40 year career of a manufacturing worker or miner is an important question.

Establish recommended exposure limits for mixed exposures of ototoxic chemicals and noise.

With acceptance of chemical ototoxicity by the European Union, Australia/New Zealand, the U.S. Army and the American Council of Government Industrial Hygienists (ACGIH), American regulators need to recognize the importance of protecting workers from solvents and noise. Without solid epidemiologic risk assessments, recommendations for regulatory action cannot proceed. NIOSH will continue to work towards better understanding and quantification of the interaction. NIOSH will also continue to encourage rules and regulations to protect workers who might be exposed to both agents in the workplace.

Conclusion

We recognize that the HLR program cannot address all of these potential research areas in isolation. As the principles that guide the NORA program into its second decade state, occupational safety and health progress depends on a collective effort of all parties involved. NIOSH has a leadership role as well as a research role to leverage resources and utilize the work of other researchers in an effort to transfer the collective research findings into the workplace for more effective prevention of occupational hearing loss. The HLR program researchers will continue to create and advance partnerships which will provide that leverage to arrive at solutions that have ownership with both labor and management. Some of the potential research efforts proposed above are relatively short-term while others are expected to require many years to accomplish. We will continue to develop the HLR program with decisions based on research priorities established in partnership with the many stakeholders who share our commitment to reducing the prevalence of occupational hearing loss through a focused program of research and prevention.

Other services, except public administration	3.5	12.1	.8	2.6	.5	1.7	.1	.4	(⁵)	.1	2.1	7.2

¹ The incidence rates represent the number of illnesses per 10,000 full-time workers and were calculated as: (N/EH) x 20,000,000, where

N = number of illnesses
 EH = total hours worked by all employees during the calendar year
 20,000,000 = base for 10,000 equivalent full-time workers (working 40 hours per week, 50 weeks per year)

² Excludes farms with fewer than 11 employees.

³ Data for Mining (Sector 21 in the *North American Industry Classification System-- United States, 2002*) include establishments not governed by the Mine Safety and Health Administration rules and reporting, such as those in Oil and Gas Extraction and related support activities. Data for mining operators in coal, metal, and nonmetal mining are provided to BLS by the Mine Safety and Health Administration, U.S. Department of Labor.

Independent mining contractors are excluded from the coal, metal, and nonmetal mining industries. These data do not reflect the changes the Occupational Safety and Health Administration made to its recordkeeping requirements effective January 1, 2002; therefore, estimates for these industries are not comparable to estimates in other industries.

⁴ Data for employers in railroad transportation are provided to BLS by the Federal Railroad Administration, U.S. Department of Transportation.

⁵ Fewer than 50 cases.

⁶ Incidence rate less than 0.05.

NOTE: Because of rounding, components may not add to totals.

TABLE SNR08. Incidence rates¹ of nonfatal occupational illness, by industry and category of illness, 2004 — Continued

