

PulseNet: 20 years of making food safer to eat

CENTRAL PILLAR OF US FOOD SAFETY SYSTEM

PulseNet is a national network of laboratories that solves outbreaks of foodborne disease. **PulseNet** scientists detect outbreaks—large and small—by connecting the dots between cases of similar illness that are happening anywhere in the country.

PulseNet investigations have brought about lasting changes in food industry practices and new regulations that have made our food safer.

HOW PulseNet works

1 DNA fingerprinting technology identifies the bacteria making people sick

2 Database managers check the national databases for more-than-expected numbers of matching DNA fingerprints, or clusters, from anywhere in the US

3 Alert state and local health departments about a possible outbreak

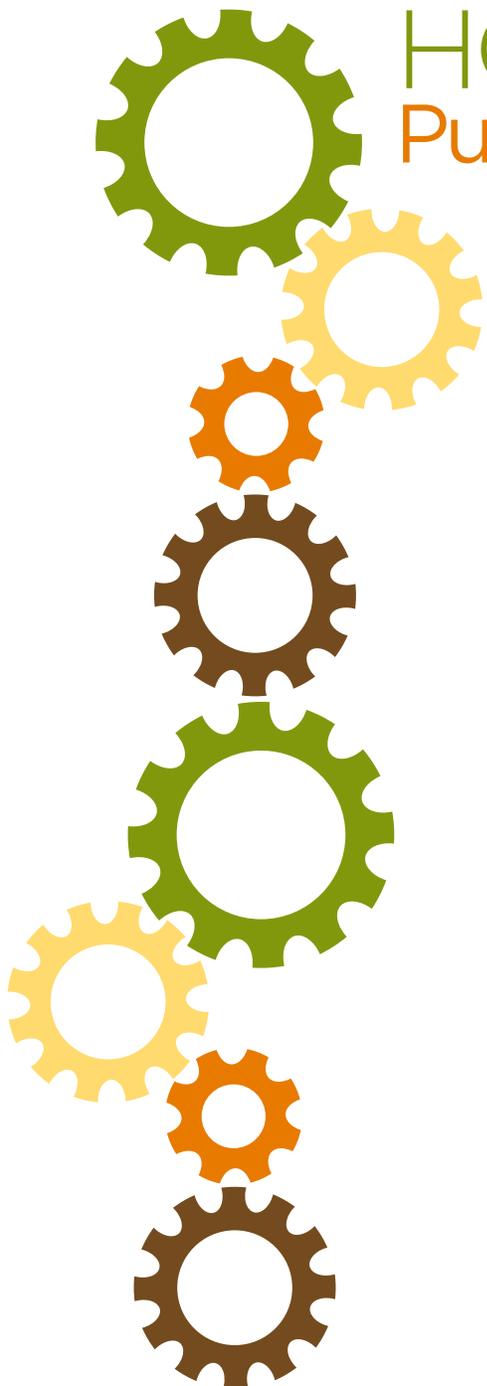

4 PulseNet scientists work with [FDA](#) and [USDA/FSIS](#)* officials, epidemiologists, and environmental health specialists to **identify the contaminated food**

5 Public alerted of the outbreak

6 Manufacturer may **voluntarily recall** the contaminated food

PulseNet by the numbers:

1 billion

Pounds of contaminated food recalled since PulseNet was launched

\$507 million

Saved each year (medical costs and lost productivity) with quick outbreak detection

1 million

DNA fingerprints of foodborne bacteria in the PulseNet USA database

89,000

Record number of DNA fingerprints of bacteria submitted to PulseNet in 2015

1,500

Clusters of illness from *Salmonella*, *E. coli*, and *Listeria* infections annually identified by PulseNet member labs

280

Multistate clusters of illness caused by *Salmonella*, *E. coli*, and *Listeria* infections identified by PulseNet each year

83

Federal, regional, state, and local laboratories in the PulseNet network

40

Clusters of human illnesses tracked weekly

Centers for Disease Control and Prevention
National Center for Emerging and Zoonotic Infectious Diseases

*FDA (US Food and Drug Administration)
USDA/FSIS (US Department of Agriculture/Food Safety and Inspection Service)

The story of PulseNet

In the beginning... there were contaminated hamburgers

In 1993, more than 700 people got sick and 4 died in the western United States after eating at a large fast-food chain. It took public health investigators 39 days to determine that these illnesses were connected and that it was an outbreak. And it also took more than a month after the first person fell ill to identify the culprit: hamburgers contaminated with a deadly type of *E. coli* bacteria. This outbreak spurred foodborne disease experts at CDC to find a way to speed up detection of foodborne outbreaks.

