Self-Study Modules on Tuberculosis

Module 4: Objectives
At completion of this module, learners will be able to:
1. List groups of people who should receive high priority for latent TB infection (LTBI) treatment
2. Describe treatment regimens for LTBI
3. Describe treatment regimens for TB disease
4. Describe principles of preventing drug resistance
5. Describe patient monitoring during LTBI and TB disease treatment
6. Describe TB treatment adherence strategies
7. List common adverse reactions to drugs used to treat LTBI and TB disease

Module 4 – Treatment of Latent Tuberculosis Infection and Tuberculosis Disease

Module 4: Overview
- Treatment of LTBI
  - Patient Medical Evaluation
  - LTBI Treatment Regimens
  - Special Considerations for LTBI Treatment
- Treatment of TB Disease
  - TB Disease Treatment Regimens

Module 4: Overview (cont.)
- Treatment of TB Disease (cont.)
  - Special Considerations and Alternative Treatment Regimens
  - Treatment and Monitoring Plan and Adverse Reactions
  - Adherence and Evaluating Patients’ Response to Treatment
  - Role of Public Health Workers
- Case Studies

Treatment of Latent TB Infection (LTBI)
- LTBI is treated to prevent the development of TB disease
- LTBI is treated with medication

Module 4 – Treatment of Latent Tuberculosis Infection and Tuberculosis Disease
Module 4 – Treatment of Latent Tuberculosis Infection and Tuberculosis Disease

**Treatment of LTBI (2)**

- Targeted testing should be used to identify and treat people who are:
  - At high risk for exposure to or infection with *M. tuberculosis*
  - At high risk for developing TB disease once infected with *M. tuberculosis*
- People in these groups should receive high priority for LTBI treatment if they have a positive tuberculin skin test (TST) or interferon-gamma release assay (IGRA)

---

**High Priority for LTBI Treatment (1)**

- High-priority groups for LTBI treatment if positive IGRA or TST result of ≥ 5 mm:
  - Recent contacts of people with infectious TB disease
  - People living with HIV
  - People with chest x-ray findings suggestive of previous TB disease
  - Patients with an organ transplant
  - Other immunosuppressed patients

---

**High Priority for LTBI Treatment (2)**

- High-priority groups for LTBI treatment if positive IGRA or TST result of ≥ 10 mm:
  - People who have come to U.S. from countries where TB is common
  - People who abuse drugs
  - People who live or work in high-risk congregate settings
  - People who work in mycobacteriology laboratories

---

**High Priority for LTBI Treatment (3)**

- High-priority groups for LTBI treatment if positive IGRA or TST result of ≥ 10 mm (cont.):
  - People with medical conditions that increase risk of TB disease
  - Children younger than 5 years of age
  - Infants, children, and adolescents exposed to adults in high-risk groups

---

**Low Priority for LTBI Treatment**

- Individuals without any risk factors generally should not be tested for TB infection
- However, individuals with no risk factors who are tested and have a positive IGRA or TST result of ≥ 15 mm should be evaluated for LTBI treatment

---

**Treatment of Latent TB Infection (LTBI)**

Patient Medical Evaluation
Patient Medical Evaluation (1)

Medical evaluations should be done to:

1. Exclude possibility of TB disease
2. Determine whether patient has ever been treated for TB infection or TB disease
3. Find out if patient has any medical conditions that may complicate therapy
4. Establish and build rapport with patient

Patient Medical Evaluation (2)

1. Exclude possibility of TB disease
   - Treating TB disease with LTBI treatment regimen can lead to drug resistance
   - Clinicians should determine if the patient has symptoms of TB disease
   - Clinicians should evaluate the patient with a chest x-ray
   - Patients with symptoms or chest x-ray findings of TB disease should be given TB disease treatment, not LTBI treatment

Patient Medical Evaluation (3)

2. Determine whether patient has ever been treated for TB infection or TB disease
   - Patients who have been adequately treated should not be treated again
   - TST or IGRA results cannot determine if patient has received treatment for LTBI or TB disease; or if they have been re-infected after treatment

Patient Medical Evaluation (4)

3. Find out if patient has any medical conditions that may complicate therapy or require more careful monitoring. These patients include:
   - People living with HIV
   - People with history of liver disorder or disease
   - People who use alcohol regularly
   - Women who are pregnant or just had a baby (within 3 months of delivery)
   - People who are taking other medications that may increase the risk of hepatitis

Patient Medical Evaluation (5)

For patients with the medical conditions listed on the previous slide, baseline laboratory liver function tests (to detect injury to liver) are recommended before starting LTBI treatment.