Industry ²	NAICS code ³	2004 Annual average employment ⁴ (thousands)	Incidence rates per 10,000 full-time workers					
			Total cases	Skin diseases or disorders	Respiratory conditions	Poisonings	Hearing loss	All other illnesses
Inorganic dye and pigment manufacturing	325131	10.9	27.6	23.6	(7)	(7)	(7)	-
Other basic inorganic chemical manufacturing	32518	43.6	26.1	8.3	(7)	(7)	6.1	9.0
All other basic inorganic chemical manufacturing	325188	32.9	27.4	11.1	(7)	(7)	-	12.0
Other basic organic chemical manufacturing	32519	41.1	26.7	(7)	(7)	(7)	16.4	8.7
All other basic organic chemical manufacturing	325199	33.0	27.5	(7)	(7)	(7)	14.8	10.7
Resin, synthetic rubber, and artificial and synthetic fibers and filaments manufacturing	3252	106.6	35.6	3.8	2.1	(7)	4.8	24.8
Resin and synthetic rubber manufacturing	32521	71.3	18.5	2.8	2.2	(7)	4.9	8.6
Plastics material and resin manufacturing	325211	57.3	18.6	3.5	2.6	(7)	3.1	9.4
Synthetic rubber manufacturing	325212	14.0	17.8	(7)	(7)	(7)	11.9	-
Artificial and synthetic fibers and filaments manufacturing	32522	35.4	71.5	5.5	(7)	(7)	4.7	59.0
Cellulosic organic fiber manufacturing	325221	10.5	22.5	(7)	(7)	(7)	(7)	(7)
Noncellulosic organic fiber manufacturing	325222	24.8	89.8	(7)	(7)	(7)	(7)	79.5
Pesticide, fertilizer, and other agricultural chemical manufacturing	3253	42.0	64.2	13.1	(7)	(7)	21.6	26.2
Fertilizer manufacturing	32531	24.8	40.7	(7)	(7)	(7)	18.8	18.4
Nitrogenous fertilizer manufacturing	325311	8.4	25.3	(7)	(7)	(7)	25.3	(7)
Pesticide and other agricultural chemical manufacturing	32532	17.2	98.8	31.8	(7)	(7)	25.9	38.2
Pharmaceutical and medicine manufacturing	3254	287.2	70.8	7.9	8.4	(7)	2.5	51.9
Pharmaceutical and medicine manufacturing	32541	287.2	70.8	7.9	8.4	(7)	2.5	51.9
Medicinal and botanical manufacturing	325411	22.9	107.0	37.6	(7)	(7)	12.4	52.6
Pharmaceutical preparation manufacturing	325412	225.5	56.8	6.0	10.1	(7)	2.0	38.6
Biological product (except diagnostic) manufacturing	325414	24.3	31.7	-	(7)	(7)	(7)	30.1
Paint, coating, and adhesive manufacturing	3255	69.0	46.4	22.0	5.4	(7)	(7)	19.0
Paint and coating manufacturing	32551	45.4	56.9	22.5	7.4	(7)	(7)	27.0
Soap, cleaning compound, and toilet preparation manufacturing	3256	115.3	26.5	4.0	3.7	(7)	4.8	13.7
Soap and cleaning compound manufacturing	32561	58.5	33.9	4.3	5.7	(7)	6.9	16.8
Soap and other detergent manufacturing	325611	25.8	49.9	(7)	(7)	(7)	11.6	32.9
Polish and other sanitation good manufacturing	325612	27.2	23.1	(7)	9.6	(7)	(7)	(7)
Toilet preparation manufacturing	32562	56.9	18.6	3.5	(7)	(7)	(7)	10.2
Other chemical product and preparation manufacturing ..	3259	106.2	66.5	21.4	5.3	(7)	2.6	37.3
All other chemical product and preparation manufacturing	32599	87.6	74.9	20.5	6.0	(7)	3.1	45.3
Photographic film, paper, plate, and chemical manufacturing	325992	30.3	140.7	8.9	13.0	(7)	(7)	117.4
All other miscellaneous chemical product and preparation manufacturing	325998	35.5	48.9	38.5	(7)	(7)	5.8	(7)

See footnotes at end of table.

TABLE SNR08. Incidence rates¹ of nonfatal occupational illness, by industry and category of illness, 2004 — Continued

