Surveillance for Babesiosis — United States, 2019
Annual Summary
Acknowledgments
The findings in this U.S. surveillance summary were based, in part, on contributions by state and local health departments.

Main Findings for 2019

- For 2019, CDC was notified of a total of 2,418 cases of babesiosis in the US, an 11% increase from the total of 2,161 cases for 2018
- Babesiosis was a reportable disease in 40 states and the District of Columbia (DC) in 2019; 25 (63%) of the 40 states notified CDC of at least 1 case
- Most of the reported cases (88%; n = 2,129/2,418) were in residents of 7 states where tickborne transmission of Babesia parasites is well established (the Northeast and upper Midwest: Connecticut, Massachusetts, Minnesota, New Jersey, New York, Rhode Island, and Wisconsin)
- Maine and Vermont reported case rates (10.3 and 5.4/100,000 population, respectively) similar to or higher than those reported by endemic states

Background

Babesiosis

Babesiosis is caused by protozoan parasites of the genus Babesia, which infect red blood cells. Babesia parasites are usually transmitted to humans by tick bites but can also be transmitted by blood transfusion or congenitally (mother to child) (1–3).

Most human cases of Babesia infection in the United States are caused by the parasite Babesia microti. Occasional U.S. cases caused by other species (types) of Babesia have been found (4, 5). Babesia microti is most commonly spread by Ixodes scapularis ticks (also called blacklegged ticks or deer ticks) primarily in the Northeast and upper Midwest, especially in parts of New England, New York State, New Jersey, Wisconsin, and Minnesota (1, 6–8). Babesiosis is spread by young nymph ticks which are often found in woods, brushy areas, or grass during warmer months (spring and summer). The ticks are very small (about the size of a poppy seed); because of their small size infected people might not remember having a tick bite.

Many people who are infected with Babesia microti are asymptomatic. Some people develop flu-like symptoms, such as fever, chills, sweats, headache, body aches, loss of appetite, nausea, or fatigue. Babesiosis can also cause severe complications such as hemolytic anemia, a very low platelet count (thrombocytopenia), malfunction of the vital organs (acute respiratory failure, congestive heart failure, and renal failure) and death (7).

Babesiosis can be a severe, life-threatening disease (1, 7), particularly in people who:
- do not have a spleen or have had their spleen removed;
- have a weak immune system for other reasons (such as cancer, lymphoma, or AIDS);
- have other serious health conditions (such as liver or kidney disease); or
- are elderly.

Surveillance

CDC has conducted surveillance for babesiosis in the United States since January 2011, when babesiosis became a nationally notifiable condition. The babesiosis case definition used for surveillance purposes is available online (http://wwwn.cdc.gov/nndss/conditions/babesiosis/case-definition/2011/) and is summarized in Table 1. Health departments in states where babesiosis is reportable notify CDC of cases that meet the definition via the National Notifiable Diseases Surveillance System (NNDSS).

Health departments submit additional information about reported cases using the CDC Case Report Form (CRF) Babesiosis CRF [PDF, 2 pages, 650 KB]; data are requested about risk factors for infection, clinical manifestations, and laboratory results. Of note, for some cases, requested data elements may be
incomplete or missing. For example, data regarding clinical manifestations are collected as distinct questions, resulting in differences in the denominator across each sign/symptom. For more information, visit babesiosis surveillance and case reporting. Healthcare providers, laboratories, and the general public should contact their state health department for information about reporting cases of babesiosis.

The number of states in which babesiosis is a reportable condition may change from year to year as additional states begin conducting surveillance. Cases are reported by state and county of residence, which is not necessarily where the exposure occurred. Changes in the number of reported cases do not necessarily represent true changes in disease incidence; ascertainment, reporting, and investigation of cases are subject to clinician awareness and public health agency resources, which may vary from year to year in and among states.

This summary focuses on babesiosis cases reported for surveillance year 2019; some data from previous years (2011–2018) are included to show differences from year to year. Babesiosis surveillance data also are presented in CDC’s Morbidity and Mortality Weekly Report (MMWR) weekly and annual summaries of nationally notifiable diseases. In addition, national surveillance data for 2011 and a 5-year summary (2011–2015) were published previously (8, 9). Because of differences in the timeline for finalizing data in the annual surveillance datasets, data provided in this summary may differ slightly from those previously published. Of note, the year in which a case is counted in national surveillance summaries is assigned by the health department and might reflect the year of symptom onset, diagnosis, or of reporting to or by the health department.
2019 babesiosis surveillance summary