Patient Medical Evaluation (6)

- It is important to find out if:
  - Patient has ever had adverse reactions to LTBI drugs
  - Patient is currently on medications that may interact with LTBI drugs
Patient Medical Evaluation (7)

4. Establish and build rapport with patient

- Health care workers (HCWs) should highlight important aspects of treatment, such as:
  - Benefits of treatment
  - Importance of adherence to treatment
  - Possible adverse reactions
  - Establishment of a follow-up plan

Patient Medical Evaluation (8)

Because of the interaction between TB and HIV, HCWs should also recommend that patients undergo HIV counseling and testing.

Treatment of Latent TB Infection (LTBI)

LTBI Treatment Regimens

- Isoniazid (INH) daily for 9 months is very effective in preventing the development of TB disease
- INH may also be given for 6 months
  - Cost effective and patients may find it easier to adhere, BUT:
    - Not as effective if given for less than 6 months
    - Not recommended for people living with HIV, individuals with previous TB disease, or children

LTBI Treatment Regimens (2)

Isoniazid and Rifapentine (12-Dose Regimen)

- Combination of INH and rifapentine (RPT) given in 12, once-a-week doses under DOT, if possible
- Recommended for patients who:
  - Are 12 years of age or older
  - Were recently exposed to infectious TB
  - Have a TST or IGRA conversion from negative to positive
  - Have chest x-ray findings of previous TB disease
- Regimen may be used in otherwise healthy HIV-infected persons who are:
  - 12 years of age or older
  - Not on antiretroviral therapy (ART), except those taking an efavirenz or raltegravir-based ART regimen

LTBI Treatment Regimens (3)

Isoniazid and Rifapentine (12-Dose Regimen)

- This regimen is not recommended for
  - Children younger than 2 years of age
  - People with HIV/AIDS who are taking certain ART regimens
  - People presumed to be infected with isoniazid or rifampin-resistant M. tuberculosis
  - Pregnant women or women expecting to become pregnant within the 12-week regimen
### LTBI Treatment Regimens (4)

**Rifampin**
- Rifampin (RIF) is also recommended for people with a positive TST or IGRA result
  - Especially if the person has been exposed to INH-resistant TB
- RIF should be given daily for 4 months
- RIF should not be used with certain combinations of ART
- In some cases, rifabutin (RFB) may be substituted when RIF cannot be used

### LTBI Treatment Regimens (5)

**Rifampin and Pyrazinamide**
- CDC advises against using a combination of RIF and pyrazinamide (PZA) due to serious side effects such as:
  - Severe liver injury
  - Death

### Treatment of LTBI Study Question 4.1

What is the purpose of LTBI treatment?

### Treatment of LTBI Study Question 4.2

Which groups of people should receive high-priority for LTBI treatment if they have a positive IGRA or TST result of $\geq 5$ mm? Name 5.
Treatment of LTBI
Study Question 4.3
Which groups of people should receive high priority for LTBI treatment if they have a positive IGRA result or a TST reaction that is ≥ 10 mm? Name 7.

LTBI Treatment Regimens
Study Question 4.4
List 4 regimens that are approved for the treatment of LTBI.

Treatment of Latent TB Infection (LTBI)
Special Considerations for LTBI Treatment

Special Considerations for LTBI (1)
Directly Observed Therapy (DOT)
• DOT is when a HCW or another designated person watches a patient swallow each dose of medication
  – Used to help patients adhere to treatment
  – Should be considered for people who are at high risk for TB or suspected to be non-adherent
  – Recommended for intermittent therapy

Special Considerations for LTBI (2)
Contacts
• Contacts are people who have been exposed to someone with infectious TB disease
• Contacts should be quickly identified, located, and assessed for LTBI and TB disease
  – If TST or IGRA result is positive, contacts should be given high priority for LTBI treatment (once TB disease is ruled out)
  – If TST or IGRA result is negative, contacts should be retested in 8 to 10 weeks

Special Considerations for LTBI (3)
Contacts
• In general, contacts with positive test result and a documented history of completion of LTBI treatment do not need to be retreated
  • However, retreatment may be necessary for persons at high risk of:
    – Becoming re-infected
    – Progressing to TB disease
Special Considerations for LTBI (4)
Contacts at High Risk for Rapid Development of TB Disease