Industry ²	NAICS code ³	2004 Annual average employment ⁴ (thousands)	Incidence rates per 10,000 full-time workers					
			Total cases	Skin diseases or disorders	Respiratory conditions	Poisonings	Hearing loss	All other illnesses
Plastics and rubber products manufacturing	326	803.7	63.5	10.4	2.7	(⁷)	16.8	33.6
Plastics product manufacturing	3261	631.8	60.9	9.9	3.2	(⁷)	15.1	32.7
Unsupported plastics film, sheet, and bag manufacturing	32611	87.7	43.2	2.9	3.9	(⁷)	10.3	26.0
Unsupported plastics bag manufacturing	326111	27.0	18.1	5.4	6.1	(⁷)	(⁷)	6.1
Unsupported plastics film and sheet (except packaging) manufacturing	326113	51.7	61.8	(⁷)	3.3	(⁷)	17.3	41.0
Plastics pipe, pipe fitting, and unsupported profile shape manufacturing	32612	57.2	52.2	3.0	2.9	(⁷)	22.2	24.3
Unsupported plastics profile shape manufacturing ..	326121	27.7	47.3	(⁷)	5.8	(⁷)	9.2	29.6
Plastics pipe and pipe fitting manufacturing	326122	29.6	56.7	(⁷)	(⁷)	(⁷)	34.8	19.2
Polystyrene foam product manufacturing	32614	31.2	33.9	(⁷)	(⁷)	(⁷)	(⁷)	29.5
Urethane and other foam product (except polystyrene) manufacturing	32615	31.2	15.5	(⁷)	(⁷)	(⁷)	5.8	8.8
Plastics bottle manufacturing	32616	35.4	49.1	(⁷)	(⁷)	(⁷)	47.1	(⁷)
Other plastics product manufacturing	32619	368.5	71.3	14.9	3.4	(⁷)	11.8	41.2
Plastics plumbing fixture manufacturing	326191	23.7	21.4	(⁷)	(⁷)	(⁷)	(⁷)	16.4
All other plastics product manufacturing	326199	338.9	75.4	15.9	3.7	(⁷)	12.8	42.9
Rubber product manufacturing	3262	172.0	72.7	11.8	1.2	(⁷)	23.0	36.7
Tire manufacturing	32621	69.0	83.9	5.0	(⁷)	(⁷)	41.9	35.9
Tire manufacturing (except retreading)	326211	61.4	93.5	4.8	(⁷)	(⁷)	47.1	40.2
Rubber and plastics hoses and belting manufacturing	32622	27.8	36.2	(⁷)	(⁷)	(⁷)	11.0	20.2
All other rubber product manufacturing	326299	29.0	63.0	21.8	(⁷)	(⁷)	14.2	26.7
Nonmetallic mineral product manufacturing	327	498.5	44.6	6.6	4.3	.3	11.7	21.5
Clay product and refractory manufacturing	3271	64.8	81.9	9.2	(⁷)	(⁷)	11.5	59.0
Vitreous china, fine earthenware, and other pottery product manufacturing	327112	15.3	28.3	(⁷)	(⁷)	(⁷)	(⁷)	21.1
Brick and structural clay tile manufacturing	327121	13.2	48.4	(⁷)	(⁷)	(⁷)	24.6	23.9
Glass and glass product manufacturing	3272	112.0	74.0	1.9	14.4	(⁷)	13.7	43.7
Glass and glass product manufacturing	32721	112.0	74.0	1.9	14.4	(⁷)	13.7	43.7
Flat glass manufacturing	327211	13.2	33.2	(⁷)	(⁷)	(⁷)	18.5	-
Other pressed and blown glass and glassware manufacturing	327212	25.3	86.6	(⁷)	36.9	(⁷)	16.8	28.9
Glass container manufacturing	327213	19.0	41.2	-	(⁷)	(⁷)	26.6	12.0
Glass product manufacturing made of purchased glass	327215	54.5	88.9	(⁷)	9.4	(⁷)	6.7	71.6
Cement and concrete product manufacturing	3273	229.7	29.6	9.9	1.6	.7	12.0	5.4
Ready-mix concrete manufacturing	32732	118.0	16.2	3.4	2.0	1.3	4.7	4.7
Concrete pipe, brick, and block manufacturing	32733	33.5	34.6	8.7	(⁷)	(⁷)	24.0	-
Concrete block and brick manufacturing	327331	21.9	31.3	(⁷)	(⁷)	(⁷)	28.8	(⁷)

TABLE SNR08. Incidence rates¹ of nonfatal occupational illness, by industry and category of illness, 2004 — Continued

