This fact sheet summarizes 2014 data on chlamydia, gonorrhea, and syphilis published in CDC’s annual report, Sexually Transmitted Disease Surveillance, 2014 (available at www.cdc.gov/std/stats). The data are based on state and local STD case reports from a variety of private and public sources. They indicate that the majority of cases are reported in non-STD clinic settings, such as private physician offices and health maintenance organizations.

Many cases of chlamydia, gonorrhea, and syphilis continue to go undiagnosed and unreported, and data on several additional STDs — such as human papillomavirus, herpes simplex virus, and trichomonia — are not routinely reported to CDC. As a result, the annual surveillance report captures only a fraction of the true burden of STDs in America. However, it provides important insights into the scope, distribution, and trends in STD diagnoses in the country.

STDs are a substantial health challenge facing the United States. CDC estimates that nearly 20 million new sexually transmitted infections occur every year in this country, half among young people aged 15–24, and account for almost $16 billion in health care costs. Each of these infections is a potential threat to an individual’s immediate and long-term health and well-being. In addition to increasing a person’s risk for acquiring and transmitting HIV infection, STDs can lead to severe reproductive health complications, such as infertility and ectopic pregnancy.

### Snapshot: STDs in the United States, 2014

In 2014, increases were seen in all three nationally reported STDs. The approximately 1.4 million cases of chlamydia represent the highest number of annual cases of any condition ever reported to CDC. Substantial increases were also seen among reported cases of gonorrhea and syphilis. While young people and women are most severely affected by STDs, increasing rates among men contributed to the overall increase in 2014 across all diseases.

Note: The data do not capture all infections due to the underreporting of cases.
Some Groups Bear a Disproportionate Burden of STDs

While anyone can become infected with an STD, certain groups, including young people and gay and bisexual men, are at greatest risk.

Gonorrhea and chlamydia primarily affect young people

Surveillance data shows both the numbers and rates of reported cases of chlamydia and gonorrhea continues to be highest among young people aged 15-24.

Both young men and young women are heavily affected by STDs — but young women face the most serious long-term health consequences. It is estimated that undiagnosed STDs cause more than 20,000 women to become infertile each year.

Most Reported Chlamydia and Gonorrhea Infections Occur among 15–24-Year-Olds

Troubling rise in syphilis infections among men, particularly gay and bisexual men

Trend data show rates of syphilis are increasing at an alarming rate (15.1 percent in 2014). While rates have increased among both men and women, men account for more than 90 percent of all primary and secondary syphilis cases. Men who have sex with men (MSM)* account for 83 percent of male cases where the sex of the sex partner is known. Primary and secondary syphilis are the most infectious stages of the disease, and if not adequately treated, can lead to long-term infection which can cause visual impairment and stroke. Syphilis infection can also place a person at increased risk for acquiring or transmitting HIV infection. Available surveillance data indicate that an average of half of MSM who have syphilis are also infected with HIV.

Disparities result from a range of factors

A number of individual risk behaviors (such as higher numbers of lifetime sex partners), as well as environmental, social and cultural factors (such as higher prevalence of STDs or difficulty accessing quality health care) contribute to disparities in the sexual health of gay and bisexual men. For example, gay and bisexual men with lower economic status may have trouble accessing and affording quality healthcare, making it difficult to receive STD testing and other prevention services. Additionally, complex issues like homophobia and stigma can also make it difficult for gay and bisexual men to find culturally-sensitive and appropriate care and treatment.

* The term men who have sex with men is used in CDC surveillance systems because it indicates the behaviors that transmit infection, rather than how individuals self-identify in terms of their sexuality.
STD Screening is Critical:
If you are sexually active, be sure to talk to your healthcare provider about STD testing and which tests may be right for you.

**Women:**
- If you are a sexually active woman younger than 25, or have risk factors such as new or multiple sex partners, you should request annual chlamydia and gonorrhea tests.
- If you are a pregnant woman, you should request syphilis, HIV, chlamydia, and hepatitis B tests early in your pregnancy. If you have new or multiple sex partners, you should also request gonorrhea testing early in pregnancy.

**Gay and bisexual men:**
- If you are a sexually active man who is gay, bisexual, or has sex with men, you should request tests for syphilis, chlamydia, gonorrhea, and HIV at least once a year. More frequent STD testing is recommended for men at high risk.