• Some contacts may be started on LTBI treatment even if their test result is negative, and less than 8 to 10 weeks have passed since last exposure to TB; this includes:
  – Children younger than 5 years of age
  – People living with HIV
• Expert consultation should be sought to determine if contacts with immunocompromised states other than HIV infection could benefit from treatment even if they have a negative TST or IGRA result

Special Considerations for LTBI (5)
Contacts at High Risk for Rapid Development of TB Disease

• Once active TB disease is ruled out, contacts at high risk for TB disease should:
  – Start LTBI treatment
  – Be retested 8 to 10 weeks after last exposure to TB
    • If negative test result: stop LTBI treatment
    • If positive test result: continue LTBI treatment
• Contacts living with HIV may be given full course of LTBI treatment even if their second TST or IGRA result is negative

Special Considerations for LTBI (6)
Infants and Children

• Infants and children are more likely to develop life-threatening forms of TB disease
• Children younger than 5 years of age who have been exposed to TB should start taking LTBI treatment even if they have a negative TST or IGRA result because they:
  – Are at high risk for rapidly developing TB disease
  – May have a false-negative TST reaction

Special Considerations for LTBI (7)
Infants and Children

• Infants and children should be retested 8 to 10 weeks after last exposure
• LTBI treatment can be stopped if ALL of the following conditions are met:
  – Child is at least 6 months of age
  – Second TST or IGRA is negative
  – Second TST or IGRA was done at least 8 weeks after child was last exposed to a person with infectious TB disease
• The 12-dose regimen is not recommended for children younger than 2 years of age

Special Considerations for LTBI (8)
Contacts of INH-Resistant TB

• Contacts of patients with INH-resistant, but RIF-susceptible TB, may be treated with a 4-month daily regimen of RIF
• In some patients, rifabutin (RFB) may be substituted if RIF cannot be used

Special Considerations for LTBI (9)
Contacts of Multidrug-Resistant TB (MDR TB)

• The risk for developing TB disease should be considered before recommending LTBI treatment
• Contacts of patients with MDR TB
  – May be treated for 6 to 12 months with an alternative regimen of drugs to which the M. tuberculosis isolate is susceptible
  – Can be observed for signs and symptoms of TB disease without treatment
• All persons with suspected MDR LTBI should be followed and observed for signs and symptoms of TB disease for 2 years, regardless of the treatment regimen
Special Considerations for LTBI (10)

**Pregnant Women**
- For most pregnant women, LTBI treatment can be delayed until after delivery, unless they have certain risk factors.
- Immediate treatment should be considered if woman is living with HIV or is a recent TB contact.
- Preferred LTBI treatment regimen is 9 months of INH with a vitamin B6 supplement.
  - INH has not been shown to have harmful effects on the fetus.
- The 12-dose regimen is not recommended for pregnant women or women expecting to become pregnant within the 12-week regimen.

Special Considerations for LTBI (11)

**Breastfeeding Women**
- Women who are breastfeeding can take INH, but should also be given a vitamin B6 supplement.
- Amount of INH in breast milk is not enough to be considered treatment for infant.

Special Considerations for LTBI (12)

**People Living with HIV**
- Individuals living with HIV should be treated with 9-month regimen of INH.
- RIF should not be used for people who are taking certain combinations of ART.
  - Dose-adjusted rifabutin (RFB) may be given.
- The 12-dose regimen of INH and RPT may be used for people living with HIV who are:
  - 12 years of age or older.
  - Not on ART, except those taking an efavirenz or raltegravir-based ART regimen.

**LTBI Treatment Regimens**

Study Question 4.5
What LTBI treatment regimen may be recommended for people with a positive TST or IGRA result who have been exposed to INH-resistant TB?

Study Question 4.6
In what circumstances may LTBI treatment be given to people who have a negative TST or IGRA result?

Study Question 4.7
What conditions must be met to stop LTBI treatment for children who are younger than 5 years of age and have been exposed to TB?
Special Considerations for LTBI

Study Question 4.8
When should pregnant women be treated for LTBI and for how long?