Industry ²	NAICS code ³	2004 Annual average employment ⁴ (thousands)	Incidence rates per 10,000 full-time workers					
			Total cases	Skin diseases or disorders	Respiratory conditions	Poisonings	Hearing loss	All other illnesses
Aluminum foundries (except die-casting)	331524	21.9	138.6	8.3	10.0	(⁷)	65.6	54.7
Fabricated metal product manufacturing	332	1,488.7	55.1	10.1	2.4	.2	18.2	24.2
Forging and stamping	3321	108.9	93.2	11.9	2.8	(⁷)	47.0	31.0
Forging and stamping	33211	108.9	93.2	11.9	2.8	(⁷)	47.0	31.0
Iron and steel forging	332111	24.6	91.6	(⁷)	5.9	(⁷)	43.9	36.6
Metal stamping	332116	57.7	114.8	16.0	2.6	(⁷)	64.9	30.2
Powder metallurgy part manufacturing	332117	10.5	62.0	(⁷)	(⁷)	(⁷)	18.4	33.9
Cutlery and flatware (except precious) manufacturing	332211	10.4	56.1	(⁷)	(⁷)	(⁷)	24.3	26.2
Architectural and structural metals manufacturing	3323	386.5	35.4	3.6	2.3	.6	9.8	19.0
Plate work and fabricated structural product manufacturing	33231	163.8	26.0	1.6	2.0	(⁷)	13.7	8.8
Prefabricated metal building and component manufacturing	332311	31.2	44.4	(⁷)	(⁷)	(⁷)	24.3	17.5
Fabricated structural metal manufacturing	332312	87.6	21.3	(⁷)	(⁷)	(⁷)	11.1	8.8
Plate work manufacturing	332313	44.9	22.6	5.0	3.3	(⁷)	11.4	(⁷)
Ornamental and architectural metal products manufacturing	33232	222.7	42.5	5.0	2.6	1.1	6.9	26.9
Metal window and door manufacturing	332321	84.4	48.1	8.8	3.6	(⁷)	11.3	24.3
Sheet metal work manufacturing	332322	100.8	49.6	3.0	2.7	2.6	5.5	35.9
Ornamental and architectural metal work manufacturing	332323	37.6	11.1	(⁷)	(⁷)	(⁷)	(⁷)	9.5
Boiler, tank, and shipping container manufacturing	3324	90.6	50.7	5.7	(⁷)	(⁷)	21.4	21.8
Power boiler and heat exchanger manufacturing	33241	19.9	21.4	13.0	(⁷)	(⁷)	(⁷)	-
Metal tank (heavy gauge) manufacturing	33242	23.7	27.0	(⁷)	(⁷)	(⁷)	10.2	(⁷)
Metal can, box, and other metal container (light gauge) manufacturing	33243	47.0	75.8	3.1	(⁷)	(⁷)	33.5	39.1
Metal can manufacturing	332431	24.3	106.1	5.7	(⁷)	(⁷)	31.2	69.6
Other metal container manufacturing	332439	22.8	39.5	(⁷)	(⁷)	(⁷)	36.3	(⁷)
Hardware manufacturing	3325	37.9	158.8	5.5	(⁷)	(⁷)	32.4	120.6
Hardware manufacturing	33251	37.9	158.8	5.5	(⁷)	(⁷)	32.4	120.6
Spring and wire product manufacturing	3326	61.7	48.5	14.0	4.8	(⁷)	5.8	23.7
Spring and wire product manufacturing	33261	61.7	48.5	14.0	4.8	(⁷)	5.8	23.7
Spring (light gauge) manufacturing	332612	12.2	61.4	15.3	(⁷)	(⁷)	18.8	27.3
Other fabricated wire product manufacturing	332618	45.3	44.7	9.8	6.5	(⁷)	(⁷)	25.1
Machine shops; turned product; and screw, nut, and bolt manufacturing	3327	325.6	50.8	13.2	1.0	(⁷)	15.7	20.8
Machine shops	33271	239.5	31.4	14.8	.7	(⁷)	5.7	10.3
Bolt, nut, screw, rivet, and washer manufacturing	332722	42.6	76.2	7.2	4.0	(⁷)	52.9	12.1
Coating, engraving, heat treating, and allied activities	3328	143.3	45.8	13.7	3.8	(⁷)	11.2	17.0

See footnotes at end of table.

