What Happens to Blood Donors Who Test Positive for Chagas Disease?

Fast Facts
- CDC estimates 300,000 or more Trypanosoma cruzi-infected individuals of Hispanic origin currently live in the United States.
- Despite being counseled to seek medical care, only approximately 11% of Chagas seropositive blood donors have contacted CDC for consultation regarding treatment.
- Chagas disease may be life threatening even when the patient feels well. Evaluation and treatment can be life saving.

Chagas Disease Background
- Chagas disease is caused by the parasite Trypanosoma cruzi and is transmitted by infected insects called triatomines.
- Chagas disease can also be transmitted by blood transfusion, organ transplantation, congenital exposure, lab accidents, and contaminated food and drink.
- Chagas disease is endemic throughout much of Mexico, Central America, and South America, where an estimated 8–11 million persons are infected.
- Chagas disease can include cardiac and gastrointestinal manifestations.
- There is a small risk of acquiring Chagas disease through infected triatomine bugs in the U.S.
- The parasite, vectors, and infected animals have been found in many parts of the southern United States.

Blood Donor Screening
- Screening of the U.S. blood supply for Chagas disease began in early 2007, leading to increased identification of people with Chagas disease.
- It is estimated that 1 in every 27,500 donors tests positive for Chagas disease nationwide:
  - Majority of U.S. states have identified seropositive donors.
  - Updated count of identified donors by state is available at the AABB Chagas Biovigilance Network website.

Are Positive Blood Donors Receiving Evaluation and Treatment?
- Treatment may prevent progression to more serious disease.
- Since blood donor screening began, the number of requests to CDC for consultation and drug release for Chagas disease has increased markedly.
- However, only approximately 11% of positive donors or their physicians have contacted CDC for consultation regarding treatment.

Possible Barriers Preventing Positive Donors from Seeking Evaluation and Treatment
- There is very limited awareness of Chagas disease among patients.
- Many patients believe there is no effective treatment.
- Many patients have limited or no health insurance coverage.
- Language barriers exist, as many patients speak only Spanish.
- There may be patient concern about immigration status.
- There is a lack of awareness of Chagas disease among physicians.

Physician Lack of Awareness of Chagas Disease
- Survey of American College of Obstetrics and Gynecology (ACOG) members:
  - Most members described their knowledge of Chagas disease as very limited.
  - Most members reported never considering the diagnosis of Chagas disease among patients from endemic countries.
- Survey of members of MedscapeCME, a leading provider of online clinical and medical information for physicians and other healthcare professionals, indicated:
  - Substantial knowledge deficits, especially among obstetricians and gynecologists.

Resources for Chagas Disease Blood Donor Counseling in the United States
- Fact sheets and additional resources are available at www.cdc.gov/chagas.
- You may contact your local health department regarding:
  - Resources available for positive donors.
  - Referral to local physician.
- CDC services, including physician consultation, testing, and treatment are available:
  - By phone (404) 718-4745 or email to chagas@cdc.gov.