Adverse Reactions and Patient Monitoring

Treatment of Latent TB Infection (LTBI)

Adverse Reactions to INH (1)

- About 10% to 20% of people treated with INH will have mild, abnormal liver test results during treatment
  - In most people, liver test results return to normal

Adverse Reactions to INH (2)

- Hepatitis
  - A major risk of INH is hepatitis (inflammation of the liver)
  - Hepatitis prevents the liver from functioning normally, causing symptoms such as:
    - Nausea
    - Vomiting
    - Abdominal pain
    - Fatigue
    - Brown urine

Adverse Reactions to INH (3)

- Hepatitis
  - INH can cause hepatitis in anyone; however, hepatitis occurs in less than 1% of people taking INH
  - Certain risk factors increase the risk of serious hepatitis, such as:
    - Older age
    - Alcoholism

Adverse Reactions to INH (4)

- Peripheral Neuropathy
  - INH can cause peripheral neuropathy
    - Damage to sensory nerves of hands and feet
    - Symptoms include a tingling sensation, weakened sense of touch, or pain in the hands, palms, soles and feet
  - HIV, alcoholism, diabetes, and malnutrition increase risk for peripheral neuropathy
    - People with these conditions should be given vitamin B6
Adverse Reactions to RIF, RPT, and RFB

- Hepatitis is more likely to occur when RIF is combined with INH.
- Other side effects of RIF, RPT, and RFB include:
  - Rash
  - Gastrointestinal symptoms
  - Orange discoloration of urine, saliva, and tears
  - Interaction with many other drugs, such as birth control pills and implants, warfarin, some HIV drugs, and methadone
  - Hypersensitivity

Patient Monitoring (1)

- All persons taking LTBI treatment should be educated about symptoms caused by adverse reactions.
- Patients need to be evaluated at least monthly during therapy for:
  - Adherence to prescribed regimen
  - Signs and symptoms of TB disease
  - Adverse reactions

Patient Monitoring (2)

- During each monthly evaluation, patients should be:
  - Asked whether they have nausea, abdominal pain, or other symptoms of adverse reactions
  - Examined by HCW for adverse reactions
  - Instructed to stop medications and contact HCWs immediately if they have signs or symptoms of hepatitis

Patient Monitoring (3)

- People at greatest risk for hepatitis should have baseline liver function tests before starting LTBI treatment and every month during therapy. This includes:
  - People living with HIV
  - People with history of liver disorder or disease
  - People who use alcohol regularly
  - Women who are pregnant or just had a baby
  - People taking medications that may increase risk of hepatitis
Patient Monitoring (4)

- For all patients, INH, RIF, and RPT should be stopped if liver function test results are:
  - 3 times higher than upper limit of the normal range and patient has symptoms
  OR
  - 5 times higher than upper limit of the normal range and patient has no symptoms

Medical Evaluation

Study Question 4.9
Name 4 reasons why patients should receive a medical evaluation before starting LTBI treatment.

LTBI Treatment Follow-Up

- Patients should receive documentation of TST or IGRA results, treatment regimens, and treatment completion dates
  - Patients should present these documents any time they are required to be tested for TB infection
- Patients should be re-educated about signs and symptoms of TB disease

Study Question 4.10
Why is it important to exclude the possibility of TB disease before giving a patient LTBI treatment?

Adverse Reactions

Study Question 4.11
What are the symptoms of hepatitis?

Study Question 4.12
Who is at greatest risk for hepatitis? What special precautions should be taken for these patients?
Adverse Reactions
Study Question 4.13

How often should patients be evaluated for signs and symptoms of adverse reactions during LTBI treatment?

Treatment of TB Disease

Treatment of TB Disease (1)

• Treating TB disease benefits both the person who has TB and the community
  – Patient: prevents disability and death; restores health
  – Community: prevents further transmission of TB
• TB disease must be treated for at least 6 months; in some cases, treatment lasts longer

Treatment of TB Disease (2)

<table>
<thead>
<tr>
<th>Intensive Phase</th>
<th>Continuation Phase</th>
<th>Relapse</th>
</tr>
</thead>
<tbody>
<tr>
<td>• First 8 weeks of treatment</td>
<td>• After first 8 weeks of TB disease treatment</td>
<td>• Occurs when treatment is not continued for long enough</td>
</tr>
<tr>
<td>• Most bacilli killed during this phase</td>
<td>• Bacilli remaining after intensive phase are treated with at least 2 drugs</td>
<td>• Surviving bacilli may cause TB disease at a later time</td>
</tr>
<tr>
<td>• 4 drugs used</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Treatment of TB Disease (3)

• Intensive phase should contain the following four drugs:
  – Isoniazid (INH)
  – Rifampin (RIF)
  – Pyrazinamide (PZA)
  – Ethambutol (EMB)

Example of pills used to treat TB disease. From left to right: isoniazid, rifampin, pyrazinamide, and ethambutol.