TABLE SNR08. Incidence rates¹ of nonfatal occupational illness, by industry and category of illness, 2004 — Continued

Industry ²	NAICS code ³	2004 Annual average employment ⁴ (thousands)	Incidence rates per 10,000 full-time workers					
			Total cases	Skin diseases or disorders	Respiratory conditions	Poisonings	Hearing loss	All other illnesses
Coating, engraving, heat treating, and allied activities	33281	143.3	45.8	13.7	3.8	(7)	11.2	17.0
Metal heat treating	332811	17.8	12.0	10.4	(7)	(7)	(7)	(7)
Metal coating, engraving (except jewelry and silverware), and allied services to manufacturers ..	332812	50.8	32.8	8.1	4.7	(7)	(7)	20.0
Electroplating, plating, polishing, anodizing, and coloring	332813	74.6	62.9	18.3	4.1	(7)	21.3	19.3
Other fabricated metal product manufacturing	3329	276.0	68.3	16.0	3.1	(7)	24.4	24.8
Metal valve manufacturing	33291	97.5	61.3	13.5	(7)	(7)	19.6	27.5
Fluid power valve and hose fitting manufacturing	332912	36.6	66.4	18.1	(7)	(7)	24.4	22.8
Plumbing fixture fitting and trim manufacturing	332913	15.7	42.9	(7)	(7)	(7)	(7)	29.9
Other metal valve and pipe fitting manufacturing	332919	21.6	77.9	11.5	(7)	(7)	18.7	47.6
All other fabricated metal product manufacturing	33299	178.5	72.1	17.4	4.4	(7)	27.0	23.4
Ammunition (except small arms) manufacturing	332993	17.4	33.0	(7)	(7)	(7)	(7)	25.4
Fabricated pipe and pipe fitting manufacturing	332996	26.9	46.9	20.1	(7)	(7)	21.5	(7)
All other miscellaneous fabricated metal product manufacturing	332999	59.6	64.7	15.7	9.4	(7)	12.0	27.5
Machinery manufacturing	333	1,136.8	51.3	8.5	1.6	.3	12.9	27.9
Agriculture, construction, and mining machinery manufacturing	3331	193.2	66.1	8.3	(7)	(7)	19.6	37.4
Agricultural implement manufacturing	33311	78.0	98.0	7.9	(7)	(7)	27.0	61.5
Farm machinery and equipment manufacturing	333111	56.7	111.6	8.4	(7)	(7)	33.8	67.4
Lawn and garden tractor and home lawn and garden equipment manufacturing	333112	21.3	61.2	(7)	(7)	(7)	8.4	45.8
Construction machinery manufacturing	33312	62.2	69.6	13.1	(7)	(7)	20.2	36.1
Mining and oil and gas field machinery manufacturing	33313	52.9	20.6	4.0	(7)	(7)	9.4	7.3
Oil and gas field machinery and equipment manufacturing	333132	42.0	13.2	4.1	(7)	(7)	(7)	6.7
Industrial machinery manufacturing	3332	119.9	44.6	4.5	1.3	1.6	11.8	25.5
Plastics and rubber industry machinery manufacturing	33322	16.8	19.4	(7)	(7)	(7)	(7)	(7)
Other industrial machinery manufacturing	33329	96.0	45.0	3.2	1.6	2.0	7.7	30.5
Paper industry machinery manufacturing	333291	11.1	28.1	(7)	(7)	(7)	(7)	(7)
Printing machinery and equipment manufacturing ...	333293	13.5	17.8	(7)	(7)	(7)	(7)	(7)
Food product machinery manufacturing	333294	18.6	15.0	(7)	(7)	(7)	-	(7)
All other industrial machinery manufacturing	333298	27.8	43.4	(7)	(7)	(7)	12.2	25.2
Commercial and service industry machinery manufacturing	3333	114.5	30.7	3.2	(7)	(7)	2.7	24.8
Commercial and service industry machinery manufacturing	33331	114.5	30.7	3.2	(7)	(7)	2.7	24.8

See footnotes at end of table.

TABLE SNR08. Incidence rates¹ of nonfatal occupational illness, by industry and category of illness, 2004 — Continued