Geographic distribution
In 2019 CDC was notified of a total of 2,418 cases of babesiosis by 25 of the 40 states in which babesiosis was a reportable condition (63%) (Table 2). This was an 11% increase from the total of 2,161 cases for 2018 and the highest number of cases reported for any year since babesiosis became a nationally notifiable disease (Figure 1). For 2019, 88% (n = 2,129/2,418) of the reported cases were residents of 7 states (Connecticut, Massachusetts, Minnesota, New Jersey, New York, Rhode Island, and Wisconsin). Tickborne transmission of Babesia parasites is well established in parts of these states. Differences within and among states in the distributions of reported cases by place of residence are evident in the county-level maps for 2019 (Figure 2) and the 8 prior years (2011–2018) in which national surveillance was conducted (Appendix). Among the 215 counties with at least 1 reported case of babesiosis for 2019, 140 counties (65%) reported 1–5 cases, 20 counties (9%) reported 6–10 cases, 20 counties (9%) reported 11–20 cases, and 36 (17%) had >20 reported cases. The number of counties reporting greater than 20 cases increased from 29 in 2018 to 36 in 2019. The 36 counties with >20 cases reported were in New York (n=10), Massachusetts (n=9), Connecticut (n=8), Rhode Island (n=4), Maine (n=2), New Hampshire (n=2), and New Jersey (n=1). Many cases in states without well-established local transmission of babesiosis had documented travel to areas with established local transmission.

Endemic states continue to report the majority of cases however, rates of reported cases increased in the Northeastern states of Maine, Vermont, and New Hampshire (Table 2).

Babesiosis by demographics
The majority of case-patients in the United States were older, with a median age of 64 years old (range: <1–102 years; n = 2,418). The age distributions for 2019 and the 8 previous years were similar (Figure 3), with the largest number of cases reported in persons aged 60–69 years. As in previous years, among the 2,417 case-patients for whom data on sex were available in 2019, 66% (n = 1,588) were male and 34% (n=829) were female.

Seasonality
A majority of case-patients reported getting sick during the spring or summer months, which is consistent with tick activity. Data on month of symptom onset were available for 70% of case-patients (n = 1,697/2,418). The proportion of case-patients with reported symptom onset during June–August has remained consistent from year to year since 2011 (Figure 4).

Symptoms and fatal cases
Among the case-patients for whom data were available, fever was the most frequently reported sign or symptom (78%: n = 1,621/2,072 patients), followed by myalgia (muscle aches) (63%; n = 1,229/1,936), chills (61%; n = 1,128/1,854), thrombocytopenia (low platelet count) (60%; n = 830/1,393), headache (55%; n= 1070/1,928), and anemia (53%; n = 747/1,403).

For 2019, 957 (44%) people were hospitalized for at least 1 day; hospitalization data were available for 2,178 case-patients. These data are consistent with previous years; overall for 2011–2019, data were available for 13,290 case-patients (84% of the total of 15,787), 6,067 (46%) of whom had reportedly been hospitalized for at least 1 day. In 2019, 8 cases died with 5 deaths occurring in New York, 2 in Massachusetts, and 1 in Maryland; with an overall death rate of 0.57%.

Epidemiologic factors
Babesiosis is primarily transmitted via tick bites but can also be transmitted through blood transfusions, transplants, and from mother to child (congenitally). In 2019, of the 1,083 case-patients for whom data were available, 454 (42%) recalled having a tick bite in the 8 weeks before symptom onset. In 2019 there were 2 cases of babesiosis in blood recipients that were classified by the reporting state as transfusion associated.

August 12, 2021
COVID-19 and case reporting
During the coronavirus disease 2019 (COVID-19) pandemic, reporting jurisdictions faced challenges that could have impacted data completeness such as the diversion of staffing and other resources from babesiosis surveillance activities. The following 21 jurisdictions where babesiosis is reportable may have incomplete 2019 data due to COVID-19 pandemic related disruptions: California, Connecticut, Delaware, District of Columbia, Florida, Indiana, Kansas, Massachusetts, Minnesota, Missouri, Montana, Nebraska, New Hampshire, New York (excluding New York City), New York City, North Dakota, Ohio, South Carolina, Tennessee, Texas, and West Virginia. Incomplete data can include case counts as well as specific case data such as onset date, symptoms reported and risk factors.