Treatment of TB Disease (4)

• Treatment must contain multiple drugs to which organisms are susceptible
• Treatment with a single drug can lead to the development of drug-resistant TB
### Preventing Drug Resistance (1)
- Drug resistance can develop when patients are prescribed an inappropriate regimen
  - TB disease must be treated with at least 2 drugs to which bacilli are susceptible
  - Using only one drug can create a population of tubercle bacilli resistant to that drug
  - Adding a single drug to failing regimen may have the same effect as only using one drug

### Preventing Drug Resistance (2)
- Resistance can develop when patients do not take drugs as prescribed
  - Patients do not take all of their pills
  - Patients do not take pills as often as prescribed
  - When this happens, patients may expose the bacilli to a single drug

### Module 4 – Treatment of Latent Tuberculosis Infection and Tuberculosis Disease

#### Treatment Regimens

<table>
<thead>
<tr>
<th>Regimen</th>
<th>Intensive Phase</th>
<th>Continuation Phase</th>
</tr>
</thead>
<tbody>
<tr>
<td>RIF &amp; INH</td>
<td>6 days/week for 54 doses (9 weeks) or 5 days/week for 40 doses (6 weeks)</td>
<td>60 to 180 doses (10 to 30 weeks)</td>
</tr>
<tr>
<td>RIF &amp; INH &amp; PZA &amp; EMB</td>
<td>6 days/week for 24 doses (8 weeks) or 5 days/week for 16 doses (6 weeks)</td>
<td>50 to 180 doses (10 to 30 weeks)</td>
</tr>
</tbody>
</table>

#### Why must TB disease be treated for at least 6 months?

- TB treatment must be completed for at least 6 months to prevent drug resistance.
- Longer treatment may be required if the patient is HIV-positive, has cavitary disease, or has taken TB medicine in the past.
- Failure to complete treatment can result in treatment failure, relapse, and acquired drug resistance.

---

### Treatment of TB Disease

#### Study Question 4.14

Why must TB disease be treated for at least 6 months?
**Study Question 4.15**

Which 4 drugs are recommended for the intensive phase of treatment for TB disease?

**Study Question 4.16**

Why should multiple drugs be used to treat TB disease?

**Drug Resistance**

**Study Question 4.17**

Name 2 factors that can lead to drug resistance.

**Special Considerations**

- TB medical experts should be consulted for complicated and challenging TB treatment issues
- Consultation can be provided by State TB Programs and the CDC-funded TB Regional Training and Medical Consultation Centers (RTMCCs)

[www.cdc.gov/TB/education/rtmc/default.htm](http://www.cdc.gov/TB/education/rtmc/default.htm)

**Special Considerations (2)**

- For HIV-infected TB patients receiving ART, the recommended treatment is a 6-month daily regimen consisting of:
  - An intensive phase of INH, RIF, PZA, and EMB for 2 months
  - A continuation phase of INH and RIF for 4 months
Special Considerations (3)
People Living With HIV
• ART should be initiated during TB treatment to improve treatment outcomes for TB patients living with HIV
• ART should ideally be initiated
  – Within 2 weeks of starting TB treatment for patients with CD4 cell counts <50/mm³
  – By 8 to 12 weeks of starting TB treatment for patients with CD4 cell counts >50/mm³
• For patients with TB meningitis or TB involving the central nervous system, ART should NOT be initiated during the first 8 weeks of TB treatment

Special Considerations (4)
People Living With HIV
• It is important to be aware of the interaction of RIF with some ART drugs
  – Rifabutin has fewer drug interaction problems and may be used as a substitute for RIF for some patients
• DOT should be provided for all TB patients living with HIV
• For patients not receiving ART during TB treatment, it is recommended to extend treatment to 9 months

Special Considerations (5)
Pregnant Women
• Treatment should begin as soon as TB disease is diagnosed
• Regimen should consist of at least INH, RIF, and EMB for a minimum of 9 months
• Clinicians should seek expert consultation to evaluate the risks and benefits of prescribing pyrazinamide (PZA) on a case-by-case basis
• Streptomycin (SM) should NOT be used
• Vitamin B6 supplements are recommended for all pregnant women taking INH

Special Considerations (6)
Breastfeeding
• Women being treated with first-line TB drugs should not be discouraged from breastfeeding
  – Only a small concentration of the drugs is found in breast milk
  – Not harmful to infant

Special Considerations (7)
Breastfeeding
• Concentration of drugs in breast milk is not considered effective treatment for LTBI or TB disease for infant
• Vitamin B6 supplements are recommended for all women who are taking INH and are breastfeeding

