Vaccine 2D Barcode Scanning

More than 100 million doses\textsuperscript{1,2} of vaccines are given annually in the United States. Manual entry of these vaccines into the Electronic Medical Record (EMR) can be inefficient and result in data entry errors. Today, most vaccines have two-dimensional (2D) barcodes, which can help healthcare providers track product identifiers and capture accurate and complete data upon vaccine administration.

\textbf{2D barcode scanning can replace manual entry} to improve data accuracy and completeness and ensure high quality of patient care.

Since 2011, CDC and its partners have been exploring the potential of 2D barcoding to streamline immunization practices and improve data quality. Three pilot projects demonstrated that 2D barcoding can lead to improved vaccine record accuracy and time savings.

\textbf{Improved Vaccine Record Accuracy}\textsuperscript{3}

\begin{itemize}
\item Scanning can lead to \textbf{a large increase in vaccine record accuracy} as compared to manual data entry.
\item +4.6\% for lot number
\item +5.7\% for NDC
\item +9.2\% for expiration date
\item 1\% change impacts +1.3M records
\end{itemize}

\textbf{Time Saved}\textsuperscript{3}

An \textbf{average of 21 seconds} can be saved per vaccine by switching from manual to scanned data entry.

- 7 seconds for scanned entry
- 28 seconds for manual entry

\begin{itemize}
\item 12+ vaccine appointments added weekly with time savings (at one pilot site)
\item It saves time, ensures accurate and consistent data entry, and provides an extra safety step prior to administration.
\end{itemize}

Survey Respondent

\begin{itemize}
\item 1 in 9 records missing or inaccurate with manual entry
\item 1 in 5,000 records missing or inaccurate when scanned
\end{itemize}