Table 1. National surveillance case definition for babesiosis*
### Clinical evidence

**Objective**
- One or more of the following: fever, anemia, or thrombocytopenia.

**Subjective**
- One or more of the following: chills, sweats, headache, myalgia, or arthralgia.

### Epidemiologic evidence for transfusion transmission

For the purposes of surveillance, epidemiologic linkage between a transfusion recipient and a blood donor is demonstrated if all of the following criteria are met:

**In the transfusion recipient**
- Received one or more red blood cell (RBC) or platelet transfusions within 1 year before the collection date of a specimen with laboratory evidence of *Babesia* infection; **and**
- At least one of these transfused blood components was donated by the donor described below; **and**
- Transfusion-associated infection is considered at least as plausible as tickborne transmission; **and**

**In the blood donor**
- Donated at least one of the RBC or platelet components that was transfused into the above recipient; **and**
- The plausibility that this blood component was the source of infection in the recipient is considered equal to or greater than that of blood from other involved donors. (More than one plausible donor can be linked to the same recipient.)

### Laboratory criteria for diagnosis

Surveillance for Babesiosis — United States, 2019

August 12, 2021
* Year as reported by the health department
† Cases were reported by state of residence, which was not necessarily the state of exposure.
‡ Rate per 100,000 population (10)
§ Babesiosis is not a reportable condition by law in these states
¶ The denominators for calculations of total incidence rates included only the populations of states in which babesiosis was a reportable condition during the pertinent year
A total of 14,042 cases of babesiosis were reported (2011, n = 1,126; 2012, n = 911; 2013, n = 1,761; 2014, n = 1,742; 2015, n = 2,074; 2016, n = 1,909; 2017, n = 2,358; 2018, n = 2,161; 2019, n = 2,418).

† Year as reported by the health department.
Figure 2. Number* of reported cases of babesiosis, by county of residence — 40 states, 2019†

* N = 2,417; county of residence was known for all but 1 (<1%) of the 2,418 total case-patients. See the Appendix for the maps for surveillance years 2011–2018.
† Year as reported by the health department.
Figure 3. Number of reported cases of babesiosis, by age group* and year, 2011–2019†

* Data on age were available for most case-patients (2011, n = 1,041/1,126; 2012, n = 785/911; 2013, n = 1,523/1,761; 2014, n = 1,740/1,742; 2015, n = 2,074/2,074; 2016, n = 1,902/1,909; 2017, n = 2,347/2,358; 2018, n=2,157/2,161; 2019, n=2,418).

† Year as reported by the health department.
Figure 4. Number of reported cases of babesiosis, by month of symptom onset* and year, 2011–2019†

* Data on month of symptom onset were available for most case-patients (2011, n = 932/1,126; 2012, n = 644/911; 2013, n = 1,352/1,761; 2014, n = 1,340/1,742; 2015, n = 1,665/2,074; 2016, n = 1,483/1,909; 2017, n = 1,772/2,358; 2018, n = 1,497/2161; 2019, n = 1,697).
† Year as reported by the health department.

Appendix. Maps for surveillance years 2011–2018

2011: Number* of reported cases of babesiosis, by county of residence — 22 states†

* N = 1,117; county of residence was known for all but 9 (1%) of the 1,126 total case-patients.  
† Year as reported by the health department.
2012: Number* of reported cases of babesiosis, by county of residence — 22 states†

* N = 904; county of residence was known for all but 7 (1%) of the 911 total case-patients.
† Year as reported by the health department.
2013: Number* of reported cases of babesiosis, by county of residence — 27 states†

* N = 1,749; county of residence was known for all but 12 (1%) of the 1,761 total case-patients.
† Year as reported by the health department.
2014: Number* of reported cases of babesiosis, by county of residence — 31 states†

* N = 1,731; county of residence was known for all but 13 (1%) of the 1,742 total case-patients.
† Year as reported by the health department.
2015: Number* of reported cases of babesiosis, by county of residence — 33 states†

* N = 2,070; county of residence was known for all but 4 (<1%) of the 2,074 total case-patients.
† Year as reported by the health department.
2016: Number* of reported cases of babesiosis, by county of residence — 35 states†

* N = 1,889; county of residence was known for all but 20 (1%) of the 1,909 total case-patients.
† Year as reported by the health department.
2017: Number* of reported cases of babesiosis, by county of residence — 37 states†

* N = 2,324; county of residence was known for all but 34 (1%) of the 2,358 total case-patients
† Year as reported by the health department.
2018: Number* of reported cases of babesiosis, by county of residence — 40 states†

* N = 2,144; county of residence was known for all but 17 (1%) of the 2,161 total case-patients.
† Year as reported by the health department.