Special Considerations (8)
Children
• Children younger than 5 years of age should start TB treatment as soon as the diagnosis is suspected
• Children can be treated with INH, RIF, PZA, and EMB for 2 months, followed by INH and RIF for 4 months
  – Children receiving EMB should be monitored for vision changes
• A 3 drug regimen (INH, RIF, PZA) can be considered in the intensive phase for children who are too young to have their vision monitored, are not infected with HIV, have no prior TB treatment history, and are not at risk for having drug-resistant TB
Special Considerations (9)
People with Extrapulmonary Disease

• In general, regimens used for treating pulmonary TB are also effective for treating extrapulmonary TB

• 9 to 12 month regimen is recommended for TB of the meninges or central nervous system

• 6 to 9 month regimen is recommended for bone and joint TB

Alternative Treatment Regimens (1)
Drug-Resistant TB

• Alternative regimens should be used for treating drug-resistant TB

• Treatment of drug-resistant TB should always be done under the supervision of a medical expert

Treatment of TB Disease
Alternative Regimens for Treating Drug-Resistant TB

Alternative Treatment Regimens (2)
Drug-Resistant TB

• INH-resistant TB can be treated with the following regimen:
  – RIF, EMB, and PZA for 6 months

Alternative Treatment Regimens (3)
MDR TB

• MDR TB is resistant to INH and RIF, and is more difficult to treat than drug-susceptible TB

• Drugs that can be used are less effective and are more likely to cause adverse reactions

• Treatment can last 18 to 24 months after culture conversion

• As a last resort, some patients undergo surgery to remove part of the disease site

• Expert consultation should be sought

Alternative Treatment Regimens (4)
Extensively Drug-Resistant TB (XDR TB)

• XDR TB is resistant to INH, RIF, plus any fluoroquinolone, and at least one injectable second-line drug (e.g., amikacin, kanamycin, or capreomycin)

• XDR TB patients have less effective treatment options

• XDR TB is very difficult to treat

• Expert consultation should be sought
Alternative Treatment Regimens (5)

XDR TB

- Successful outcomes for the patient depend greatly on:
  - Extent of drug resistance
  - Severity of disease
  - Whether the patient’s immune system is compromised

Special Considerations
Study Question 4.18

What treatment regimen should be used for HIV-infected TB patients?

Special Considerations
Study Question 4.19

In what situations should treatment for TB disease last longer than the usual course of treatment?

Treatment of TB Disease
Treatment and Monitoring Plan and Adverse Reactions

Treatment and Monitoring Plan
TB Disease

- Every TB patient should have a specific treatment and monitoring plan developed in collaboration with local health department
- Plan should include:
  - Description of treatment regimen
  - Methods of:
    - Monitoring for adverse reactions
    - Assessing and ensuring adherence to treatment
    - Evaluating treatment response

Monitoring Adverse Reactions (1)
TB Disease

- Before starting treatment for TB disease, patients should have baseline blood and vision tests to detect problems that may complicate treatment
  - For example, patients who are taking ethambutol should have baseline visual acuity testing and testing of color discrimination
Monitoring Adverse Reactions (2)

**TB Disease**

- Follow-up tests should be done periodically if:
  - Results of baseline tests indicate abnormalities
  - Patient has symptoms that may be due to adverse reactions

---

Monitoring Adverse Reactions (3)

**TB Disease**

- Patients should be educated about symptoms caused by adverse reactions to drugs
- Patients should be seen by a clinician at least monthly during treatment and evaluated for possible adverse reactions
- Public health workers who have regular contact with patients should ask about adverse reactions to treatment

---

Adverse Reactions to TB Drugs (1)

<table>
<thead>
<tr>
<th>Adverse Reaction</th>
<th>Caused by</th>
<th>Signs and Symptoms</th>
<th>Significance of Reaction*</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allergic</td>
<td>Any drug</td>
<td>Skin rash</td>
<td>May be serious or minor</td>
</tr>
<tr>
<td>Eye damage</td>
<td>EMB</td>
<td>Blurred or changed vision</td>
<td>Serious</td>
</tr>
<tr>
<td>Hepatitis</td>
<td>PZA, INH, RIF</td>
<td>Abdominal pain, Abnormal liver function test results, Brown urine, light colored stool, Fatigue, Fever for 3 or more days, Flu-like symptoms, Lack of appetite, Nausea, Vomiting, Yellowish skin or eyes</td>
<td>Serious</td>
</tr>
</tbody>
</table>