Industry ²	NAICS code ³	2004 Annual average employment ⁴ (thousands)	Incidence rates per 10,000 full-time workers					
			Total cases	Skin diseases or disorders	Respiratory conditions	Poisonings	Hearing loss	All other illnesses
Automatic vending machine manufacturing	333311	5.8	43.8	(7)	(7)	(7)	(7)	43.8
Office machinery manufacturing	333313	11.3	44.8	(7)	(7)	(7)	(7)	43.9
Optical instrument and lens manufacturing	333314	21.7	33.5	13.4	(7)	(7)	(7)	17.7
Other commercial and service industry machinery manufacturing	333319	55.6	17.3	(7)	(7)	(7)	4.6	12.1
Ventilation, heating, air-conditioning, and commercial refrigeration equipment manufacturing	3334	152.2	74.8	5.3	4.2	(7)	21.2	43.7
Ventilation, heating, air-conditioning, and commercial refrigeration equipment manufacturing	33341	152.2	74.8	5.3	4.2	(7)	21.2	43.7
Air purification equipment manufacturing	333411	17.0	93.0	15.3	28.1	(7)	(7)	42.2
Heating equipment (except warm air furnaces) manufacturing	333414	20.2	32.6	—	(7)	(7)	16.0	14.1
Air-conditioning and warm air heating equipment and commercial and industrial refrigeration equipment manufacturing	333415	104.4	81.2	4.7	1.5	(7)	22.4	52.0
Metalworking machinery manufacturing	3335	200.0	23.1	8.7	1.2	(7)	5.6	7.3
Metalworking machinery manufacturing	33351	200.0	23.1	8.7	1.2	(7)	5.6	7.3
Industrial mold manufacturing	333511	43.1	11.6	(7)	(7)	(7)	(7)	7.3
Special die and tool, die set, jig, and fixture manufacturing	333514	77.2	22.4	6.8	(7)	(7)	(7)	12.1
Cutting tool and machine tool accessory manufacturing	333515	27.8	43.9	16.5	(7)	(7)	25.3	(7)
Engine, turbine, and power transmission equipment manufacturing	3336	93.1	79.5	22.6	(7)	(7)	20.4	35.1
Engine, turbine, and power transmission equipment manufacturing	33361	93.1	79.5	22.6	(7)	(7)	20.4	35.1
Speed changer, industrial high-speed drive, and gear manufacturing	333612	12.9	30.3	25.7	(7)	(7)	(7)	—
Mechanical power transmission equipment manufacturing	333613	16.8	113.9	47.5	—	(7)	40.8	20.1
Other engine equipment manufacturing	333618	45.5	93.1	14.6	(7)	(7)	22.2	55.9
Other general purpose machinery manufacturing	3339	263.8	48.8	9.5	1.7	(7)	10.8	26.6
Pump and compressor manufacturing	33391	51.0	47.5	7.2	4.6	(7)	11.4	24.3
Pump and pumping equipment manufacturing	333911	28.2	58.0	7.7	(7)	(7)	9.4	38.4
Air and gas compressor manufacturing	333912	20.0	40.2	7.7	8.1	(7)	15.8	8.6
Material handling equipment manufacturing	33392	73.8	58.9	9.3	2.1	(7)	6.6	40.4
Conveyor and conveying equipment manufacturing	333922	29.5	26.8	6.6	(7)	(7)	(7)	17.9
Industrial truck, tractor, trailer, and stacker machinery manufacturing	333924	22.9	128.3	18.4	(7)	(7)	10.4	94.8
All other general purpose machinery manufacturing	33399	139.0	43.8	10.5	(7)	(7)	12.7	20.2

See footnotes at end of table.

TABLE SNR08. Incidence rates¹ of nonfatal occupational illness, by industry and category of illness, 2004 — Continued

Industry ²	NAICS code ³	2004 Annual average employment ⁴ (thousands)	Incidence rates per 10,000 full-time workers					
			Total cases	Skin diseases or disorders	Respiratory conditions	Poisonings	Hearing loss	All other illnesses
Power-driven handtool manufacturing	333991	12.8	62.0	(7)	(7)	(7)	(7)	51.9
Welding and soldering equipment manufacturing	333992	14.4	44.6	(7)	(7)	(7)	33.8	10.8
Packaging machinery manufacturing	333993	18.0	36.5	(7)	(7)	(7)	18.8	15.6

TABLE SNR08. Incidence rates¹ of nonfatal occupational illness, by industry and category of illness, 2004 — Continued