A few years later, in partnership with the [Association of Public Health Laboratories \(APHL\)](#), federal partners, and public health labs in 4 states, CDC created PulseNet. The goal was to create databases that would be the central repository for DNA fingerprints extracted from gut bacteria of patients with foodborne disease. Public health laboratories around the United States could submit these DNA fingerprints to PulseNet, which would be managed by CDC. When investigators searched the PulseNet databases and discovered that several ill people had bacteria with the same DNA fingerprint, they would suspect an outbreak.

Now, every state has at least one public health laboratory that uses PulseNet's technology and can access its databases of close to 1 million fingerprints of bacteria. Because it has connected the dots between current illnesses and stored DNA fingerprints, PulseNet has revolutionized the way foodborne outbreaks are detected and investigated.

"APHL is proud of its long-standing connection to PulseNet, from the first software purchases to whole genome sequencing."

Scott J. Becker, Executive Director, Association of Public Health Laboratories

A Tale of Two Outbreaks

BEFORE PulseNet

1993 Outbreak of *E. coli* in western states

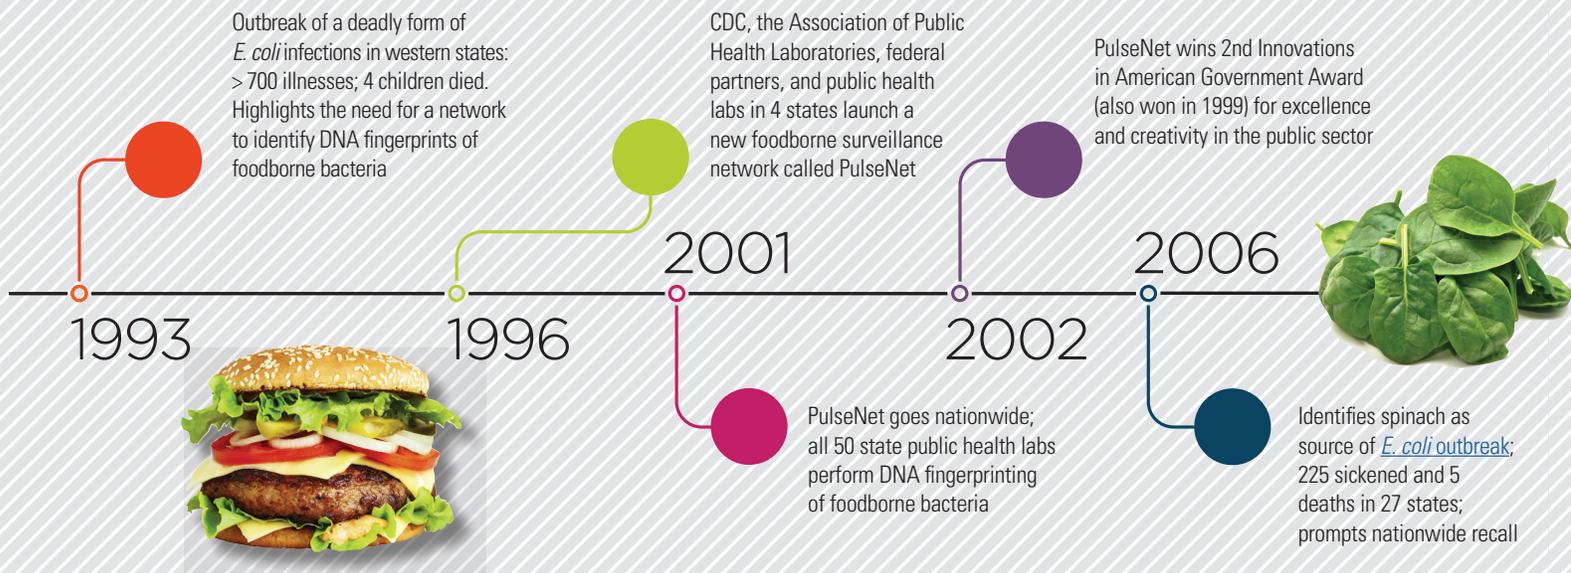

39 days to detect outbreak:
726 ill, 4 deaths

AFTER PulseNet

2002 Outbreak of *E. coli* in Colorado

18 days to detect outbreak:
44 ill, 0 deaths

PulseNet's 20-year history of making food safer to eat

PulseNet has made these foods safer to eat:

Peanut butter, Sprouts, Eggs, Tree nuts, Poultry products, Leafy greens, Tomatoes, Frozen entrees, Lunch meat, Spices, Melons

PulseNet in action: Making food safer

Food safety requires that we pay close attention to every step in the food supply chain, from farm to fork. Diligent efforts by farmers, producers, distributors, regulators, and consumers have made the US food supply among the safest in the world. Nevertheless, an estimated 48 million people, or 1 in 6 Americans, get sick every year from foodborne illnesses. That is where PulseNet comes in.

During outbreak investigations, scientists can use PulseNet data to identify the specific type of bacteria that caused people to get sick, track down the food that was contaminated, and find out what happened to cause the contamination. For example, in the early 2000s, PulseNet traced an outbreak of *Salmonella*

infection to raw almonds grown in California. The outbreak prompted regulators to mandate that almonds for sale in the United States be pasteurized (by fumigation or hot steam treatment) to control the problem and prevent similar outbreaks in the future.