---

Monitoring Adverse Reactions (4)

**TB Disease**

- If patient has symptoms of a serious adverse reaction, HCWs should:
  - Instruct patient to stop medication
  - Report situation to clinician and arrange for medical evaluation
  - Note symptoms on the patient's form

---

Adverse Reactions to TB Drugs (2)

<table>
<thead>
<tr>
<th>Adverse Reaction</th>
<th>Caused by</th>
<th>Signs and Symptoms</th>
<th>Significance of Reaction*</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nervous system damage</td>
<td>INH</td>
<td>Dizziness, Tingling or numbness around the mouth</td>
<td>Serious</td>
</tr>
<tr>
<td>Peripheral neuropathy</td>
<td>INH</td>
<td>Tingling sensation, numbness, or pain in hands and feet</td>
<td>Serious</td>
</tr>
<tr>
<td>Stomach upset</td>
<td>PZA</td>
<td>Stomach upset, Vomiting, Lack of appetite</td>
<td>May be serious or minor</td>
</tr>
<tr>
<td>Gout</td>
<td>PZA</td>
<td>Abnormal uric acid level, Joint aches</td>
<td>Serious</td>
</tr>
</tbody>
</table>

---

Adverse Reactions to TB Drugs (3)

- Patients should stop medication for serious adverse reactions and consult a clinician immediately. Patients can continue taking medication if they have minor adverse reactions.

---

Monitoring Adverse Reactions (5)

**TB Disease**

- Patients should be educated about symptoms caused by adverse reactions to drugs
- Patients should be seen by a clinician at least monthly during treatment and evaluated for possible adverse reactions
- Public health workers who have regular contact with patients should ask about adverse reactions to treatment
TB Treatment and Monitoring Plan

Study Question 4.20

What should be included in each patient’s treatment plan?

Adverse Reactions to TB Drugs

Study Question 4.21

Name the drug or drugs that may cause each of the following symptoms or adverse reaction.

- Nervous system damage:
- Hepatitis:
- Eye damage:
- Orange discoloration of the urine:

TB Treatment Monitoring

Study Question 4.22

How often should patients be monitored for adverse reactions to TB drugs?

Treatment of TB Disease

Adherence and Evaluating Patients’ Response to Treatment

Adherence to TB Treatment (1)

- Most effective strategy to encourage adherence to treatment is DOT
  - Should be considered for ALL patients
  - Should be used for all children and adolescents
  - Should be done at a time and place that is convenient for patients

Adherence to TB Treatment (2)

- Incentives and enablers can be used to improve patient adherence
  - Incentives are rewards given to patient, e.g., gift cards
  - Enablers help patient receive treatment, e.g., bus tokens
Adherence to TB Treatment (3)

- Patients should be educated about TB disease and treatment
  - Cause of TB, transmission, diagnosis, and treatment plan
  - How and when to take medication

Monitoring Patients’ Adherence to Therapy

- Patients not receiving DOT should be monitored for adherence to treatment:
  - Check if patient is reporting to clinic as scheduled
  - Ask about adherence
  - Ask patient to bring medications to clinic and count number of pills taken
  - Use urine tests to detect medication in urine
  - Assess patient’s clinical response to treatment

Evaluating Patients’ Response to Treatment (3)

2. Conduct bacteriologic examination of sputum or other specimens
   - Specimens should be examined every month until culture results have converted from positive to negative
   - Any patient whose culture results have not become negative after 2 months of treatment, or whose results become positive after being negative, should be reevaluated

Evaluating Patients’ Response to Treatment (4)

3. Use chest x-rays to monitor patient’s response to treatment
   - Repeated x-rays are not as helpful as monthly bacteriologic and clinical evaluations
   - Chest x-rays taken at end of treatment can be compared to any follow-up x-rays
Evaluating Patients' Response to Treatment (5)

- TST or IGRA cannot be used to determine whether the patient is responding to treatment
- Treatment completion is defined by number of doses the patient takes within a specific time frame
- Length of treatment depends on drugs used, drug susceptibility test results, and the patient’s response to therapy

Reevaluating Patients Who Do Not Respond to Treatment (1)

- Reevaluating the patient means
  - Obtaining a new specimen for TB culture, and (if positive) drug susceptibility testing
  - Assessing whether the patient has taken medication as prescribed
  - Reviewing symptoms
  - Performing a clinical examination
  - Repeating chest x-rays

Reevaluating Patients Who Do Not Respond to Treatment (2)

- Patients should be reevaluated if:
  - Symptoms do not improve in first 2 months of therapy
  - Symptoms worsen after improving initially
  - Culture results have not become negative after 2 months of treatment
  - Culture results become positive after being negative
  - Chest x-rays show worsening

Adherence to Therapy Study Question 4.23

Name 4 ways clinicians can assess whether a patient is adhering to treatment.