Industry ²	NAICS code ³	2004 Annual average employment ⁴ (thousands)	Incidence rates per 10,000 full-time workers					
			Total cases	Skin diseases or disorders	Respiratory conditions	Poisonings	Hearing loss	All other illnesses
Ophthalmic goods manufacturing	339115	31.9	62.3	5.8	(7)	(7)	(7)	54.7
Dental laboratories	339116	49.6	26.9	10.4	(7)	(7)	(7)	16.7
Other miscellaneous manufacturing	3399	351.9	35.3	3.9	2.6	(7)	6.5	22.2
Jewelry and silverware manufacturing	33991	43.6	23.0	(7)	(7)	(7)	3.8	16.5
Jewelry (except costume) manufacturing	339911	29.2	18.8	(7)	(7)	(7)	(7)	15.5
Sporting and athletic goods manufacturing	33992	57.0	73.3	(7)	(7)	(7)	11.1	58.6
Doll and stuffed toy manufacturing	339931	3.0	(7)	(7)	(7)	(7)	(7)	(7)
Office supplies (except paper) manufacturing	33994	24.9	40.3	(7)	(7)	(7)	(7)	34.6
Pen and mechanical pencil manufacturing	339941	6.6	58.2	(7)	(7)	(7)	(7)	40.7
Lead pencil and art good manufacturing	339942	8.8	31.4	(7)	(7)	(7)	(7)	29.0
Sign manufacturing	33995	72.2	17.8	(7)	(7)	(7)	2.9	13.0
All other miscellaneous manufacturing	33999	134.9	30.4	7.4	3.3	(7)	8.3	11.4
Gasket, packing, and sealing device manufacturing	339991	36.4	27.6	6.4	(7)	(7)	(7)	15.9
Musical instrument manufacturing	339992	13.5	30.0	18.9	(7)	(7)	(7)	(7)
Fastener, button, needle, and pin manufacturing	339993	6.7	75.1	(7)	(7)	(7)	30.7	(7)
Broom, brush, and mop manufacturing	339994	11.6	(7)	(7)	(7)	(7)	(7)	(7)
All other miscellaneous manufacturing	339999	60.7	30.9	6.0	3.2	(7)	10.0	11.8
Service providing		84,896.3	19.6	3.7	1.9	.3	.6	13.0
Trade, transportation, and utilities⁹		25,273.3	17.5	2.8	1.3	.2	1.5	11.6
Wholesale trade	42	5,642.5	13.2	2.8	1.3	.1	1.1	8.0
Merchant wholesalers, durable goods	423	2,942.2	14.7	2.5	1.1	.2	1.3	-
Motor vehicle and motor vehicle parts and supplies merchant wholesalers	4231	338.0	22.0	6.2	2.7	(7)	.9	12.2
Furniture and home furnishing merchant wholesalers	4232	112.5	7.3	-	(7)	(7)	(7)	6.1
Lumber and other construction materials merchant wholesalers	4233	241.1	8.7	2.4	(7)	(7)	.8	5.4
Professional and commercial equipment and supplies merchant wholesalers	4234	636.3	7.6	1.4	(7)	(7)	.3	5.7
Metal and mineral (except petroleum) merchant wholesalers	4235	120.3	32.2	1.5	(7)	(7)	20.6	9.1
Electrical goods merchant wholesalers	4236	340.2	11.6	(7)	3.0	.5	(7)	7.6
Hardware, and plumbing and heating equipment and supplies merchant wholesalers	4237	234.7	5.7	2.5	(7)	(7)	(7)	3.1
Machinery, equipment, and supplies merchant wholesalers	4238	649.4	14.5	3.2	1.4	.4	.4	9.2
Miscellaneous durable goods merchant wholesalers	4239	269.7	-	3.1	(7)	(7)	1.5	31.0
Merchant wholesalers, nondurable goods	424	2,000.0	12.9	3.6	1.9	(7)	.9	6.5

See footnotes at end of table.

TABLE SNR08. Incidence rates¹ of nonfatal occupational illness, by industry and category of illness, 2004 — Continued

Industry ²	NAICS code ³	2004 Annual average employment ⁴ (thousands)	Incidence rates per 10,000 full-time workers					
			Total cases	Skin diseases or disorders	Respiratory conditions	Poisonings	Hearing loss	All other illnesses

See footnotes at end of table.

