PRELIMINARY SURVEY REPORT:
CONTROL TECHNOLOGY FOR MANUAL TRANSFER OF CHEMICAL POWDERS

AT

City of Hamilton
Municipal Electric Plant
Hamilton, Ohio

REPORT WRITTEN BY:
Frank W. Godbey

REPORT DATE:
August 1984

REPORT NO.:
149-15a

NATIONAL INSTITUTE FOR OCCUPATIONAL SAFETY AND HEALTH
Division of Physical Sciences and Engineering
Engineering Control Technology Branch
4676 Columbia Parkway
Cincinnati, Ohio 45226
PLANT SURVEYED: City of Hamilton Municipal Electric Plant
960 N. Third Street
Hamilton, Ohio  45011

SIC CODE: 4911

SURVEY DATE: May 8, 1984

SURVEY CONDUCTED BY: Frank W. Godbey

EMPLOYER REPRESENTATIVES CONTACTED: Donald E. Stewart, Superintendent,
Electric Production - 513/868-5867
G. Thomas P'Simer, Assistant
Superintendent, Electric Production
- 513/868-5863

EMPLOYEE REPRESENTATIVES CONTACTED: Ernest Mackinnon, Water Tender - No
Affiliation
I. INTRODUCTION

The National Institute for Occupational Safety and Health (NIOSH) is the primary Federal agency engaged in occupational safety and health research. Located in the Department of Health and Human Services (formerly DHEW), it was established by the Occupational Safety and Health Act of 1970. This legislation mandated NIOSH to conduct a number of research and education programs separate from the standard setting and enforcement functions carried out by the Occupational Safety and Health Administration (OSHA) in the Department of Labor. An important area of NIOSH research deals with methods for controlling occupational exposure to potential chemical and physical hazards. The Engineering Control Technology Branch (ECTB) of the Division of Physical Sciences and Engineering has been given the lead within NIOSH to study the engineering aspects of health hazard prevention and control.

Since 1976, ECTB has conducted a number of assessments of health hazard control technology on the basis of industry, common industrial process, or specific control techniques. Examples of these completed studies include the foundry industry; various chemical manufacturing or processing operations; spray painting; and the recirculation of exhaust air. The objective of each of these studies has been to document and evaluate effective control techniques for potential health hazards in the industry or process of interest, and to create a more general awareness of the need for or availability of an effective system of hazard control measures.

These studies involve a number of steps or phases. Initially, a series of walk-through surveys is conducted to select plants or processes with effective and potentially transferable control concepts or techniques. Next, in-depth surveys are conducted to determine both the control parameters and the effectiveness of these controls. The reports from these in-depth surveys are then used as a basis for preparing technical reports and journal articles on effective hazard control measures. Ultimately, the
information from these research activities builds the data base of publicly available information on hazard control techniques for use by health professionals who are responsible for preventing occupational illness and injury.

This plant was visited as part of a study of dust control during the manual handling of dry chemical powders and the manual transfer of those materials to some type of processing device, i.e., V-blender, Banbury mixer, etc. Ultimately, this project will result in a concise article describing dust control techniques during manual transfer of chemical powders.
II. PLANT AND PROCESS DESCRIPTION

PLANT DESCRIPTION

This facility consists of a multi-storied brick and concrete reinforced electric utility building containing approximately 60,000 square feet of floor space. The plant employs 48 workers and operates three shifts per day, seven days a week, in the production of electricity.

PROCESS DESCRIPTION

The dry materials are manually scooped from drums and sacks, using a small bucket, and dumped into 75-gallon water tanks. The mixture is manually stirred with a stick until the dry materials are in solution. The solution is then automatically pumped into one of three boiler drums (steam generators) where steam is generated. The steam is used to drive the electricity generating rotors.

POTENTIAL HAZARDS

The major dry ingredients in the area of interest—water treatment—are soda ash, phosphates, and flake caustic soda.
III. CONTROLS

PRINCIPLES OF CONTROL

Occupational exposures can be controlled by the application of a number of well-known principles, including engineering measures, work practices, personal protection, and monitoring. These principles may be applied at or near the hazard source, to the general workplace environment, or at the point of occupational exposure to individuals. Controls applied at the source of the hazard, including engineering measures (material substitution, process/equipment modification, isolation or automation, local ventilation) and work practices, are generally the preferred and most effective means of control both in terms of occupational and environmental concerns. Controls which may be applied to hazards that have escaped into the workplace environment include dilution ventilation, dust suppression, and housekeeping. Control measures may also be applied near individual workers, including the use of remote control rooms, isolation booths, supplied-air cabs, work practices, and personal protective equipment.

In general, a system comprised of the above control measures is required to provide worker protection under normal operating conditions as well as under conditions of process upset, failure and/or maintenance. Process and workplace monitoring devices, personal exposure monitoring, and medical monitoring are important mechanisms for providing feedback concerning effectiveness of the controls in use. Ongoing monitoring and maintenance of controls to insure proper use and operating conditions, and the education and commitment of both workers and management to occupational health are also important ingredients of a complete, effective, and durable control system.

These principles of control apply to all situations, but their optimum application varies from case-to-case. The application of these principles are discussed below.
This electric utility does not use any type of ventilation controls in the water treatment area.

WORK PRACTICES

Workers are encouraged to use good work practices. They are provided instruction when they start the job and receive updates and reinforcement as needed. Health and safety educational materials are provided to encourage a sustained good work practices effort.

MONITORING

Employees are given preemployment physical examinations. First-aid supplies are provided and employees are trained in their use. The city life squad is utilized in emergency situations.

PERSONAL PROTECTION

Safety glasses, respirators, and gloves are provided on an "as-needed" basis.
IV. CONCLUSIONS AND RECOMMENDATIONS

This plant represents a general type of manual dry materials handling operation and does not have sufficiently unique controls to warrant performing an in-depth study. Therefore, an in-depth survey is not recommended.