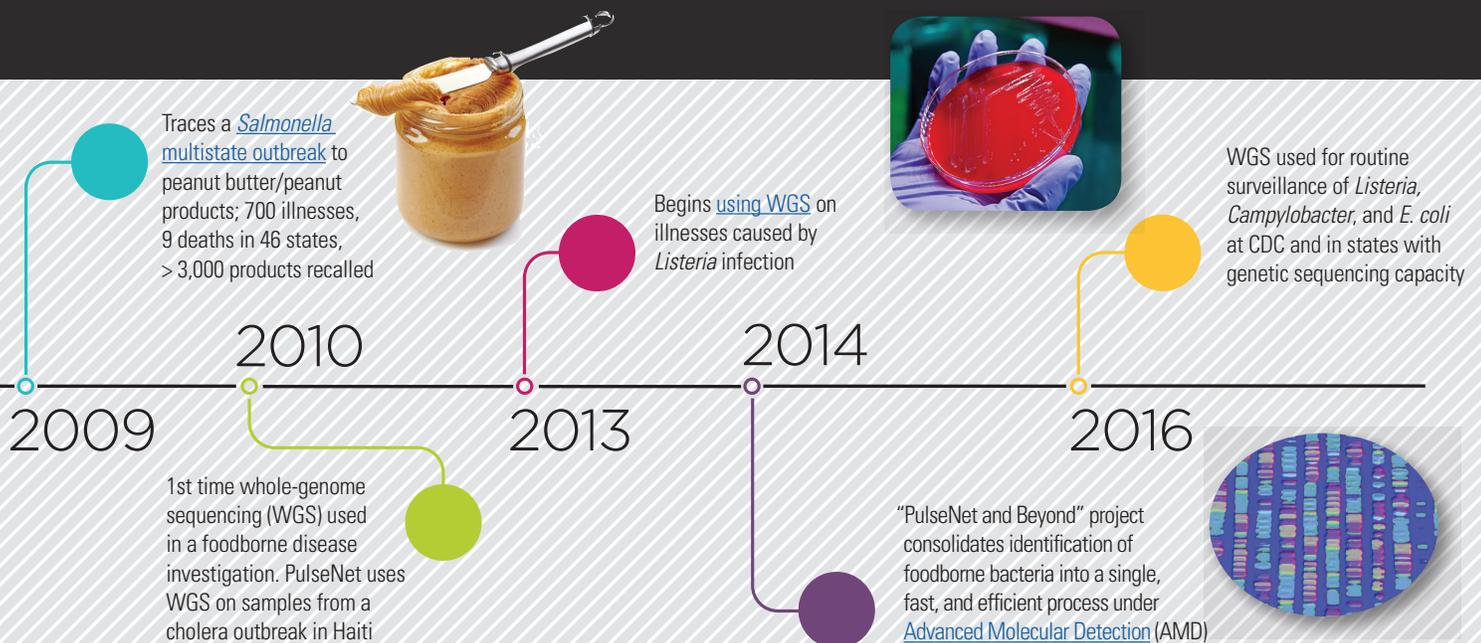

Outbreak investigations supported by PulseNet help scientists find gaps in food safety systems that would otherwise be unrecognized. Information from PulseNet has stimulated production changes by the food industry and helped federal agencies create new or improved recommendations and regulations to make our food supply safer.

Case study:

Listeria-contaminated caramel apples

In November 2014, PulseNet scientists detected two clusters of illness (35 people from 12 states, including 7 who died) caused by the foodborne bacteria *Listeria*. Using traditional lab analysis methods, the scientists linked sick patients who were likely to have eaten the same contaminated food. They also used whole-genome sequencing (WGS) to more precisely determine which illnesses were linked. Armed with this information, investigators interviewed patients about foods they had eaten and identified a [new source of *Listeria* infection](#): caramel apples.

Real-time WGS helped investigators solve the outbreak at least 1 week sooner than would have been possible using traditional methods. The apple producer and several caramel apple manufacturers recalled apples to prevent more illnesses.

The Future of PulseNet: Faster, cheaper, and better foodborne disease detection

A new test

Culture-independent diagnostic tests, or CIDTs, are new tests that can detect the DNA of bacteria directly from patient samples like stool. As their name implies, CIDTs do not need a culture (cells grown in a lab) to identify the bacteria that caused a patient's illness. Clinical laboratories are increasing their use of CIDTs because they save costs and diagnose illnesses faster.

The challenge to PulseNet

For PulseNet to work, scientists need genetic information drawn from cultures. Because CIDTs skip the step of producing a culture, these newer tests don't produce DNA fingerprints to store in PulseNet's database. Without these data, public health scientists will not be able to find, monitor, and prevent foodborne disease outbreaks or follow trends to know if prevention policies are working. Many outbreaks will go undetected or be detected later when the outbreak has grown, and contaminated products will remain on the market longer.