Adherence to Therapy Study Question 4.24

What is the best way to ensure that a patient adheres to treatment?

Response to Treatment Study Question 4.25

How can clinicians determine whether a patient is responding to treatment?
Reevaluating the Patient
Study Question 4.26
Under what circumstances should patients be reevaluated?

Reevaluating the Patient
Study Question 4.27
What does reevaluating the patient mean?

Treatment of TB Disease
Role of Public Health Workers

Role of Public Health Workers (1)
• Successful TB treatment is the responsibility of medical providers and HCWs, not the patient
• Case management can be used to ensure that patients complete TB treatment
• A health department employee is assigned responsibility for the management of specific patients

Role of Public Health Workers (2)
• Provide DOT
• Help monitor patients’ response to treatment
• Educate patients and families about TB
• Locate patients who have missed DOT visits or clinic appointments
• Act as interpreters, arrange and provide transportation for patients, and refer patients to other social services
• Work with private physicians to make sure TB patients complete an adequate regimen

Role of Public Health Workers Study Question 4.28
What is the goal of case management?
Role of Public Health Workers
Study Question 4.29

What should a public health worker do if he or she notices that a patient has symptoms of a serious adverse reaction?

Module 4: Case Study 4.1 (1)

You are sent to visit the home of a TB patient who was admitted to the hospital last week and diagnosed with infectious TB disease. Living in the home are his wife and his 1-year-old daughter. Neither one has symptoms of TB disease. You give them both a TST and return 2 days later to read the results. You find that the wife has 14 mm of induration, but the daughter has no induration.

Should either one receive further evaluation for LTBI or TB disease?

Module 4: Case Study 4.1 (3)

Should either one start LTBI treatment? Explain.

Module 4: Case Study 4.1 (2)

Should either one start LTBI treatment? Explain. (cont.)

Module 4: Case Study 4.1 (4)
Module 4: Case Study 4.2 (1)

A 65-year-old man is prescribed LTBI treatment with INH because he is a contact of a person with infectious TB disease and he has an induration of 20 mm to the TST. His baseline liver function tests are normal, but he drinks a six-pack of beer every day.

Module 4: Case Study 4.2 (2)

What kind of monitoring is necessary for this patient while he is taking INH?

Module 4: Case Study 4.3 (1)

An 18-month-old girl is admitted to the hospital because of meningitis. Doctors discover that her grandmother had pulmonary TB disease and was treated with a 6-month regimen. The medical evaluation of the child confirms the diagnosis of TB meningitis.

Module 4: Case Study 4.3 (2)

How long should the child be treated?

Module 4: Case Study 4.4 (1)

You are assigned to deliver medications to TB patients as part of the DOT program where you work. When you visit Mr. Jackson’s house, you ask him how he is feeling. He tells you that he was up all night vomiting.

Module 4: Case Study 4.4 (2)

What are the possible causes? What should you do?
Module 4: Case Study 4.5 (1)

Ms. Young, a patient who started treatment for TB disease last week, calls the TB clinic to complain that her urine has changed to an odd color.

Module 4: Case Study 4.5 (2)

Name 2 possible causes, and explain how each would affect the color of urine.

Module 4: Case Study 4.6 (1)

Mr. Vigo was diagnosed with smear-positive pulmonary TB disease in January. He was treated with INH, RIF, and PZA by his private physician. He visited his physician again in March. His drug susceptibility test results were not available at the time of this appointment. Nevertheless, the physician discontinued his prescription of PZA and gave him refills of INH and RIF. Mr. Vigo visited his physician again in April. He had a persistent cough, and his sputum smear was found to be positive.

Module 4: Case Study 4.6 (2)

What should be done next?

Module 4: Case Study 4.7 (1)

Ms. DeVonne began treatment for pulmonary TB disease 2 months ago, at the beginning of September. You have been supervising her DOT. During the first few weeks of therapy, you noticed that Ms. DeVonne’s symptoms were improving a little. However, at a visit in October, you see that Ms. DeVonne is coughing up blood, and she tells you that she feels like she has a fever.

Module 4: Case Study 4.7 (2)

What should you do?