TABLE SNR08. Incidence rates¹ of nonfatal occupational illness, by industry and category of illness, 2004 — Continued

Industry ²	NAICS code ³	2004 Annual average employment ⁴ (thousands)	Incidence rates per 10,000 full-time workers					
			Total cases	Skin diseases or disorders	Respiratory conditions	Poisonings	Hearing loss	All other illnesses
RV (recreational vehicle) parks and recreational camps ..	7212	50.8	—	—	(⁷)	(⁷)	(⁷)	(⁷)
Rooming and boarding houses	7213	11.1	(⁷)	(⁷)	(⁷)	(⁷)	(⁷)	(⁷)
Food services and drinking places	722	8,829.6	11.1	4.0	.5	.1	(⁷)	—
Full-service restaurants	7221	4,194.9	—	4.1	.6	.2	(⁷)	—
Limited-service eating places	7222	3,737.3	—	4.5	.6	(⁷)	(⁷)	—
Special food services	7223	531.3	6.7	2.7	(⁷)	(⁷)	(⁷)	3.7
Other services		3,785.2	12.1	2.6	1.7	.4	.1	7.2
Other services, except public administration	81	3,785.2	12.1	2.6	1.7	.4	.1	7.2
Repair and maintenance	811	1,222.0	8.5	1.8	1.2	.9	.3	4.3
Automotive repair and maintenance	8111	884.7	5.6	1.3	.3	.8	.2	3.0
Electronic and precision equipment repair and maintenance	8112	101.2	7.2	(⁷)	(⁷)	3.2	(⁷)	4.1
Commercial and industrial machinery and equipment (except automotive and electronic) repair and maintenance	8113	157.7	23.1	4.6	6.2	(⁷)	1.2	11.0
Personal and household goods repair and maintenance	8114	78.4	11.6	4.4	2.9	(⁷)	(⁷)	4.3
Personal and laundry services	812	1,266.1	12.9	3.3	2.0	.2	(⁷)	7.4
Personal care services	8121	560.0	5.8	1.3	(⁷)	(⁷)	(⁷)	4.5
Death care services	8122	137.0	21.6	4.4	(⁷)	(⁷)	(⁷)	15.5
Drycleaning and laundry services	8123	349.7	20.9	5.0	5.7	(⁷)	(⁷)	10.1
Other personal services	8129	219.3	9.5	4.4	(⁷)	(⁷)	(⁷)	4.6
Religious, grantmaking, civic, professional, and similar organizations	813	1,297.2	15.7	3.0	2.0	.3	(⁷)	10.5

¹ The incidence rates represent the number of illnesses per 10,000 full-time workers and were calculated as: (N/EH) x 20,000,000, where

N = number of illnesses
 EH = total hours worked by all employees during the calendar year
 20,000,000 = base for 10,000 equivalent full-time workers (working 40 hours per week, 50 weeks per year)

² Totals include data for industries not shown separately.

³ North American Industry Classification System — United States, 2002

⁴ Employment is expressed as an annual average and is derived primarily from the BLS-Quarterly Census of Employment and Wages (QCEW) program.

⁵ Excludes farms with fewer than 11 employees.

⁶ Data for Mining (Sector 21 in the North American Industry Classification System— United States, 2002) include establishments not governed by the Mine Safety and Health Administration rules and reporting, such as those in Oil and Gas Extraction and related support activities. Data for mining operators in coal, metal, and nonmetal mining are provided to BLS by the Mine Safety and Health

Administration, U.S. Department of Labor. Independent mining contractors are excluded from the coal, metal, and nonmetal mining industries. These data do not reflect the changes the Occupational Safety and Health Administration made to its recordkeeping requirements effective January 1, 2002; therefore, estimates for these industries are not comparable to estimates in other industries.

⁷ Fewer than 15 cases.

⁸ Data for mining operators in this industry are provided to BLS by the Mine Safety and Health Administration, U.S. Department of Labor. Independent mining contractors are excluded. These data do not reflect the changes the Occupational Safety and Health Administration made to its recordkeeping requirements effective January 1, 2002; therefore, estimates for these industries are not comparable to estimates in other industries.

⁹ Data for employers in railroad transportation are provided to BLS by the Federal Railroad Administration, U.S. Department of Transportation.

¹⁰ Incidence rate less than 0.05.

NOTE: Because of rounding, components may not add to totals. Dash indicates data not available.