Harmonizing the system

CDC is working closely with public health officials, diagnostic laboratories, CIDT kit manufacturers, and clinicians to ensure that PulseNet collects the DNA fingerprints it needs. PulseNet is also developing a new way to detect outbreaks that doesn't depend on cultures. These innovations are in the early stages of research and development, but we are heading toward a system that answers both needs: rapid and less costly diagnosis for individuals and a way to ensure essential data are still collected.

Transforming disease detection

In 2013, CDC began using whole-genome sequencing (WGS) to detect outbreaks caused by *Listeria*, the most deadly foodborne pathogen. WGS reveals all the genetic material, or the genome, of an organism (like bacteria and viruses) in one efficient process. The *Listeria* project was one of the first to receive support from CDC's [Advanced Molecular Detection](#) (AMD) initiative, a program that uses newer, more powerful, pathogen detection technologies to find outbreaks sooner. CDC is partnering with other federal agencies and state and local health departments to analyze *Listeria* from human cases and possible food sources.

Since the *Listeria* project began, scientists have detected more clusters, solved outbreaks faster with fewer cases, linked cases to likely food sources, and identified *Listeria* in unexpected foods, such as caramel apples and ice cream. CDC is quickly expanding the use of WGS in state laboratories and has begun using WGS for investigations of other foodborne pathogens such as *Campylobacter*, *E. coli*, and *Salmonella*. WGS has been a game changer for outbreak detection, spurring innovation and new discoveries. With WGS and PulseNet working in tandem, we have taken a significant leap forward in making food safer to eat.

Detecting *Listeria*: Before and After WGS*
